This proceeding of the third WebNet conference--WebNet 98--addresses research, new developments, and experiences related to the Internet, intranets, and extranets. The 265 contributions of WebNet 98 presented in this volume consist of the full and short papers accepted for presentation at the conference from a collection of more than 600 submitted from 40 countries. Included are position papers by leading experts in the field; descriptions of ideas and products; reports on concrete applications of the Web; discussions of the impact of the Web on various aspects of life; plus considerations as to how society might adjust to the resultant changes. Major areas covered at the conference include: (1) commercial, business, professional, and community applications; (2) educational applications; (3) electronic publishing and digital libraries; (4) ergonomic, interface, and cognitive issues; (5) general Web tools and facilities; (6) personal applications and environments; (7) societal issues, including legal, standards, and international issues; and (8) Web technical facilities. (AEF)
Proceedings of WebNet 98 —
World Conference of the WWW, Internet & Intranet
Orlando, Florida: November 7-12, 1998
On behalf of the Program Committee and AACE, it is our pleasure to present to you the proceedings of the third WebNet conference – WebNet 98. This conference addresses research, new developments, and experience related to the Internet, Intranets, and Extranets.

The 265 contributions of WebNet 98 presented in this volume consist of the Full and Short Papers accepted for presentation at the conference from a collection of more than 600 submitted from 40 countries. All submissions were carefully reviewed by at least three members of the Program Committee and their recommendations used for selection. Borderline cases were reviewed at a special Program Committee meeting where appropriate decisions were made based on re-reviews.

The coverage of the contributions is very wide, which is one of the features that distinguishes the WebNet series of conferences from others that focus on more specific areas. Our intention has been to provide an application oriented conference - a meeting place of developers, researchers, practitioners, and users - as a forum wherein persons from disparate but related fields can meet and learn about new developments that impact their activities.

This volume contains position papers by leading experts in the field; descriptions of ideas that are on the borderline between an idea, a prototype, and products; reports on concrete applications of the Web; its impact on various aspects of life; plus considerations as to how society might adjust and react to the resultant changes.

The major areas covered at the conference and presented in this volume include:
- Commercial, Business, Professional, and Community Applications
- Educational Applications
- Electronic Publishing and Digital Libraries
- Ergonomic, Interface, and Cognitive Issues
- General Web Tools and Facilities
- Personal Applications and Environments
- Societal Issues, Including Legal, Standards, and International Issues
- Web Technical Facilities.

These general areas have been divided into fifty-six more specialized topics.

In addition to the papers included in this volume, participants in the conference also heard leading experts present Keynote and Invited lectures; participated in tutorials, workshops, small-group discussions, and poster sessions; and had a chance to see demonstrations of various items of interest. The conference was also preceded by two days of tutorials and workshops. This printed record cannot show all aspects of this highly interactive, media-rich Web meeting, but it does convey the depth and breadth of the conference.

Let us take the opportunity to urge you to plan now to attend WebNet 99 in Hawaii Oct.30 - Nov.4. To attend and observe the WebNet series is one of the best ways to stay current with the rapid and intriguing developments of the Web. Periodically check http://www.aace.org/conf/webnet/ for information.

All of us realize that the Web is coming to have a major impact in international society. There is increasing confusion and concern on the part of many, in a wide variety of fields, as to what the implications and possibilities of the Web are. We all, as persons immersed in the topic, have a responsibility to explore, and clarify for others, the practical possibilities. We urge that you, and those with which you are in contact, consider these matters and reflect that thinking in your participation in WebNet 99.

In closing, we would like to thank all authors for submitting their work, and all members of the Program Committee, listed on the following page, for their cooperation and time spent reviewing submissions. Special appreciation is extended to Gary Marks (AACE), who is one of the main driving forces behind this volume as well as the WebNet series of conferences, and the AACE staff who contributed so much to the success of the conference.

Program Chairs:
Hermann Maurer, Institute for Information Processing and Computer Supported New Media, Graz University of Technology, Austria
email: hmaurer@iicm.edu

Richard Olson, Computer Science Department, Växjö University, Sweden
email: richard.olson@masda.hv.se
Steering Committee:

John Boot; Motorola (USA)
Gary Marks; AACE (USA)
Hermann Maurer; Graz Univ. of Technology (Austria)
Charles Owen; Michigan State Univ. (USA)

Program Co-Chairs:

Hermann Maurer; Graz Univ. of Technology (Austria)
Richard G. Olson; Växjö Univ. (Sweden)

Business/Corporate Session Chair: Valery Petrushin; Andersen Consulting (USA)
Poster/Demo Chair: Ivan Tomek; Acadia Univ. (Canada)
Tutorials Chair: Sam Rebelsky; Grinnell College (USA)

Program Committee:

Bjoern Baaberg; NKS-Gruppe (Norway)
Joergen Bang; Aarhus Univ (Denmark)
Philip Barker; Univ. of Teesside (UK)
Meera Blattner; Lawrence Livermore Laboratory (USA)
John Boot; Motorola (USA)
Peter Brusilovsky; Carnegie Mellon Univ. (USA)
Alexander Bugaev; Moscow Inst. of Physics and Tech. (Russia)
John Buford; GTE Laboratories (USA)
Gordon Davies; Open Univ. (UK)
Paul De Bra; Eindhoven Univ. of Tech. (The Netherlands)
Roger Debreceney; Nanyang Technological Univ. (Singapore)
Erik Duval; Katholieke Univ. Leuven (Belgium)
John Eklund; The Univ. of Technology (Australia)
Dieter Fellner; Braunschweig Univ. of Technology (Germany)
Josef Fink; German National Research Center for Information Tech. (Germany)
Richard Furuta; Texas A&M Univ. (USA)
Franca Garzotto; Politecnico di Milano (Italy)
Joachim Hasebrook; Bank Akademie (Germany)
Colin Hensley; Toyota Motor Europe (Belgium)
Roland Hjerpe; Linköping Univ. (Sweden)
Kristina Höök; Swedish Institute of Computer Science (Sweden)
Bengt Kjollerstrom; Lund Univ. (Sweden)
John Leggett; Texas A&M Univ. (USA)
Jennifer Lennon; Univ. of Auckland (New Zealand)
Eva Lindencrona; Swedish Inst. for Sys. Dev. (Sweden)
Suave Lobodzinski; California State Univ. (USA)
Nadia Magnenat-Thalmann; Univ. of Geneva (Switzerland)
Gerald Maguire; Royal Institute of Technology (Sweden)
Filka Makedon, Dartmouth College (USA)
Gary Marks; Assn. for the Adv. of Computing in Ed. (USA)

Hermann Maurer; Graz Univ. of Technology (Austria)
Maria Teresa Molino; Consiglio Nazionale delle Ricerche (Italy)
Max Mühlhäuser; Univ. of Linz (Austria)
Kyoshi Nakabayashi; NTT Information and Communications Systems Laboratories (Japan)
Raymond Neff; Case Western Reserve Univ. (USA)
Vladimir Nikolaevich (Russia)
Andrew Odlyzko; AT&T Labs - Research (USA)
Henk Olivié; Katholieke Univ. Leuven (Belgium)
Richard G. Olson; Växjö Univ. (Sweden)
Charles Owen; Michigan State Univ. (USA)
Gilbert Paquette; Tele-Univ. (Canada)
Valery Petrushin; Andersen Consulting (USA)
Reinhard Posch; Graz Univ. of Technology (Austria)
Rodney Prescott; Terabyte Interactive (New Zealand)
Samuel Rebelsky; Grinnell College (USA)
Vytautas Reklaitis; Kaunas Univ. of Tech. (Lithuania)
Nick Scherbakov; Graz Univ. of Technology (Australia)
Gunter Schlageter; Univ. of Hagen (Germany)
John Schnase; Missouri Botanical Garden (USA)
Daniel K. Schneider; Univ. of Geneva (Switzerland)
Manolis Skordalakis; National Technical Univ. of Athens (Greece)
Fay Sudweeks; Univ. of Sydney (Australia)
Laimutis Telksnys; Inst. of Mathematics and Informatics (Lithuania)
Klaus Tochtermann; FAW (Germany)
Ivan Tomek; Acadia Univ. (Canada)
Vladimir Vasilev (Russia)
Saulius Vengris; Vilnius Univ. (Lithuania)
Wil Verreck; Open Univ. (The Netherlands)
Bebo White; SLAC, Stanford Univ. (USA)
Jan Wibe; Univ. of Trondheim, NTNU (Norway)

Abstract: Following the recommendations of the W3C Web characterization group to characterize Web accesses and tasks, we analyze client accesses to Web Information Retrieval Systems (IRS), and in particular their queries. Instead of focusing on one server logfile, we compare accesses from groups of clients to different Web IRS. Although the analysis covers a number of client groups, the results show that clients' behavior does not vary much between different groups. Clients tend to use simple queries with a small number of terms and operators regardless of user computer background or knowledge. By identifying client sessions based on some reasonable heuristics we quantify the amount of searching and browsing per session. One of the interesting findings is that increased searching corresponds to reduced network and server traffic. With more searching steps, there is less need for browsing steps, which leads to a reduction in the number of bytes transferred.

Introduction

To help users locate information on the Web, special search tools and cataloging systems were developed. We call these tools Web Information Retrieval Systems (IRS). Web IRS have evolved rapidly over the last five years, and have been used by millions who thereby had their first experience with search engines. [Borgman et al. 96] observed that "The end users who now dominate searching are using systems with exploratory interfaces, under less time pressure, and have less clear retrieval goals than do skilled search intermediaries."

As part of a larger effort to characterize WWW traffic so as to support modeling, planning and prediction, and to help scale up the Web, we seek to study Web IRS-related traffic. In the HTTP-NG activity statement they stated "It is important to understand the actual system and how it is being used before attempting to optimize it", and "The task of the first group is to characterize the kinds of tasks actually performed using HTTP, and the kinds of documents that are retrieved" [W3C 97]. In this paper we study sessions, queries, and browsing activities using five log files collected from diverse situations. We characterize queries by looking at their complexity with respect to numbers of terms and operators. We also demonstrate that sessions with searching tend to consume less network bandwidth than other sessions. We do that by first defining an algorithm to extract client sessions. Second, we analyze the sessions and show that those with more search steps are responsible for fewer transferred bytes. We define user sessions in terms of "Browsing," "Searching," and
"Next step" activities. Then we look at the most popular patterns in the identified sessions. Using regression, we discover a correlation between amount of searching in a session and the bandwidth requirement.

Related Work

[Pollock and Hockley 96] demonstrates that user background does not affect the search process or results. The authors demonstrate this through an experiment that compares naive and non-naive user searches. The authors conclude that there are misconceptions and problems with Web searching due to the design of available search tools. [Catledge and Pitkow 95] characterized browsing strategies to the World-Wide Web. The objective of the study was to understand user behavior and come up with usability suggestion for design of web pages. The data was captured using a modified version of Mosaic. Based on their analysis they used 25.5 minutes to be the time that separates two sessions. Based on our statistical analysis we found that this value is too high and we suggest 5 minutes to be the session separator.

Our approach in this paper is different in many ways from studies like those mentioned above. First, our data has been collected from a variety of user groups in natural environments, not experimental situations. Second, we do not evaluate the different search systems, however, we do study user queries to see if they utilize available functionality. Third, we look at the usage of search engines and compare it to browsing. Fourth, we demonstrate the value of searching by observing that sessions with more searching frequently have less browsing, so there are fewer bytes transferred over the network.

Workloads Studied

[Tab. 1] describes the workloads used in this study, showing dates of log file collection and number of accesses. The workloads represent different groups of users with different ages and backgrounds so we can contrast those groups and generalize our results whenever feasible. For a detailed description of the workloads used please refer to [Abdulla et al. 97].

<table>
<thead>
<tr>

<td>11/96 (1 hour)</td>
<td>897</td>
</tr>
</tbody>
</table>

Table 1: Workloads used in this study

Accesses to Web IRS

We define accesses to Web IRS to include all accesses to Web IRS such as Lycos, Infoseek and to cataloging systems such as Yahoo. For comparison, we count the number of accesses that do not contain a search command and compare it to the total number of accesses in the workload. This way we compare total accesses to Web IRS to the total accesses to other servers. However when we analyze queries we only look at accesses with an explicit query command.

[Tab. 2] compares accesses to search servers to the total number of accesses in each workload. We notice that in all workloads the percentage of accesses to Web IRS is no more than 20%. This is reasonable since the search activity is always followed by browsing activity to explore the returned URLs and how relevant they are to the search. However, we also notice that in the high school case the percentage is very high compared to the
others; this is because the students were instructed to use the Web to find information. Interestingly the library workload was second highest, which reflects a key service of libraries, namely locating information. We call this the task effect; because the students were assigned a certain task and library users often focus on search for information.

<table>

<td>9</td>
</tr>
</tbody>
</table>

**Table 2: Accesses to Web IRS and their percentages**

The Korea workload has the lowest percentage. One reason could be that the data was collected a year earlier and Web users were not very well informed about Web IRS or because all search engines are located outside Korea, hence users avoid searching due to slow network connections. We expected that the CS workload ratio would be higher than other workloads in using Web IRS but local CS clients search the Web during only 6% of their accesses. This ratio is low compared to all other workloads except Korea. By examining the log file further we noticed that accesses from the CS clients are mostly to servers inside the department and those accesses are mostly repeated accesses to pages they are developing.

**Table 3: Total number of clients and clients which accessed a Web IRS**

[Tab. 3] lists the total number of clients in each workload and compares it with the number of clients who have accessed a Web IRS. We see that the ratio differs for different workloads. All clients in the high school have accessed Web IRS because they were supervised by teachers who knew about the available search tools and how to use them and who instructed the students regarding how to search.

The results in tables 2 and 3 confirm that Web users do use Web IRS to locate information. However the degree of computer knowledge does not appear to predict the percentage of accesses that are queries, for our workloads. This is consistent with the findings reported in [Pollock and Hockley 96]. However, the task effect is very clear in two cases, the library and the high school (AUB).

**Table 4: Number and percentage of accesses that contain queries**
In this section we study queries submitted by users and also attempt to identify inefficiencies. We start by counting how many accesses to the Web IRS are queries and compare that with the total number of accesses to the Web IRS. [Tab. 4] shows the number of accesses to Web IRS in each workload which of those contains a query. The rest of the accesses to Web IRS may be to load the home page of the Web IRS, to read help pages about how to do the search, or to access inline images. The CS (VT) workload has the highest percentage. A higher percentage in this table means that the users in this workload accessed the Web IRS more to submit queries and less to take other actions.

**Query Complexity**

![Figure 1: Number of terms/query](image)

We measure query complexity by counting the number of terms and number of operators used in queries. We refer to each word in the query as a term; and each "and," "or," "not" or any proximity operator as operators. [Fig. 1] shows the distribution of number of terms in the issued queries for each workload. From the figures we can see that users often use more than one term in their queries; in fact for all workloads except Korea (where perhaps search skills most need improvement) two terms per query is the most popular situation. When using more terms users may be trying to be specific to get more relevant results. In some queries the number of terms exceeded 5. In a ranked system this is beneficial in spite of the large number of partial matches if good terms are chosen, due to statistical correlation, since users can define a threshold when they will stop looking at retrieved documents, or can just examine the K best documents (e.g., for k=20).

We studied the distribution of number of Boolean operators/query for each workload. In all workloads most of the queries had no operators, as would be expected for one-term queries, or queries to a "natural language" Web IRS. (Note: This is the case for the Web IRS that we have examined; all have a ranking feature, or allow Boolean queries if special syntax roles are followed.) We noticed that the majority were simple natural language queries. Clients rarely use the Boolean operators or the advanced features of the Web IRS.

**Analyzing Clients' Sessions**

User and client sessions contain important information. The problem of extracting sessions is very hard and needs more research. In our study we used heuristics to identify sessions and then studied the correlation of number of searches and the total number of bytes transferred. We also classified the behavior of clients in
terms of three steps: "browse" or "b", "search" or "s", and "next set of results" or "n". Here "search" or "s" is defined to describe accesses with an explicit query; "next" or "n" is for accesses with "n" in the query field. Any other action is considered to be a "Browse" or "b".

The first step in processing was to extract the interactions for each client from the log file that contains all accesses generated from that client. The next step was to identify session boundaries in each client's log file using the algorithm of [Fig. 2]. By examining the log files we selected 300 seconds as a safe threshold to indicate a session break. We scanned the client logs generating a sequence of interactions for each identified session. For example a certain client might have 10 sessions in its log file. Each session is represented as a sequence of "b", "s", and "n" codes. The most frequent common sequence, which appear in all workloads, in effect yield a partial grammar of client sessions, empirically based; for the details please see [Abdulla et al. 97].

We explore the correlation between searching steps and the number of bytes transferred. We defined $R_{SNB} = (s+n)/b$, which is the ratio of search and next steps over the browsing steps. We conjectured that if we have more search-related steps then the number of bytes transferred for the session should be less. We used regression and correlation to determine the relation between the above ratio as well as counts of b, s, and n codes, and the number of bytes transferred.

We separate accesses for each client into a separate file;
For each client do
  {if (accessed path is related to the previous accessed path)
    (this is the same session)
    else {
      if (time between accesses< 300 seconds)
        (This is the same session)
      else {different session}
      }
  }

Table 5: Percentage of the most frequently repeated string patterns in all workloads.

The correlation analysis for four of the workloads (Korea, AUB, CS (VT), Library(VT)) showed that there is a negative correlation between the ratio $(s+n)/b$ when compared with the number of bytes transferred. The regression results for all four workloads are highly significant. This negative correlation suggests that a higher searching and browsing ratio corresponds to fewer total bytes transferred. The regression analysis for number of bytes transferred as a function of b, s, and n counts revealed that the coefficients of the variable b are significant in all workloads. The coefficients of the variable s are only significant in the library and AUB.
workloads. The coefficients of the variable n are only significant in the Korea and library workloads. It appears that b is the most important variable that determines the total bytes transferred.

To simplify the analysis of access patterns, we replace a sequence of b's with "B". [Tab. 5] shows the top 10 popular access patterns for the workloads. The most popular access pattern in all sessions is the sequence with b steps only and it is represented by B in the table. This pattern occurs in over 85% of all sessions which suggests that users are browsing most of the time. This is consistent with our previous conclusions. This high percentage suggests how much bandwidth we might save if we enable users to search more and browse less when they look for specific information, such as by having more effective retrieval methods. It is interesting to note that the first three access patterns not only are common between all workloads but also that they have very close percentages. The second popular access pattern is "BsB", which implies that the client has done one search after browsing and ended the session with browsing. Access pattern “BnB” is interesting because we had an n appearing without a search. By examining the log file we found out that this can occur if the client uses the catalogue in some Web IRS to get to a certain category, then presses "next screen" to get more hits.

Discussion

Although clients use Web IRS to locate information, they rarely use the special additional features available through the Web IRS interface. It appears that users prefer to issue queries with one term and without Boolean operators. These findings imply that the Web is either dominated by inexperienced searchers or Web IRS interfaces are not intuitive enough. Future work should identify why users rarely invoke advanced Web IRS features during searches which can be due to lack of training or the interface is not clear. By looking at the access patterns in the sessions we found that the most frequent repeated pattern is browsing only. By using regression and correlation analysis we found when a session involves more searching, then less network and server bandwidth is used. This is another reason to encourage use of searching.

Abstract: MEDIT is a Web-based environment for various pedagogical issues. It aims at offering complementary support to traditional practices. Our approach distinguishes a set of virtual working spaces and provides the appropriate services for each of them. In addition to a generic hypermedia authoring system, we implemented advanced tools for multiple view representation of a course, creation and maintenance of private workspaces, the aim being to stimulate information exchange, interaction, and collaborative work among the actors involved. The project is currently under evaluation through three undergraduate courses in the Swiss Federal Institute of Technology.

1. Introduction

The last decade is witness of the widespread use of NICT in many different applications such as public administration, medicine, education, edition and press, social services, commerce, etc. Education is one of the fields, which can take advantage of bringing down barriers of time and space with the use of WWW and Internet. A new training method, the Web Based Training (WBT) has raised the interest of private industries who see in it an economic and effective way to train their employees as well as of educational organizations. WBT [Kilby 1998] uses the techniques developed for the CBT (Computer Based Training) coupled with telecommunications networks and with WWW technology (HTML, HTTP, TCP/IP) and adds to CBT's advantages (Multimedia capability, personalized learning pace) the characteristics of the Web such as platform independence, integration of infinite information sources, discussion possibility, easy delivering of training and easy updating of data. From the point of view of the effectiveness of education, what makes the difference between a simple distribution of information and a real class or lesson, is interaction; interaction with teachers, with other students, practical problems, and real examples make learners more motivated and productive in the task they do. WBT offers a priori all the services that make possible the realization of interaction. Numerous projects currently deal with the development of computer-aided learning and tutoring environments to address a variety of pedagogical issues. However, the majority of them focus on the replacement of the role of a tutor with the features offered, without taking care about retraining teachers and students and changing their attitude and their ability to interact effectively with technology. In this context we present the prototype of the environment MEDIT, taking place in the Swiss Federal Institute of Technology (Jan. '97-Dec. '98) that aims at developing a Web-based environment for a variety of pedagogical services [Abou Khaled 1997]. The project intends to offer a valid support to traditional practices in education allowing instructors to decide which level of integration of NICT to use within the traditional course, from an information board for the class, to an instructional medium. The environment provides all the course component a learner is intended to experience in a course [Collis 1997]. To let teachers and students cooperate and easily work with Multimedia documents, specific Hypermedia Authoring Systems are implemented for the needs of the project. The originality of our approach lays on the use of highly structured documents that allows reusing of pedagogical materials in multiple purposes, as well as in an efficient management of all document classes. The environment offers adapted tools for different services; a HAS allows teachers, or administrators, to manage a virtual space for the creation of multiple courses, with rights of access for instructors, assistants and students. When a space has been assigned for a course, the professor can construct his/her own architecture and choose the services he/she wants to offer, via an efficient authoring system. Another service allows to provide four different views of the course: two classical views (by Chapter and by Session), a new one, namely the Semantic view for which the author is the teacher, but also a fourth view Private view completely managed by the students. The paper is organized as follows. [Multidisciplinary approach] highlights the development of a Web based pedagogical environment [Abou Khaled 1998], approaching the problem from a point of view
of involved know-how and sciences: pedagogy of distance education, HAS and HCI research axis. [MEDIT] discusses in detail the features of automatic creation of a virtual course space, and one of the important pedagogical issues addressed in MEDIT system, the course customization and views. Finally, [Conclusion and Future Works] concludes the paper with an argue of the implication of the distance education system we implemented, and future work plans.

2. Multidisciplinary approach

WBT is a science involving several research axes deeply linked to the very nature of the system; we group here the disciplines in three main ones: the first is dealing with the analysis of different components of a course to use them in a distance education environment, and to exploit and enrich all the possibilities of NICT with respect to the real users' needs; we will call this science Pedagogy of distance education. The second science involved is the HAS study, which let create a system allowing users to easily accomplish their tasks (teach and learn) overcoming technological problems. The third science involved is HCI (Human Computer interaction), based on the analysis of user's requirements and judgments which aims at improving and certifying the qualities of the interactive system.

2.1 Pedagogical issues in distance education

The aim of this science is to provide high quality education using NICT; this necessarily involves a retraining of students and teachers. Learners have to become active and have to be actively engaged in creating personal knowledge, changing the degree of interaction and depth of learning. They should be guided in changing their attitude and skills as to became self-directed and self-motivated. On the other side, teachers have to be the intermediary between students and available resources, create new teaching applications and organize instructional materials [Parker 1997]. Traditionally a course is characterized by the following components [Collis 1997]: course content, lectures/presentation, group discussions, learning events (experiments, visits, research etc.), private communication with instructors and classmates, self-study (reading, simulations, exercises), individual/group projects, testing (supervised exercises, exams).

The difficult purpose of Pedagogy in distance education is to discover new pedagogical issues for the course components, to enrich traditional learning. Our attempt in this sense has led to build and design new formative tools taking advantage of current technology. One examples among these issues is the possibility to create new views to access to the course content: by Chapters (traditional, linear access), by Session (chronological access), by Concepts (semantic, transversal access); the use of the combined views allows a great flexibility of presentation of information with respect to the users' needs. Another feature is the possibility to create a Private working space for students in which they are free to create their own information repository organized and structured as it's most suitable for the individual learning techniques. Services will be detailed later in the paper [MEDIT], as they are realized in the MEDIT prototype.

2.2 Usability issues: Human Computer interaction

HCI is a discipline concerned with the design, evaluation and implementation of interactive computing system for human use [Preece 1994]. The aim of HCI studies is to develop criteria to improve utility, efficiency, effectiveness, usability and safety of the system. In other terms it aims at improving the qualities of the computing system, which are observed and measured through the User Interface. The design process of an interactive system has to be user-center, that is, it has to involve real users in all the phases of development and it has to be highly iterative [Preece 1994]. To be effective, HCI techniques have to follow guidelines and rules both in Design and in Evaluation [Schneiderman 1998]. The hard of the matter is to realize objective criteria on which it's possible to build guidelines and evaluation techniques. In this context it's being developed an international standard, namely the ISO 9241: Ergonomic requirements for office work with visual display terminals. Several studies have been conducted to realize reliable tools to develop and test the interactive systems. In the development of our educational environment we are concentrating on the aspects of evaluation which plays an important role in software development aiming at determining
whether the user's needs are met, and assessing the system suitability for the task. A lot of evaluation techniques have been developed, both oriented in the employment of real users or of experts, and there are arguments that distinguish them [Oppermann 1997]. After a study of the state of the art in this field, we choose to use the ISOMETRICS evaluation questionnaire [Willumeit 1996] developed for formative evaluation of software at the Psychology University of Onesbrück. The questionnaire is based on ISO 9241/10 standard, is developed on experts' as well as on users' opinion and it foresees the involvement of real users (Subjective evaluation).

2.3 Technical issues: Hypermedia Authoring Systems

At present the cost of developing and producing large hypermedia information systems is very high and the process is time consuming. Authoring takes the major part in the development process. The Hypermedia Authoring System (HAS) is an assistance environment intended to help authors in the production of various Multimedia applications. It has to provide a user-friendly interface, involve most adequate tools for text and images processing, and automates most of the production tasks [Abou Khaled 1997] [Lowe 1996].

In MEDIT project we created a HAS allowing instructors to produce and organize locally or remotely their courses, supporting collaborative work between different users. MEDIT offers possibilities to organize and structure pre-existing information into sets of WWW pages; it permits also to design pages for readability and user-friendliness with hypertext links, content definition tags, and page layout tags. Finally it provides possibilities to create graphical and text-based navigational tools, banners, and widgets which improve the attractiveness and usability of the course site.

3. MEDIT

MEDIT is an aiding environment allowing the management and the distribution of an on-line interactive course. MEDIT's purpose is to create an environment for tele-teaching and tele-learning, even if actually it can be considered to be a complementary tool for traditional courses. The prototype is being developed for the Fluid Mechanic course taught in the Mechanical Engineering at the EPFL, but developed authoring tools and the new pedagogical issues can be re-used in any educational context.

MEDIT provide a virtual course space model which provides different services (those required in a tutoring and learning environment) for different category of actors (teachers, students and administrators). Our approach for the virtual course space model was based on discussions with experts and users involved in the pedagogical domain (instructors, students, pedagogues, computer scientists, etc.).

We have distinguished a set of course-related activities, the idea being that each of them is often associated with different actors and/or services and, therefore, different tools are needed. This partition was based on the concept of virtual course spaces. The proper specification of the above concepts and their relationships was a prerequisite for the implementation of the system. Every workspace deals with specific teaching services and offers "tailored" tools. A working space can be viewed as an instantiation of the teaching environment (with its own document classes and tools) to one's specific teaching context or needs. Each space is further divided in different sub-spaces [Abou Khaled 1997].

MEDIT offer a specific HAS for each users, in order to let them easily accomplish their tasks. Teachers and assistants have mainly the task to choose spaces that are interesting for him, as well as to create and distribute course content and exercises, dialog with students, supervise the exercises. Students have to access the course, to learn, to make researches, to self-test, to create their own documents, to be evaluated and to discuss with teachers and classmates. Administrators have to manage the accesses to the space with multiple course and the rights of access for instructors and learners in each course. The majority of existing approaches in web-based tutoring views the course as an indivisible entity, and doesn't allow teachers to have a wide choice of services or a personal configuration of the course. On the contrary, our environment allows instructors to select the spaces they desire for the course and the corresponding virtual course environment is generated automatically (this incorporates on-the-fly creation and compilation of the associated software classes) [Fig. 1].
3.1 Multiple course views

MEDIT environment has been designed to implement advanced pedagogical issues that stimulate information exchange, interaction, and collaborative work between actors. It offers to teachers the possibility to reuse the basic information contents in order to build several views with different ways of access. The first view is by Chapter (traditional view with sequential access), allowing easy updating of course content; the second is the Session view with chronological access, and third is the Semantic view with a transversal access, that we will explain here in detail. Semantic view allows readers to select what and how they want to learn, according to their specific needs (for example, the Semantic view of a course could be used as an aiding tool to solve exercises).

To create the Semantic view the teacher has first to conceive his/her view of the course structuring it in a tree-like course representation, based on his/her conceptual view of the subjects. MEDIT offers an easy-to-use tool to support this task [Fig. 2]. Every leaf of the tree corresponds to a course concept or options. Having finished with this task, the teacher has just to click on a button and the system will generate a set of HTML files corresponding to the tree created. By selecting such a file, he/she can then launch an editing tool and use existing views (by Chapter or Session) and external information to edit it as he/she prefers (note that in each such file there is information about the corresponding path in the tree). The students may also access the Semantic view of a course through the interface shown in the left window of [Fig. 3] (the choices appear in this interface are related to the tree constructed by the teacher and are updated
automatically whenever the teacher modifies the tree). The right window of [Fig. 3] corresponds to what the student has selected.

![Fig. 3: Interface to access to Semantic view.](image)

In MEDIT, students are viewed as active actors, i.e., they are not only consumers of information but, on the contrary, they are able to enrich the course through questions, notes and discussions, as well as by generating a customized version of the course. Personalized course gives to students an active role and improves their critical attitude. In this context, MEDIT reserves a Private space for each student registered for the course. The space remains his property during the semester. The management of the space is totally autonomous for each student. Features involved here are the easy creation, editing and deletion of the space and its components, access protection capabilities, and attachment of annotations and external existing documents (according to different views, after searching the Web, etc.).

![Fig. 4: Creating a private workspace.](image)

In the example shown in [Fig. 4], a student can browse the course documents both by chapter and session. Having selected a link, the corresponding file appears in [Fig. 4 right window]. This file is highly segmented according to a predefined set of HTML tags (the buttons shown are inserted in the existing document on the fly). Finally, the student selects the segments he/she is interested in, and can preview the file he/she has been working so far in the window appearing in the left part of the [Fig. 4]. The Private space makes the student responsible for the content of his/her course and may improve the quality of learning according to their preferred way of learning (namely active, reflective, visual, verbal, and intuitive learners [Felder 1996]).
4. Conclusion and future works

In this paper we described the functionalities, the services, and the new pedagogical contribution of a Multimedia environment for teaching and learning on the Web: MEDIT. The system foresees and autonomous and customized organization of virtual working spaces based on user's needs. We discussed the main features of the different views of the course and of the management system of the course space. The system is currently under evaluation through three undergraduate courses (Fluid Mechanics, Vibratory Mechanics in EPFL and Database in University of Geneva) with the participation of 6 teachers (2 professors and 4 assistants) and about 100 students (20, 30 and 70 in the above courses, respectively). A system introduction (less than an hour for students and about three hours for teachers) were sufficient to get the users acquainted with it. A member of our development group supervised and assisted the users during their first try. The feedback we have received so far was very positive. Teachers were satisfied of the functionalities of the authoring environment and the easiness of its use (locally or remotely), and appreciated the fact that they can still use their preferred editors to create the required course documents, while students liked the idea of having their own Private work spaces. Both teachers and students liked the ideas of course decomposition and multiple views. The system is now being evaluated with HCI evaluation tools (ISOMETRICS) on a sample of users; feedback are collected and analyzed in order to improve the usability of the system.

Future works on functionalities presented in this paper include tracking of the student acts during the creation and maintenance of their private workspaces to extract valuable information about their profiles, interests, and learning attitudes. This information will aid teachers to re-evaluate their course conception, design of exercises and projects, and in general, their course environments.

THE INTERACTIVE, VIRTUAL MANAGEMENT INFORMATION SYSTEMS (MIS) CLASSROOM: CREATING AN ACTIVE LEARNING ENVIRONMENT ON THE INTERNET

Thomas Abraham, Ph.D.,
Management Science Department
School of Business, Government & Technology
Kean University
USA
	tabraham@turbo.kean.edu or thos60@AOL.COM

ABSTRACT: This proposal describes the methods I am using to try to create an active learning environment within an Internet-based course. The introductory Management Information Systems (MIS) course is an elective that has become increasingly popular with our junior and senior Business majors. The main objective of this class is to provide an overview of the field of information systems and also to strengthen some of the computer skills developed in earlier, required classes. This spring (Spring '98) I am teaching one section of the course as a partially Internet-based class. The challenge is to apply active learning strategies and other effective classroom practices to the virtual classroom. Course materials, which are posted on the World Wide Web (WWW), are designed to be interactive. We use E-mail extensively to promote discussion, participation and feedback. Students conduct Webquests to facilitate individual assignments and a cooperative group assignment. They then create their own Web pages to present the results of the Webquest to the rest of the class. It is too early to evaluate the effectiveness of these methods. However, in the first test, students in this section performed slightly better than students from another section taught in a conventional classroom setting. By making use of widely available software tools, the teaching methods I have developed are readily transferable.

LITERATURE REVIEW

Research from learning theorists demonstrates that the "empty vessel" approach to learning is simply not very effective. This approach views students as empty vessels to be filled with knowledge by passively listening to those founts of wisdom, the instructors. Meyers and Jones [Meyers & Jones1993] cite studies that found that students retain only 20% of the information provided during the last 10 minutes of a lecture. They also state that students are not paying attention to the lecture 40% of the time, and, most disturbing of all, that 4 months after taking a course students knew only 8% more than a control group that never took the course.

The active learning approach appears to provide a more effective learning strategy. This concept is not
restricted to educational institutions. Most corporations "re-engineered" their businesses by empowering their employees. Similarly, students become the "architects of their own learning" [Verity 1994] [Graham 1992]. The underpinning of this approach is experiential learning theory. According to this theory [Kolb 1984], there are four learning styles that people use. These are the convergent, divergent, assimilative, and accommodative styles. The theory has many implications for business schools. First, our student bodies are increasingly diverse and their learning styles are very likely to be proportionately diverse since age, gender, and cultural factors often affect the learning styles used. It would appear that, to effectively meet their needs, these students must be offered more than one learning method. Second, if a key objective of education is to produce well-rounded, fully developed individuals, it is important to help students become integrated learners. Third, the marketplace demands creative and adaptive employees and this appears to also require an integrated learning style.

A large number of practical tools and strategies are being developed to create an environment where students can use more than one learning style and can actively pursue knowledge rather than passively receive it. Meyers and Jones [Meyers & Jones 1993] describe the structure of active learning as being composed of elements, learning strategies, and teaching resources. The key elements are talking and listening, writing, reading, and reflecting. Students do not passively receive knowledge but must actively construct their own frameworks. Each student has a preferred learning style that involves using some combination of reflection, talking, listening, reading, and writing that works together to add to and refine his or her knowledge structures. Active learning strategies attempt to provide an environment in which students have some flexibility to direct their own knowledge acquisition and can combine more than one learning element to suit their learning style. Learning strategies include small groups, cooperative work, case studies, simulations, discussion teaching, problem solving, and journal writing. Teaching resources include readings, homework assignments, outside speakers, teaching technology, and television.

Other educators have applied technology to support feedback. Strasser [Strasser 1993] discusses the use of E-mail to improve communication between student and instructor. Love and McKeen [Love & McKeen 1993] describe a real-time student feedback system where students can request a number of actions from the instructor. These actions include speaking faster or slower, using less technical language or summarizing, and so on. Students record their requests by pressing a particular key. The Internet has created new opportunities for extending the classroom. Web-based classes and other distance learning approaches offer many benefits. Bernie Dodge [Dodge 1998] describes the use of WebQuests. A WebQuest is an inquiry-oriented activity in which some or all of the information that learners interact with comes from resources on the Internet.

The content of the MIS core course typically involves introducing students to information technology, business applications, information ethics and computer security. I had introduced an active learning component into the MIS course. My approach [Abraham 1995] applies the learning strategies of small groups and cooperative work to the core MIS course. It also introduces timely feedback, a key principle of Total Quality Management (TQM), into the course. I facilitated these strategies by using the teaching technologies of groupware and presentation software. Now I am teaching a section of MIS as an Internet-based class. In the rest of this proposal, I describe my attempts to port the active learning environment to the virtual classroom.

DISCUSSION OF THE APPROACH

There are two main aspects to the approach I adopted. One is to create a virtual classroom. Students should have more flexibility as to when and where they learn. This is particularly useful for students who work part-time, which includes most of our student body. It is also an opportunity for most Colleges and Universities to leverage their existing infrastructure. The World Wide Web (WWW) now makes it possible for most course materials, including lectures, to be made available to students wherever and whenever they choose to learn.

The second aspect of my approach is interactivity - an active learning environment in which students interact with the materials and direct their own learning. As some of the research discussed in the earlier section
indicates, active learning improves the quality of the learning experience. The Web once again proves to be a valuable tool in providing an interactive environment. Links to related Web pages allow students to follow a path of their choice. JavaScript and other programming tools make it possible to transform Web pages into dynamic, interactive learning tools. E-mail provides students with a means to communicate with the instructor and with classmates in an asynchronous mode.

The introductory MIS course has traditionally provided undergraduate business students with an overview of management information systems. Students are introduced to information technology (IT) and its application to business. In addition students are also expected to acquire some computer skills. I have broken down the course into eight learning units. These are (i) Introduction to MIS (ii) Hardware (iii) Software (iv) Managing Data (v) Business Applications of IT (vi) Telecommunications & Networks (vii) Internet and (viii) Social Impacts of IT. I also expect students to learn to use a graphics package such as PowerPoint or Presentations, become very comfortable surfing the Web, use an E-mail package such as Pine, use a file transfer package such as Rapid Filer or WS-FTP, and learn to create their own Web pages. My course outline is posted on the Web at the start of each semester. It provides a detailed description of the course objectives, student obligations, class schedule and grading scheme.

The learning units are now being published as Web documents. A central switchboard allows students to choose a specific unit. Each unit has a main page containing links to other related materials. This main page typically contains the learning objectives of the unit, a link to lecture notes, links to articles on major figures (such as Larry Ellison or Andrew Grove) and major companies in the area of discussion, historical trends, review questions, class exercises and a sample quiz. The lecture notes were constructed using Microsoft's PowerPoint (Office 97) to create a set of slides and publish them in HTML. The software automatically creates an interactive set of frames that allow students to either view the slides (in any order) or print out the notes in outline form. JavaScript is automatically generated for this purpose.

Students E-mail me at the start of the semester. I take their addresses from these messages and create a class E-mail list. This allows me to reach all the students when I need to make any announcements or pose questions or respond to them. Also, students are encouraged to carbon copy that list when they send in comments and suggestions. The first individual class assignment requires students to learn to use a graphics package such as PowerPoint (Microsoft) or Presentations (Corel). They then construct a series of slides or charts using the software. In addition to learning a useful skill, this exercise also plays a part in integrating other assignments such as the cooperative student project discussed below. Teams presenting their project now have an impressive visual aid to help enhance the experience.

Students create a similar presentation of their own and hand in either a printed copy of the charts or attach an electronic copy to E-mail. They usually get about 10% of their overall grade for completing this assignment. Every chart of each student must be unique - this results in very creative, and occasionally disturbing, output! After successfully completing this assignment, most students become comfortable with the software.

Teams of two to three students are formed early in the semester to carry out a cooperative student project. The project consists of researching a specific area of MIS and presenting the research findings or the system developed to the rest of the class. In the process of carrying out this assignment, I believe that students learn a lot about MIS, acquire new computer skills, and improve their communication, creativity, learning, and group skills.

Teams select a topic of their own choice. They could analyze an existing information system, design and/or develop a new system, compare various software packages or hardware devices, or research a topical area. The objective here is to promote self-directed learning and creative choices. Next, each member of the team conducts a WebQuest to research the topic. The final stage of the project involves presenting the project to the class. Despite the discomfort that presentations cause, they are an important pedagogical tool and learning experience. The sharing of experiences among students can also be a very effective means of learning. As noted earlier, talking and listening are two of the basic elements of active learning. Students can improve their communication skills by watching and participating in these presentations. Graphics packages like PowerPoint help students make professional presentations. Starting around mid-semester, teams of students present their term projects to the rest of the class.
As discussed earlier, a WebQuest is an inquiry conducted on the Internet. Each member of a team conducts a longer-term WebQuest [Dodge 1998] to research some part of the topic chosen by the team. They surf the Web looking for interesting Web sites and identify at least 3 URLs that provide relevant material for their topic. Each member of the team creates a Web page containing a summary of the materials they found on the WebQuest. They insert links to interesting sites that they found. Each Web page is analogous to a poster in a poster session [Drummond 1998].

There are a few procedures I use to help manage the approach effectively. I make sure the students know what to expect by providing them (on the Web) with a detailed course outline. This outline clearly describes the objectives of the course, grading policies, classroom procedures, and a tentative class schedule. It fulfills the requirements specified by active learning theorists [Meyers & Jones 1993]. I allow students to join any group. However, to provide some control over the group processes, if the majority of a group complains about any member, that person must complete the project individually. Students recognize that their success depends partly on maintaining a good working relationship with their teammates.

Generating ideas for the project is a crucial step. In the past, this step often ran into a number of difficulties. Some teams would wait till the last possible moment and pick a topic randomly from the textbook. Most teams would generate only one or two topic choices. In fact, a number of teams would pick the same topic, usually something that was discussed recently in class. I have attempted to improve this process by spreading the presentations over the second half of the semester and assigning chapters to each team. Topic selection must be guided by certain criteria. The criteria include relevance, usefulness, audience interest, and feasibility. The topic must be relevant to the course, must be useful to the team members, should be of interest to the rest of the class, and should be feasible in terms of resources. If more than one team picks a topic, there must be other choices to pick from. It is often useful to stress that topics should be connected to their own interests, both personal and professional [Shack 1993]. Once the topic is selected, the instructor should approve it and monitor the teams' progress. As with any group project, I have encountered problems such as procrastination and loafing.

I insist that graphics software be used in the presentations. The presentations are usually about ten to fifteen minutes long and attendance is compulsory. The rest of the class is expected to take notes on each presentation since they are included as material for the final exam. The teams must also turn in a one-page summary or outline of their presentation.

I created the main page for each learning unit using Word for Windows 95, a word processor built into Microsoft Office 97. I published the document in HTML format to generate the Web page. I edited the resulting document in Word Pad, a simple word processor built into Windows 95. I used my rudimentary knowledge of HTML and a couple of templates downloaded off the web to get the look I wanted. To create the lecture notes, I selected some slides from the textbook support materials. I used PowerPoint to add additional slides or modify existing ones. I then published the presentation in HTML format. This is a very nice feature in recent versions of the software. PowerPoint automatically creates a four-frame page for viewing the presentation. One frame presents the slides in GIF or JPEG formats. A second frame provides an outline of the presentations. A third frame provides a navigation toolbar for the images. The fourth frame has two buttons - clicking on one presents a detailed outline in frame two and clicking on the other present a summary outline. I recommend that students print just the outline of the lecture instead of the whole page. I modified the index button on the navigation bar to point back to the main page of the learning unit. Finally, I used WS_FTP95, a freeware file transfer program to upload all the html documents to the Web server. I also used a program called Rapid Filer on occasion. Rapid Filer is built into the NetWare operating system and can be used from any NetWare workstation.

RESULTS

As with most instructional approaches, it is difficult to precisely measure the effectiveness of my method. To conduct a scientific experiment, I would have to have a control group which would be excluded from using this
teaching approach. For ethical and practical reasons, this was not possible. In the first test, I found that students from this section scored somewhat better than their counterparts in a regular classroom section. I find that students are more enthusiastic about the course, make better presentations, and occasionally make helpful suggestions that improve the class. By exposing students to a variety of learning strategies, this approach allows a diverse student body alternative paths to knowledge acquisition while promoting a more integrated learning style. Finally, the tools themselves update the traditional skills component of the MIS class by replacing spreadsheets and word processing with graphics and Web page design.

Students have consistently rated the term project and computer labs as being the most useful and enjoyable parts of the course. They have used presentation software in other courses and pressured other faculty to use the multi-media rooms. After they become comfortable with web-browsers and E-mail, students will often stay on after the class to complete a session. This is in stark contrast to their behavior at the end of a lecture!

A few aggressive or better-informed students tend to dominate class participation in the traditional classroom. By promoting E-mail as a means to participate, I have found that students, who would otherwise be silent, begin to participate enthusiastically. Information sharing improves too. For instance, one student recently sent me mail asking me for help on how to buy a PC. I forwarded this to the rest of the class and soon she received four or five very useful suggestions on where to shop and how much to pay.

Feedback is a critical component of any quality initiative [Thomson 1993]. Feedback from students, however, is unfortunately usually overlooked. Student evaluations are usually collected at the end of the semester when there is little motivation to make suggestions. Very often, the time provided for filling out the forms is limited. Our method uses E-mail to collect feedback from students in the middle of the semester when their suggestions can still be implemented. Feedback to the students is also speeded up. Often, I can post grades on the Web within a few hours after the test or quiz.

Cooperative student projects improve social skills and prepare students for the real world [Bruffee 1987] [Meyers & Jones 1993] [McKinney 1993]. Our students have been exposed to team projects in a number of courses and are increasingly comfortable with the format. Once they understand that they can "fire" a team member for not contributing they feel more in control. These procedures also tend to keep potential free riders in line.

There are a few drawbacks and caveats to using this method. First, obtaining multimedia rooms and computer labs are not always feasible. Perhaps, one day, every classroom will have a computer and screen instead of an overhead projector and every student will carry his or her own laptop. A short-term solution could be for the multi-media center to provide a mobile setup on request much as they now deliver TVs and VCRs. At our school, all the classrooms have sockets that allow one to plug into the Internet. Computers that attach to overhead projectors are also available and seem to offer an attractive alternative. Second, as with any technology, the potential for breakdowns exists. We have all occasionally been in situations where the projector didn't work properly or the whole system went down. Web servers can crash, FTP programs can stop transferring files and some browsers may not support certain features. Third, some students are still uncomfortable with computers and may not have easy access to the Internet. Fourth, some students get so caught up in trying to make dazzling charts and web pages, they err excessively on the side of style over substance. Fifth, this approach can be very time-consuming. Preparing the course materials took a great deal of time. Monitoring the E-mail and downloading files was also very labor-intensive.

Colleges and Universities are looking to the Internet as an opportunity to expand their course offerings while maintaining the same infrastructure (faculty, buildings, labs, etc). This paper described an approach used to adopt an active learning environment within an Internet-based course. I described how I used the Web, E-mail and graphics software to support a cooperative student project in the core MIS course. Information Technology itself is a key topic in the course and so it is naturally a very appropriate medium for instruction. Students learn about information technology by using computers and accessing information through the Internet. Preliminary results seem to indicate that students are enthusiastic about using a 'high-tech' approach to learning, especially if it is grounded in active learning methods.

Applying Cluster-Based Connection Structure in the Document Base of the SDI System

Abstract: Since 1994 in Poznań University of Economics has been implementing a Selective Dissemination System (SDI) for economic information [see Abramowicz and Piskorski 1997]. To build the SDI system more efficient there has been applied mechanisms based on methods of cluster analysis. One of the most important mechanism is the cluster-based connection structure (CCS) developed in 1997 (Dariusz Ceglarek doctor's dissertation) and described in [Abramowicz and Ceglarek 1998]. This paper describes new mechanisms, which improve the SDI system. Using the CCS structure a user of the system can improve (a) relevance calculation for newly provided documents, (b) navigation in a document base, and (c) presentation of the set of documents according to the relevance.

1. SDI Systems

In SDI systems users (we call those information consumers) have expressed their interests in using consumer profiles, those are sent back to information producers. Terms in consumer profiles have weights, which describe their significance for the consumer.

Information producers, using a distribution system, check, which of the produced documents are relevant to the consumer profile. These, which are similar to his/her profile are then send to him/her. First the consumer validates received documents, then rejects the non significant ones. Because of this procedure the weights of terms which appear often in rejected documents, are diminished, and weights of terms which appear often in accepted documents are increased. Such an improvement of a consumer profile uses a feedback mechanism to gather more relevant information. This helps the consumer to rebuild his profile to achieve only interesting documents. The distribution system improves consumer’s profile.

Unfortunately, the SDI systems used today, do not have the mechanisms, that would enable them to answer the question: which of the documents in the user’s database are similar to specified document and in what scale they are similar to each other? In those systems there is a lack of synthetic information (measurement) about similarity between documents. Furthermore, during validation of new documents, SDI systems do not provide the mechanisms to compare them with documents already placed in the document base.

2. The Cluster Analysis

The basic idea of the cluster analysis is clustering of objects based on their similarity in the space of features. In the information retrieval systems (IR), the clustering of objects features means a gathering of terms from a profile of analyzed document or a group of documents. The measure of similarity is then coefficient of taxonomic similarity. The cluster analysis leads to exhaustive and separable classification - a defined document belongs to at least one and no more then one cluster. This method of classification has been shown in [Cutting et al. 1992]; [Lewis 1992]; [Botafogo 1993]. In the article, there a more complex connection structure between clusters with using data, which originate during iterative procedure of typical cluster analysis. Thanks to this more complex cluster-based connection structure (CCS) in the document base, a document can be an element of any number of clusters at the same time. The obtained CCS is partially hierarchical (smaller clusters are elements of larger clusters - see picture 1). But, there are also connections, that are not hierarchical (a document has connections to clusters, not being its element), there are also connections between clusters, which are not in the generalization relationship.

1 Comparison should be understood as an assignment of the similarity metric.

2 Methods of cluster analysis have been described in [Bijnen 1973], [Sokal and Sneath 1973]

3 On the picture 1 there are 3 small clusters A,B and C. Each of them is an element of bigger cluster D.
Based on CCS, and using the algorithms proposed, a consumer can improve the following processes: see abstract

- The selection of newly provided documents
- Navigation within documents from the document base
- Presentation of result of a query

3. The Algorithm to Build the CCS in the Document Base

Given is a consumer profile $P = \{p_1, \ldots, p_n\}$, defined as a set of $n$ terms. There is also a set of $\delta$ documents, which makes the document base $\Delta = \{\Delta_1, \ldots, \Delta_\delta\}$.

For each document in $\Delta_i$ there is a defined profile of document $D_i = \{d_{i1}, \ldots, d_{in}\}$. Non-zero values $d_{ij}$ are sets of terms from the consumer profile, which appear in documents.

Besides this, there is a set of weights $W = \{w_1, \ldots, w_n\}$, that assigns significance, that the consumer attaches to each of terms from a profile $P$.

The distances between objects (documents or clusters of documents) of the document base apply for the following relations:

- document $\Leftrightarrow$ document
- document $\Leftrightarrow$ cluster
- cluster $\Leftrightarrow$ cluster

All those relationships are explained below:

Measure 1: (document - document)

To define similarity between documents there is used a measure of cosine:

$$SIM(i, j) = \frac{\sum_{k=1}^{n} d_{ik} \cdot d_{jk}}{\sqrt{\sum_{k=1}^{n} (d_{ik})^2 \cdot \sum_{k=1}^{n} (d_{jk})^2}}$$

Measure 1 will be used in the article to establish a similarity between documents, what will be done during the first step of algorithm of building CCS between elements in the document base.

However, in the measuring similarity of multi-document clusters (a document is simply a cluster having just one element), the fact, that a term belonging to a cluster’s profile, does not mean, that it is frequent in this profile, and, that it is typical of this cluster. If the documents profile, that is attached to a cluster has the same terms, as the cluster’s profile, it means, that this document is certainly the most similar to the cluster’s profile. But, if in the documents profile there is a lack of important term typical of the cluster’s profile, it means, that this document is less similar to the cluster than the document, in which there is a lack of terms, which are in cluster but with a low importance for the consumer.

In each step of an iterative procedure of connecting documents (just after connecting them), there is correction of distance between just done cluster and remaining documents.

Measure 2 (cluster - cluster and document - cluster)

There is an assumption, that for each cluster at its profile there is stored information about the number of documents, in which there were defined terms. For $i^{th}$ cluster there is:

$$L_i = \{l_{i1}, \ldots, l_{in}\}$$

$$L'_i = \{l'_{i1}, \ldots, l'_{in}\}$$

where $l'_{ij} = l_{ij} \cdot w_j / s_i$

$s_i$ – a number of documents at $i^{th}$ cluster

$w_j$ - a weight of significance of $j^{th}$ term.

$L'_i$ means participation (representation) $j^{th}$ term at the whole profile of $i^{th}$ cluster. $L'_i$ will be called a structure of $i^{th}$ cluster.

The distance between two clusters will be there $o_{ij} = 1 - (D'_i \cap D'_j) / (D'_i \cup D'_j)$ i.e. measure showing how much clusters differs in structure of terms of the documents profile. The formal notation:
\[ O_{ij} = \frac{1}{\sigma} \sum_{k=1}^{n} |I'_{ik} - I'_{jk}| \] for there \( k \), for which \( I_k + I_j > 0 \) (there are \( \sigma \) of them).

Steps of the algorithm for assignation the CCS in the document base:

**Step 1**: For the whole document base, each document becomes the set of nodes of graph and at the same time it becomes cluster of one element.

**Step 2**: For the whole document base there are calculated distances between documents according to the measure 1. In the graph of similarity there are stored only links connecting documents with similarity not smaller than \( \alpha \). The coefficient \( \alpha \) is assigned by consumer.

**Step 3**: Documents are set to elementary clusters\(^4\). The gathering goes on as long as the similarity between connecting objects (document - document, document - cluster) becomes smaller than the coefficient \( \alpha \) (stop criterion).

**Step 3a**: For each document (which belongs to an elementary cluster) there are assigned clusters strongly connected to it (above some value of similarity measure - coefficient \( \alpha \)). The calculation to assign this list of clusters is made after step 3, because only then the ultimate structure of the elementary cluster is available. If the similarity between document \( \Delta_i \) and the elementary cluster \( \Delta_j \) is larger than \( \alpha \), a link \( Y_k \) to the list of clusters links near to \( Y \) is introduced.

**Step 4**: The elementary clusters are gathering together in larger structures as long as the similarity between connected clusters become smaller than \( \alpha \). The number of clusters, which is achieved after ending the gathering, will be assigned to \( \omega \).

The algorithm has been described (in pseudo C++ language) in [Abramowicz and Ceglarek 1998]. There has been also shown that it has computational complexity higher than linear and lower than quadratic. The algorithm gathers documents into clusters and establishes a CCS structure in the document base in deterministic way.

The structure CCS built up this way (graph showed on Picture 1) enables to look at the documents with many aspects. For example: a document signed \( \Delta_{2,n_2} \) except belonging to cluster \( S_2 \), has indicator to a cluster \( S_n \) (\( S_n \) is close in relationship to this document).

---

\(^4\) The elementary cluster is a cluster, which does not contain any cluster, but only documents. Documents, which do not belong to any cluster, are these, that were not similar enough to any document and do not have any link \( s \) connecting them to the \( X \) list. So, there is no reason to analyse them from the point of view of similarity to any connection.
Having CCS, the consumer can navigate:

- to a defined document through similar to it or close to it documents,
- to a defined document through clusters, to which belongs ("more general" - "more detailed"),
- to a specific defined cluster, through "more general" cluster or "more detailed" cluster for it.

During the clustering in part III of the algorithm, there originates information about a nearness of elementary clusters. The fact, that finally they become elements of different, non-elementary clusters (it may happen), does not mean a loss of nearness between them. Inclusion in structure of connection between clusters, the clusters near to each other, enables to move through clusters not connected hierarchically ("related" - "more general" and "more detailed").

For example on the Picture 1 there are connected clusters S1 and S2. There is assigned a connection between clusters, if a similarity becomes larger than coefficient α, during absorption, one of these two connections by another or by absorption another cluster by one of these two clusters. The fact, that the elementary clusters become the element of the same, not elementary cluster, does not mean deletion of connection between them. The CCS can be also achieved by not precisely stated and not deterministic classification, provided by the algorithm Buckshot, which has been demonstrated in [Cutting et al. 1992] and in [Hearst et al. 1996]. Because it splits a collection of objects into definite number of clusters, there are required some modifications to obtain the similar structure, like the one at shown algorithm CCS. The inaccuracy of that algorithm, is there made up by its speed.

For new documents in the document base, for which clusters are already assigned, the procedure is different. It should find a cluster, which a document should belong to (also it should find indications to clusters, in which documents are very similar to the definite one) and assign the influence of the new document on the already originated clusters. To estimate a cluster, which the new document should belong to, we may of course look through all the originated clusters, but also we may find another solution - namely: the elementary clusters are looked through and the most similar to the document is chosen.

4. The Mechanisms of Assistance the Consumer of Information

4.1. The selection of new documents

With a new document, the consumer gets from module of distribution a profile of the document and its relevance in relation to the consumer's profile. Till now, for this document [see Abramowicz 1991]:

- choosing term from a profile of documents, the consumer could get the next document, in which there is definite term,
- choosing term from a profile of the document, the consumer could get a set of documents having this term (term as a query),
- explicit information about relevance - this part of a profile of the document, which is not in the profile of the consumer, and which comes from profiles of other consumers, for whom this document was also relevant. The consumer can treat this information as an instruction. This could cause, him to get similar documents with higher probability.

For a new document, owing to a CCS, the consumer can get:

- Documents, which are the most similar to this document. The search is made in centroid way [Salton and McGill 1983].
- The most similar, with this document, cluster or a centroid of this cluster to acquaint the subject typical of this cluster.
- One of the clusters, highly similar to the document (the information originates during estimation at the former point).

Beside that, the consumer can use a connection between these clusters and other clusters, according to possessed structure of clusters and navigate in the document base. Owing to this, the consumer can compare the relevance and the quality of a new document that is highly similar to it documents that are already accumulated in the document base.

The acceptance of the document by the consumer means, of course, the addition it to the base, but also inserting the connections into the CCS of the document base.
4.2. Navigation in the document base

For the document selected from the document base (in the navigation procedure in the set of answer to the query), till now:

- choosing term from a profile of document, the consumer could get next document, in which there is definite term,
- choosing term from profile of document, the consumer could get a set of documents having this term (term as a query),
- explicit information about relevance - this part of a profile of document, which is not on profile of the consumer, as an instruction, what could contribute to obtain similar documents with higher probability.

However, this information does not enable the consumer to find documents not having definite term, but strongly relevant to it. For example: the consumer requested system to find documents having terms "insurance" and "policy". Obtained set of documents, which fulfill these criteria, we designate as S. If seems, that is a good point to start to search for documents about estimation of insurance risk, according to the state of health. In the document base there is a document, which does not have a word "insurance", but it has "risk", "estimation of risk", "policy", "opinion about health", "insurance analysis". After getting the set of documents fulfilling criteria, the consumer asks to inform about:

- the cluster, of which element is one of documents from set S (to inform about it, because it is already assigned),
- the list of clusters similar to a document from set S,
- the cluster, which is the most similar to a document from set S,
- one of clusters connected with a document from set S (to inform about it, because is already assigned to),
- one of clusters the most highly similar with the whole set S. There should be done some calculations, because S every time can be different.

The calculations are done according to measure 2 e.i. SIM(S, S_i) for i=1,...,8.

This enables to find documents, which, to be sure, do not have any terms from query, but by belonging to the same clusters are strongly connected.

In each of above variants, the consumer of information can go from definite cluster to one of its specializations (subcluster) or generalization (more general cluster - this one, which definite cluster belongs to).

During estimation of definite document from analyzed cluster, the consumer, gets information about connections between document and cluster. He may learn how much of them differ in regard to structure in comparison with current cluster.

**Example:** The estimated document is: "car accident insurance - analysis of offers of the insurance companies" which belongs to analyzed cluster S1 "property insurance". Cluster S1 and S2 differ about structure in significant way in relation to terms "cars" (for example suitable values differ of structure amount 0,99 and 0,60), "real property" (for example - suitable 0,1 and 0,6) etc. It is a result of a subject of documents of both clusters. So, the consumer can acquaint subject of the cluster S2 without looking through documents of the cluster S2!

4.3. Mechanism of assistance presentation of the result of a query

The SDI system has a build-in retrieval system, which built answers to queries. The main task of the retrieval system is to retrieve the appropriate information in answer to queries submitted by the consumer. Applying the CCS structure may be useful during a presentation of a result of a query because the CCS structure gives additional information about documents. In the result of the query built by the search system the consumer gets a set of documents from the document base which are relevant to the query. The set is presented to the consumer as a list of documents in order of relevance value (see Picture 2). Each of these documents from the list has additional information about it's cluster (the cluster it belongs to) - within the confines of the CCS structure. The document has also information about other documents which are very similar to. The basic function in this moment is to look over the list and to read documents. The consumer can move, from any document from the list, to it's cluster or to similar documents. Afterwards he may continue navigation in whole document base owing to the CCS structure. Naturally, there is no obstacle to return to the list.
1. The Bundesbank and European Currency Union

The Pekao SA branch in Berlin, Germany

Bank Gesellschaft Berlin - corporate accounting

Bundesbank reports record earnings for 1997

Addresses of foreign banks in Berlin

Wechsel Bank - company information

Way clear for Germany's biggest bank merger - Bayerische Vereinsbank and

---

**Picture 2: List of relevant documents**

**Example:** The query condition contains three following words: "Germany", "Berlin" and "bank".

Let's assume that analyzed document is about the branch of Polish bank Pekao S.A. in Berlin. Owing to the CCS structure the consumer can examine the cluster it belongs to (probably the documents from the cluster are related to the bank). He may also examine the documents similar to it e.g. documents about branches of the bank in other countries.

When the set of documents is heterogeneous, e.g. documents refer to several fields of knowledge or couple of subjects, it is proper to divide it into clusters. Profiles of documents from the set are used to dividing the set into clusters. The result of division is \( k \) separate clusters, where \( k \) is a number specified by the consumer. If any of obtained clusters is recognised by the consumer as a heterogeneous, he may decide to dividing it into several smaller clusters. Each of the \( k \) clusters has his own profile (see Picture 3). The consumer can examine the cluster's profiles and can choose this cluster which profile is the most interesting for him. On the picture 3 terms which are specific for given cluster (i.e. they appear more often than on the average in all clusters) are in bold type.

**Picture 3: Profiles of clusters**

---

**5. Conclusion**

In this paper the cluster-based connection structure (CCS) in the document base of information's consumer has been presented.

This structure enables to obtain additional knowledge about information accumulated in the document base. This knowledge, by using suitable algorithms, is conductive to overcome difficulties connected with estimation the usefulness of new documents, to navigate in the document base already accumulated, and to search for information in the document base.

The reason to gather this knowledge is the designation of similarity between objects, for which there are defined mutual connections. These objects are documents and clusters of documents, and a measure of similarity is defined based on document's profiles or profiles of clusters. In our paper two measures of

\[ \text{Similarity} = \text{Profile similarity} \]

---

\( ^5 \) A division analogous to the CCS structure (inseparable) was acknowledge as inexpedient because each query requires new division.
similarity have been proposed: the similarity between two documents and the similarity between documents (or clusters) and clusters.

Obtained CCS structure enables an information consumer to improve the document selection process, in which producers provide information to consumers. Improving the document selection means, that the consumer can compare delivered him documents with documents already accumulated in his document base. On demand of consumer system provides him clusters, profiles of which are the most similar to profiles of a new document. The consumer can then give feedback, if already provided documents introduce new information in relation to similar in the subject documents from the base of already accumulated documents.

Next process, in which the consumer of information is assisted by, defined in the article, CCS in the document base, is navigation in the document base, namely in the assemblage of documents, which are an answer to a question led to a search system. During navigation in the document base, the consumer, owing to CCS, can get a set of documents, which is similar in a subject to the present analyzed document or group of documents. The consumer can also compare a profile’s structure of analyzed in turn cluster, what enable the consumer to achieve the estimation of these cluster’s opinion different in a subject. Difference in structures of two clusters provides the consumer with information where are the differences between this cluster and formerly analyzed clusters, so it informs what subject should be expected in average document of cluster, which the consumer would like to look through.

The last process, in which the consumer is assisted by, is presentation of the result of a query. A set of documents, which are relevant to a query is divided into separate clusters. This enables the consumer to compare difference between obtained clusters and then enables to choose the most interesting one.

Abstract: We present recent evolutions in the development of DReSS, a “Document Repository Service Station”. DReSS allows World Wide Web users to collaboratively create and maintain hypermedia documents on a Web server without the need for a login (or ftp upload) access to the server machine. DReSS emphasizes the manipulation of hyperdocuments consisting of several files that are linked together. DReSS is a small system, that is easy to install on any Web server, and that offers users the ability to up- and download sets of files. At the Eindhoven University of Technology DReSS has recently been integrated with an adaptive courseware system to enable students to upload assignment work to the Web-server containing the course text and the assignments. New features in DReSS 2.0 include the ability to use a browser’s upload capabilities, a new and more user-friendly user-interface, the ability to use a browser’s upload facilities, and machine independent client helper applications and server-side scripts, all written in Java.

1. Introduction

World Wide Web (or WWW) [Berners-Lee 94] is a distributed publishing platform. Authors create and change documents locally and upload them to a server, where they can be accessed by their collaborators. While downloading (or “reading”) documents is usually allowed for everyone, and done in an anonymous way, authors need login or ftp upload permissions on the server machine in order to publish their documents. Alternatively, in a local area network (Intranet) the server may have access to the author’s machine or home directory, and copy or even serve the documents from there. To avoid the need for such permissions some document repository systems have been created like BSCW [Bentley 95] and DReSS [De Bra 95].

Groupware is defined [Bock 95] as a computer based system that supports people in the execution of common tasks (or the achievement of a common goal) and that provides an interface to a shared environment. Document repository systems represent a lightweight form of groupware: they offer uploading and sharing of documents among varying groups of authors. Through Internet technology we can create shared workspaces that can be reached from outside the institute or company (see also [Goossenaerts 97] for a business oriented application of a shared workspace) and support collaboration in geographically distributed environments. Apart from shared workspaces systems like BSCW also offer (threaded) discussion groups and on-line meetings.

DReSS (for Document Repository Service Station) has been developed at the Eindhoven University of Technology. It is a tool that provides collaborative information sharing; it enables authors to move hyperdocuments to the WWW server and to update such documents later on. The emphasis of DReSS is on the support for hypertext documents, i.e. for documents that consist of a possibly large number of small files that are connected by hypertext links. BSCW (Basic Support for Collaborative Work) is sometimes compared to DReSS because both systems offer shared workspaces. However, DReSS is specifically designed to be just a document repository, while BSCW aims at providing more complete support for collaborative work, and therefore includes many features not found in DReSS. The strong points of DReSS are the transparent use of URLs, and the ability to upload sets of files in one operation. BSCW is only able to resolve hypertext links (using the HTML <A> tag) in some limited cases, while DReSS handles links transparently, even between documents in different workspaces. At the Eindhoven University of Technology we have integrated DReSS into an adaptive courseware system [De Bra 96, Calvi 97] in order to enable students to upload assignment work to the Web-server containing the course text and the assignments. Such assignment work typically consists of sets of pages

* Paul De Bra is also affiliated with the “Centrum voor Wiskunde en Informatica” in Amsterdam and the University of Antwerp, Belgium.
that contain links to each other and that also contain images, applets, and possibly other types of objects as well. It is important for students to be able to upload assignment work in a single operation, and perform validation tests on the uploaded work immediately.

2. Document Repository Systems

2.1 Requirements for and History of DReSS

The main reason for using a document repository system is to avoid the need for authors to have login or ftp upload permission on the server machine, or for shared file systems between clients and servers. More advanced features like link databases, versioning, and on-the-fly generation of indexing information are worthwhile, but secondary to the goal of providing a document repository system that is easy to install and use, and that can be used with different browsers (and servers) without requiring any modifications to “standard” WWW software. In 1995 DReSS, a tool that turns a WWW server into a “Document Repository Service Station”, was introduced (version 1.1 was described in [De Bra 95]). DReSS enables authors to move documents to the WWW server, and to update documents on the server, without compromising the server’s or client’s security. To ensure that the security of the server and the author machines is not compromised by using DReSS, the set of requirements given below contains several constraints related to security:

- Authors need no login permission on the server machine.
- The server machine needs no (NFS) access to the author’s home directory (or any other directory on the author’s machine).
- The author’s machine must not need to host an ftp- or WWW-server in order to upload documents to the main server.
- All communication is done by means of HTTP. (This may be changed to S-HTTP or HTTP over SSL at a later date for better security.)
- The system must use standard and/or platform independent software: unmodified WWW browsers and servers, and only Java programs where additional software is needed.
- Most of the functionality of the system must be implemented on the server machine (so as to use “thin” clients).
- The author’s WWW browser is the user-interface for the whole system.
- Elaborate access control is needed. The Webmaster must be able to decide which authors may create and edit documents in which directories and the authors must be able to decide who may edit and view their documents.
- The system must prevent simultaneous editing of the same document by different authors.

DReSS, version 1.1 met most of the above requirements. It used CGI-scripts on the server side, and two small auxiliary programs on the client side that were completely invisible to the author. These programs were based on the common WWW library (from W3C) to ensure easy portability. However, that WWW library proved to be difficult to port to non-Unix systems such as Windows-3.1 and Windows-95. Version 1.1 of DReSS was written in C and used on Solaris (release 2.4 on both Sparc and x86) and SunOS 4.1.3 for both the client and server, although client and server could run on a different OS.

Several changes in the IT-environment have taken place since the introduction of DReSS in 1995. A standard for file uploading was defined (cf. RFC 1867 [Nebel 95] which is supported by such browsers as Netscape Navigator. Office environments like the MS-Office and the Wordperfect Office suite offer built-in support for HTML-editing. The Java programming language has been introduced and has found widespread support and usage for Internet/Intranet applications. These developments have led us to reconsider the design and implementation of DReSS to take advantage of these developments. This led to the present version of DReSS: version 2.0. Our key design goal has been to build a low key application that requires a minimum of changes to the Web-client and -server. To make version 2.0 of DReSS portable, both the client helpers and server scripts are written in Java. For DReSS 1.1 two client helper programs were always required. In DReSS 2.0 these helpers are only required for handling hyperdocuments that consist of several files. Single file upload and download can be handled by any modern browser (which supports RFC 1867). The two helper programs perform the following functions:

- When a document is retrieved from the server, a helper program can be used to start a local editor (instead of just saving the document on disk).
When the author has finished editing the document a second helper program uploads the document to the server. (The browser can do this as well, for a single file.) When a set of documents is uploaded to the server, the transfer is performed using a single HTTP request. (In DReSS 1.1 uploading a set of documents required a request per file.)

### 2.2 Client- and Server-Side Helper Applications

The architecture of DReSS (and also of the document repository part of BSCW) consists of four standard components and two types of helpers. Figure 1 shows this architecture.

![DReSS architecture](image)

- On the client side the author of a document is using a standard editor (for text, images or other data types) to create and modify documents, and a browser to interact with the repository system on the server.
- A client-helper application guides the communication between the editor(s) and the browser. It ensures that the editor receives as input the document which the browser received earlier from the server. It also ensures that when the server sends an archive containing a set of documents the individual files are extracted from the archive before an editor is invoked. Another helper ensures that the document is sent back with the appropriate name, and also takes care of uploading sets of documents.
- On the server side a database (called "repository") maintains not only the documents but also some meta-information and history of each document.
- A server-side helper, in the case of DReSS a CGI-script, handles the communication between the Web server and the repository system. It generates appropriate confirmation or error messages for each request from the browser, and it archives sets of documents before sending them to the browser and extracts them from archives before depositing them back in the repository system.

The basis for activating the correct helper program, and for using the correct archival formats is the use of MIME-types. (MIME stands for Multi-purpose Internet Mail Extensions.) A WWW-browser has, as part of its configuration, a list of MIME-type/application pairs. When a Web-server answers a request it sends an HTTP-reply to the server. This reply consists of a standard header, possibly followed by a document. The Content-Type field of that header defines the MIME type of the document that follows. The browser checks its list to determine whether it should try to display the document all by itself, whether to use a plug-in the user has installed, or whether to use a separate (external) application. In order to use DReSS, a special new MIME type needs to be added to the browser’s list, and bound to the appropriate helper application. (On a Unix system this binding can be done in the user’s mailcap file, thus without changing any of the browser’s settings.)

Up- and downloading multiple files is achieved through the use of multipart MIME types (as defined by RFC 1521). This eliminates the need for special archival programs on the server- and client-side, of which few are readily available on all platforms. The DReSS helpers take care of bundling and extracting files to and from the multipart messages.

The possibilities of file systems for maintaining status information about documents are insufficient for document repository systems. DReSS maintains the following information about a document:

- **creator**: the author who first created this document; this info cannot be changed.
- **current author**: the author who is “currently” editing the document.
- **lock status**: when an author wishes to modify a document, that document is “locked” and the author becomes the “current author”; only the current author can release the lock.
- **authors**: the authors who are entitled to modify this document; this is like the Unix “group” concept, but each document by have a different set of authors, without the need for explicitly naming groups beforehand.
- **log file**: a log of all actions (downloads and uploads) performed on the document.

Unlike BSCW DReSS does not have a versioning system, which provides access to all versions of a document that ever existed. Documents are stored as files on the Web server and are available through the URL, which corresponds to that file. This makes it easy to use hypertext links between documents in the same and in different workspaces. The files on the server are all owned by the WWW server daemon. Ownership information is kept in the status database.
3. User-Interface for DReSS

While working with DReSS version 1.1 we identified several points that needed attention to improve the usability of DReSS:

- **DReSS 1.1** only supported one editor (the default was Emacs, but this could easily be changed). DReSS 2.0 supports more editors and a dialog for configuring the editor from within the browser. For different media types such as text, and images, different editors are needed, but also for different textual document formats such as HTML, and MS-Word.
- The original dialog between the user and DReSS was too complicated. The user-interface almost always displayed many buttons for actions that were not possible in the current state. Figure 2 and Table 1 show the (simplified) state-transition diagram for DReSS 2.0.
- The upload protocol supported by DReSS 1.1 was implemented using an ad-hoc encoding, thus preventing the use of the emerging browser-capability to upload files according to RFC 1867. DReSS 2.0 uses the protocol of this RFC, and allows single file upload from within the browser. (Multiple file upload is still handled through a helper application.)
- The multi-file upload in DReSS 1.1 was limited to uploading an entire directory. In DReSS 2.0 uploading specific sets of files can be done through the client uploader interface, which is shown in Figure 3.

4. Application Issues for DReSS

4.1 Machine independence

The main problem we encountered in employing DReSS version 1.1 was the limited portability of the client helper programs. Despite the use of the standard WWW library from W3C it proved difficult to port the helpers to non-Unix systems. This prevented us from employing DReSS for its primary purpose: to enable students to upload assignment work for the hypermedia course 2L670 [De Bra 96]. A finished assignment is a hyperdocument of between 50 and 150 pages (files), so employing a single file upload system like BSCW was out of the question. To solve this problem, and to provide better file (or directory) browsing as well, the helper programs for DReSS 2.0 are written entirely in Java, which means that they should run unmodified on any platform that supports Java. (They have been tested on Windows'95 and Solaris, which are the platforms used by most of our students.)

In order to achieve machine independence on the server-side as well, the CGI-scripts for the document repository have been rewritten in Java. However, this does not result in a completely platform-independent solution, since CGI relies on the ability to pass environment variables from the Web server to the scripts, something which is not possible with Java programs from JDK version 1.1 onwards. (Reading environment variables has not only been marked deprecated but has been effectively removed from the Java support libraries.) The need for reading environment variables is circumvented by wrapping the CGI-scripts in a shell script. The needed shell script for Unix is different from the necessary “bat” file for Windows.

4.2 Groupware aspects

In the present configuration DReSS supports a limited form of groupware functionality, called information sharing [Gibbs 91], which is aimed at the use (and modification) of the same information by different people for performing knowledge intensive activities. BSCW, (and also Lotus Notes) offers an integrated message board, similar to HyperNews or WWWboard. For our courseware we decided to use HyperNews which was readily available, rather than developing yet another message board.

Lotus Notes supports replication of documents but does not offer an automated conflict resolution strategy for updates of the primary copy. In DReSS conflict prevention is realized by providing locks on documents currently being edited by one of the authors. Locking is done at the document level. In [Munk 96] we studied the use of an object oriented database for storing hypertext. The database replaces the file system, and the...
WWW-server is modified to store documents directly in the database. By using an object model for
hyperdocuments which allows them to be decomposed according to their HTML-structure it becomes possible
to access paragraphs or smaller parts in a document. Using the locking mechanism of the database system a
more fine grained access to documents can be supported allowing different authors to work concurrently on
different parts of the same document. Integration of DReSS with the OODB-based WWW-server is a project
which will be started in the near future.

Recently we started another DReSS-related project: to combine DReSS with a Workflow Engine, based on the
ExSpect (Executable Specification Tool) system [Somers 93] developed at the Eindhoven University of
Technology. This effort is part of an educational project aimed at student collaboration in a Software
Engineering course. DReSS is used for sharing the deliverables of the assignment work for this course between
members of a group of students who are jointly performing the assignment. The workflow engine is used to
 guard the orderly executions of the various activities of the project life cycle, and the timely delivery of the
different required documents.

5. Conclusions

DReSS (in release 2.0) has evolved to a platform independent document repository system, through the use of
standard protocols (RFC 1521 and 1876) and helper applications written in Java. The main advantages of
DReSS over similar systems (like BSCW) are:

- **Simplicity**: DReSS is small and easy to install on most Web servers. It offers shared workspaces, to
  which users can upload documents, which can then be updated by a group of authors (but one at a time).
- **Hypertext Functionality**: DReSS is especially suited for applications where documents consist of many
  files, possibly connected by means of hypertext links. A whole set of files can be uploaded or downloaded
  at once.

In the near future we will be evaluating the use of DReSS as part of our hypermedia courseware. This evaluation
will be used to further improve the user-interface and the dialog between user and system.

Abstract: This paper presents the proposal of a model to administrate WWW sites, focusing the communication between the users and the administrator. The main purpose is to minimize and to characterize the tasks involved in publishing Web pages. The prototype, called CallUs, of an automatic system of submission of pages for publication and request of services is presented, as well as the benefits of the proposal.

1 Introduction

Nowadays, many organizations are concerned with the publication of information via Internet Web pages. There are many issues to be addressed in this respect, such as the design and implementation of Web pages, the maintenance of servers and files, the interaction between the network/Internet administrator and users and so on. With the great development of information system and marketing groups in many companies, the design and implementation of Web pages are not network administrator tasks. As a result, many people in charge of developing Web pages are not computing expert. Therefore, they sometimes do not know what steps are involved in publishing their homepages, that is, they know how to build the pages, but they do not know how to make them available for the Internet. In this case, designers have to send the pages to the administrator and ask it to publish them.

Based on the scenario above, we observe how important it is to have a direct relationship between the administrator and the users (Web page designers). This is possible in small companies, but it is not so easy when the company has many groups or departments.

In this paper we propose a model for Web page publication, focusing on the administrator-user relationship. This model can be applied to companies or groups of people with centralized Web administration and with distributed Web page development. Our case study was carried out at the Internet Management Group (LGSI), within the Global Campus Project witch is an agreement between PUCRS and IBM. The Internet Management Group is in charge of publishing almost all the Web pages of PUCRS Departments and we propose some automatic facilities to improve the communication (publishing) process. Thus the CallUs prototype will be presented in the description.
2 Case Study

Our case study is the process of publishing the official Web pages of PUCRS – an university with 50 departments and many administrative groups. This task involves many different people and is sometimes slow.

The Web page publishing process connected to PUCRS main Web page (PUCRS Web server) goes along the following steps: (1) the department establishes the first contact with the Web administrator (webmaster) to identify the resources available and the requirements; (2) one person in that department is nominated the manager of the department pages - this procedure creates a level of security; (3) the Web pages are designed and created by the user; (4) finally, the files are sent, via e-mail or floppy disks, to the administrator who manages the publishing process.

By analyzing all those steps we notice that the contact between the administrator and the users is a presental meeting instead of a virtual contact such as e-mail messages. After some time working on this kind of relationship, we found that many problems such as delays in publishing the pages, off-line updating of pages, change in users attitude towards the Internet and services such as ftp (file transfer protocol) as well as many repeated operations for the administrator had risen.

Therefore, we decided to group up the users into categories based on their knowledge and offer them a better way of publishing their pages. Moreover, we created a structured way of communication between administrator and users. The structure is based on some definitions: dept: it is the name given to any department or group that is allowed to publish a homepage in the PUCRS official Web page; director: is the head of the dept; resp: is the person (indicated by the director) that manages the dept page - he/she is the only one allowed to include, update and cancel the page; webmaster: is the Web server administrator

The first contact is between the director and the webmaster to establish an official entry in the system. After that, the resp is able to access the automatic publication system to include, update and cancel the dept page.

3 The System Proposed

The management of the site is made up by many tasks performed by one or more administrators. The tasks can be listed as follows: receiving the files with the Web pages; identifying their target (directory); testing the pages; creating the links; replacing some pages; canceling some pages temporarily; helping users with the implementation of their pages; managing the News groups; among many other more specific activities. Furthermore, since we found many tasks have to be performed repeatedly and each dept may ask for the same task many times according to the different requirements as shown above, the tasks were included in
the automatic publication system and the result is a different approach to the management of the communication between users and administrator.

From the administrator point of view, the pages can be managed in three ways: no control, partial control and full control. In no control schema the dept pages are fully controlled by the dept. Thus, the webmaster has no control over structure or contents (the webmaster only creates the link in the main page). In partial control, the pages are designed and implemented in the dept and the webmaster is in charge of uploading the pages to the server (main server or dept server) and creating the link in the main page. Finally, in full control, the pages are designed and implemented in the dept and the webmaster is in charge of uploading the pages to the main server, creating the link in the main page and managing the users requirements concerning disk space and others.

4 The CallUs Prototype

The model of an automatic publishing environment was implemented as a Web page that comprehends all the issues discussed in section 3. The main idea is to keep the first contact between the director and the webmaster to create an UserId and a Password that will give access to the automatic system - CallUS. This aims at reducing the direct contact between the webmaster and the user and all this can be done via the CallUs tool.

The CallUs page offers many options such as help systems, ways to manage their pages (in any modes - no control, partial control and full control) and News groups, ways to ask questions to the administrator. A manage page option allows the resp to upload the files, cancel the page for a period of time, change the structure, ask the administrator to change links or include new ones, change any information about the dept and so on.

The results of these requests are presented in three ways: an on-line answer in a Web page, an e-mail message to the resp, or a record in the Web server. All these operations are stored in log files to keep a record of the changes in that page.

The implementation of CallUs included HTML and CGI programming [KewÉ1997]. There are many electronic forms in the Web page to allow data input since the resp has to manage the dept page using the CallUs Web page. In order to perform the tasks, CGI programming which is the way to send information from the client (Browser) to the server was used. The programs were developed in Perl [AndrazaÉ1996; StocktonÉ1996] and C language in a SUN workstation.

Some important issues, such as security, quality and user friendliness were used. It is important to ensure that only authorized users can access the system. Users are happy with the system and the system is easy to use.

5 Final Comments
The project started in May 1997 and the first prototype was made available in August 1997. Since that time, the process of submitting Web page for publication has been done using CallUs. Since the system was introduced, 70 users at PUCRS University have been using it. As a consequence, most of the communications between the administrator and the users is accomplished via electronic mail and electronic form submitting. According to suggestions from users, new features have been added to the system, such as directory management and subgroup options.

Considering that the Internet is available to various kinds of users, we believe that it is extremely important to improve its usage conditions. As we are in charge of publishing Web pages from all departments in the University, our contribution to the improvement of Internet users environment was to introduce novel ways of communication between users and administrators.

Abstract: As a result of the decline in the number of university students in Japan, universities are creating extensions located near major train and subway hubs, the "ekimae daigaku" ("university in front of the station"), permitting easy access to university training for those interested. This concept is now being extended to graduate studies for the first time in Japan by the Graduate Program in Information Management Sciences at Asahi University. Since the main campus of Asahi University is located far from the nearest large city (Nagoya), an extension facility has been set up near the Nagoya train-subway hub. This facility is connected to the main campus by an ISDN-based teleconferencing system together with Internet and Web access. The results of initial experiences with this system are reported. Finally, the authors discuss a number of the problems facing tele-learning in graduate education as well as some possible system modifications.

Graduate Education in Japan - Needs and Crisis

There is a state of crisis in graduate education in Japan in that the number of students is declining. In order to appeal both to full-time working students as well as to students enrolled full-time, the Graduate Program in Information Sciences at Asahi University was created. This program offers both the Master's as well as the doctoral degree in interdisciplinary fields covering telecommunications, multimedia communications, urban planning, economics, and so on. In order to accommodate working students as well as full-time students, night courses as well as courses on Saturday were introduced, perhaps a first in Japan at the graduate level. This gives the program the flexibility needed to handle such a potentially rich source of graduate students. Students working in full-time jobs account for about 90% of the total graduate body at this time. However, the University's main campus is located in the countryside about thirty miles northwest of the major city of Nagoya in central Japan. Nagoya is the center of industry and commerce of that region, and most potential students live and work in nearby areas that permit easy access by subway or train to Nagoya, but require an additional travel burden to access the university. Japanese workers tend to work long hours and students often arise at the university after a long hard day at work as well as after a long trip by car or by public transportation. All these considerations have led to the creation of an extension facility in Nagoya located near the main train-subway hub of that city, hence easily accessible by those working in the Nagoya area. Indeed, there has been a recent trend in Japan of placing colleges and other specialized schools near such hubs, giving rise to the term "ekimae daigaku" or "university in front of the station." The case of the Asahi University facility in Nagoya is the first example, to the best of the authors' knowledge at least, of such a facility dedicated to graduate studies alone. This facility, called the Asahi University Nagoya Satellite (AUN), and the main campus are interconnected by an ISDN-based videoconferencing system and the University's intranet allowing internal and external firewall-protected Internet access.

The Asahi University Tele-Learning Facility

The University's tele-learning facility, inaugurated in the fall of 1997, uses an ISDN-based videoconferencing system as well as an intranet based system to interconnect a seminar room on the main campus and the AUN Satellite in Nagoya. In addition, several professors' offices and laboratories may connect to the system. The equipment configurations at the two sites consist of NTT's Phoenix workstations, Phoenix Wide equipment, Windows NT workstations, overhead projectors as well as standard fax machines and telephones. The overhead projector connects into the Phoenix Wide system, so one is able to display figures or text both locally and remotely. The Phoenix workstations are multimedia Windows 95 machines with Phoenix boards, speakers, cameras and
microphone. The cameras may be moved around manually and arranged as one wishes, as may the microphones. The Phoenix Wide equipment at each site consists of a large television screen and a desktop unit containing speakers, microphone and camera. Camera movement and focus are controlled by a hand-held remote control unit. A user may control the camera at his location as well as at the remote location. Two way connections are easily established, either for the Phoenix Wide or for the Phoenix workstation configurations. Both may be used at the same time. In the case of the Phoenix workstations, one may see the local site as well as the remote location in two separate screens. With the Phoenix Wide system, one may alternate between viewing the local and the remote sites. The sites are connected by ISDN BRI lines. The Windows NT machines are connected to the university’s intranet with a gateway through a firewall to the Internet. An important consideration here is that in Japan, ISDN connectivity is virtually complete throughout the country and the costs are steadily declining, putting ISDN in the reach of the private citizen. For this reason, one might say that the approach towards tele-learning that has been adopted is a potentially inexpensive one using commercially available desktop videoconferencing systems and ISDN.

**Initial Tele-Learning Trials at Asahi University**

The system has been used rather extensively as an adjunct in teaching several graduate classes as well as for various administrative purposes, for example committee meetings with out-of-towners. In the graduate courses, the emphasis has been on creating an atmosphere conducive to the level of thought and reflection required by graduate studies and, in one case, to the use of the system in a bilingual English and Japanese mode. One of the graduate courses is conducted as an interactive seminar on multimedia systems in which the students are queried and encouraged to discuss certain points among themselves. Other courses are given in the more traditional professor speaks-student listens mode. In addition, the system has been used for remote consultations with graduate students on their Master’s or doctoral work. The system is relatively easy to use. Since both cameras can be controlled both locally as well as remotely, there can be conflicts if both sides attempt moving one camera at the same time. But, with minimal preparation, the professor can indeed merely walk into the room and give his course in the modality described above. The physical configuration is critical for optimal use of the facility. Image quality of the Phoenix Wide system was marginally adequate, in fact, inadequate for regarding figures on the whiteboard and marginally adequate for images received from the projector. Voice quality was good, except that care had to be taken about room echoes. The system seemed in fact well adapted to the teaching modality of the courses offered. For large classes, the Phoenix Wide system would not be adequate unless substantial improvement were made to image quality, for example, by increasing the transmission bandwidth to 1.5 Mbps. For large classes, the large enrolment might cost-justify the additional expense.

**Conclusions and Future Work**

Essentially the initial experiences gained show that the satellite facility and the teleconferencing system certainly can be used effectively in dispensing graduate courses as described above. Equipment configuration is critical and more work must be done to determine optimal configurations. The facility can be used effectively now for students who cannot easily come to the main campus. Moreover, as ISDN costs continue to fall throughout Japan and accessibility to ISDN continues to increase, one might expect economies of scale to bring down the equipment prices even further, so that the kind of tele-learning system described in this paper may well become an economical and cost-effective means of offering distance education. Given the specific needs in graduate education for animated interactivity between the professor and his or her students and among the students themselves, the initial results obtained suggest that the kind of system described will be adequate. New equipment configurations and classroom configurations, together with economic feasibility analysis are now being carried out.

Teaching Visual Communication Using the Web

J. Thomas Allen
Robert Chance
Furman University, 3300 Poinsett, Greenville, SC 29613,
864-294-3221, e-mail: tom.allen@furman.edu

Abstract: The World Wide Web is an excellent medium for introducing general students to the elements and principles of visual communication and design. Issues which might have been too esoteric can be explored quite naturally in the context of Web publishing. We describe the rationale for and some of our experiences in conducting an unusual cross-disciplinary course in introductory computing and art. Students learn not only about the technology that supports the Web, but how to exploit the visual medium for communication.
Maximizing the Learning of Information Systems via World Wide Web

Prof. Dennis Anderson
Chairman
Computer Information Systems Department
St. Francis College
180 Remsen Street, Brooklyn, NY 11201
(718) 489-5201
andersnd@cs.nyu.edu

As the Internet and World Wide Web find their place in the global community, they are revolutionizing the way people learn, entertain themselves and conduct business. Companies have realized the potential of these new technologies, turning them into vital conduits for training, information exchange and commerce. Unfortunately, our own discipline, which has laid the foundations for these advances, has failed to take full advantage of the benefits the Internet and World Wide Web offer IS teachers and students.

This presentation discusses how IS educators can revise their current course curricula to incorporate the resources of the Internet and World Wide Web by introducing a schematic model that details dynamic and static structures of Web-based learning environment. It focuses on building Web sites that present case studies. This encourages instructors to reexamine their current teaching methods and redesign their IS programs for their students. This also serves as an opportunity for an exchange of ideas on how to design new IS curriculum and/or the formation of an International IS Consortium for IS professionals.
Improving Lectures and Practical Classes in using an Automatically Feedback System

Bo Ilin Andreas, bollin@ist.tu-graz.ac.at
IICM Software Technology
Technical University Graz, Austria

Abstract: This paper presents an electronically feedback system for use in lectures and practical classes. The system itself is based on Java and provides a configurable feedback form, a managing tool for administrators and a statistic viewer for presenting the generated statistical data in various ways. In addition it generates a statistical history, which is an important instrument in comparing lectures and in tracing effects of improvements (or alterations) of the lecture. The paper shows how anonymity can be guarantee to the user and outlines the resulting problems. It concludes with possible improvements to prepare the system for a more general use.

1 Introduction

Because of today’s big amount of students, teaching and working is, for both sides (tutors and students), hard effort. Materials are often that extensive, that lecturers can only teach parts out of it and only can help students in understanding the whole material. The more it is important to react to students’ wishes and to understand their problems as early as possible. A crucial part of a lecturer’s work is keeping contact to the students (during the lectures, office hours, email, news groups). In addition it is usual to use feedback forms to produce statistics over the lecture. On many universities (as in private companies) feedback is an important tool for comparing lectures and lecturers (or institutions). Ignoring this way of assessment is therefore not only a way of ignorance, it is also stupidity.

Usually at the end of semester feedback sheets are distributed and then again collected. With a one or two days effort (depending on the amount of students) all the forms are analysed and statistical data is generated. In most cases the data is not electronically stored and a comparison between different lectures is not possible. This approach has the following main disadvantages:

- too much time is needed for analysing the data,
- students are (generally) not informed about the results of the feedback,
- possible problems within the lecture are found too late.

It turns out, that only a few points should be altered which then is leading to an improvement of the lecture (see also [Lesgold 98]):

- the feedback should be analysed automatically,
- the data should be available electronically (for later evaluation),
- statistical history should be available,
- the data should be able to be accessed or entered from (nearly) everywhere,
- students should stay anonymous whenever possible (especially when entering feedback data),
- students should see the results of the feedback,
- feedback should be available as early as possible (during the lecture).
Finding solutions for that demands will lead to more motivated students, better lectures and less work for the lecturers. The system itself has to be that interesting, that both, students and lecturers, like to use it. Statistical history is a powerful tool in tracing the development of lectures. As „Illustration is the basis of all cognition’s“ (Pestalozzi) graphical presentation of statistical data helps in understanding the results of the assessment and illustrates the (hopeful) improvement of the lecture.

This paper presents an approach of an electronically feedback system using the World Wide Web (WWW for short) and Java that is trying to fulfil all the demands listed above. The whole work is based on a project [Bollin, Luidolt 95] in 1995, where a feedback system was analysed using an object oriented approach (the Jacobson Method). With Java 1.0 (in 1996/97) it became possible to implement the system over the net and the first try run started in the winter term 1997/98.

2 Strategy for Improvement

At the beginning of the project our students had to fill out the feedback form in one of the last lectures of a term. The data was analysed and the results presented (and discussed) in the last lecture. Strongly motivated from the results of the discussion but stressed from the work of analysing hundreds of feedback forms our institute decided to provide a further service to the students: an electronically feedback form. In 1995 (based on the theoretical study of such a distributed system [Bollin, Luidolt 95]) we implemented parts of it in HTML and used CGI scripts to store the data. This system did not implement the system, as it was designed in 1995. There where two main disadvantages (leading to less motivation to use it):

- no feedback generated for the students,
- statistical data was not generated automatically.

As it turned out, the system was only used by a couple of students. Most of our students did not want to spent their time in filling out forms and saw no profit in using an electronically system. For short: it was not interesting to them. As our institute began to improve its services on the net and started to use an intelligent working environment [Bollin 97], the students became more motivated.

Motivation is the key factor for both, students and tutors. As common Internet browsers became able to run Java applets, we decided to implement the whole system using Java. The system then provided not only a feedback form, but also a viewer for students to display the statistical results of the feedback. With looking at the statistical history of a lecture every student is now able to trace the public mood in a lecture - which indeed is leading to more motivation. Using this approach we were able to increase the numbers of students using the system dramatically [ Tab. 1].

Table 1: Filled out feedback sheets and electronic feedback forms in the lecture „Informatik I“ from 1995 to 1998.

As you can see in table 1 (which is including the trial run of our system in 1997/98) the new system provided much more motivation for students than the old version (with simple scripts in the background) or the paper version. In addition to the fact that analysing the data needed no time, students were highly satisfied with the possibility in looking at the results and used the system more often.
Another problem at the beginning was the scepticism in concern with anonymity. Filling out a feedback paper during the lecture (among hundreds of other students), looked much safer for most of the students. They seemed to be afraid that their opinion might influence their marks. Therefore we decided not to implement identification at the moment.

Every user is allowed to fill out the electronic feedback form, it is also possible to fill out the form more than only once. At the first glance this seems to be a problem, because one student could influence the statistics more than it is wished to, but on the other hand this kind of influence is, to a great extent, also possible with the paper form of the feedback. The problem could only be overcome with partial identification, which will be part of one of our next releases.

As mentioned above statistical history is a main factor for motivation. It is based on the fact, that feedback forms can (and should) be filled out throughout the whole lecture. The statistical history is then generated in the following manner:

1. the deadline is always the end of a month. The monthly summarising statistical data cannot be displayed for the running month,
2. the statistical data collected during the month is analysed and stored separately. This guarantees fast loading times and avoids time consuming computations,
3. the results of all months are summarised and can be displayed graphically.

Following this strategy, every month the data is collected and analysed. A lecture that starts in February and ends in June (five months) leads to six sets of statistical data - the average statistics of the whole lecture (which can be displayed at any time) and the statistics over every month (which can be displayed after the end of the first month). Displaying the results of a question (for example: „How interesting is the lecture?“) leads to a good representation of the mood during the lecture (see [ Fig. 1]). This graphical interpretation of the mood during the lecture could be a good basis for tutors improving their lectures.
3 Design and Implementation of the Client

The latest version of our system is now fully based on the object oriented design and was implemented in Java JDK 1.0.2. We decided not to use JDK 1.1 to be sure, that our applets are also running on older versions of Internet browsers (like Netscape). The system is designed to be used across the Internet and therefore all class files are stored in a JAR (Java Archive) file, whose size is only 76 Kbytes. The JAR file together with a starting page now resides on our Hyper Wave Server [Kappe 93] and is accessible through the Internet (http://www.ist.tu-graz.ac.at/Feedback/Feedback.html).

![Diagram of Client and Server](http://www.ist.tu-graz.ac.at/Feedback/Feedback.html)

Figure 2: Principal structure of the feedback system. The feedback server has to run on the same machine as the http server, applets are started on demand.

At the moment the feedback system provides following functionality:

- feedback form for anonymous users. It provides an electronic implementation of a typical feedback sheet. The user is able to select a lecture and to fill out all or only some of the questions in the form. *No identification* is necessary to fill out the feedback form. At the moment there are two types of questions possible. Questions with radio buttons (one out of five: 0%, 25%, 50%, 75% and 100%) as a rating and questions with a textual entry field for answers or comments.

- viewer modes for anonymous and identified users. The viewer modes for anonymous and authorised users differ a little bit. Without identification every user is able to look at the statistical results. Anonymous users can get numerical and graphical feedback of a lecture and are able to trace its statistical history. The authorised user (the lecturer or tutor in praxis) has the same possibilities than the anonymous, but furthermore he is able to look at the comments and to browse through single feedback forms. This design decision guarantees, that private comments are not public to all students and students cannot see feedback forms in detail (which providing a higher level of anonymity).

- feedback administration across the net. As for authorised users a user name and password (encrypted) must be supplied. The administrator has the possibility to add, modify or remove lectures. Removing lectures is only possible after storing old statistical data to disk. Furthermore it is possible to administrate users and modify the feedback form. At the moment there is only one kind of feedback form, which means that the modification of the form leads to the modification of all forms of all lectures.
on-line help available in every mode. It describes the functionality of the system and tells the users how to
work with the system (filling in the form, browsing through statistical data or editing the feedback form).

The system itself consists of several Java classes, that are downloaded on demand (see [Fig.2]). At the
beginning (browsing an index page that includes the „Start Page Applet“) the user has the possibility to choose
between filling out a feedback form („Feedback Applet“) or to look at results of the feedback („Viewer Applet“).
Depending on the user’s choice, all necessary classes are downloaded from the http server and the applet tries
to connect to the feedback server via sockets. For technical reasons (the standard security manager of Java that
is implemented in common Internet browsers allows connections only to the computer, from where the applet
comes from) the feedback server must reside on the same computer as the http server.

Every time the user wants to look at different data, a connection to the server is established, the needed data is
transferred and then the connection is closed. This approach has two main advantages:

- it is not necessary to transfer the whole data to the client
- every time it is guaranteed that the user receives the latest information.

Every client uses commands for filtering out only that information that is needed for representation on the
display. This guarantees short loading times and fast presentation of the data on the display.

4 Design and Implementation of the Feedback Server

Client and feedback server are using sockets for communication. We decided to use a simple (textual based)
protocol for transferring commands and data. After a keyword a space is necessary, the hyphen is the
semicolon. The server listens on a specified port till a connection is opened. It then starts a new process and
resumes listening on the port. The new process now waits for a command, responds to it and then again waits
for the next command. After a time-out (default is one minute after the last command) the server kills the
process and closes the connection.

This strategy provides following advantages:

- the system is stable because old connections are at least closed after one minute
- the system is easy to debug,
- it is possible to implement textual based clients (GNU Emacs for example),
- the user always gets the latest data.

Some of the commands require prior identification. In this case the client has to send the user name and the
encrypted password to the server. The server process then checks the password and changes the process status.
User names and passwords can be stored by:

- using the server’s database
- using network information services like NIS or NIS+

In addition to storing user names and passwords in the local database the server has the possibility to look up
user names and passwords in local or global information systems. This is implemented by a configuration file,
that specifies a way in accessing the local or global password database and describes how to filter out the full
user name and (encrypted) password.

At the beginning of a new month the server process collects all the data from the last month, generates a
statistical representation and stores it in the database. If a client wants to view the statistical history of a lecture
the server looks up in the database if such data is available. If he finds the data, he sends it to the client, otherwise he tells the client, that up to now no data is available.

5 Future Work

Though this version of our client runs without problems, there are a few things that we like to improved in the future:

- multiple feedback sheets,
- more kinds of question types,
- multilingual interface,
- different levels of identification,
- secure communication channel.

At the moment, only one standard form of feedback is supported. That means, that the feedback form is the same for all lectures (even after modifying the form). That is surely enough for universities where there exists one standard form for all lectures. When thinking about a universal use, different forms of feedback sheets should be possible. analogue to this demand there should be more kinds of question types possible. Entry fields and radio buttons should be extended with check boxes, slide bars, graphical entry fields, or even a voice recorder. Universal use also implies the possibility of using different languages (not only German as in this version).

Another extension is the implementation of different levels of anonymity. As stated above, identification might be a problem for students. Nevertheless, to restrict the number of votes, identification is necessary. A three-level identification will be built into the next release (totally anonymous, registered but anonymous to the lecturer and identified). With identification encryption of the password is not enough. Feedback data is then sensitive data, so that using a secure connection will be necessary.

Even without all the improvements to our system the automatically feedback is surely of big help for students and lecturers. In times, when more and more work is done across the Internet, quality and motivation should always be of main interest - this electronic feedback system should be a brick in the wall of things that should be done to guarantee high quality in education and assessment.

Teacher Training for Intranet-Internet Technologies in the Curriculum

Dr. George Araya
Technology Department, Desert Sands Unified School District, U.S.A., george@surf.dsusd.k12.ca.us

Abstract: Teachers from grades K-8 began a training process of effectively using computers in the curriculum which, when finished, will give them 150 hours of training. The most challenging part of the project is to produce profound results in the learning that occurs in classrooms and to be able to produce enough data to prove the efficacy of the new learning system. In order to accomplish these changes, we have decided to implement the training using the latest Internet-Intranet technology available. The main features of this Internet-Intranet technology is that it allows teachers to prepare students' activities and lessons on-line on the fly. Information is stored in a SQL database allowing immediate generation of reports and feedback for future training.

1. Introduction

The big challenge for school districts that have technology in place is to motivate teachers and students to use the latest technology in the learning process. A systematic and sustained training using Internet and Intranet technologies for teachers is one of the most efficient alternatives to change classrooms into 21st century learning centers.

Desert Sands Unified School District began to train its teachers in March, 1998. Teachers from grades K-3 were selected to begin the training process. Approximately 120 teachers from grades 4 - 8, and 12 more teachers from grades K-3, will begin the training process in September 1998. In two and a half years, teachers will complete 150 hours of training to effectively use computers in the curriculum. In the following years, 185 teachers from grades 4-8 will complete the training process. During the next four years, we will train over 350 teachers, grades K-8, in a systematic approach of incorporating computers into the classroom activities.

2. Project description

In order to motivate teachers to participate in training, each teacher will receive in exchange for their learning time a personal 233 MHZ MMX multimedia laptop computer. In addition if they agree to training, their classroom will be equipped with 4 networked multimedia 300 MHZ MMX computers and a 16-port 10/100 Mbs Switch.

In order to be effective, teachers will come to training for only 2.5 hours a week. The intent is to allow teachers time to assimilate the information they will receive in classes and to put that information into practice in their classrooms. They will become doers and not just listeners.

The most challenging part of the project is to produce profound results in the learning that occurs in classrooms and to be able to produce enough data to prove the efficacy of the new learning system. In order to accomplish these changes, we have decided to
implement the training using the latest Internet-Intranet technology available. The following is the format for the systematic training process:

1. The trainer will develop a set of activities that teachers will do in the training session using the Web Browser. Teachers will open the activities for the day and will submit their answers on-line. They will also submit their activity projects to the web page. Assignments for teachers for the next session will be related with concepts that they learned in the training session.

2. As part of the assignment, teachers will prepare a set of activities for their students using the same format that was used for their own training. Students of these teachers will do the activities in the classroom that their teachers prepared for them. All students' answers will be submitted on-line on the web page.

3. In order to understand the benefits of this approach, it is necessary to mention that all reports and information are stored in a SQL database server. All forms and on-line resources are located in the Intranet, securing the information from outside viewers. Students can access lesson plans only from their teacher, but teachers will have access to the bank of lesson plans created by their colleagues. Every teacher has a unique identification and students are correlated with their teacher's name.

4. One of the main advantages for the instructor who is participating in the staff development is the generation of reports that can link training activities that they do in training sessions to the results of their students. Because most of the activities that students will accomplish in the classroom are related to teachers' training, the information stored in the database will provide valuable information about the process.

5. The use of this stored information will provide the instructor with valuable information weekly which he/she can use to adjust the training in relation to the failures and successes of teachers as they are applying their learning. Instructors will have the opportunity to adjust their instruction according with to the results of students in actual classrooms.

6. The continuous training-feedback process for two and a half years will provide high quality training results.

Our condensed presentation of this in-progress project at the WEBnet98 conference will include the presence of at least two instructor-teachers who are participating in the project.

3. Summary

In summary, the project will develop one of the most unique ways of combining staff development and Web technologies to accomplish prominent results. Only with the availability of the Web technologies that we have in place today we can accomplish immediate feedback. This feedback from the effects of the training allows adjustment of instruction. The accumulation of all related data will provide more than sufficient proof of the winning combination of high-end technology applied to a structured training process. Students will be the winners!
ABSTRACT: We describe a series of lab exercises developed for an Internet course targeted at non-Computer Science majors. These hands-on experiments were designed as a means of providing concrete examples of how the Internet works. Our goal is that students should not merely acquire the skills to make effective use of the Internet, but should gain an understanding of the underlying concepts and principles.

Introduction

Recognizing that email and the web are essential tools for all college students, many colleges have introduced courses on the Internet for the general student. In developing a college-level course on the Internet, we are wary of designing a course that is narrowly focused on teaching skills. Rather than merely teaching our students how to use the Internet, our goal is to provide a conceptual understanding of the way the Internet works.

Students can more easily learn "how to" when they understand how and why these techniques work. Computer science in general, and the Internet in particular, is a rapidly changing field. The state-of-the-art tools of today are likely to become obsolete in the near future. Students who understand the principles involved will be better prepared to use new software as the technology evolves.

It is our responsibility to prepare our students to be informed citizens in a technological society. Social and ethical issues relating to the Internet cannot be fully addressed without a true understanding of the underlying technology. For example, a student who understands the way email software works can appreciate the ease with which email can be forged or tampered with. This student will be better prepared to analyze controversies regarding wiretapping and encryption.

Non-computer science majors require very concrete demonstrations and hands-on experience in order to understand concepts and principles. These students generally have had little computer experience, and have not developed the abstraction skills that computer science majors acquire through their program of study.

In this paper we describe a series of hands-on exercises that we developed to provide insight into how the Internet works. The experiments afford the students the opportunity to experience the way various protocols and software interact, transforming students from passive listeners to active explorers.

Background and Context

Brooklyn College has an undergraduate enrollment of about 10,000 students. The student body is diverse and reflects the City's many ethnic groups and socio-economic classes.

Our course, CIS 3, The Internet, is a two-hour lecture/two-hour lab, three-credit course for non-Computer Science majors. Although students registered for this course are not expected to be computer-savvy, they all will have taken a one and a half credit of computer literacy course.

The course goes beyond the Internet-based Math/Computer literacy course described by [Gurwitz 97]. The course shares a treatment of HTML [Musiano & Kennedy 97] and JavaScript [Flanagan 97] with that described by [Mercuri et al. 97], but does not go as far in programming, opting instead to include forms, network concepts, ethics and the labs we describe below.
In developing the course, we were disappointed that we could not find a textbook that would serve our approach. We found that texts on the Internet tend to fall into two categories: highly technical books suitable for Computer Science majors, and very light "cookbook"-style texts targeted at non-CS majors.

Two notable exceptions are the books by [Comer 97] and [Lehnert 98]. Comer's book provides a non-technical explanation of the way the Internet works, but is lacking in terms of providing direction for further exploration. Lehnert's book (which we have adopted as the course text) is an excellent "how-to" book which includes many references and suggestions for hands-on learning.

Although Lehnert's book contains suggestions for many online exercises, these exercises are for the most part skills-based. For example, typical hands-on exercises are a Web scavenger hunt and design of a home page. These types of exercises should certainly be included in a course such as ours. However, our aim is to go beyond skills-based exercises and develop experiments that can provide insight into the nature of the Internet.

Our Environment

Brooklyn College has a campus LAN that connects a variety of PC labs and classrooms, Mac labs and classrooms, and Sun labs to each other and the Internet. All students received Unix accounts in one of the Sun labs for this course. Because these were non-majors, an extremely minimal but relatively gentle environment was created for them, one that allowed them to create, edit and manage files-- mostly so they could create web pages-- and have experience with the standard Unix mail client. From the perspective of the lab modules that are described below, the most important tool that the students had access to was telnet. The telnet tool was used by students to access their accounts from anywhere on campus. More significantly however, telnet can be used to open any TCP connection with a TCP server. The telnet user controls this by specifying the appropriate port number for the server to be contacted. Thus, telnet machine 25 contacts an SMTP server at machine whereas telnet machine 80 contacts an HTTP server at machine.

Five Insightful Experiences

(1) Experiencing IP: The traceroute Experiment

At the heart of the Internet is IP, the protocol that among other services creates a virtual network that provides the illusion of direct point-to-point connectivity. To comprehend the Internet, appreciate its achievement, understand the nature of slowdowns, and recognize the complexity of certain social, legal and ethical issues, the illusion must occasionally be dropped. There is no better way of doing this in a concrete fashion than using the traceroute facility.

The traceroute ("tracert" in DOS) utility displays the path that a packet takes from the executing machine to a given IP address. Each hop (i.e. router) is shown along with additional timing information. A typical example of output is:

```
traceroute to www.aace.org (205.197.102.18), 30 hops max, 40 byte packets
  1  default (146.245.1.90)  0 ms  0 ms  0 ms
  2  146.245.3.9 (146.245.3.9)  2 ms  2 ms  2 ms
      ...  9  sl-bb6-pen-6-0-0.sprintlink.net (144.228.60.21) 11 ms 21 ms 12 ms
      10  core4-hssi5-0.WestOrange.mci.net (206.157.77.105) 19 ms 40 ms 16 ms
          ...  13  nibbles.cstone.net (205.197.102.18) 139 ms 94 ms *
```

The output reveals the unseen part of the Internet, exposing an institutional complexity and technical virtuosity rarely appreciated by most users. Repeated use of traceroute reveals the dynamic character of the net, as timings and even routes change.

Following a demonstration of traceroute in the lab, students are invited to trace routes to their favorite web sites and note the differences. Although this demonstration/experience did make a big impression, we went further. We assigned our students the task of deducing as much as they could about the campus LAN topology by going from one lab or office (with permission) on campus to another, tracing internal routes.
Unfortunately, in many labs and offices, traceroute was unavailable; as a result, there were not enough
obtainable routes to deduce the campus LAN technology. However, some deductions could be made and the
better students greeted this task with enthusiasm and increased intuition about IP and routing. In the future,
we plan to arrange for a greater number of points from which to do traceroute.

(2) Experiencing Client-Hood: Playing the Role Of An Email Client

If the Internet's heart is IP, then its soul is client-server computing. As casual users of the net, our
students are frequently working with client software. Often they are aware of the existence of servers (thanks
to messages informing them that the server is down or refusing their request). However, they have little sense
of the nature of client-server computing and are only dimly aware of the distinction between different kinds of
servers. Part of the goal of this lab module and the next is to correct this.

We start by showing students a live session of sending mail on a Unix system, with the -v switch turned
on. What they see is something like:

```
louis (1) > mail -v arnow@its.brooklyn.cuny.edu
Subject: show off SMTP
here is the message

```

What we see after the message is sent is the client reporting its TCP connection to the appropriate mail
server and a transcript of its dialog -- using the SMTP protocol -- with that server. We provide a hardcopy of
this to the students, clearly indicating the client's lines (boldface above). In the context of this
demonstration we discuss the nature of client-server computing, protocol in general, and SMTP in particular.

Again, the key to reaching students is not to leave the topic with a demonstration but to give them hands-
on experience. In this lab, they are to use telnet (on DOS or Unix) to contact the machine with the mail-server
for the class on port number 25 and engage it in a client-server exchange. They are to use SMTP as a language
with the goal of sending themselves email.

The second part of the lab is to recognize the possibility of sending faked email. Their task is to send
mail to their instructor so that the header appears to come from their favorite fictional character or celebrity
but with their own name in the message body so that they can get credit. As they work on this, the instructor's
mail headers are continuously displayed on the overhead monitors and soon mail from the likes of BugsBunny
from CartoonLand.org starts to appear.

The fake email lab provides a setting for a discussion on ethics in cyberspace [Baase 97]. It also
generates a good deal of healthy skepticism regarding the automatic authenticity of Internet information.

(3) Experiencing Client-hood: Playing the Role of a Web Client

BEST COPY AVAILABLE
In this exercise, students used telnet to establish a connection to HTTP servers. The protocol they used was much simpler than SMTP. They just had to send a line starting with "GET", a path specifying the resource, and the version of HTTP, all followed by a blank line. A typical interaction (student typing shown in bold) was:

```plaintext
atrium15>telnet 146.245.2.68 80
Trying 146.245.2.68...
Connected to 146.245.2.68.
Escape character is '^]'.
GET /~arnow/index.html HTTP/1.0
HTTP/1.1 200 OK
Date: Tue, 03 Mar 1998 17:21:48 GMT
Server: Apache/1.2.5
Last-Modified: Mon, 13 Oct 1997 01:18:38 GMT
Content-Length: 1698
Accept-Ranges: bytes
Connection: close
Content-Type: text/html

<HTML>
<HEAD>
<TITLE>David Arnow's Home Page</TITLE>
</HEAD>
<BODY>
<H1>David Arnow's Home Page</H1>
</BODY>
</HTML>
Connection closed by foreign host.
```

This experience again highlights the control-information/data-content duality of network communication and reveals a different kind of client-server relationship than the one they experienced exploring SMTP. Applying this to a web page that contains multiple images demonstrates another point that benefits from concrete experience: each web page displayed typically requires multiple repeated connections and HTTP interchanges. After this lab, the flurry of status bar messages seen in browsers became more understandable.

To enhance the lab experience, we arranged for the large overhead monitors to continuously display the last 20 lines of the access log file that the HTTP server maintained. As the various student web clients made contact, their information was displayed. We had earlier discussed the fact that an HTTP server may maintain access, referrer and error logs and had actually examined these files. However, the students were startled to see their own web activities instantly displayed on the monitor of a different machine. Novices apparently do not fully grasp the distributed character of the net without concrete demonstrations like this-- mere use of a web browser is too much like any other desktop computing experience.

In addition, students were intrigued by the "Big Brother" aspects of this. Again, we believe that although they all knew "in principle" that their web activities could be recorded in part, this aspect of web use isn't appreciated until they directly experience it for themselves.

(4) Experiencing Encryption: Using Pretty Good Privacy Encryption Software

Students who have completed a lab in which they sent fake email are eager to learn how safeguard against such forgeries. In this lab exercise, we illustrate the use of PGP (Pretty Good Privacy) software, which provides an implementation of double-key cryptography.

The first part of the lab is to have each student generate a key pair. When a key is to be generated, the user is offered a choice of security levels - low grade, high grade, and "military" grade. We ask different students to select different choices. The students requesting the higher security levels find that it takes more time for their keys to be generated than for the lower grade keys. This provides a concrete example of the tradeoff between tight security and fast execution time.
The second step is to have the students clear sign a text file with their private key, and verify the signature. Then we ask the students to edit the file slightly - perhaps change only one word of the text - and then attempt to verify the signature of the tampered file. An abbreviated sample session is shown below:

```
atrium46> pgp -sat +clearsig=on testmessage

... Copyright notice displayed here
A secret key is required to make a signature...
You need a pass phrase to unlock your RSA secret key.
Key for user ID "Chaya Gurwitz <gurwitz@sci.brooklyn.cuny.edu>"

```

A naive user might be amazed when the verification fails -- after all, he may realize that he wouldn't have been able to detect the change on his own!

The final step involves verifying email coming from the instructor. We post our public key and have the students add that key to their virtual key ring. Then we send a series of email messages, some authentic and some not, and have the students determine which messages are legitimate.

The PGP lab naturally ties in to a discussion of the controversy over digital wiretapping and attempts by the government to limit the use of cryptography [Baase 97]. These issues relate to the broader conflict between individuals' rights to privacy and government's need for access to privileged information.

(5) Experiencing Cookies

Whether because of their whimsical name or the discomfort of having external entities modify one's computer, students and Internet users in general have a fascination with cookies. In this module, we leveraged the work the class did with forms and JavaScript so that each student could set cookies and then discover the cookies their machine was providing.

Setting cookies is easy in JavaScript. It simply involves assigning a long string to document.cookie:
The string consists of a name-value pair which is the content of the cookie, an expiration date, and two fields, domain and path, that control which web pages can receive the cookie. No web page outside the indicated domain will get the cookie. Furthermore, the string following "path", in this case "/-arown" prevents any web page whose path does not start with "/-arown" from receiving the cookie. Thus, in the case above, only web pages on the server acc6.its.brooklyn.cuny.edu and within user arnow's web pages will receive the "food=junk" cookie.

Reading cookies in JavaScript is complicated and beyond the scope of the class. Reading cookies is easy in CGI, but the students were not allowed to write server-side scripts. We therefore provided a simple CGI script that students could reference in the ACTION field of a form as a means to discover the cookies their browser is sending:

```bash
#!/bin/sh
# showcookie CGI script
echo "Content-type: text/html"
echo "cookies received = $HTTP_COOKIE"
```

Students could include a minimal form in a web page to activate this script with a submit button:

```html
<form action=http://acc6.its.brooklyn.cuny.edu:/cgi-bin/showcookie method="post">
<input type="submit">
</form>
```

With this apparatus in place, the fun and the insight begins. The key point for the student to see is that the domain and path fields control the circumstances under which the cookie is sent back. Changing path to "/-studentA" prevents the cookie from being sent when the web page belongs to studentB. Students readily could verify this by accessing each other's showcookie pages.

Unlike the other exercises, this exercise demonstrated that there is "less than meets the eye". This demystification is as necessary as the four ones above-- and is appreciated by at least some of the students.

Summary/Conclusion

The experiments described here are easy to incorporate into an Internet course. Our experience has been that students are intrigued by these labs and find them the most interesting part of the course. The hands-on activities enhance their absorption of the lecture material. We feel that these experiments illuminate some of the inner workings of the Internet and that our students gain a firmer understanding of the Internet than they would from either a purely skills-oriented course or even an Internet-programming (e.g. JavaScript) course.

darinad@fmi.uni-sofia.bg

Abstract: The topic of the reported research concerns how the overall information management task is split into several sub-tasks that are distributed among team of information agents. We aim to design an architecture of a distributed agent-based system allowing co-ordination and communication between single agent entities according to the main tasks involved in information management. The work is based on a generic way of structuring the information, based upon conceptual mapping of the information domain. We model the relationships between attractive user-oriented visualisation of information and information structures and the effectiveness of information retrieval, search, and usage by users. In respect to these objectives a small system prototype, called AIMS - an Agent-based Information Management System, is under development.

1. Introduction

There are number of problems encountered in respect to the task of searching and finding relevant information in large scale information contexts. Some of them concern complexity of human-computer interaction, unstructured and dynamic searchable information, dominant mode (textual) of its presentation, lack of effective information management tools and support of collaboration in Information Search and Use (ISU) task. Due to these factors, the ISU task as situated in the Internet context involves extreme complexity.

Our research is purposed to find possible directions for overcoming the problems as mentioned. When discussing ways of solving them we do not consider a single-item technique, but a combination of methods and techniques in order to provide an integrated solution. This paper discusses some findings resulting from our research in respect to problem solving potential of combination of several technologies, like knowledge representation, automated-learning, graphical representation and visualisation, user modelling, collaborative work support, and agent-based technology. This could result in the construction of flexible, adaptive, user-oriented information management environments.

2. AIMS: Main Design Principles

Our paper discusses work in progress related to the design and development of an Agent-based Visual Information Management System (AIMS). It is resulting from several research projects involving the Department of Educational Science and Technology at University of Twente, The Netherlands, and the Department of Information Technology at the University of Sofia, Bulgaria.

The main design principle is based upon the 3A (Accessibility, Adaptation, Attractiveness) approach to organisational memory [Aroyo, De Diana, Diakov 98]. We do not conceive information manipulation as the mere application of simple search engines to collections of information items, but as a task that necessitates a concise system architecture bringing together the main functional modules for manipulating collections of resources situated within a knowledge- and information sharing environment. A 3-dimentional architectural framework is applied employing multi-agent support for intelligent information manipulation over a visual
representation of the information domain, and a conceptual organisation of resources involving semantic mapping techniques.

3. General System Architecture and Main System Modules

The main activities in AIMS are carried out by agent modules based upon theoretical and empirical results of current agents research [Maes 94, Mueller 96, Wooldridge, Jennings 95]. The system architecture is presented in [Fig1].

Figure 1: AIMS General Architecture.

The objective of the search abilities is to allow for mapping between users' specified needs and the items in the information domain that could be answers to the need. The Search Agent performs intelligent search activities over the given information domain by receiving well specified queries and finding the relevant documents. The working algorithm is based on relations among documents, keywords, synonyms, and domain terms.

The main goals for embedding visualisation techniques within AIMS are to facilitate the users' comprehension and to provide means for easy navigation and manipulation of large amounts of information by a conceptual knowledge-based structuring and organisation [Donald 83], and to provide an easy manipulating overview of search results, information domain and terms with their conceptual relations. that can make the search process more efficient for the user (VUI, Conceptual Dimensions, Inc.). The User Interface Agent in AIMS takes care of the direct system-user communication.

Our approach to user modelling is mainly based on observing users' actions (in interaction with the system) and collecting system and user information that is afterwards transformed into the system's knowledge about the user.

4. Conclusions and future perspectives

Future perspectives are aimed at development of functions that can assist users in finding valid and relevant answers to queries, coupled with the potential for application of answers to those queries in multilingual environments and not in the last place- the development of tools to support information visualisation. In respect to visualisation one of the prime issues is advanced adaptability of the user interface and related information presentation.

5. References

Abstract: There is currently a strong interest in web database tools for building web applications, particularly dynamic web sites. This paper briefly discusses the advantages and disadvantages of three major classes of web database solutions — CGI, server-side programming languages (APIs), and database tools with built-in web capabilities. In general, server-side programming languages are the most cost-effective solution for moderately-sized applications.

Types of Web Database Tools

One of the hottest topics in the Internet development community in recent months is web-enabled or web-based databases (Spitzer, 1997). It is no accident that this rise in popularity coincides with the increase in industry and business use of the inter- and intranet. The largest single type of business and enterprise computing application is client-server database transactions — this need is driving the production of a wide variety of web tools for interfacing with and controlling databases. Though the majority of these tools are designed for traditional database tasks in the corporate environment such as data entry and retrieval, they also provide the opportunity to fundamentally change the way websites are produced, managed, and delivered (Yang, et. al., 1996). This paper will discuss the tools that can be used with databases to dynamically manipulate web pages.

There are three basic methods for integrating databases with the web: Common Gateway Interface (CGI)-based scripting; server-specific application programming interface (API) programming; and publishing capabilities and plug-ins for data-oriented products. Each of these approaches has a different balance of costs, reliability, portability, as well as effort on the part of the designer(s). The underlying assumption is that the benefits of database-web interfaces is worth the trouble!

CGI is the standard method of interfacing a HTTP server with an external program. Theses external programs are normally some sort of script, commonly written in Perl. CGI can also interface with compiled programs in a languages such as C and Java. The major advantage of CGI is that it is a standard feature of all HTTP servers; it’s a viable solution on all web servers and requires no special software to make it work. Another advantage is that there are literally thousands of public domain Perl scripts for CGI available online. The biggest disadvantage is that executing a CGI program requires a significant amount of the server’s resources, a situation that can lead to serious performance problems if the script is commonly accessed by multiple users. It also requires knowing a programming language and having some facility with server software.

Despite the disadvantages of CGI, it remains a popular method of interfacing databases and the web. The databases are typically flat text files that are accessed through text-processing scripts. Perl is the language of choice for text processing, with Python also offering advantages for text databases. A public domain UNIX database, mSQL, is a more sophisticated solution that interfaces with the web through CGI. Neither method is particularly applicable to existing databases or causal users.

The problems with CGI, particularly the performance issue, has been addressed by several server manufacturers through the development of application programming interfaces (API) for their server products. A server API allows clients such as web browsers to interface directly with the server instead of an external program. They typically work with any ODBC-compliant database, which covers the range from access to Microsoft SQL server to high-end Oracle databases. This has the advantage of increasing the speed that the server can respond to data requests, especially in multi-user systems. The biggest disadvantage is that these methods are server-specific, so programs can’t be shared between platforms. Netscape (NSAPI), O’Reilley...
(WSAPI), and Microsoft (ISAPI) have all developed their own incompatible frameworks to handle a variety of server tasks, including database access.

One distinct advantage of using a server with a data-enabled API is that third-party tools exist to help create applications that use the server API. Cold Fusion (Hightower, 1997) is a superb database interface tool that rapidly decreases the amount of time it takes to develop web-based applications. Microsoft's Internet Database Connector (IDC) (Dobson, 1996) and ActiveServer Pages are also tools that make it easier to develop applications using server APIs. Writing applications that take advantage of APIs directly is beyond the capabilities of most casual programmers, so third-party tools such as these provide an excellent way to create high performance web sites at a moderate cost.

The most intriguing, most expensive, and most powerful solutions to web databases probably are the enterprise-level, object-oriented database products (Davis, 1996) from such manufactures as Netdynamics, Oracle, and Informix (McKenzie, 1996). Object-oriented databases are well-suited to the web since there are many types of media other than text that can be stored in web databases. Many of the existing large-scale database products have been extending their capabilities or designing new products to meet the needs of dynamic websites (White, 1996). These products are robust, especially in multi-user systems and can be adapted to virtually any task, but they are very expensive. They also require a significant investment in manpower and obviously the programming and development work is not portable to other platforms. Another interesting feature of this type of solution in that the data is central to the tool, and the web is simply treated as a way to display or publish that data; the other approaches to web databases put the web at the center of the effort with the data in a supporting role.

Conclusions

It is clear that databases and the web are clearly a useful combination of computer technology (Hadjiefthymiades, 1996); the real question is what tool to use to implement that connection. From the preceding discussion, it is clear that the appropriate solution is most dependent on the database traffic on the website and the technical capabilities of the support staff. In most moderately sized applications, a casual programmer can learn to use a third-party, API-based tool to create web-based web applications. These tasks are also fairly modularized, so they can be outsourced for modest initial cost and low maintenance overhead. Individual, low-use, and budget applications can make use of public-domain CGI scripts for effective, if not high-performance, data access. The high-end solutions are only appropriate for institutional-level commitment of time, money, and personnel. Since effective solutions exist for all project sizes and budgets, there is no reason for not incorporating dynamic data-delivery into any website today.

Abstract
Assistance in retrieving of documents on the World Wide Web is provided either by search engines,
through keyword based queries, or by catalogues, which organise documents into hierarchical
collections. Maintaining catalogues manually is becoming increasingly difficult due to the sheer
amount of material, and therefore it will be necessary to resort to techniques for automatic
classification of documents. Classification is traditionally performed by extracting information for
indexing a document from the document itself. The paper describes the technique of categorisation
by context, which exploits the context perceivable from the structure of HTML documents to extract
useful information for classifying the documents they refer to. We present the results of experiments
with a preliminary implementation of the technique.

1. Introduction
Most Web search engines (e.g. Altavista™, HotBot™, Excite™) perform search based on the content of
documents and provide results as a linear list of such documents, typically ranked in order of relevance. The
often unsatisfactory aspect of this approach is that the list can be quite long, with many replications, and
without any indication of possible grouping of related material. For instance, issuing a query with the keyword
"garbage", one would obtain a list of documents that discuss ecological issues interspersed with documents
about garbage collection in programming languages. Splitting the list of retrieved documents into thematic
categories would significantly facilitate selecting those documents of more interest to the user.

Notable exceptions to this approach are Lycos™ and Yahoo™, which maintain a categorisation of part of
their search material. Actually Yahoo gave up its general search service in favour of Altavista and supports
only searches within its own catalogue. This allows a more focused search restricted to the documents within a
given category and also the results of a query are presented arranged within subcategories.

However both Lycos and Yahoo are based on manual categorisation of documents performed by a small
set of well-trained categorisation technicians (even though Lycos™ recently announced the development of an
automatic classifier).

It is questionable whether manual classification will be able to scale well with the growth of the Web,
which will reportedly reach over 30 terabytes within 2 years, a size larger than the whole US Library of
Congress.

First, manual classification is slow and expensive, since it relies on skilled manpower. Second,
categorisation is quite a subjective task and the consistency of categorisation is hard to maintain when several
human classifiers are involved.

Finally, the task of defining the categories to use (hereafter called catalogue) is also difficult and
subjective, and new categories emerge continuously in many domains. For example, documents relating to
ActiveX technology might fall within operating systems or within graphics or within object-oriented
programming. None of these categorisations would be satisfactory, since each of them would miss to establish
close connections with other related technologies, like CORBA, JavaBeans, etc. In this case it seems that a new
category is emerging ("Software Components") which is not currently envisaged. In fact, by browsing the Web,
we may discover several pages that contain references to documents relating to these subjects: each such page
in fact determines a context for these documents. These contexts can be exploited for creating the appropriate
category and to discriminate between documents falling within different categories.

A similar problem arises in the organisation of personal material, for instance mail and bookmarks
[Maarek 96, Weiss 96].
In this paper we investigate a novel technique for automatic categorisation, which may be dubbed categorisation by context, since it exploits the context surrounding a link in an HTML document to extract useful information for categorising the document it refers to. Combining contextual hints from several documents, a high degree of accuracy can be achieved. This technique is complementary to the traditional technique of categorisation by content [Ng 97], which extracts information for categorising a document from the document itself. Such approach may exploit linguistic analysis to determine relevant portions of the text [Fuhr 91] and then it exploits probabilistic or statistical analysis to perform feature selection and to weight selected features.

A significant advantage of context-based indexing categorisation is that it can be applied to multimedia material, including images, audio and video [Shrihari 95], since it does not depend on the ability to analyse and index by content the documents to be categorised.

Furthermore, the mechanism that we will describe can be used to restructure a catalogue: in fact classification is performed with respect to a base catalogue hierarchy. Therefore, supplying a different catalogue hierarchy will produce a new categorisation. This is quite useful in the non-infrequent case when one discovers that a certain catalogue is no longer appropriate. With other techniques, manual or automatic, re-categorisation of a document set according to a different catalogue requires significant effort and one tries to avoid it. The technique of categorisation by context provides an automatic tool for doing it.

Categorisation by context leverages on the categorisation activity that users implicitly perform when they place or refer documents on the Web, turning categorisation, form an activity delegated to a restricted number of specialists, into a collaborative effort of a community of users. By restricting the analysis to the documents used by a group of people, one can build a categorisation that is tuned to the need of that group.

2. Related Work

Hypertext links pointing to the document to be categorised have not been used so far for categorisation, although they have been used as clues for searching documents [Chalmers 98], and for measuring the "importance" of a Web site [Brin 98].

Vistabar [Marais 97] is a desktop assistant for Web browsing that provides also a categorisation tool, which uses the YahooTM classification hierarchy. A category profile is precomputed for each category in Yahoo and Vistabar performs a traditional vector space matching on the weighted word frequencies of a document relative to the corpus, exploiting however the hierarchy of categorisation to prune the search. Vistabar also allows sharing categorisation and annotations by a group of users.

Automatic categorisation is the approach used by Northern Light in their new search service, which dynamically organises search results, creating Custom Search FoldersTM of documents with similar subjects, sources, or types. Within each folder a new subset of the original result list is produced containing only more focused results.

Contextual information is exploited in ARC [Chakrabarti 98], a system for automatically compiling a list of authoritative Web resources on a topic.

3. Architecture

The technique of categorisation by context consists in extracting contextual information about documents by analysing the structure of Web documents that refer to them. The overall architecture of the task of categorisation by context is described in [Fig. 1], and consists in spidering Web documents, HTML structure analysis, URL categorisation, weight combination and catalogue update.

3.1 Spiderring and HTML Structure Analysis

This task starts from list of URLs, retrieves each document, analyses the structure of the document expressed in terms of its HTML tags. For an introduction to HTML we refer to the HTML Primer [HTML].

The tags considered are currently: <TITLE>, <Hn>, <UL>, <DL>, <OL>, <A>. Whenever one of these tags is found, a context phrase is recorded, which consists of the title within a pair <Hn> </Hn>, or the first portion of text after a <UL> or <DL> tag, or the phrase within a <A> tag. When a <A> tag is found containing an URL, an URL Context Path (URL: C1; C2; ... : Cn) is produced, which consists of the sequence of the context strings so far (C1; C2; ... : Cn) associated to the URL. Therefore C1 is the text in the anchor of the URL, and the other C, are the enclosing contexts in nesting order.
In the analysis tags related to layout or emphasis (<EM>, <B>, <CENTER>, <FONT> etc.) are discarded.

Another possible element for a context is the title of a column or row in a table: tag <TH>. Such title can be effectively used as a context for the elements in the corresponding column or row.

For example, consider the following fragment of an HTML page from Yahoo™:

```
<html>
<head><title>Yahoo!-Science:Biology</title></head>
...<i>
<a href="http://muse.bio.cornell.edu;">Biodiversity and Biological Collections</a> - information about specimens in biological collections, taxonomic authority files, directories of biologists, reports by various standards bodies, and more.
...</html>
```

the following context paths are created:

```
http://esg-www.mit.edu:8001/esgbio:
"M.I.T. Biology Hypertextbook":
"introductory resource including information on chemistry, biochemistry, genetics, cell and molecular biology, and immunology":
"Yahoo! - Science:Biology"

http://muse.bio.cornell.edu:
"Biodiversity and Biological Collections"
"information about specimens in biological collections, taxonomic authority files, directories of biologists, reports by various standards bodies, and more"
"Yahoo! - Science:Biology"
```

Any URL found during the analysis is passed back to the spidering process, if it points to a document within the current site and stored for later analysis if it points to an external site. This allows us to perform a depth-first visit of a site, collecting any categorisation information it contains about itself and other sites.
3.2 Categorisation

The categorisation task exploits the database of URL Context Path and the Category Tree within which the URL must be categorised. The Category Tree consists of a tree, where each node contains a title, i.e. a single word or phrase, which identifies the category.

The goal of the categorisation is to find the most appropriate categories under which an URL should be categorised. The output of the categorisation is a sequence of weights associated to each node in the Category Tree:

\[ URL: N_1=w_1, N_2=w_2, \ldots, N_n=w_n \]

Each weight \( w_i \) represents a degree of confidence that the URL should belong to the category represented by node \( N_i \).

The weights from the Context Path for a URL are added with all other Context Paths for the same URL and normalised. If the weight for a node is greater than a certain threshold, the URL is categorised under that node.

The mechanism should allow for categorising an URL under more than one node, but never in two nodes which are descendant of one another.

4. Algorithm

The categorisation algorithm considers each node in the Category Tree as a path. For instance, a subset of the Arianna category tree (Arianna is a search engine for the Italian Web space that we are using for our experiments) corresponds to the following paths, translated into English:

| Business and Finance: Insurance | Computer: Sale |
| Business and Finance: Associations | Computer: Distribution |
| Business and Finance: Banks | Computer: Events |
| Business and Finance: Events | Computer: Fairs |
| Business and Finance: Fairs | Computer: Schools |
| Business and Finance: News | Computer: Courses |
| Business and Finance: Services | Computer: Associations |
| Business and Finance: Companies | Computer: Software |
| Business and Finance: Publications | Computer: Hardware |
| Business and Finance: Schools | Computer: Telecommunications |

Notice that the term Events appears in several categories, therefore the title of a category is not sufficient to identify the category: the whole path is necessary to disambiguate among the categories.

The categorisation algorithm works as follows: for categorising an URL it computes first a vector of matching weights for each path in the Category Tree, then it determines the paths with the best matching vectors, and finally it updates the catalogue.

4.1 Computing path match vectors

Given an URL context path (URL: \( C_1: C_2: \ldots: C_n \)), the algorithm considers in turn each \( C_i \), starting from \( C_1 \). To each level we associate a weight \( d_i \), decreasing from \( C_1 = 1 \), for instance with a value \( 1/\log_2(n - 1) \). It may be worthwhile to adapt these weights take into account the significance of a tag, for instance a \(<TITLE>\) tag may have a slightly higher weight than its position would imply.

Then we extract from \( C_i \) the noun phrases \( n_0, \ldots, n_k \) it contains. For each path \( p \) in the Category Tree, we create a path match vector \( pv \) with as many fields as the path length, initialised to 0.

Each phrase \( n_i \) is matched against each title in each path. If there is a match between \( n_i \) and the title of category in the \( k \)-th position in path \( p \), with matching weight \( mw_i \), then \( d_i \times mw_i \) is added to \( pv_k \). This process is repeated for each level \( 1 < l < n \).

Notice that since there can be several matching, the value in a field of a path match vector can be greater than one; therefore these values are normalised before performing comparisons.

To compute matching weights, we exploit several tools and data structures. To extract noun phrases from contexts we currently use LTPOS [Mikheev 98], a lexicon-based part of speech (POS) tagger with a stochastic disambiguator. A POS tagger like LTPOS is essential, since the lexical information provided by WordNet is not sufficient to determine the proper meaning and role of a word in the context of a phrase.
Since it is unlikely that noun phrases use the exact terms present in the titles, we must widen somewhat the search. In order to do this we precompute a neighbourhood of words for each term in a title, exploiting information from WordNet, which we store in an inverse neighbourhood table.

Matching a noun phrase with a title, which in general is also a noun phrase, requires matching multiple words. For each word from right to left in a noun phrase we compute the matching weight with a neighbour word in a title. We compute \( mw_i \) as the average of all such weights for a series of words that compose a full title.

4.2 Selecting best matching categories

Any path match vector \( pv \) that contains non-zero fields is considered as a potential candidate. The selection among these candidates is performed as follows:

1. discard any path with \( 0 \)'s in its leading fields. This means that that we found matches only in some subcategory but not in the top-level categories. For instance an URL relating to a business event we matched Events, but not Sports. The URL in fact will match both categories Business and Event in the Business:Event path.
2. among candidates with similar overall score, select the one with longer path. This forces categorisation under the most specific category.

The selected estimate records are stored in the database, associated to the URL. When the same URL is reached from a different path, the new estimates are combined to the previous ones. This will either enforce the indication of the category for a URL or suggest alternative categories for the URL.

5. Experimentation

A prototype tool for categorisation by context has been built in order to verify the validity of the method.

An HTML structure analyser has been built in Perl, derived from the analyser used in Harvest. A spidering program has been written in Java\(^\text{TM}\), which uses the HTML analyser to produce a temporary file of URL Context Paths. Also in Java\(^\text{TM}\), we developed a categoriser program that interfaces to WordNet [Miller 95] to perform morphing of the words appearing in the context paths and other linguistic analysis.

We have used the Arianna [Arianna] catalogue for the experiment, translating into English their names, and we categorised a portion of Yahoo\(^\text{TM}\) [Yahoo].

We show part of the results of categorisation for the URL http://esg-www.mit.edu8001/esgbio, appearing in page http://www.yahoo.com/Science/Biology For each candidate paths on the left we show the corresponding match weight vector, which has an entry for each element of the path representing the weight of the match for the corresponding title.

Despite the limitation of the current prototype, the results are quite encouraging. In all the cases we examined the prototype was able to categorise each URL in the most appropriate category.

As an experiment to determine the quality of the categorisation, we asked the system to categorise a subset of the Yahoo! pages according to the same Yahoo! catalogue. In principle we should have obtained exactly the original categorisation, and this is what we obtained in most cases. In a few cases the algorithm produced an even better categorisation, by placing a document in a more specific subcategory: for instance

6. Conclusions

We described an approach to the automatic categorisation of documents, which exploits contextual information extracted from the HTML structure of Web documents. The preliminary results of our experiments with a prototype categorisation tool are quite encouraging. We expect that incorporating further linguistic knowledge in the tool and exploiting information from a large number of sources, we can achieve effective and accurate automatic categorisation of Web documents.

We plan to apply our technique to the Arianna service in various ways: (1) using automatic categorisation to extend the Arianna catalogue, (2) adding to the Arianna search a facility to group the results of queries by categories, (3) a facility to restrict a search within a category.

A further area of research is evolving categorisation, i.e. to discover cases when the categories in the catalogue need to be extended or revised. Such analysis could be based on the Context Paths for documents.

Student WWW Pages: An Investigation into How Students Learn to Create Web Pages

Dr. Patricia Ryaby Backer
Associate Professor
San Jose State University, USA
EMAIL: pabacker@email.sjsu.edu

Abstract: The development of a new pedagogical model predicates the use of new assumptions in teaching at the university level. The first assumption is that the traditional design and behavior of university classrooms might not be appropriate for the instruction of computer-based curriculum. The second assumption is that students will change their learning approach to solve the problem of creating a project in a new medium. During this presentation, the researcher will summarize the result of this investigation into how students learn to design web pages. In addition, there will be a demonstration of the intermediate and final web pages. Through the interaction of the audience and the researcher, it is hoped that further discoveries about the learning of students will be uncovered.

Introduction

In the past two years, there have been many articles about specific uses of the WWW in education but few have investigated the Web as a learning medium. Antchev et al. [96] described the components and implementation of a WWW-based learning environment for mathematical sciences. These researchers used HTML documents, hypertext links, animations, and video clips to display and expand on mathematical ideas. They enhanced the Web content by using EMAIL, bulletin boards and videoconferencing software. In another course developed for the Internet, researchers found that WWW-based instruction acted like a catalyst for student achievement--it changed the "student role from passive learner to a partner in the goal of constructing meaning and understanding through interaction" [Campos, Salcedo, & Rossel 96, p. 60].

Universities across the country and world are pursuing full-course implementation on the Web [see McGreal 96; Paquette et al. 96]. Models for WWW-based instruction exist in the literature [Team Web 95; Rebelsky 96]; however, few studies exist that look at developing a pedagogical model for instructing students to construct their own web pages. One study on this topic [Bos et al 97] focused on students' use of web authoring to improve their cognition and motivation in science. The authors believed that web creation was an effective method for the science curriculum because it supports the sociocultural aim of science in that "learning to communicate with other scientists is an important part of learning to do science" (Abstract). Reed [96] points out that computer-mediated writing classes tend to be democratic and inclusionary--one could extend this principle to web creation by students.

Fryatt [95] focused on the complex issues of Internet training and implementation in her comprehension review of training. Particularly, her review targeted three questions:
1. What are the factors that distinguish successful Internet implementation and training strategies from those are not successful?
2. What models or approaches might be effective in reaching educators?
3. What systems/resources are necessary to support and extend the training process?

Fryatt discovered through her review that the actual training of instructors in just the beginning of the implementation plan. "What is often implied by such efforts is altering a mindset or philosophy about teaching and learning that requires teachers to acquire a whole host of related skills -- which are not usually even recognized within the training process."
Methodology

This investigation builds upon previous work on the nature of student use of computers for instruction [Backer 97]. Backer had analyzed student learning in constructing an electronic portfolio using computer-based multimedia development tools. The development of portfolios by students was not a cursory process. In order to be effective, portfolios require students to become self-reflective and view their work as a whole rather than as unrelated pieces. Electronic resumes, as natural technological outgrowths of portfolios, can expand this active process further by encouraging students to express themselves visually as well as in written form. In addition, this study shows that the use of electronic portfolios brings learning that is interactive and socially based.

The question then evolved for this current investigation. Since students approach the design of multimedia in diverse ways and with varying results, how do they approach and learn how to create web pages? This question forms the basis of this qualitative study. Twenty students, taking an undergraduate multimedia and web design course, were tracked over the course of the semester. Samples of web pages were taken from the students at three intermediate points throughout the semester. In addition, their final web page was evaluated. The web pages that the students constructed were analyzed as to various HTML design attributes to attempt to determine how the students' web designs evolved over a semester.

A qualitative approach was taken with these web creation activities to better analyze them for style as well as content. All students in this class were divided into teams and given the same assignment for developing the web pages. The majority of this presentation will be on the analysis of the students' intermediate web pages and a comparison of these intermediate points with other students in the class. The focus in this study, however, is on attempting to determine how students learn to use new tools rather than on the final projects. In this way, this present project differs from others completed. Most research on students (and/or faculty) is directed towards the analysis of their final projects. Inside of highlighting the final outcome, the emphasis on intermediate steps should provide more information about the learning processes of students. Consequently, it is hoped that this research will give insight in to the development of new pedagogical methods for instructing in multimedia.

Kerr [91] stated that "those of us who try to foster the use of technology in the schools are often guilty of hubris: We start from a premise that the value of the new approach we urge is self-evident, and that teachers should naturally want to shift their ways radically to take advantage of the new." Although Kerr was writing about teachers, this point also rings true about students. Despite the use of new technologies in both teaching and learning, we forget that education is also a social process with hundreds of years of explicit and implicit rules of behavior. Previous research [Backer 97] has found that students freely collaborated with each other, both in designing the multimedia as well as critiquing the content of their work. Therefore, a concerted effort was made in this investigation to encourage such collaborations by using teams of students to design web pages.

Results

The development of a new pedagogical model predicates the use of new assumptions in teaching at the university level. The first assumption is that the traditional design and behavior of university classrooms might not be appropriate for the instruction of computer-based curriculum. The second assumption is that students will change their learning approach to solve the problem of creating a project in a new medium.

During this presentation, the researcher will summarize the result of this investigation. In addition, there will be a demonstration of the intermediate and final web pages. Through the interaction of the audience and the researcher, it is hoped that further discoveries about the learning of students will be uncovered.

Abstract:

We present an information agent and latent semantic based indexing architecture to retrieve documents on the internet. This system optimises the search for documents in the internet by automatically retrieving relevant links. The information used for the search can be obtained, for instance, from Internet browser caches and from grades of relevance manually informed. To leverage the scope of retrieved documents, the system makes use of existing indexing mechanisms. Returned documents are then filtered using Latent Semantic Indexing (LSI). In a co-operative environment, the proposed architecture provides for sharing of documents and grades among the group. The architecture has been used in a “Co-operative Learning Environment” where students share their browser caches and retrieved documents.

1 Introduction

The huge amount of information available in the Internet allows research on virtually any subject. However, this wealth of data makes it almost impossible to retrieve relevant documents for, say, a school project. Therefore, we need automatic methods to retrieve information in an easy and significant way. If we can make the process transparent its usefulness would be even bigger.

Some of the common solutions available today include search using indexing servers. The problem with this approach is that the user must explicitly select keywords, activate the search mechanism, wait for the response and identify the relevant documents returned. All steps require user input. We propose an architecture that makes use of existing indexing mechanisms but automatically filters the relevant URLs, presenting only the relevant ones. In our system, although the user may manually give some information, the whole process can be automatic.

2 The architecture

The proposed architecture automatically retrieves relevant documents over the internet. It makes use of context information as input to perform the search and to filter the returned URLs. The mechanism is called Metasearcher.
The document retrieval mechanism is implemented using an information agent. The architecture is made up of three modules: context reconnaissance module, search module and filter module, as we describe in the following sections.

3 Information agents

Information agents are programs that model an information space of a user. They are not well defined. An agent are characterised for operating at high levels of abstraction and usually for the use of distributed resources. Like specialist systems, “information systems are hard to be characterised but easy to be identified” [Cybenko et. al 1990]. However, unlike a specialist system that models one specialist (one person) and makes his knowledge available to many users, an agent models one user, his needs of information and actions. Therefore, an agent must be customised for each user, making programmability a basic requirement for it. A definition of an information agent can be found in [Cybenko et. al 1990].

3.1 The architecture of the information agent

The proposed information agent models a human assistant that creates links using a behaviour similar to a human being [ACM, 1997]. A human assistant would read the information searched by an user and would extract the context from this information. In the next step, he would define keywords to search the internet using existing indexing mechanisms (e.g. Altavista). Finally, he would “read” the returned documents and select those that are really relevant in the context identified. Finally, he would build an HTML page to be presented.

To perform its role, the agent executes three basic tasks: first it reads the context information and identify keywords; second it submits searches to indexing mechanisms and finally it filters the information returned using the context obtained in the first task as model. The process is shown in Figure 1 where:

- The context reconnaissance module identifies the context and creates keywords to be presented to the search module. The scheme used to generate the keywords is shown in Figure 2. This module also creates a semantic space (using LSI [6]) from the context information.
- The semantic space will be used in the filter module to verify relevance of returned documents. Context information can be obtained from Internet browser caches, users’ bookmarks, a set of documents regarded as interesting, etc.
- The search module submits (in parallel) the actual search to indexing mechanisms, receive the responses and assembles an HTML page to be submitted to the filter module.
- Finally, the filter module retrieves the full documents whose URLs were returned in the search module. It then retrieves (in parallel) the full documents and adds them to the semantic space computed in the first module. Documents that position themselves near the existing documents are regard relevant and presented to the final user. Documents that do not stay near the existing ones are discarded. The filtering module is the kernel of the proposed architecture is explained in detail below.
3.2 The filter module

The search using keywords has many drawbacks. The search may fail because of synonyms and polysemy (more that one meaning to the same word). To reduce these problems several filtering techniques can be used [Foltz & Dumais, 1992]. We have decided to use LSI [Dumais, 1991] [Dumais et al. 1988] to filter the documents retrieved.

LSI takes advantage of the higher implicit order of the association of terms to documents in order to create a multi-dimensional semantic structure of the information. Using the patterns of co-occurrence of words, LSI is able to infer the structure of relationship between terms and documents. The singular Value Decomposition of the association term-document matrix is obtained producing a matrix, with reduced dimensions, with the k best orthogonal factors to approximate the original matrix to the “semantic space” model for the collection. This semantic space reflects the main associative patterns in the data ignoring some minor variations that may be produced by idiosyncrasies in the use of the term in particular documents. Therefore, LSI produces a representation of the adjacent information “latent” semantics.

Because LSI produces an adjacent similarity semantics space, documents on similar topics tend to be grouped in the space. That is the base of the use of LSI. We first create a space based on information known to be (or regarded as) relevant and then new documents are added to the space. If they position themselves near the existing ones, they are regarded as relevant, otherwise they are discarded.

To implement LSI, a term-document matrix is built. The elements in the matrix are the occurrences of each term in a document. Therefore, the matrix can be represented by $A = [a_{ij}]$ where $a_{ij}$ denotes the frequency that term i occurs in document j. Global and local weights can be applied [Dumais et al. 1988] to increase or decrease the importance of terms within between documents. We can then write $a_{ij} = L(i,j) \times G(i)$ where $L(i,j)$ is the local weight of term i in document j, and G(i) is the global weight of term i. Matrix A is factored in a product of three matrixes using the Singular Matrix Decomposition (SVD): $A = U \ \Sigma \ V^T$. 

---

**Figure 1: The Architecture of the Agent**
SVD derives the model of the latent semantic structure from the orthogonal matrixes $U$ and $V$ with the left and right singular vectors of $A$ respectively, and the diagonal matrix $\Sigma$, of the singular values of the original relationships into linear independent vectors. The use of $K$ factors is equivalent to approximate the original term-document matrix by $A_K$ as defined in equation

$$A_K = \sum_{i=1}^{K} u_i \sigma_i v_i^T,$$

where

- $A_K = \text{best approximation of rank } k \text{ to matrix } A$
- $U = \text{term vectors}$
- $\Sigma = \text{singular values}$
- $V = \text{document vectors}$

$A_{m \times n}$

Term Vectors

$k$

$m \times r$

$r \times r$

$r \times n$

Figure 2: Keywords generation process

Figure 3 is a mathematical representation of the decomposition into singular value. $U$ and $V$ are the term and document vectors, and $\Sigma$ represents the singular values. The shaded regions in $U$ and $V$ the diagonal line in $\Sigma$ represents $A_k$.

SVD captures most of the adjacent structure in the association terms-documents and, at the same time, it removes the variability in the use of words. Intuitively, as the number of dimensions $k$ is much smaller than the number of unique terms $m$, minor differences in the terminology will be ignored. Terms that occur in similar documents, for example, are close even if they do not occur in the same document. That means that documents that do not share any words with the keywords in the search may be close to a keyword in the $k$-space. This representation captures term to term associations and it is used to retrieve information. The main idea in LSI is to model the inter-relationships among terms and use them to improve retrieval.

As we have explained, Metasearcher retrieves documents obtained from the indexing mechanisms. To be filtered, these documents are used in a "query" to obtain their similarity to relevant documents in the vetorial
space. One query is a set of words. The retrieved document, or query, must be represented in the k-dimensional
space as \( \mathbf{q}^* = \mathbf{q}^T \mathbf{U}_k \mathbf{\Sigma}_k^{-1} \), where \( \mathbf{q} \) is the vector of words in the new document, that can be multiplied by the
appropriate term weights. The sum of these k-dimensional vectors is reflected by term \( \mathbf{q}^T \mathbf{U}_k \) and the right
multiplication by \( \mathbf{\Sigma}_k^{-1} \) weights differentially individual dimensions. Thus, the query vector is located in the
weighed sum of its constituents term vectors. The query vector can then be compared to all existing document
vectors, using a similarity function. One similarity function is the cosine between the query vector and the
closest vector in the vectorial space of relevant documents. Usually, if the cosine exceeds a threshold the
retrieved document is regarded as relevant [Dumais, 1991].

Documents not regarded as relevant are discarded and relevant ones are presented to the output system
as an HTML document.

4 Scenarios of usage

Metasearcher can be used together with several systems. It is implemented as a modular architecture
that allows the input and output modules to be changed to adapt to different requirements.

For example, the input system can collect data from one user and use that information to retrieve other
document on the same subject, or the input can come from an intranet supporting a co-operative environment as
it has been tested in [Badue et. al, 1998]. In this case context information (including information manually
entered), and returned documents are shared by a group. Another scenario would be the one where a student who
needs to write an essay to “train” Metasearcher with a set of papers on the subject and have it to retrieve other
related documents.

5 Performance

The system is still being tested. It has been used by a group of five students who are given a task and
should search the Internet (starting with an empty cache) until they build a cache of about 1.5MB of html
documents for each user. After the cache is loaded, the system is left to work, usually overnight because of slow
connections.

Although the number of documents retrieved by indexing engines vary a lot, typically 60% of them are
filtered by the engine. We have found that the input system, specially the interface, has to be improved to allow
users to manually discard non relevant documents. In tests where non relevant documents were discarded from
cache manually, the rate of filtered documents raised to near 80%.

Although the results are very promising we still need more tests to assess the system. We have found
that the input system has to be improved to allow users to input feedback with less effort, and to share their
“filtering” with other users. Users have had the “feeling” that the system retrieves more relevant information
when caches are shared than when they use their caches only. However, we have not yet assessed how correct
that “feeling” is.

6 Acknowledgements

This work was partially supported by CNPq/PROTEM-CC project SAM Sistemas de Autoria Multimídia.

7 Conclusion

This work has proposed an architecture based on information agents to automatically retrieve
documents in the Internet and filter the returned documents, using LSI, according to context information. The
proposed architecture makes use of indexing mechanisms and is modular, in the sense that its input and output
modules can be changed.
To perform its role, the system obtains context information from a source that can be Internet browser caches, a directory of papers, etc. Then it uses that information to generate keywords that are submitted to existing indexing mechanisms, the returned URLs are retrieved and the full documents are matched to the context using LSI. Finally, it generates an HTML page that is passed on to the output system that may perform further computation or just present the page to the final user.

Metasearcher has been “plugged” to an intranet environment in an University environment, where it is used to support co-operative learning. Currently, the system is being tested and data is being gathered to assess its effectiveness as a learning aid.

THE STATE OF THE ‘NET IN SECONDARY CLASSROOMS:
RHETORIC AND REALITY

Dr. Lawrence Baines, Berry College, Mount Berry, Georgia, lbaines@berry.edu

Dr. R. Edward Deluzain, Curriculum Technology Task Force, Bay County, Florida, deluzhe@bnmis1.bay.k12.fl.us

Dr. Yolanda Hegngi, Berry College, Mount Berry, Georgia, yhegngi@berry.edu

Abstract: While 96% of teachers profess to use technology, our study of 85 teachers in Florida and Georgia found that only 4% of teachers actually integrated technology in their instruction. The majority of schools had few computers, fewer Internet-ready computers available for student access, and teachers who had never received any training whatsoever concerning how to use computers. Most teachers lacked even a rudimentary knowledge of the Internet; many could not explain how to turn on a computer. The reality of public school classrooms contrast sharply with the rhetoric and possibilities of using technology effectively in schools as exemplified by some interesting, high-tech classrooms.

"While those who talk about schooling describe its penchant for change, teachers who do schooling proceed about their business in a manner that is remarkably resistant to change....the introduction of technology to classrooms does not radically change teaching; instead, technology can serve as a symbol of change." [Sandholtz, Ringstaff, & Dwyer, p. 171]

The point is well taken that most classrooms today look and sound as they did a hundred years ago—blackboards, functional seating with built-in desks and storage for books underneath, a pencil sharpener, an American flag, a teacher speaking at the front of the room. In contrast, the tools and the core knowledge of today’s doctors, lawyers, accountants, dentists, engineers, police officers, and farmers would be unrecognizable to professionals from one hundred years ago. In many respects, the computer is perceived as a possible remedy for the flagrant datedness of most classrooms, and several federal and state initiatives continue to help bring computers into schools. Yet, getting prospective teachers to abandon pedagogical habits far removed from their comfort zones is no easy task. In fact, the complexities of integrating technology into the classroom seem to continually increase for teacher educators. But, the difficulty of the enterprise does not negate the potential that computers may offer. Many teacher education programs find themselves in the precarious position of mandating that their students gain expertise with computers while the school districts that may hire them may have classrooms straight out of 1898.

At the same time that the massive effort to equip schools with a necessary infrastructure for technology, some have begun to question the benefits of such investments, leading to speculations on the effects of technologies on teaching and learning [Dickey & Robyler, 1997; Dede, 1997; Oppenheimer, 1997]. Even technology enthusiasts would agree that simply unloading boxes of computers into K-12 classrooms will not improve instruction much. There is a need for practical examples of expert computer use in K-12 classrooms, a set of “best practices” that demonstrate how computers can be integrated into instruction to offer a clearly richer curriculum. In this article, we will discuss research from a three-year study of “best practices,” describe the level of computer use in these classrooms, relate the findings to the preparation of prospective teachers, and briefly describe a day in the life of a teacher from the research study who might serve as a model of “best practices.”

According to Fisher, Dwyer & Yocum [1996], criteria for best practices for the computer-literate teacher should include the following:

- Availability of tools for acquiring information, thinking, and communicating,
- Teacher’s balanced use of instructional strategies--direct instruction, collaborative, and inquiry approaches to teaching and learning, and
- Ability to formulate innovative and variable assessments of student competencies and skills.
In order to study the best practices of current teachers, we asked principals and administrators for a list of their most effective teachers who wouldn’t mind being observed or videotaped. We logged over 500 hours in classrooms watching and videotaping 84 teachers [in grades 5-12] from Florida and Georgia over a period of three years. Administrators and teachers were told that the researchers were interested in “effective practices” and nothing about computers was ever mentioned.

The classrooms in Georgia and Florida are considered among the most sophisticated in the nation regarding the integration of technology. According to a report in Education Week [November 11, 1997], “Florida is one of the nation’s leaders in school technology, and financial resources are a major reason why” [available: http://www.edweek.com/srepornts/tc/intros/in-n.htm]. The student to computer ratio in Florida is purported to be 6:1.

Since 1994, the lottery in Georgia has provided more than half a billion dollars for technology in schools and the legislature also approved $15.4 million to pay for district technology specialists. The ratio of students to multi-media, Internet-ready computers is among the best in the nation in that category--13:1.

Computers in instruction: A disparity between reported and actual use

Teachers were observed from these subject areas--English, reading, math, science, social studies, family & consumer sciences, foreign language, and art, grades 5-12. All teachers observed had at least three years of experience, and a few had as many as 25. In general, the classrooms observed were not well equipped with computers, almost all teachers confessed that they had never received any form of professional development from their school districts regarding the integration of computers into instruction, and computers were not integrated into instruction. While we witnessed many innovative, unique, and highly effective lessons, the use of computers was conspicuously absent in 81 of 84 classrooms. Table 1 summarizes some major findings of the study.

Obviously, our findings of actual classroom practice differ markedly from reports attesting to the proliferation of computer use in schools. When surveyed, almost every teacher in the country says that they use computers to some degree in their teaching. According to Quality Education Data, 96% of teachers integrate computers in their instruction [1996]. The Tenth Planet Teachers & Technology survey found that 91% of K-6 teachers use computers with their students [1997]. The disparity between the results of these surveys and the actual approaches teachers took during our observations provided a rather startling contrast. Perhaps one problem with surveys of computer use is that they rely upon data that is self-reported. In the current age, when use of
technology has become associated with competency and modernity, little wonder that few teachers would admit that they never boot up. Still, the difference between actual observation of computer use in teaching—3.6% [3 of 84 teachers] and the purported use—96%—seems nothing short of stunning.

The dilemma of “best practices” and teacher preparation

According to Sternberg [1995], expert teachers are those who “possess knowledge that is more thoroughly integrated — in the form of scripts, propositional structures, and schemata—than is the knowledge of novice teachers” [p. 11]. One of the difficulties of integrating computers effectively into the curriculum may be that teachers have not yet begun to integrate the use of computers into their teacher “scripts.” Indeed, of the three teachers who used computers, only one [George, to be discussed later] seemed to have integrated computers seamlessly as part of his pedagogical toolkit.

A second teacher [of sixth graders] arranged her class so that all twenty-seven students sat in a circle on the floor around a computer monitor “interacting” with a science CD-ROM. She selected one student at a time to walk up to the terminal and point and click on an object on the screen while the other twenty-six children sat, watched, and listened—a technique that we found to be of questionable educational value. A third teacher who integrated computers as instructional tools used the four Internet computers in her classroom as stations where students could pursue their individual research projects once or twice a week. When we observed the class, the students assembled around the computers were seeking information concerning the life and times of William Shakespeare. While there may be nothing inherently superior about learning that is facilitated through the use of computers, our research helps point out the entrenched, almost covert resistance to computers as instructional tools.

The dilemma faced by many teacher education programs is that they must prepare prospective teachers who are informed users of technology at a point in time when few practicing teachers seem to be exhibiting the kinds of expert behaviors that would qualify them as practitioners of computer-mediated “best practices.” Indeed, if prospective teachers are going to be expected to move beyond the methodology of the teachers who taught them, the need for living, breathing teachers who use computers creatively and effectively is essential. Below, we offer some observations of a day in the life of George, a fifth-grade teacher and the “star” of the cohort of 84 teachers. George seemed to use computers effectively, though his classroom was not particularly well equipped and he learned about computers without the assistance of any college coursework or help from the district administration.

George, an exemplar of “best practice”

At 9:00 on a Tuesday morning, George is describing the listed day’s events, written on the chalkboard to some fifth graders seated in a semi-circle, on the floor. After the description, the students disperse to their desks as they are instructed to begin with the Language Arts unit. Some students pull-out their journals, others turn to the hand-out from the student teacher, and three girls in one corner take out novels from their book bags. George announces that he expects the students to continue the special research projects. He bids Jon to move to the scanning station [a Pentium 75 hooked to a scanner and a color inkjet printer] with his baby picture. Jon is shown how to scan his picture using a generic scanning software. After he scans, the image is cropped and pasted on a card in Microsoft Publisher. Jon selects the appropriate “Happy Birthday” text and wording for the card. George helps him print and fold the card. Two other students rush to see Jon’s finished product which he completes in about seven minutes.

George next beckons Stacy to join Jon at the scanning station, bringing along a recent picture of herself. Jon moves to the chair next to her to assist her in creating her Xmas card. Jon’s words and actions indicate a slight hesitancy as he and Stacy explore the steps from scanning to card creation. But, as Stacy darts to the printer to retrieve the card, the look on both faces changes to quiet confidence. It is now Stacy’s turn to assist Mike in creating his Thanksgiving card.

At George’s laptop [the only computer with Internet access], Josh is searching for pictures to include in his research project on minerals. He suddenly remembers that he forgot his picture for the greeting card project, so he decides to page his dad on the Internet. He logs on to “www.metrocall.com” and leaves a message on his dad’s toll-free pager number, to “drop-off the baby picture at school.” He then logs on to www.altavista.com [a search
engine on the Internet] for pictures on minerals. He first searches the keyword “quartz” and sorts through some hits on wrist-watches. He then searches for “minerals” and gets several more hits, one of which is simply titled, “Rhombohedron.” He clicks on that site and discovers 20 or more colorful digital pictures of six-sided prisms. He bookmarks the site and prints some pictures. The printed pictures are added to his resource folder which also contains magazine clippings, photocopies from books, and a crumpled set of handwritten notes.

Until the fall of 1996, the only computers at George’s school were Apple IIe’s. In the Fall of 1996, George and a concerned parent networked the donated Mac Classic IIC’s to the only laser printer in the school. For years, the only computer with Internet access in school has been George’s laptop [though the school is scheduled to be wired as this is being written], and he paid for the America On-line [AOL] account from personal funds.

His class now has 4 computers: a Pentium 75, a Compaq laptop [Pentium 150], a Mac Performa 616CD, and a Mac LC. In addition to some input and output peripherals such as a scanner, a digital camera, and printers, he also has a television and VCR set. Although George teaches 5th grade, some 4th and 6th graders participate in the language arts and math learning activities upon occasion. Although George would not mind if his school had a computer lab, he prefers having computers in his classroom as part of the learning environment. George encourages students to pursue divergent thinking by using whatever other resources they can get their hands on. During the first semester of fifth grade, George introduces students to:

- Classroom resources [digital camera, computers--CD-ROM, scanners, Internet sources and databases, textbook, and publications],
- School-based resources [library, VCR, camcorder, and photocopier],
- Community resources [parents, good hiking trails, and libraries].

George balances direct instruction with collaborative and inquiry approaches. When George brings in new technology, he will demonstrate use of a tool to the entire class, then walk several students through the entire process individually. Next, the students who received individual instruction, in turn, assist a classmate. When a student gets confused or needs help, George will refer them to resources in the room rather than give straight answers. “I expect students to develop critical and higher order thinking and they won’t get that by my class if I spout off the answers all the time. Frustrations arising from using new technologies and doing research are part of life. Students need to learn such life lessons.”

He admits that his teaching practice during the first semester is largely direct instruction, but maintains that 5th graders need to be taught the inquiry process as well as see it modeled before they are required to collaborate and/or independently explore with multimedia tools.

His second semester activities often involve data gathering for science and math projects to writing, editing, and publishing in language arts. Some of the publications are on-line, but one project revolves around the production of an annual section in the local newspaper.

George’s assessment methods include student self-evaluations and documentation of the processes students use to create their projects. He insists students keep portfolios that fulfill a few rigorous requirements, though he allows students to customize their portfolios to some extent to reflect their personal interests. George regularly schedules conferences with students to discuss portfolios.

The desperate need for models of best practice

There is a private university in the Southeast that graduates 1000 undergraduates and 500 graduate teacher education students every year. The College of Education at this institution is housed in a 100,000 square foot building that includes 113 miles of fiber-optic cable, 1100 plug-in ports hooked to the Internet, and at least one multimedia laboratory in every room. The teacher’s station has a pop-up LCD panel, which can electronically control a screen that drops down out the ceiling, mechanized drapes which can be opened and closed at the touch of a button, and a built-in projector in the ceiling for illuminating computer screens, videos, or cable television programs. Access to the building and to each room within the building is controlled by card-readers which restrict access to only those who possess the correct chip. One floor of the building is dedicated to graduate students, who eagerly plod away in corporate-type offices on projects for professors who may want to design supplemental course materials on CD-ROM.
A few blocks away from this university is an inner city public school, in which there are few classrooms with computers for teachers, let alone students. Windows are broken, doors are chained shut, there is no Internet access, and no teacher has an office of her own. Imagine the soul-searching that a prospective teacher who gets trained in the private university teeming with high-tech toys undergoes the first day that she steps foot in the battened-down urban school down the street. To what extent can she draw on her university courses to enhance instruction in such a foreign and technologically barren environment?

From our research of computer use among practicing teachers, it would difficult to foresee that the prospective teacher in this situation would find a willing, technologically-innovative mentor among the school faculty who could ease her transition into teaching, while simultaneously encouraging her to take chances in her choice of instructional methodologies. To be sure, without models of best practice, like George around, someone to demonstrate the plausibility of technological approaches, most pre-service teachers would likely adopt survival strategies that minimize complexity and eschew the kinds of complications that computers inevitably bring.

Perhaps the time is right for the establishment of a National Technology Project, a nationwide program built along the lines of the highly-successful National Writing Project, a professional development effort that has trained over 100,000 teachers over the past quarter of a century to become better teachers of writing. By using a teachers-teaching-teachers model such as that of the National Writing Project [Gray & Sterling, 1995], a National Technology Project could provide the ongoing professional development necessary to bridge the gap between the reality of public schools struggling to get up to speed and vast potential offered by emerging technologies. Teachers are key to educational reform. Although teachers like George seem to be quite rare, it is they who must help lead the transformation.

Disorientation on the Web—Adventure or Distraction?

Amy L. Baylor, Ph.D.
San Diego State University
Department of Educational Technology
abaylor@mail.sdsu.edu

Abstract
This experimental study investigated both internal (personal characteristics) and external (web site features) factors influencing disorientation in web navigation. The research design is a 2X2 ANOVA with mode of navigation (linear, nonlinear) and distractions (high-distraction, no-distraction) as the two factors. The paper reports findings of the following dependent measures as they relate to the 2-factor research design: friendliness of the web site, attribution of disorientation, overall level of disorientation, accuracy at stating main point of the passage, number of ideas recalled from content of passage, confidence in navigating the web site passage, and interest in web site passage topic. One primary hypothesis that was not supported was that preference for sensation-seeking behavior and/or spatial-holistic ability would influence the participants’ perceptions of disorientation.

1.0 Introduction
A common phenomenon on the World Wide Web is for a participant to become sidetracked by other links and become disoriented when seeking a particular location. From the participant’s perspective, did s/he make the right choice or will s/he have to back-track? Did she temporarily ignore her original intent because she has a high need for novelty and stimulation? Additionally, much of the inconvenience of disorientation may be perceptual. Like waiting in line at the grocery store, where some people become livid while others use it as a chance to start up a conversation, disorientation on the web may be considered as exciting or as an annoying distraction that prevents the participant from staying on-task.

Given the rapid growth of the Internet and the commensurate need to design improved systems for participant access and learning, this study investigates psychological issues related to navigation in the World Wide Web. Specifically, the focus is on internal and external factors related to disorientation, defined as uncertainty in one’s location.

Results have important implications for Internet participants and directly impact web-based system configuration and participant interface development. By assessing perceived factors relating to web navigation, the research provides information regarding the web site features that participants believe are important for a site’s participant-friendliness. Furthermore, this research will consider the factors influencing whether the participant attributes his/her disorientation internally (to him/herself) or externally (to the web site).

2.0 Purpose
The purpose of this experimental study is to characterize internal (personal characteristics) and external (web site features) factors that influence Internet navigation and disorientation. This research also facilitates the development of web-site features that better accommodate navigation preferences and learning. For example, a person low in sensation-seeking tendency may prefer a more streamlined approach to navigation with limited links whereas a person high in sensation-seeking tendency may prefer more varied navigational features with a greater number of available links or distractions. In terms of learning, the participants will be tested for content learned from the participant’s navigation of the web site passage. This has direct implications for design and development of web-based learning environments.
3.0 Participants

Volunteer participants were recruited from Internet listings that advertised the study, drawing from a diverse nationwide population. All participants had prior experience navigating the Web as a requirement of participation in the study. They were compensated for participation.

The seventy-five participants represented a diverse population, with 79% white and 21% non-white (including primarily Asian and Hispanic). The mean age was 30.47 with a standard deviation of 1.26. Of the 74 participants reporting gender, 34 (46%) were female and 40 (54%) were male.

4.0 Experimental Design

The study was designed as a two-way ANCOVA design with system knowledge as the covariate because systems knowledge has been shown to directly affect participants' competencies at navigation (Hill & Hannafin, 1996). However, systems knowledge scores were very high (X=4.08 on five point scale) and positively skewed, precluding the value of using them as a covariate.

Consequently, the experimental design is comprised of a 2-factor (2x2) ANOVA design with the two factors of navigation mode (linear, nonlinear) and distractions (high-distraction, no-distraction). There are four web sites that reflect different instantiations of the two factors (e.g., linear + high-distraction; linear + no-distraction; nonlinear + high-distraction; nonlinear + no-distraction). The four web sites all contain nine web pages of identical text that comprise a passage on Internet use for education, adapted from Andy Carvin’s web site at http://edweb.gsn.org/web.intro.html. The software randomly selected one of four web sites for each participant to navigate.

In the linear navigation condition, the participant is forced to proceed through the site similar to reading a textbook, only able to move forward and backwards. While this is a somewhat artificial treatment, it was designed to maximally contrast with the nonlinear mode of navigation. In the nonlinear navigation mode, the participant has immediate access to all pages at any given time through a navigation bar on the left-hand column.

The high-distraction condition contained six distracting links placed throughout the nine pages of the web site. The six distracting links (referred to as “distractors”) were designed to figuratively “seduce” the navigator to click on the link (e.g., David Letterman’s Top Ten, jokes, Dilbert cartoons) and encourage off-task behavior. Each distractor was comprised of a small picture with a link indicating to “Click here to ...” The no-distraction condition did not contain any distractors.

4.1 The Task

The task for all participants was to successfully find the headings under which five statements were located within the nine-page online passage. Participants could access the statements from any page on the web site.

In determining the appropriate heading location, the participant did not have open-ended access to the Internet; rather, s/he was limited to the pre-defined web pages for each web configuration. The toolbars were de-activated so that s/he could only access web pages included in the experimental web site. Software was developed in Perl to track the participant’s path through the web site in terms of total time spent, time spent on distracting links, and the number of distracting links selected. The whole procedure took approximately an hour.

5.0 Research Procedures
Following completion of the initial task, the participant was profiled online according to the following two psychological dimensions: preference for sensation-seeking behavior and visual-spatial ability. Also in terms of personal characteristics, participants were queried about prior content knowledge of the passage and systems knowledge. Additionally, the following dependent measures were assessed through an online questionnaire:

1. Friendliness of the system
2. Attribution of disorientation
3. Overall disorientation
4. Accuracy at stating main point of the passage
5. Number of ideas recalled from content of passage
6. Confidence in navigating the site
7. Interest in passage topic

**6.0 Key Predictions**

1. Individuals differing in sensation-seeking preference and visual-spatial ability will prefer different web-site features. For example, a person low in sensation-seeking tendency may prefer a streamlined site with limited links and options whereas a person with high sensation-seeking tendency may prefer more varied navigational features with more links and/or distractions. Furthermore, it was predicted that these two factors would influence perceived disorientation and frustration with navigation on the web site.

2. Different web configurations (as defined by level of distractions and navigation mode) would differently affect performance on learning and affective measures (as listed 1-7 above).

**7.0 Results**

**7.1 Participants' characteristics**

The following information was collected about the participants: preference for sensation-seeking behavior, spatial-holistic ability, content knowledge of the passage’s topic, and systems knowledge.

**7.1.1 Sensation-seeking preference**

Participants answered a battery of questions pertaining to preference for sensation-seeking tasks (from Zuckerman, 1979). These 34 questions consisted of paired statements from which the participant would select the one statement best describing him/her. For example: A) I would prefer living in an ideal society where everyone is safe, secure, and happy; or, B) I would have preferred living in the unsettled days of our history. The mean score of the participants was 18.50 (sd=5.83) with a possible range of 0-34.

**7.1.2 Spatial-holistic ability**

The Street Test (Street, 1931), a thirteen-item gestalt completion test, assessed spatial-synthetic ability and required the participant to mentally construct the whole picture from a partially-represented figure, such as a figure of a bearded man, a cat, or a locomotive. The mean score of the participants was 7.36 (sd=2.52) with a possible range of 0-13.

**7.1.3 Content knowledge**

Participants’ mean prior content knowledge of the use of the Internet for education was 3.65 (on a 1-5 Likert scale where 5 is extremely knowledgeable) with a standard deviation of 1.05.
7.1.4 Systems knowledge

As mentioned previously, systems knowledge scores were very high ($X=4.08$ on five point scale) and positively skewed, thus not lending much information to differentiate participants.

7.2 Dependent measures

7.2.1 Friendliness of site

On a Likert scale of 1-5, participants were asked to assess the friendliness of the site. There were no statistically significant results in the 2-way (navigation mode, distractions) ANOVA with site friendliness as the dependent measure. As would be expected in considering all of the participants (who represent all four web site combinations), participants' confidence in navigating the site was positively correlated to their reported friendliness of the site ($r=.411$, $p < .0001$).

7.2.2 Attribution of disorientation

On a Likert scale of 1-5, participants were asked the following: “Consider the times when you felt disoriented during the task. Overall, do you attribute your feelings of disorientation to your self or to the web site? (with 1 representing to the self and 5 representing to the web site.)” This question served to assess to what extent participants attributed (i.e., blamed) navigation problems on the web site as opposed to themselves. However, there were no statistically significant results in the 2-way (navigation mode, distractions) ANOVA with attribution of disorientation as the dependent measure.

7.2.3 Disorientation with site

Level of disorientation was determined from ten Likert-scale questions from Beasley & Waugh's Non-Linear Media Disorientation Assessment instrument (Beasley & Waugh, 1995). As expected, participants' disorientation scores correlated negatively to systems knowledge ($r=-.253$, $p<.05$), interest in content ($r=-.351$, $p<.005$), and confidence in navigating ($r=-.605$, $p<.0001$).

From a two-factor ANOVA (navigation type, distractors), there was a marginally significant main effect for navigation type ($F=3.318$, $p=.07$), where those in linear condition were more disoriented ($X=13.58$) than those in nonlinear condition ($X=10.63$). This indicates that participants feel more oriented with a nonlinear web site format as compared to a linear format.

7.2.4 Main point of passage (1-5)

Participants were asked to state the main point of the passage. Items were scored on a 1-5 scale, with a representative answer receiving a “1” as “It provides a general discussion about the web.” and a representative answer receiving a “5” as “It analyzes the possibilities the web offers to educators and its importance as a learning tool.”

From a two-factor ANOVA (navigation type, distractors), there was a statistically significant interaction of navigation type and distractors ($F=4.70$, $p<.05$) for the main point score. This interaction indicates that participants performed better in the linear condition with no distractors ($X=3.63$ vs 2.62), and in the nonlinear condition with distractors ($X=3.56$ vs 3.42). Perhaps the distractors in the nonlinear condition forced subjects to expend more effort in discerning the meaning of the passage and were thus beneficial. In contrast, in the linear condition, the presence of distractors negatively affected performance by not fitting in with the linearity of the passage navigation.
7.2.5 Benefits of using web for education (0-9)

Participants were asked to “list as many benefits of using the web for education as possible, according to the web site.” They were awarded one point for each benefit listed that was stated in the passage. The range of scores was 0-9, with the mean as 3.34 (sd=1.97).

A two-factor ANOVA (navigation type, distractors) indicated that there was a significant main effect for distractors (F=6.68, p=.01), where those in web sites with no distractors (X=3.90) performed better (listing more relevant benefits) than those with distractors (X=2.76). This indicates that the presence of distractors negatively affects idea production (in the form of listing benefits) following the learning experience. Perhaps the distracting links distracted the participant from focusing on and then later recalling passage content.

7.2.6 Confidence on this site

There were no statistically significant results in a 2-way ANOVA where confidence in navigating the experimental web site was the dependent variable. As expected, there was a strong negative correlation of perceived disorientation with confidence in navigating the site (r=-.605, p<.0001). Interestingly, females reported more confidence navigating the site than males (X=4.68 vs X=4.26, p=.001), yet they also reported more overall disorientation with the site (X=10.52 vs 13.24; p=.07).

7.2.7 Interest in topic

There were no statistically significant results in a 2-way ANOVA where interest in passage content was the dependent variable.

8.0 Discussion and implications

The first prediction, that preference for sensation-seeking behavior and spatial-holistic ability factors would influence perceived disorientation and navigation site, was not supported based on analysis of the data. However, there was a marginally significant difference in main point scores between those (N=36) with high spatial-holistic scores (X=3.51) and low spatial-holistic scores (X=3.06, p<.1 ), thereby indicating that spatial-holistic ability facilitated discerning the main point although did not interact with other navigational factors.

In terms of the second prediction, three findings regarding motivation, orientation, and learning will be briefly discussed.

First, in terms of motivational factors regarding navigation, there is a clear connection between perceived web site friendliness and perceived orientation within the site.

Second, in terms of web site and interface construction, this study indicates that participants feel more oriented with a nonlinear web site format as compared to a linear format. As would be expected, it was found that perceived disorientation was highly negatively correlated to both site friendliness and confidence in navigation.

Third, when factoring in learning from the web site (or other open-ended learning environments), it was found that recalling examples from the text (e.g., benefits of Internet use for education) was facilitated when the site had no distracting links. However, when the navigation mode was nonlinear the presence of distractors was not necessarily bad for influencing participants’ conception of the main point of the passage. An important caveat is that the participants’ task was not to learn the passage; consequently, the two learning measures (stating the main point of the passage, and listing educational benefits of using the Internet) actually assess incidental learning. Overall, this evidence begins to suggest that participants may indeed learn more from a nonlinear than a linear navigation mode. It is not clear whether or not the role of distractors, or “seductive” links, negatively affects learning. Future research should include more comprehensive learning measures.

The Development of Simulation Models of Plant Systems as a Bridge Between Current Scientific Research and Students or Teachers

Abstract: Plant science is crucial to understanding our natural environment and agricultural systems. The scientific method is a vital part of scientific literacy, and can be effectively presented using simulation models as the experimental setup. We describe the design as well as some of the challenges we faced in two projects aimed at making current plant science available for classroom and independent educational use in the form of interactive simulation models.

1. Introduction

Science education is critical to our future as the youth of today become decision makers of the next century. Without the ability to understand and interpret scientific discoveries and developments, young people today will be unable to make informed decisions as they face the challenges of the future. As studies show that science literacy among the general public is weak, there is a critical need to help young students better understand what science is all about. This includes building closer ties between current research and the general public. In addition to imparting knowledge, we need to help teach scientific methods as they are practiced today, and to motivate students to both care about scientific study and have a desire to participate.

Computer technology and the Internet could play an important role in achieving the transfer of scientific research out of the laboratory. Computer simulations are important scientific tools that play roles in our lives such as predicting future climates, estimating the spread of diseases, and setting limits on exposure to toxic substances. The challenge in using computer technology in education is to create high quality and effective learning experiences [Weller 1996]. Programs based on scientific methods of inquiry, like computer simulations, can help students learn how to apply such methods to other fields of study [Regian & Shute 1994].

Plant science, in particular, is vital in understanding our environment, both natural and agricultural. Yet plant science only receives a small fraction of the time allotted to science in secondary schools. The Plant Modeling Group of the Boyce Thompson Institute for Plant Research (BTI) is working to facilitate the transfer of exciting plant research to classrooms and the public at large. This paper discusses our design approach for developing simulations used in two related educational projects.

2. Project Descriptions

The first project, funded by the National Science Foundation's Informal Science Education (ISE) program, involves creating a Web-based activity allowing visitors to experiment with plants from different climates in different growth conditions, to observe the response of plants to water stress. This activity consists of a multimedia tutorial on basic plant physiology and an interactive simulation of an experimental setup that presents the user with virtual tools to investigate plant responses, much like a real laboratory.

The ISE project's model simulates the water use of a growing woody shrub. Two shrubs with different tolerances for water stress are available to the student. The student picks shrubs for inclusion in a virtual growth chamber, and sets the humidity and watering schedule. The model, through a series of mathematical relationships governing water uptake, transport, and loss through transpiration, predicts the carbon uptake and hence the growth of the plant. The model simulates the breakdown of water conducting tissue in the plant.
during drought conditions, and maintains several daily values. The student can go to any point in time during the simulated growth of the plant and take virtual measurements of these daily values. From there they attempt to draw conclusions from the experiment or ask new questions.

The second effort in progress (IMPACT-Interactive Models of Plants to Augment Classroom Teaching) is a foundation-funded pilot study to develop a series of computer simulation models that allow hands-on experimentation in the classroom. This series is designed for CD-ROM with possible Web links to supporting material. The models incorporate current research findings into "virtual laboratories" where students are able to explore and experiment with plants and ecosystems.

A tropical forest restoration experiment in Costa Rica is the first scientific research study we have translated to a simulation model. We created a spatial model of tropical forest succession which tracks the height growth of up to 12 species of native trees across a rugged landscape. The student attempts to achieve a diverse mature tropical forest by first planting pioneer species to establish shaded plots and soil stability, then planting other, shade tolerant species, and species to eventually replace the pioneer trees. In the model, the trees compete for light and nutrients and grow in response to their immediate environment and their genetic abilities.

The projects have in common an emphasis on experimental design and the scientific method, in this case the experiments being conducted by changing parameters within the simulation. The critical feature of providing an interactive experimental model as part of the educational software is that it provides an open-ended, exploratory educational experience. It allows an unlimited number of outcomes and can convey the uncertainty that is usually present in experimental research, and it can often raise additional questions while answering others. Therefore, is in even more important for the student to have a clear and answerable question, or hypothesis, in mind as they begin a simulation experiment.

The two efforts differ in the intended audience and learning environment. The ISE project is for interested students learning on their own, outside of a classroom, while the IMPACT project targets classroom teaching, from high school to early college level. The Web-based ISE project presented us with unique design challenges because it is delivered over the limited bandwidth Internet to a solitary user. We needed to provide more supporting material, including an animated tour of how to use the model to guide them along. By contrast, we aimed at making the IMPACT product adaptable to varying teaching goals and styles by making the model not as dependent on the supporting materials and providing a teacher guide.

3. Design Process

Project personnel include experimental scientists, plant modelers, educators, designers, and programmers. The models are created from the best scientific data available to us, and are derived from the same kinds of functions and assumptions that would be employed in actual research models. Out of necessity, much detail is left out compared to a research model, but we maintain the standard that the model should produce the expected result within its own realm of possible inputs. They are programmed in Java because of the language's advanced features, cross platform capability, and Web delivery capability.

Early feedback from members of our potential audience for IMPACT emphasized the importance of creating a flexible program that can be used in different ways. In one setting, the teacher may assign the science question and suggest the experiment to perform, while in a more advanced setting, the teacher may only provide broad goals for the students, and in still another scenario, the whole class may participate in a single model exercise. One method to achieve this is to have the model be capable of falling back on default numerical input values that make sense in the current context, so that not all model parameters need to be specified explicitly. It is also important to have enough background material available in the program for more independent work.

In creating the model, we had success with having the plant scientist build a spreadsheet model as a starting point, having the programmer re-create that spreadsheet using the software's built-in language (Microsoft Visual Basic), and using the result as a tool to interactively refine the model. The majority of the effort was expended achieving an acceptable model in this way; it did not take long to convert the result into Java code. However, for every line of code for the simulation itself, there were five lines of user-interface support code.

During the design process, we noticed a continual tension between the goals of communicating the science accurately and being able to reach a target audience of high school aged or younger students, perhaps working on their own. It is not clear how to overcome some of these formidable challenges. The model provides significant depth, however, for students motivated to work hard exploring several experiments.
There is a dichotomy between the experience we are trying to provide, which is discovery learning that requires reflective thought, and the computer interface, which is reminiscent of television or a video game. The latter suggests an experiential interaction where the user can be either passive or simply try to point and click their way to all of the information. A major challenge for us is to find ways to guide the student's expectations and actions to be more conducive to them being able to use the program as a powerful learning tool, posing questions, trying new experiments, and thinking about the implications of their results.

4. References

Abstract: Perusal of textual displays of document surrogates produced by Web-based ranked-output retrieval services may require much user time, effort, and money. In this paper we present VIEWER, a graphical interface that allows visualization and manipulation of views of retrieval results, where a view is the subset of retrieved surrogates that contain a specified subset of query terms. We argue that VIEWER helps the user focus on relevant parts of the results and, in addition, it may facilitate query reformulation. We present an experimental evaluation in which VIEWER, used as an interactive ranking system, outperforms both best match ranking and coordination level-based ranking.

1. Introduction

Search of document databases is an interactive process in which users submit a query, see the ranked documents returned in response to the query, and submit a new query, until either they are satisfied with the results or become frustrated and give up. While most research and commercial efforts have focused on producing effective systems for retrieving and ranking relevant documents in response to a query, little attention has been paid to ease the process of result inspection and query reformulation, especially in the Web domain.

Currently available search engines (e.g., Alta Vista, Excite) score queries against documents, compute the highest scoring documents, and present the user with a set of document surrogates in ranked order. While the display of surrogates should allow the user to make a quick and possibly accurate judgement about the relevance of retrieved documents without downloading the full documents, its utility is reduced by the lack of effectiveness of current retrieval engines’ interfaces.

One main reason for users dissatisfaction is the use of standard similarity scores. Roughly, a document receives a higher score if the terms in the query are in the headline, if the terms appear many times, if the terms do not appear in other documents, or if phrases occur as they do in the query. These criteria are then combined in various ways and produce a final numerical coefficient. This numerical coefficient - the only global document characteristic provided by the system - is difficult for the user to evaluate and can be hardly used as an indication of whether the corresponding surrogate should be perused or not. Another related limitation of current Web retrieval interfaces is the lack of a concise representation of the content of all retrieved documents; conventional textual displays take much perusal time and screen space and does not enable inspection of more documents at a time. Given these characteristics of the interface, the inspection of Web retrieval results usually implies for the user to go through the document hitlist produced by the system, spending a considerable amount of time, effort, and money (for those systems that charge the user based on connect-time and the volume of downloaded data) for perusal of document surrogates.

One way to alleviate this problem is to develop a graphical interface that displays the characteristics of documents which are significant in supporting the decision to peruse or not, while giving the user more control over the set of document surrogates that can be selected for perusal. The need for concise display and user-oriented manipulation of retrieval results has been addressed by various systems. Among others, Bead [Chalmer and Chitsons 1992] and LyberWorld [Hemmi, Kunkel and Willet 1994] depict clustering patterns in a document space using three-dimensional visualization schemes, InfoCrystal [Spoerri 1994] uses a particular visual representation of a Venn diagram to suggest how to refine Boolean queries, TileBars [Hearst 1995] displays distribution of query terms within each document to locate its relevant parts. Most of the proposed approaches, however, cannot be applied to Web-based retrieval because they are either computationally expensive, or require sophisticated graphical facilities, or do not scale well, or rely on...
different underlying retrieval models, or, more often, present a combination of these features. One notable
exception is [Veerasamy and Heikes 1997]'s system. Its main goal is to clarify the role played by query
constituents in the result of ranked output systems, it is computationally efficient, and it uses a relatively
simple graphical display. Our approach shares a similar concern but employs a radically different visualization
and interaction scheme. Instead of visualizing the weights of the query terms of each retrieved document and
let the user select those of interest, as in Veerasamy's system, we concentrate on all the possible subsets of
query terms (i.e., subqueries) that can be generated from the user query, showing their distribution in the set of
retrieved documents and letting the user to select the associated set of documents. We speak of view, because
in this way the user may see parts of results without seeing the whole list. Views are defined in a precise way
from the retrieved documents through a simple and comprehensible characteristic of their content, i.e., the
subset of distinct query terms that they contain.

In the rest of this paper we present VIEWER (VIEws of WEb Results), a system for seeking information
over the Web based on view manipulation. VIEWER copes with most computational constraints of Web-based
retrieval (e.g., efficiency, portability, adaptability) that are not usually addressed in other document
visualization systems and can be used as an interface to currently available search engines. We argue that
VIEWER can be used both for focusing on relevant items of the document hitlist returned by the search
engine and for driving the process of query reformulation. A major part of this work is then an experimental
evaluation of the former aspect. We compare the effectiveness of VIEWER, seen as an interactive ranking
system, and that of two automatic ranking systems, namely the search engine to which VIEWER is linked and
a coordination level-based system. The results of the experiment are encouraging.

2. Visualization and manipulation of Web retrieval results with VIEWER

VIEWER is built around available "primary" Web search services, presenting users with a single unified
interface [Fig. 1]. Users enter a query, which VIEWER forwards to a selected search engine (Alta Vista, in the
current implementation).
Figure 1: Visualization of retrieval results with VIEWER. The graphical distribution of subqueries in the first 40 retrieved document surrogates is displayed. Clicking a horizontal bar brings up the associated document surrogates in the document window.

VIEWER then collects the query results and shows, in a scrollable window, a subset of the document surrogates, in the same ranked order as returned by the search engine; in addition, it shows, in the rest of the screen, a graphical visualization of results. The visualization consists of an aligned sequence of horizontal bars, one for each of the $2^n - 1$ nonempty subqueries that can be formed with the $n$ query terms. Subqueries are displayed in the order of increasing number of terms, with the longest subqueries at the bottom; the length of each bar is proportional to the number of document surrogates containing that subquery, which is also explicitly displayed next to the bar. By clicking on a bar the user may select the corresponding view, bringing up the associated surrogates into the document window. As an example session with VIEWER, consider searching the following subject: "archeological excavations for Roman temple". [Fig. 1] shows the response of the interface to the user query: archeological excavations roman temple, as of February 20, 1998. The graphical display quickly shows that the results produced by Alta Vista are, in general, dissatisfying, because most retrieved documents do not apparently deal with Roman temples. In fact, there is only one truly relevant document - the one whose surrogate contains all query terms, which is, incidentally, the eight item returned by Alta Vista - with most of the first 40 retrieved documents concerning archeological excavations of different kinds. VIEWER allows the user to select those few surrogates that appear to or might be relevant, without perusing the others. In addition, it suggests that if the user is primarily interested in "Roman temples", he or she should submit a new query that does not contain the two words: archeological excavations.

3. Utility of view display and selection

It is often the case that some subsets of query terms are so important for a search topic that they will appear in all relevant documents (e.g., the subqueries "archeological excavations" and "Roman temple", in the example given above). In this situation, we would like to ask such questions as: how many documents contain the subquery $s$?, which documents contain subquery $s$? Also, if subquery $s$ is contained in too many documents, we would like to ask: which terms can be added to $s$ in such a way that the resulting set of documents is more manageable? If, on the contrary, subquery $s$ is contained in few documents, we might ask: which terms can be deleted from $s$ in such a way that the resulting set of documents is still manageable? We might also be interested in the relationships between different subqueries. So we might ask: what is the contribution of subquery $q$ compared to subquery $s$?, does subquery $q$ occur more frequently alone or in conjunction with $s$?, and so on.

With conventional ranked output systems such questions would remain unanswered, because the logic behind the retrieval mechanism of these systems does not allow the user to understand how the query constituents influenced the retrieval results. By contrast, VIEWER's graphical display of subquery distribution together with the possibility for the user to choose the relevant views seem to allow a quick answer for such questions. In addition to enriching inspection of retrieval results with facilities for selection, comparison and refinement involving groups of query terms, VIEWER has also potentials for facilitating query reformulation. It may help the user detect that some term (or subquery) is much more frequent than others in the first retrieved documents, in which case the user may formulate a new query using a narrower term or adding a term that helps to specify its intended sense, or, conversely, it may show that some query term is very rare, which may imply using a broader term or deleting some other frequent term from the query. In fact, the latter information may be very useful in Web-based retrieval, because it is often the case that while there are thousands of retrieved documents that match some query term, none or very few of them is contained in the first pages returned to the user (as the subquery "Roman temple" in the example given above). The graphical component of VIEWER may also help detect failure of intended senses of words, i.e., when two terms used in the query to identify one particular meaning do not occur together in the retrieval results, or, symmetrically, discover unwanted senses of words [Cooper and Byrd, 1997].

---

1 It should be noted that some search engines, including Alta Vista, do full-text indexing. So it may happen that some query term is contained in the full document but not in its surrogate. However, given the ranking criteria described above, for best-ranked documents this is not usually the case.
4. Architecture of VIEWER

VIEWER is a client-server system with two main components: the user interface and the search manager. The interface program is implemented as a Java applet in a Web browser, which can be downloaded with the web page http://www.fub.it/VIEWER/VIEWER.html. The user interface sends the user query to the server machine, which forwards the query to a selected search engine and then collects and parses the first pages retrieved by the search engine in response to the query. The server, then, sends back to the client the parsed retrieved document surrogates, which are used by the interface component to produce the information displayed by VIEWER on the client’s screen. VIEWER’s code can be easily modified to work with different search engines or to adapt to their interface changes. The number of collected pages is a system design parameter, currently set at four.

5. Evaluation of VIEWER

The goal of the experiment was to evaluate the effectiveness of VIEWER in helping the user focus on relevant items of the document hitlist produced by a ranked output retrieval system on a subject searching task. We did not perform subject searching over the Web because it would be difficult to assess the system’s retrieval effectiveness and do comparative studies in this unrestricted domain. Rather, we used a set of two to four term queries based on the 52 topics taken from the CACM test collection, an electronically-available bibliographical collection of 3204 documents widely used for laboratory tests. The queries were created by selecting terms from the topics and had an average length of 3.8 terms. We evaluated the performance of three ranking methods: WAIS, coordination level-based ranking and VIEWER.

WAIS is a classical ranked-output retrieval engine. We chose WAIS because it can be used for indexing and searching site specific information, as opposed to global Web search. We connected the WAIS server to the CACM collection and executed the 52 queries against the corresponding WAIS database.

Coordination level (CL) is a well known retrieval method that ranks the documents according to the number of distinct query terms that they contain, which is referred to as their coordination level (see for instance [Van Rijsbergen 1979] ). Coordination levels therefore resemble of views, but should not be confused with them: a coordination level contains all views with a same number of distinct terms, regardless of the actual terms that describe each view. The CL method automatically returns a complete ranking. If the user query contains n terms, the documents that contain n query terms are ranked before those containing n-1 terms, which, in turn, are ranked before those containing n-2 terms, and so on. As CL produces a partly-ordered retrieval output, we further ranked the (equally-ranked) documents within each coordination level by using the ranking produced by WAIS for those documents. The 52 queries were then executed over the CACM database using overall ranking.

VIEWER cannot produce a ranking by itself, but it can be used to help users build their own document ranking. We designed an interactive procedure that was executed by six subjects. The subjects were recruited in our institute; they had a computer science background with little knowledge about the document domain. The procedure for building the interactive ranking works as follows. Each subject was shown the topic, the query extracted from it, and VIEWER’s visualization of the distribution of query terms among the documents returned by WAIS in response to the query. Then the subject was asked to choose a sequence of views by repeatedly selecting one of the views offered by VIEWER until all views had been selected. The documents were thus ranked according to the order chosen by the user to select the views. Documents contained in more views were ranked based on the earliest view in which they occurred. As with CL, we used the ranking produced by WAIS as a secondary ranking procedure to rank the documents within each view. As a result of this process, the final ranking built by the user corresponds to a particular sorting of the documents contained in the output returned by WAIS. Each subject took about one and a half hour to execute all the 52 queries.

The results are displayed in [Fig. 2]. The precision-recall curve is normalized considering, for each query, only the relevant documents that contain at least one query term; i.e., those that are actually retrieved and ranked by the three methods. The [Fig. 2] reports interpolated precision at eleven recall levels, averaged over the 52 queries; the results of VIEWER are averaged over the six subjects. [Fig. 2] shows that the performance of VIEWER was better than WAIS and CL, which, in turn, was better than WAIS. The better precision of VIEWER over WAIS and CL, and of CL over WAIS is apparent at almost all the recall levels. A paired t-test
performed over the whole set of data (i.e., values of precision for all queries at all recall levels) revealed that
the difference between VIEWER and CL and between CL and WAIS were not statistically significant ($p = 0.15$ and $p = 0.10$, respectively), but it did confirm the superiority of VIEWER over WAIS ($p = 0.04$). These
results therefore support our main claim that views selection allows the user to extract relevant documents
from the output returned by best-match search engines. In addition, our results show another interesting and
somewhat less expected phenomenon.

![Figure 2: Precision and recall graph for the CACM test collection](image)

That the performance of CL was better than WAIS might, in effect, seem counter-intuitive, because best-
match retrieval methods are generally considered to be more effective than exact-match retrieval methods,
including CL. However, some evidence has been recently reported [Clarke, Cormack and Tudhope 1997] that
shows that coordination level-based ranking performs better than best-match ranking when the user queries
are short. In this respect, our results confirm these earlier finding on a different test collection; also, they suggest
that interactive subquery ordering may be more effective than automatic ordering based on coordination level,
although we should emphasize that [Clarke, Cormack and Tudhope 1997] employ a method for ranking the
documents within a coordination level that is different from ours. The main reason for justifying the
superiority of the interactive method over the automatic one is that the latter is a purely syntactic method. The
automatic method therefore fails to recognize all the situations in which documents containing fewer query
terms are more relevant than documents containing more query terms. This usually happens when there is a
short subquery that corresponds to a concept that is relevant to the subject being searched while other longer
subqueries are theoretically available that do not convey a precise meaning. For instance, one of the CACM
topics was: "optimization of intermediate and machine code", which was translated into the four term query:
"optimization intermediate machine code". It is clear that while "code optimization" is a relevant subquery for
the topic, there are longer subqueries that are less relevant ("intermediate machine code") or even meaningless
("intermediate machine optimization"). This problem is made more acute by the fact that there is no simple
way of dealing with such lexical items as initials, acronyms, and proper nouns, which frequently occur in user
queries. In our experiment, it was often the case that users favoured shorter subqueries. In particular, for a
significant percentage (27%), the users applied a view which would have not been selected by the syntactic
method.
6. Limitations and future work

The visualization component of VIEWER works with a limited number of query terms (in the current implementation, up to four), because the display of the subquery distribution in the retrieved documents would become cumbersome for longer queries. In practice, however, this may not be a serious limitations, for it has been often remarked that, at least in Web settings, queries to text retrieval systems are usually extremely short, often containing no more than two or three terms [Rose and Stevens 1996; Clarke, Cormack and Tudhope 1997]. Another important design parameter of VIEWER is the amount of textual information extracted from the retrieval results and used as input data to the interface. For each query, VIEWER processes only a limited subset of the document surrogates returned by the search engine, where each documents is usually described by a few tens of terms. Of course, it would be useful to work with more documents and more terms per document. However, increasing the number of terms per document is unfeasible unless we download the full documents referenced by the search engines, which would take an exceedingly long time, while increasing the number of document surrogates can only be done at cost of significantly slow down the response time, although such an additional time cannot be exactly estimated. Since the computation time required to build the visualization scheme is negligible, taking no more than a few seconds, the key parameter for VIEWER’s efficiency is the search time. With a few tens of document surrogates, the total response time of VIEWER is usually fairly acceptable.

This research can be extended by further exploring the issue of the utility of graphical displays of Web retrieval results on more robust and realistic basis. The experiment reported in this paper has taken a first step into this somewhat overlooked direction, but our results can only be taken as indicative and much more work is needed. As suggested above, one factor that needs to be controlled for evaluating the efficiency and effectiveness of this kind of systems is the fraction of retrieval results used by the visual interface. In operational situations, however, there may be other important parameters that affect their overall utility. We plan to perform further experiments to evaluate how the performance results change when controlling a wider range of factors including database scale, query length, and possibility for the user to formulate more queries.

Abstract: This article describes a Marketing elective in the Business School which integrates technology into the curriculum using a series of assignments in which analysis of Marketing Communications is taught using HTML, PowerPoint, and Web Board, an on-line conferencing system. Students learn to analyze Marketing Communications and later to develop Web sites that are strategically sound. Other software which is taught for use in Marketing Communications includes Paint Shop Pro and Wave Studio. The final project for the course is a Web site for a fictitious company as well as a paper that explains the marketing strategies, tactics and rationale for the site.

Background

The Lubin School offers a variety of majors in the business disciplines. This paper deals with an interdisciplinary, collaborative effort on a Marketing elective course that teaches students about Marketing Communications on the Web and is entitled Strategic Internet Marketing. While the technical component does not include in-depth study of any of the programs, it does provide students with the knowledge and skill to design relatively simple Web sites. Although students are given some hands-on experience with the software and are required to do assignments demonstrating some proficiency, the long range goal is to give them enough experience to be able to direct the building of a Web site both from a strategic and an operational point of view. E-mail and the university on-line conferencing system, called Web Board, are used to support and extend classroom instruction.

Students must (1) use e-mail, (2) participate in on-line conferences on the subject matter of the course, (3) practice using basic HTML (4) make presentations using a PowerPoint (5) use a drawing program (Paint Shop Pro) to manipulate an image, and (5) create a simple sound file using Wave Studio.

Course Objectives

- To learn how companies use the World Wide Web for marketing.
- To apply established and emerging concepts from marketing to the analysis of Web sites.
- To construct Web pages using HTML, Netscape, Paint Shop Pro, and Wave Studio.
- To prepare and give a presentation using PowerPoint as well as communicate informally and
- To exercise and strengthen their critical thinking skills.
Course Structure

The course is taught on two days. A two-hour session on Mondays is held in a computer classroom. An important feature in this classroom is the ability to project the teacher's station or any student station to everyone's screen. On Wednesdays, there is a one-hour session in an ordinary classroom devoted entirely to marketing work.

Course Assignments

The course has two major homework assignments and a final project. In the first assignment, students analyze a company Web site and present their analysis in the form of a Web page. They use HTML and incorporate images and links. The instruction in HTML is done by giving students an HTML document in source form with corresponding hard copy of the display form. This hand-out includes questions which must be addressed in their Web site analysis, including type of business, purpose of the Web site, communications strategy, target market, and the like. Students are also asked to reflect on their experience viewing the site and maintenance issues.

In the second assignment, students compare advertisements from magazines with company Web sites. The students should include in their analysis the target market, the message, offers to customers, visitor information and overall marketing objectives. In addition, students are asked to analyze design elements, such as the layout scheme, images, graphics, icons, links and the like. Students are asked to look at these design elements in terms of their ability to "execute" or support the strategy. As with the first assignment, this one serves multiple purposes. The comparison and contrast exercise deals with the subject of Marketing, but the vehicle of expression is a set of presentation slides developed using PowerPoint which students then use in their classroom presentations.

The third assignment is to plan a campaign involving a Web site. This is a team assignment and the requirements include a preliminary presentation to which the rest of the class gives constructive feedback in class and through Web Board, a final presentation in class and a written final report. The teams are cautioned to pay attention to the integration of the Web site with other forms of promotion, and not focus exclusively on Web page design. A storyboard or layout for the site is required with a statement of the rationale for key elements of the site.

Reflection on course

The Web is a new, evolving medium. It is an essential for anyone who expects to be involved with communication to become acquainted with it. Advertising on the Web is growing with expenditures in 1997 reaching 900 million dollars, a 300% increase over the previous year (Higgins, 1997).

One challenge, of course, is that it is difficult to maintain the proper amount of control in a busy classroom. Web sites themselves are very busy and interactive. Further, it is very easy to get distracted or become focused too much on the use of the technology and not on the content itself. Team teaching has the positive benefits of sharing the responsibility and allowing each professor to contribute. The teachers are learning from each other and, therefore, are modeling life-long learning for the students. There is a de-centering of the classroom that can allow students the opportunity to take responsibility for their learning. However, time in classroom continues to be a challenge given the wide range of knowledge in marketing and technology. Professors must strive to find a happy medium, so that the course is a successful learning experience for all. On-going efforts include building a web site to provide support for students and to post exemplary student work (http://csis.pace.edu/~meyer/mar396ws.htm).

From Syllabus to Infinity:  
The Gradual Implementation of Websites

Joanne E. Beriswill  
Instructional Systems Technology, Indiana University, Bloomington, IN 47405  
E-mail: jberiswi@indiana.edu

Abstract: There is an alternative to the all-or-nothing approach to website design. The purpose of this article is to provide an example of a gradual website implementation and to list guidelines for future incremental website design. By separating a project into phases and following some simple guidelines, it is possible to create an effective website and then improve it systematically.

Introduction

When I began teaching a computers in education course, I was a WWW novice. Before classes began, part of my job responsibilities was to put my course syllabus on the Internet for students to access. The thought of putting course materials on-line frightened me, so I decided to start small and grow from there. I began with a simple syllabus on the Internet and now, after five semesters, I have a complete course website with an interactive calendar, class notes pages, project descriptions, and Internet course resource links. Additionally, there are links for students to log onto the class discussion forum, to view class sample files, to turn in finished class assignments, to check their university course grades on-line, and to fill out course evaluations. The purpose of this article is to describe this example of a gradual website implementation and to list guidelines for future incremental website design.

Example of Gradual Website Implementation

Faced with the necessity of creating a course website, I had two main limitations: a lack of time and a lack of knowledge of web authoring. This made a gradual website implementation vital. The implementation took place in four phases in which I focused upon (1) the bare essentials, (2) daily class notes, (3) an inter-face-lift, and (4) continual polishing.

The first semester I decided to simply put the bare essentials on the website and to have the rest of the website emerge from the needs of my students. One of my colleagues generously allowed me to use the interface he had used for other courses as a basis for my own. My simplistic website included a main page with links to my course syllabus and scant page of links to useful web resource sites, such as html guides, teacher websites, etc.

During the second semester, I decided to focus on putting daily class notes pages on the website. Since there were approximately 45 class meetings, this meant a considerable effort and a large number of new webpages. I decided to modularize my website by creating separate directories for different types of webpages. This modularization made it easier to find the different types of pages. I also made a template for the class notes pages so that they would all have the same format. Since the repeated text and format was included in the template, it saved much time and also increased the consistency between the webpages.

By the third semester, the website had the majority of its functionality. The only problem was that the interface I was using was still not my own. I decided to give my course website an inter-face-lift. I began by thinking about the theme of my class—unraveling the computer puzzle. I used the puzzle theme throughout
the graphic design. The existing pages had black text and a white background. Therefore, I just added colorful puzzle piece images to the tops of the pages. I saved time by just adding one new tag to the pages rather than making major changes to each page. I began the semester by making changes only to the menu and the webpages which were used during the first few weeks of class. Then, every week I would change the format of the class notes and project descriptions for the following week. By the end of the semester all the pages were updated with the new interface features with a minimal time investment of five to ten minutes each week.

It seems to be the nature of website implementation that there are always little things to improve. My class website is no different. Each semester I add new content or functionality to the website. For example, one semester I added assignment instructions to the bottoms of the daily class notes. Another semester I added grading criteria or rubrics to the class notes. Since I never seem to have a large amount of time to devote to my website, I gradually make changes over the course of the semester, beginning with the earliest pages and continuing until the end. After five semesters, the changes are now minimal updates to information.

**Guidelines for Gradual Implementation**

Over the past few years, I have been involved in additional website implementations both in corporate and educational settings. Through this design experience, I have found several guidelines can facilitate the gradual implementation process.

**Keep It Simple:** Focus on the content and necessary functions of the website. Focus on those web features which are efficient, effective, and within your capabilities. Add new webpages on as they are needed so that you don’t have links or pages which are never used. Keep designs for the various menus and content pages as simple as possible to facilitate easy upgrades and changes. Remember that fancy features may give your programming ego a boost, but they may distract users and they might take hours to debug.

**Have Reasonable Goals:** Set reasonable goals for completing phases of the website. The key to gradual implementation is to be able to make updates with just a few minutes of time each week. Avoid the temptation to make major upgrades in the middle of the process. Those can be integrated into the next iteration.

**Keep It Consistent:** There should be an overarching consistency of form for a given website. This is usually developed as a visual theme. This visual theme should include the way in which similar pages of content are designed, the use of color, the use of font or heading styles for emphasis, the way in which links are marked, the graphics design, etc. One of the easiest ways to ensure that similar webpages have consistent appearances is to use templates. These templates can contain the repeated structures for a given type of webpage. For example, they can contain the tags for repeated graphics, website navigation links, author/copyright information, repeated headings, tables, or text, etc.

**Have a Modular Construction:** Modular construction refers to the way in which files for a given website are organized. When developing or redeveloping a website, it makes the programming process easier when related files are located in the same directory. This makes it easier to move from one file to the next without having to navigate through various website directory levels.

**Keep a Web Notebook:** Perhaps one of the most understated guidelines for gradual website implementation is to keep a notebook containing printouts of all the webpages in the website. This makes it possible to note changes or improvements which should be made in later stages of the implementation.

**Keep Content General:** The key to having a reusable website from semester to semester is to keep content free of specific references to textbook page numbers, dates, etc. If it is absolutely essential to include such
specific information, it would be helpful to highlight that information in the web notebook so that it is easy to find and change in future semesters.

Some Final Thoughts

When time or programming knowledge are limiting the development of a complete website, a gradual implementation is in order. By separating the project into phases and following some simple guidelines, it is possible to create an effective website and then improve it systematically. As the old saying goes, "By the mile it's a trial, by the inch it's a cinch."
The ABC's of Web Interface Design

Joanne E. Beriswill
Instructional Systems Technology, Indiana University, Bloomington, IN 47405
E-mail: jberiswi@indiana.edu

Abstract: After learning a short list of HTML tags, novices with Internet accounts are able to place their own pages on the World Wide Web (WWW). While these novices may have the technical tools to create a website, their lack of design skills often results in the creation of websites which are difficult to use. A new field called web interface design has arisen to guide designers with regard to the navigation, programming, and visual design of websites. This paper focuses on visual web interface design and outlines the ABC's R' US visual design principles. (15 print and WWW references)

Introduction

Internet usage in the past decade has grown exponentially. After learning a short list of HTML tags, novices with Internet accounts are able to place their own pages on the World Wide Web (WWW). While these novices may have the technical tools to create a website, their lack of design skills often results in the creation of websites which are difficult to use.

If you've spent much time exploring the Web, you've almost certainly encountered some badly designed Web sites. Since almost anyone can create Web pages, it's not surprising that many sites are confusing, overwhelming, ugly, or incredibly slow-o-o-ow. Tantalizing content can be hidden forever from the world when a site is poorly designed [Ben Benjamin quoted in BUILDER.COM - Webgraphics - elements of Web design, 1998].

Websites with poorly designed interfaces are simply not viable. In order to help novice designers increase the effectiveness of their websites, a new field called web interface design has arisen. This field addresses the navigation, programming, and visual presentation issues specifically related to website design. This paper addresses the third issue of web interface design—visual design It describes research sources for visual design, and summarizes the over-arching design with the ABC's R' US visual design principles.

Literature Review

The ABC's R' US visual design principles for web design are a synthesis of three main sources of research: interface research, visual design research, and web design guidelines. While the two former types of research were derived from printed research (articles and books), the later category is based more heavily upon online web design guidelines which are available via the WWW.

Interface Research

Interface research deals with the design and testing of human-computer interfaces [Apple 1989; Cates 1994; Laurel 1990; Nielsen 1990; & Shneiderman 1992]. Its link to visual design revolves around the consistency between the content, the media, the functionality, and the metaphoric theme of a multimedia product. Instructional designers can use this research to help them develop a product which supports clear and consistent interaction between the user and the computer program.
Visual Design Research

Visual design research addresses the visual principles used in interface design. These heuristics are extensions of the ancient Greek aesthetic principles of symmetry, order, emphasis, unity, and balance. These principles have been extended to also include proximity, and parsimony [Heinich, Molenda, Russell, & Smaldino 1996; Reilly & Roach 1986; Williams 1994]. Instructional designers can use these principles of aesthetic visual design decrease feelings of stress among learners and increase feelings of confidence and stability [Rambally & Rambally 1987; Reilly & Roach 1986].

Web Design Guidelines

Certain web design guidelines relate to the visual design of the layout [All Things Web, Apple Web Design Guide, BUILDER.COM - Web graphics - elements of Web design, Improving Web Site Usability and Appeal, Top Ten Mistakes in Web Design, Yale C/AIM Web Style Guide]. The focus of these guidelines is the appeal and ease of use of webpages. The main visual design principles resulting from these guidelines relate to consistency, simplicity, and utility.

The ABC's R' US Design Principles

The visual design principles which appear in the three above-mentioned types of research, were selected and sorted into synthesis categories (the entire data set included principles from over 125 print resources and over 30 online resources). The results summarized the data into seven categories or overarching principles: alignment, balance, contrast, chunking, repetition (theme), utility, and simplicity (by taking the first letter of each word, one forms the acronym "ABC's R' US"). These seven visual design principles should be followed for effective visual design.

Alignment: Alignment refers not only to the alignment of text, but also to the alignment of all visual objects. Objects have six points of alignment: right, center, left, top, middle, and bottom. The eye can perceive the strongest alignment when objects are aligned on the outer points on the right, left, top, and bottom. All text and visual objects should be aligned with one another.

Balance: The center of a page or a screen is its fulcrum of balance. In order to maintain visual balance, the weight of the objects on the left side of the webpage should be relatively equal to those on the right side and the objects on the top half of the webpage should be relatively equal to those on the bottom half. On a light background, objects which are darker have more visual weight than those which are lighter. On a dark background the opposite is true.

Contrast: Contrast is the level of difference in appearance between objects. Contrast can be achieved by placing a dark object by a light object or by putting a thin-featured object by a thick-featured object. In order to draw attention to an object, it should have a high level of contrast from its surrounding objects. The key to effective contrast is to use it sparingly. If one object stands out on a page or on a screen, it will draw the learner's attention. If a number of objects contrast on a page or on a screen, they can distract or even confuse the learner.

Chunking: Visual chunking refers to the placement of objects. Objects which carry out similar functions, such as navigation buttons, should be chunked or placed in the same visual zone of a page or a screen. Likewise, text headings should be chunked with the text which supports them.

Repetition: Repetition has many related layers. It refers to the consistent use of objects, effects, fonts, sizes, styles, and colors both on an individual page or screen and also throughout the product as a whole. Repetition also refers to the metaphor or theme used throughout the product. In this sense, all objects should support the same visual message.
Utility: Utility refers to the usability of the visual interface. It should be clear to the learner which objects are interactive and where the learner is located within the instructional product.

Simplicity: Simplicity addresses the appropriateness and the necessity of the visual objects on a page or on a screen. The purpose of visual objects is their instructional value not their impact value. Objects which do not support instruction can detract from learning. The key is to keep the visual design simple and only include those visual objects which are necessary to convey the instructional message.

Conclusions

The ABC's R' US visual design principles represent a summary of design research in order to present novice users with heuristics to guide effective web design. In this manner, they are descriptive of the current research in the area, while, at the same time, they indicate prescriptive heuristics for design. While it is not within the scope of this short paper to discuss applications of the principles to actual design projects, it is this author's hope that such applications will be discussed in the future.

Abstract: In this paper we will describe the proposal Web site to ISEC (Instituto Superior de Engenharia de Coimbra). It has been set up with the aim of stimulating at the cultural change needed to transform the Institute, in the long run, into a learning organization. We will describe the solutions that have been found to adapt to those requirements the architecture and management of the site. Although designed for general use, it can be explored in a large number of strictly educational tasks because it has been developed with organizational and cultural factors in mind.

1. Introduction

A learning organization is an organization that gives maximum priority to the aim of learning – an organization that is continually expanding its capacity to create its future – so as to be able to continually improve every facet of itself, its products and its services [Senge 1990]. Models for learning organizations change cultures focused on performance enhancement and decentralized management structures [Kotter & Heskett 1992] are now just beginning to be adapted by many companies. In learning organizations, both the individuals and the organization, as a whole, commit themselves to trying to become better every day, employees feel a renewed commitment to their work, and customers fill better served and satisfied. This philosophy is becoming increasingly widespread in enterprises. However, though higher education institutions have as their primary goal that of supplying learning, they paradoxically tend to be the absolute opposite of learning organizations, in the sense that they stress individualism, internal competition, and a major disregard for patient, widely shared, daily improvement. One of our concerns went to creation of the friendly interface through the uses of traditional icons, distributed in a discreet way and visually attractive. In Figure 1 we can see the front page of the site.

![Figure 1: FrontPage of the site.](image)

2. Some Features of the Site

We will describe the solutions that have been found to adapt ISEC to those requirements, in the long run. Unlike most sites developed for educational environments, whose requirements tend to be established almost uniquely on technological grounds – this one has been developed – from the very beginning, with organizational and cultural factors in mind. Although designed for general use, it can be explored in a large number of strictly educational tasks, since it includes the facilities of most sites built for interactive learning environments [Carlson et al. 1996]. The major features of the site, so as to comply with those requirements, are as follows:

**Personal pages:** To make possible the creation of personal pages by users with no knowledge of HTML a uniform pattern has been established for all the personal pages, granting the user interface coherence for all personal pages.
This has been implemented as a Perl script that produces on the client's browser a Perl-generated form from which the page is automatically created upon completion of the form by the user.

**Gradings:** The students have the possibility of consulting their gradings online by simply supplying a password that gives access to the student's process. This is done by resorting to another Perl script that checks username and password, validates them against the corresponding values on an encrypted password file. This is similar to the Unix passwd file, and, if the whole security check is positive, lets the student enter a page containing all the grades received, discriminated by course. Each such page is a private space that can only be viewed by each student.

**Organization and presentation of the information regarding the courses:** To establish the standard pages for the courses, a questionnaire has been sent to all teachers, requesting all the relevant information. This information provided a description of the course, teaching staff, syllabus, summaries, and recommended bibliography. Also any additional documents and transparencies, software available (so that it could be made available by ftp), project work carried out in the past and programmed for the future, relevant internal and external Internet links, exams (preferably with corresponding answers) and finally a FAQ, are provided. See Figure 2 for an example.

![Example of one course.](image)

**Forums.** In order to establish opportunities for open interpersonal exchanges, the site includes a forum divided into a variable number of themes. User friendliness has been a major concern, so, instead of setting up a standard news like interface, the forum system has been set up as a Perl script that automatically constructs the evolving HTML page that registers the evolving discussion. The forum also includes text and pattern searching capabilities.

**Tool of Statistical Analysis.** At the same time it was built a statistical tool (WebReport), based in logs generated by the server, to analyze the information of the number of accesses to the site separated by categories, origin address, pages visited, time spent, browser used, etc.

### 3. Conclusions and Future Work

Building learning organizations involves developing people who learn to see, who develop their own personal mastery, and who learn how to surface and restructure mental models, collaboratively. We believe that the aim of building an institutional Web site that contributes to promote the cultural change required to move our Institute into the direction of learning organizations has been achieved.

In future developments of the site, further automation will be introduced, namely by extending the principles used for automating personal pages and forum management to other key areas, such as the automatic production of tests by teachers, and the production, by students, of the corresponding individual answers. It will also be extended to the construction of course pages, grading sheets and administrative information coming from the Institute's Administrative Services. This is the new image of one institution that could involve all of their elements to participate more and better in the diversity of activities that are taking place at ISEC, and the new image of our Institute that we would like to promote for the next century.

Learning Through Design-oriented Experience
With Technology

Joy (Xiaoshi) Bi, Electronic Instructional Design Specialist, Division of Lifelong Learning, Ohio University, U.S.A.
Linda Edmiston, Ph. D. Student, College of Education, Ohio University, U.S.A.
Linda Jones, Ph. D. Student, College of Education, Ohio University, U.S.A.

Abstract: Design-oriented activities with technologies are powerful tools for students’ learning. This panel presents the views of using educational multimedia technologies in classroom learning among elementary, middle school and high school students. There are three hands-on design projects: 3D graphic design, Lego-Logo construction and programming of Robots, and Web site creation to demonstrate what students have created and completed. From the literature review and research, it is known that design-oriented experiences can provide opportunities for students to gain the abilities of active participating, higher-level thinking, creative problem-solving, interdisciplinary usage of knowledge, and interactive reflection of ideas. Particularly with new technologies, students engage themselves in the authentic design activities to learn the subject concepts such as math, science, and the arts together with the computer software and Lego bricks and blocks.

Multimedia & Distance Learning

The purpose for young students to create a Web site and put their finished work online is to provide them with design-oriented experience. Because students who got involved in both 3D and Lego-Logo learning activities are from different school districts, the Web site they created would be not only valuable resources for schools as a virtual community, but also good examples to stimulate further involvement of more students in learning new technologies. We called it a “distance learning experience”. The following is the procedure of how to design and publish students’ products on the Web.

Design Principles

In fact, design is a process of decision-making (judgement and choice). For one’s life (both personal and professional), decision-making skill constantly influences the quality of it. Now students in schools learn scientific knowledge and life skills, preparing to be adults responsible for themselves and for the society in the future. Therefore, we are sure that the design-oriented experience is the tool to teach them how to make decisions.

Teachers and students all agreed on the major decisions of how to design the Web site. These decisions are that the Web site should (1) include the information about students; (2) have a simple style of layout and fewer colors; and (3) have a opening page to introduce the design-oriented projects, within which there are links to other pages of project details. As for the Lego-Logo in motion, we videotaped it, plugged it into computer, and made it a quick-time movie. To create a web site, students learned three basic design principles: Determining

• what it is – to define the site, recognize the information to be put in, plan the scope and sequence, and organize the content into a diagram;
• how it looks – to define the style of the site (always keeping in mind simplicity and consistence), layout of all elements of the Web site, and modify the details;
• and how it works – to decide what multimedia elements to use, design the navigation of the site, recognize functions of each page, and controls of interaction.

Theory Into Practice
After teaching students how to judge and choose what is necessary on the Web site, we worked with them to transfer the design process from paper onto the computer. All students were taught how to create a Web page and how to use a scanner. Students were divided into several groups which are in charge of different tasks of placing all the information on the site. For example, one group was to create Web pages and links; another group was to take pictures of Lego-Logo products and scan them into computer; the other group was to do the research about other Web sites which are related to 3D and Lego-Logo. Students chose the group they wanted according to their own interests and strength. Those who are strong with multimedia technologies were responsible for formatting and testing multimedia elements, such as sound, animation and quick-time movie.

As soon as information layout and navigation links were done, we made sure the files were on the server and ready to be reviewed. All students would examine everything on the site and give feedback to us for edition and revision. Then according to the decisions we had made at the beginning of the procedure, we discussed some issues with students, like color, font and multimedia functions. This was to confirm that we created the Web site for every school, which is user-friendly to accommodate lower level computers. Finally, the schools of these creative students would review the Web site before it was really open to the public.

Interactive Learning Environments

The student created a sundial and used the lighting source in the environment to simulate time. Stemming from this concept the students had discussed: Earth’s rotation around the Sun, other planetary movements, seasonal changes, directional settings, shadows made by the Sun, etc. This activity engaged students in interaction with their living environment. Once they realize their capabilities in this artificial environment, they will try and recreate concepts found in their own lives.

Hands-on Process

We incorporated the 3D art process as a tool to reinforce curriculum being taught in other areas. This simulation would: 1. Start with the students learning the 3D environment (x, y, z axis) and the computer program as a tool to create visual media. 2. Incorporate this curriculum to enhance the learning process (introduce, review, reinforce and/or extend material being taught in the regular classroom setting). 3. Publish their finished work on a web site

Teaching/Learning Strategies

The major subject area that fits our 3D renderings is math oriented- parts to whole, patterns, shapes, geometry, ratio, and percentages, perimeter, area and volume. These were items and words used by the students to describe the on going, problem solving activities for most of our sessions. Students were taught by using a step by step procedure to get into the computer program and execute the commands needed to solve the problem.

Step 1: (a) How to get into the program; the use of mouse, pull down charts, folders, and double clicking (b) What are the “universe”; “hierarchy”; lighting, camera position, and the Primitive Objects: (Cone, Sphere, Icosahedron, Cylinder, and Cube). (c) How to start a drawing in the universe and save it on a disk.

Step 2: (a) Students learned to draw objects in the universe and size them. (b) Students learned how to move around in the universe and find the way back to the preset position.

Step 3: (a) Students continued drawings and how to manipulate through the viewing commands to make sure that the objects were -really aligned. (b) Menu Bar = View, Preset Position, and one of these: Top, Bottom, Lift, Right, or Back. (c) The Magnifying tool was introduced to zoom in and out of the settings.
Step 4:  
(a) Students continued drawing items and adding parts.  
(b) They learned how to use the Numerical Properties chart to resize objects but most of them felt comfortable using visual commands to do this (resizing by clicking on the corners of the object and dragging in the desired directions| out for larger; in for smaller).  
(c) The rotating tools were introduced for turning the objects in space.  
(d) There were two of them: one to rotate in a flat spin (x and y axis), the other would move all three Directions on the x, y, and z axis. Students’ work could be adjusted to fit on the arm of the sundial and lighting adjustments would act as our sun for the shadow needed to make the sundial work.

Step 5:  
(a) Students had been using all the above skills learned from Session 2 through 6.  
(b) The command of Group and Ungroup was introduced so that students could put many multiples of small objects together and duplicate.

Step 6:  
(a) Students learned how to use color, pattern, and texture to render their objects.  
(b) Students learned the commands to create a scene with their object inside the Production Frame (View, Prod. Frame) and how to set the lights and camera for the best angle of view for a finished product.  
(c) Students would adjust the lighting, and decide on the atmosphere to use in the background.

Step 7:  
Students changed the view and production frame to create a “slide show” of multiple views.

Multimedia & Artificial Intelligence

The students in this project used Lego-logo robotic models as a focus for applying content knowledge toward creative design projects. The students in this project were ninth and tenth grade students with no previous experience with Lego-Logo projects. They were encouraged to follow sample project models to learn the basic construction skills for Lego constructs and computer programming. Later in the projects to control their robots. The students were encouraged to participate in emergent communities to invent their own programmed constructs and to share their design ideas through a web site in order to build a virtual learning community.

Programming

Students used logo command language to create computer-controlled projects. The participants programed vehicles to maneuver along predetermined route and performed specific tasks. Scientific sensors were also used as input devices to control robotic constructs.

Hands-on Construction

Students were given the Lego bricks, blocks, gears and motors and some simple plans for construction. Students needed very little time on sample projects. They began to modify the original plans very quickly. Some groups moved into very creative building while others experimented with different ways to program the function of their creation. Students soon began combining Lego kits to build more and more complex models.

Interaction

Students worked in teams of three to five per project. The teams were flexible in number and selection of project. Some students were more interest in building vehicles while others were more interested in building robotic arms and computer programmed devices using the light, heat, touch, angle sensors. Interaction among students within their own team and with other teams was enhanced through the use of a Web site to
display designs and ask questions of the virtual community concerning problems they have encountered. They also used the Web to find sites with plans from other students and tried to improve on those designs.

**Conclusion**

The members of this panel represent diverse backgrounds and experience in public school and university level education. The perspectives of the members are from the arts, technology, and the humanities. It is creative design that has been the force behind the energetic enthusiasm of this panel as an emerging community of learners. And it is the power of their own design-based learning experiences with teaching young learners that provides a great depth of knowledge to be shared with the larger community at the Web Conference.
Statistical Information Resource Discovery and Retrieval Using Statistical Metadata

Y. Bi
Faculty of Informatics, University of Ulster at Magee College
Northland Road, Londonderry, BT48 7JL, N. Ireland, UK
(Email: yaxin@infm.ulst.ac.uk)

Abstract: Enhancing the description and representation of information resources provides a very important basis for information discovery and retrieval. Such an approach overcomes the complexity of statistical information. In this paper, we address an approach for statistical information retrieval and discovery using statistical metadata and the search engine Isite.

1. Introduction

Handling and analysis of statistical information start with information retrieval and resource discovery. However, such tasks are becoming more and more difficult to accomplish as the Internet and statistical data sources continue to grow in size and complexity. That is because the conventional database management system and techniques for information retrieval cannot be effectively applied in dealing with complex organisation of information such as the mixture of textual, numeric, and even graphic data, etc. and searching complex data objects.

The complexity of statistical information arises from various data types, various data formats, various cross-relationships between data and the diverse distribution of data, of course, also arises from different platforms and information management systems. It is obvious that the effectiveness of the search method depends on how much this complexity is overcome. There are two ways to tackle this complexity: to offer more powerful functionality in the search engine, and to enhance the ability to describe and organize statistical data stores. Clearly, the latter is a straightforward way and relatively simpler to obtain compared to the former. This is our motivation to describe and organize statistical data in a distributed environment by means of statistical metadata and SGML (Standard Generalized Markup Language).

In this paper, statistical metadata is used to refer to the characteristics of statistical data. It is divided into the two categories of declaring metadata and processing metadata. The former is used to describe statistical information for the purpose of locating, accessing and organising the statistical data residing in diverse locations. In particular, we concentrate on using statistical metadata to describe the compound textual documents containing numeric tables, graphical figures, and even more links connecting remote data objects. The typical approach adopted for statistical metadata involves the selecting of representations of concepts that characterize the structure, context, and content of statistical information; the generating of metadata structure based on the statistical domain, a minimal metadata set, called statistical metadata structure.

With respect to the processing metadata, it involves the handling and analysis of statistical data incorporating statistical macrodata and microdata. At issue here is the first category, declaring metadata.

There is a natural correspondence between statistical metadata structure and SGML’s DTD (Document Type Definition). The DTD provides a good facility for the specification of metadata and for the description documents using the metadata. SGML focuses on the document description – hence its content – and not on the display of the document [Bryan 1997]. The structure of an SGML-coded document is formally defined in a set of markup declarations that form a DTD. These markup declarations describe a set of markup instructions, known as tags, which can be used to identify the start or the end of logically constituted parts in the coded documents, and the links with external information resources. In this work, statistical metadata are directly mapped as tags in the DTD.

Retrieving a collection of SGML-coded statistical documents using statistical metadata distinguishes from existing search methods such as Lycos, Alta Vista, InfoSeek, etc. An underlying difference is that in the existing search engine methods, META tag is designed for constructing an HTML header to declare keywords and a description such as AUTHOR, DESCRIPTION, and KEYWORDS [Int_inf], rather than for describing and representing the content, structure and external links of a document. The benefits of supporting full document search using metadata are shown in the following section.

2. A Statistical Metadata Framework

A single document is not able to contain complex data objects. However, a statistical container is capable of containing these data objects, and the relevant descriptors of these objects, statistical metadata. That is a proposed statistical metadata framework. In contrast to Dublin Core [Weibel and Iannella 1997]
which describes essential features of electronic documents and document-like objects, the statistical metadata is focused on describing the content of textual documents and connections with external complex objects, thus imposing a structure on the unstructured document and establishing links to the external objects that remain the original formats. In fact, this framework is a wrapper of content of a document and URI (Uniform Resource Identifier) of the objects embedded in a document.

The combination of statistical metadata and SGML leads to the creation of a DTD associated with the statistical domain, which may be viewed as a standardized format with an SGML syntax. This provides a good facility for organizing statistical data, because all of statistical data objects, including textual documents, numeric tables, graphic figures, and cross-reference links, etc. are described, represented and organised in the same DTD environment. Therefore, the consistency of describing data objects and their relationships is achieved. Following this scheme, a comprehensive document is partitioned into a collection of small and manageable segments according to the DTD, and for each segment, there is a tag – statistical metadata describing or representing it semantically. As a result, an unstructured document can be transformed into a structured document with statistical metadata structure. The advantages thus obtained are: to provide a linking mechanism between the complex data objects; to overcome the complexity of statistical data to some degree; to facilitate the development of handling and analysis of statistical data; to make effective use of existing search engine tools; and to cross different platforms.

To illustrate the specification of the statistical information using SGML, we consider a flat structure model of the OECD “Economic Indicators” [OECD] tagged by the statistical metadata. We have:

```xml
<Indicator>
  <Title>Main Economic Indicators</Title>
  <National Accounts>
    ...
  </National Accounts>
</Indicator>
```

A formal specification corresponding to the above structure can be defined in the following DTD. The DTD is expressed as a set of declarative statements using a simple SGML syntax. The following declaration is an example of a formal SGML specification of the above structure:

```xml
<!- - DTD for Main Economic Indicators - - >
<!ELEMENT indictor    (title, naccount, production,... ,
                        bpayment?)>
<!ELEMENT title      (#PCDATA)>
<! - - National Accounts- - >
<!ELEMENT naccount   (line+)>
<!ELEMENT line        (#PCDATA)>
```

A complex structure ensures when the sections and subsections in the Economic Indicators are properly nested, implying that a hierarchical structure is associated with this document. This structure can represent cross-references or external complex objects though reference linkages.

3. Conclusion

We implemented a prototype for retrieving SGML-coded statistical documents using the Isite search engine, which is developed by the Center for Networked Information Discovery and Retrieval (CNIDR) [Gamiel 1996]. Its search methods are based on free-text and fields demarcated by tags. One important characteristic of the field search method in the prototype is that it can be used to retrieve and discover relevant and external data objects through links. The results demonstrate this approach can not only be served as a remedy to the deficiency in text query and in accommodating complex data objects of the statistical database, but also provide an extension to the conventional bibliographic-like search method as well. Meanwhile, the domain-specific metadata standard offers a solution to overcoming the complexity of statistical data objects.

INTERACTIVE EXERCISES AND AUTHORING PROGRAMS FOR LANGUAGE LEARNING ON THE WEB

Peter Biddulph, Language Net, UK pb@soi.city.ac.uk

We demonstrate original Web-based interactive materials for language learning and the authoring tools for their creation. These programs, which incorporate text, audio and video, run on the Internet or an Intranet, or on a stand-alone machine without an Internet connection.

The programs present examples of language from authentic contexts, evaluate a user's input and provide feedback automatically, or, in the case of a free practice exercise, the learner's input is forwarded to a teacher via e-mail.

We have developed a variety of tasks to develop the learner's reading, writing and listening skills with exercises designed to raise awareness of the structural and lexical systems of the target language. The tasks aim to engage learners cognitively by requiring them to analyze, compose, order, edit, and reconstruct text: learners select or type in appropriate words or phrases to complete a text, match elements ranging from morphemes to sentences and paragraphs, compose sentences from 'chunks' of text, or edit a text identifying words which have been omitted, added or spelled incorrectly.

Some exercises incorporate video clips: the learner listens and reconstructs the text, which has been segmented into tone units.

The user may set an exercise to 'learn mode' or 'test mode': students may try an exercise with the words displayed in a list before testing themselves by entering their own text. Few exercises require the learner to simply click on the correct answer to a question.

AUTHORING PROGRAMS

The learner or teacher may create their own interactive exercises for a given language using any simple text editor or word processor, or by using the on-line authoring programs. No knowledge of HTML or programming is required.

We have designed the authoring programs to enable the user to produce a wide variety of exercise formats, and to facilitate the creation of exercises to focus on syntax, collocation and other lexical phrases, hyponymy, meronymy, etc.

The programs are on-line at http://www.point2.co.uk/lnet/
http://www.language-net.co.uk (From October 1998)
Back Pain School on the Web: 
Clinical, Technological and Pedagogical Challenges

Hélène Bilodeau 
Université du Québec en Abitibi-Témiscamingue

Presentation of a pedagogical and clinical Web site concerning chronic low back pain (http://uriic.uqat.uquebec.ca). This important health problem is multidimensional and an educational approach is required to bring relief to those who suffer.

The Interactional Back School (L’École interactionnelle du dos), developed at the University of Québec in Abitibi-Témiscamingue in collaboration with the University of Bordeaux, is a structured, therapeutic program designed to teach sufferers to treat their own lower back pain. Involving an interdisciplinary approach, the method includes physical and mental preparation, attitude and behavior changes, and cognitive learning of anatomic and ergonomics concepts.

The Web site is dedicated to two types of users, patients and practitioners, and include these sections: Interactive documentation for the patients, Virtual clinic, Credited courses for training clinicians.

On the Web site of the Interactional Back School, hundreds of pages have already been organized but many challenges remain: Clinical, Technological and Pedagogical challenges.
Form Follows Function: Using an Intranet to Mirror Library Staff Reorganization

Abstract: In 1996, the Medical University of South Carolina Library created Webster, an intranet comprised of various toolkits and divisional resources. This paper describes the 1997 development of a new toolkit designed to help reorganize several public services and education departments into one division, and to foster collaborative communication.

1. Introduction

In the developing Internet, much attention has been directed towards the establishment and maintenance of "virtual communities" formed by geographically distant individuals and groups with similar or tangential interests. For the past year, the Medical University of South Carolina Library has used an existing intranet as a virtual launching pad for a new work unit. The Department of Library Science & Informatics manages and provides access to resources, systems, facilities and personnel that support the educational, research and clinical interests of the university. In the recent past, ownership of library resources defined access. Present and emerging digital technologies have redefined access, regardless of physical location. Technology has shifted the emphasis towards user-centered services [Harris et al. 1996] and away from place-centered collections [Riggs 1997]. The evolving body of biomedical knowledge requires libraries to establish lifelong relationships with users from school days to clinical practice to retirement years, and to extend access to near and distant sites.

2. Approach

In August 1997, several Library departments were reorganized to form the Public Services & Education (PS&E) division. Spread out over 48,000 square feet of assigned space on different floors of the same building, these departments were managed by relatively independent managers, and consequently developed different approaches to problem solving, program development and service provision. We used intranet technology to establish a group identity, maintain a divisional focus, emphasize collaboration, provide content needed to function in new roles, reduce reliance on paper files, and normalize expertise throughout.

This new set of neighbors needed specialized information and original content. A new toolkit was organized within Webster, the intranet framework designed and developed by Systems staff. Intended for all Library
faculty/staff and originally showcased in January 1996, Webster functions as a dynamic snapshot of a modern day academic health sciences library.

The PS&E toolkit subsumed separately designed and maintained toolkits for circulation, reference and learning resources. The care and feeding of this resource is intended to mirror, parallel and ease the reorganization of several departments into a single division, and to provide a forum in which to discuss and discover.

As described in an article discussing criteria for building communities [Kim 1998], the project required a purpose. The new toolkit's purpose was predicated by the division reorganization itself and the need to redefine work routines. Staff members were asked about the kinds of resources needed to improve work flow and customer service. Content was customized to reflect present and future needs, and organized by function rather than department.

As did Allsport Photography [Mullich 1997], we encountered concerns that the project might destabilize the network, consume remaining server space, and/or reduce available memory on staff workstations. Like our commercial counterparts [Sliwa 1998], we decided that collaborating electronically, sharing information, and exchanging ideas over an intranet would improve customer service.

Recognizing the human tendency to limit or guard access to data, future plans include the selective use of cookies to customize content, exploration of useful agent technologies and utilization of security technologies such as digital certificates [Sliwa 1998].

3. Concluding Remarks

The toolkit's sustainability and viability depend on buy-in, ownership and the ability of each employee to contribute ideas and resources [Callaway 1998], regardless of their individual Web publishing skill level. An important step towards realizing an open intranet [Gibson 1997], encouraging division-wide contributions and shifting the maintenance burden away from the original developers was the March 1998 introduction of do-it-yourself file uploading. It is not necessary to seek administrative approval or ask someone else to upload the files. The next steps include providing easy-to-use templates and allowing WYSIWYG real-time updating.

The human side of developing an intranet cannot be underestimated. Prior to the establishment of the division, employees tended to seek permission, and convene large group meetings in efforts to reach consensus, resulting in long project timelines and uncertain completion dates. This project encouraged expansion into new areas of interest, developing new expertise and taking decisive action. The new toolkit is one way to keep people informed and acknowledge their contributions, important considerations when phasing and implementing organizational change. Administrative support for this project fostered the desired changes in critical thinking and problem solving skills. Prior to the reorganization, each department functioned as an autonomous and somewhat isolated unit. The process of developing the new toolkit reflects a new focus on interdepartmental collaboration. This experience helped us reduce production cycles, take chances, trust co-workers and work in small, productive teams. As the division evolves, the toolkit will mirror and reflect a dynamic and collaborative enterprise.

Using Internet Technology to Assist Parental Involvement in Education

David A. Blohm, President and CEO, Virtual Knowledge, USA, Dblohm@VirtualKnowledge.com

As the fastest growing educational software publisher, Virtual Knowledge has helped hundreds of thousands of parents assist their children with their Children Skills Tests. With the great progress that has been made in Internet technologies, and as on-line communications have become more accepted, the Company has developed new solutions for the World Wide Web.

Virtual Knowledge realized that the country is experiencing a back-to-basic skills trend in education, focusing attention on assessing and tracking what students know and can do. Parents want to become more involved with their children’s education, yet they are often unsure of their children’s relative level of academic development in key subject areas. When it comes to finding appropriate tools to help their children, parents frequently do not know which educational products to purchase for their children’s particular needs. In short, parents are extremely eager to help their children, and need help to do so. Virtual Knowledge developed SmarterKids.com to address this need.

Virtual Knowledge set out to create SmarterKids.com as the most authoritative resource for children’s education at home. Realizing that this is quite a formidable task, the Company began to map out how to take the concept to reality.

There would be a variety of challenges ahead. Could the Company’s current Web server support the volume of hits that would come? What software would be used to manage the countless number of educational products, learning profiles, and users—not to mention the order processing, fulfillment, and inventory operations that the site would need to perform?

SmarterKids.com is very different from a traditional retail or catalog-like experience for the consumer. It is, rather, a personalized experience built around authoritative and credible assessment testing, and high quality educational products. This requires a capability for parents to upload test results, and then for the site to interpret these results in a way that delivers meaningful results to parents.

David Blohm will share with the conference attendees the strategies and techniques used to bring SmarterKids.com to life. Mr. Blohm will detail the development from the initial concept to the creation of the SmartPicks engine. This fascinating and educational presentation delves into the ideas and technologies that created the first ever service for parents to make informed recommendations by linking children’s assessment results to the directly to skill areas of the items that are recommended.

David Blohm is the President & CEO of Virtual Knowledge, Inc., a publisher of multimedia children’s testing software. The Company’s flagship products, marketed as the Sylvan Children’s Skills Tests, assist parents in measuring and tracking their children’s overall scholastic development, and help parents develop strategies for maximizing their children’s potential.

Prior to joining Virtual Knowledge, Mr. Blohm co-founded MathSoft, Inc., in 1985. MathSoft develops and markets Mathcad, a mathematical calculation software package. From 1985 to 1994 Mr. Blohm served as president and chief executive officer of MathSoft. During his tenure at MathSoft, Mr. Blohm grew the company to $30 million in sales and led it to its initial public offering in 1993. Prior to 1985, Mr. Blohm was chief financial officer of Higher Order Software, a developer of computer-aided software engineering tools.

Mr. Blohm serves on several committees which focus on expanding the use of technology in the educational community. Currently, Mr. Blohm is chairman of the Massachusetts Software Council and chairman of the Council’s Education Task Force. In this capacity he oversaw the development of The
Switched-On Classroom, a widely-used guide for educators who are integrating computers into the classroom. He also guided the committee in establishing the Massachusetts Tech Corps, a program which partners volunteers from the high-technology industry with educational institutions as they implement high-technology programs. A U.S. Tech Corps, endorsed by President Clinton, has been established based on the Massachusetts model. Mr. Blohm is also a member of the Corporate Board of the Massachusetts Net Day initiative, is an overseer at the Boston Museum of Science where he co-chaired the Museum’s first Educational Software Fair and serves on the Corporate Executive Council of WGBH-TV public television.
A Web Based Virtual College

Abstract: The need for tele-education is rapidly growing. This paper describes a tele-educational environment and reports on experiences obtained during international trials. The tele-educational environment is build around the metaphor of a college. The virtual college offers the opportunity for students to participate in desktop tele-education from their homes or offices. The environment is based on Internet technology and the user interface is a common Web browser. Students navigate through the virtual college by entering classrooms, group rooms, studies, and teacher offices. During breaks students can visit a virtual tea room.

Keywords: Group work, lectures, self study, tele-education, virtual college.

1. The Virtual College

Tele-education will play an increasingly important role in the future. The need for education is rapidly growing due to the rapid changes in society. New technology is introduced with an astonishing speed never seen before. This makes vocational education at least as important as basic school education. Education will be a life long activity, and social and economic welfare will be linked with education. This is true for both individuals and countries.

The propagation of the Internet now makes tele-education based on Internet technology possible in most places. Hereby is introduced a means to make life long education achievable in an efficient way. In particular the Internet supports “desktop tele-education”. This concept means that individual students participate in tele-educational courses from their offices or homes using a desktop computer online connected to a course provider. What is needed is a multimedia PC, a headset and an Internet connection.

The tele-educational environment described in this paper is developed with “desktop tele-education” in mind.

It is very important that a tele-educational environment is easy to use. The environment itself should constitute a minimum learning threshold for the students. This goal has been achieved in two ways. First of all, the main user interface is a common web-browser. This means that everybody familiar with the Internet will be familiar with the interface of the tele-educational environment. Secondly, the environment is build around the metaphor of a college. This means that the user interface looks like a real college with different rooms for different purposes. The students will find a classroom for lectures, a group-room for group-work, a study for self-study work, a teacher’s office, and a tea-room.
for social interaction. The different rooms make it easy and intuitive to navigate in the educational environment.

The virtual college applies different modes of teaching and learning. This includes synchronous modes like on-line lectures and group exercises as well as asynchronous modes like interactive self-study, participation in threaded billboard conferences and sharing of documents.

Figure 1 - The user interface to the virtual college

A challenge in designing the tele-educational environment has been to integrate these modes of education and to combine them with the metaphor of the college. This integration has resulted in a tele-educational environment, which is intuitive and easy to understand for both students and teachers.

The virtual college is based on Internet technology. The present implementation of the virtual college uses the Netscape Web-browser, extended with loosely integrated audio and video tools. It is an obvious advantage to base the virtual college on this well-known industry standard, which makes it immediately accessible to everybody familiar with Web-browsing.

The virtual college is highly scalable. This means that it can be adjusted to the actual needs and existing infrastructure, in particular to the available communication bandwidth. Although it was developed with broadband communication in mind, the virtual college can be scaled down to an Internet environment by carefully restricting the usage of audio and video conferencing facilities. A more detailed description of the tele-educational system in a broadband telecommunication environment can be found in [1].
2. The Rooms

The virtual college looks like the plan of a "real" college. There are different rooms each serving a specific purpose. The design of the virtual college is modular. This makes it easy to furnish the rooms according to their intended usage. The furniture consist in tools like audio and video conferencing, a shared white board, a slide presentation tool, etc.

In addition a first version of a floor control system has been included in the environment. It enables the teacher to control who is able to speak thereby making the communication more disciplined. Students can add themselves to a list of speakers, e.g. for making questions. This list is part of the floor control system.

- **Class Room**

  The classroom is the place for on-line lectures and presentations. This implies that students must be "present" in the class room during lectures. The class room can be furnished with an audio tool and depending on communication facilities also with video conferencing facilities. There will be a whiteboard to allow the teacher to write and draw, and a slide presenter for the teacher to show educational material. It is also possible to show any page from the Web on this slide projector.

- **Offices**

  The office is available for the teacher and is furnished with course administration tools. For example this could be tools for making new self-study material available for students during a course. The office can also be used for private consultation for students. In this case audio and video conferencing tools could naturally be part of the room as well as a shared note pad.

- **Study**

  The study is the student's office. Here the student will find self-study material, exercises, slides from previous lectures, supplementary material (like in a library) and links to other sites on the Web. The self-study material is made highly interactive with animations, self tests, indexes and bookmarks. This room is for the asynchronous mode of education and the student can work here at any time. There is no interaction with teachers and other students in the study room.

- **Group Rooms**

  The group rooms are furnished for small groups of students to meet and work together on exercises and to do group works. This requires audio and preferably also video conferencing facilities, shared cooperative tools like a note pad and whiteboard, and of course the relevant group exercise.

- **Tea Room**

  The tea room is supposed to be used for informal chat and social contact with fellow students during breaks. The tea room is furnished with a number of tables where students can sit and have a virtual "cup of tea". Each table has its own audio and video conferencing facility.

- **Information**

  The information poster in the hallway gives all the administrative information about the course. This includes timetables and descriptions of lectures, group work and self study modules. Descriptions and pictures of all teachers and students participating in the course can also be found here.
The billboard contains different threaded conferences, each related to a particular topic. These conferences are related to the topic of the course and students are expected to make contributions as part of the education. The teacher will regularly monitor the billboard.

3. The tools

Each of the room in the virtual college is furnished with different tools according to the needs for a particular room.

- The shared whiteboard has the basic functionality for drawing and writing. It can be used with a background image. This is useful for group exercises where students discuss a diagram and during lectures where the teacher can draw on a slide.

- The shared notepad is related to the whiteboard. It is used for shared working on small text documents. The notepad has the basic text editing functionality needed for collaborative work on text, however the functionality is limited compared with professional text editors.

- The slide presentation tools primarily used in the class room. It allows the teacher to show slides and students to view these slides. The whiteboard can be included on slides. This allows the teacher to add notes on slides during presentations.

- The shared bullet tool is closely related to the slide presentation tool. The teacher can use this facility to put the attention of the students to specific points on a slide.

- The audio and video control starts and stops conferences. It includes functionality for muting and un-muting audio and video. This control is partly integrated in the floor control system.

- The message tool is used for sending and receiving small messages between persons present in the virtual college.

- The other users is a tool that shows who is also present in a room. By clicking the name of a person the personal data of that person will appear.

The virtual college and accompanying tools are implemented in Java, which makes it platform independent. The rapid development of Internet technology has made it a challenge to comply with the latest releases of Java and Web-browsers.

4. The Trials

The virtual college has been used in different trials during the last year and further trials are planned in the near future. The first trials were run in a local area network environment in order easily to monitor and control the students and the technology. Two major pan-European trials were conducted recently. The trials included about 40 students and 2 teachers located at 6 sites in four countries: Denmark, England, Germany and Ireland. The JAMES (Joint ATM Experiment on European Services) broadband network connected the sites during the experiments.

The topic of the course was “An Introduction to ATM”. The students were partly recruited from industry and partly from academia. They were not required to have any specific qualifications related to the topic of the course. Each course was run over 4 days and consisted of 4 class room lectures, 3 self-study modules with exercises, 3 group exercises, and one class room discussion.
This very tight schedule was made for practical reasons such as network availability. To some extent it hampered the experiments. In a real application of the system the course should have run over at least two to three weeks and less activity each day.

5. The Experiences

The trials have been carefully monitored and evaluated. After each trial parts of the system was updated based on experiences gained. The main conclusions were that the users liked the virtual college. They found the college metaphor easy to understand. They had no problems navigating through the virtual college. Another result was that the two modes of teaching complemented each other very well.

Generally on-line teaching and group work seem to be a motivating way of learning. But it also appeared to be very demanding for the students to follow a course in this environment. This is because the student’s attention is concentrated on the computer screen and the audio input received. Students simply get tired and lose attention. For this reason lectures must be relatively short, not more than half an hour. Also the total course activity each day must be limited.

Students are positive about the class room form of teaching. However, all students are not equally prepared to ask questions. Some students never ask questions in this environment, others quickly become heavily engaged in discussions and trying out the boundaries of the media. Generally students find it easier to ask questions here than in an auditorium. On the other hand it is more difficult than in a classroom. In other words, the “communication distance” between student and teacher is perceived smaller than in an auditorium but still bigger than in a “real” classroom.

Experiences from the group exercises showed that students might have difficulties in initiating and performing efficient group work. Some students seemed alienated towards the environment and made no attempts to get engaged in the group work. Other students worked very well in this environment, so no definitive conclusion could be made.

The billboards are easy to accept and to use. However, it is necessary to engage the students to really using these facilities, e.g. by giving them specific assignments. During the trial some very interesting discussions took place, but only few students participated. This might be due to the tight schedule of the course.

The teachers require some new skills in the virtual college. For example must the teacher be able to coach the students into using the media. Also in case of technical problems the teacher must be able to help.

It is well known that it is very time consuming and hence very expensive to develop the self-study material. The experience is that with high quality material the students are satisfied and the learning effect is good. The combination of self-study material and online lectures and group exercises seems to be a cost-effective way to conduct tele-education.

6. Conclusion

The feedback from experimenting with the virtual college in an international setting has been encouraging. The concept was well accepted by the students. They quickly became familiar with the environment, the learning effect was good and they appreciated the attempts to introduce some social ingredients into this virtual environment.

Abstract: The Performing Arts Data Service (PADS), funded by the Joint Information Systems Committee (JISC) and based at the University of Glasgow, aims to support research and teaching in UK Higher Education by collecting and promoting the use of digital data relating to the performing arts: music, film, broadcast arts, theatre and dance. The PADS is one of 5 service providers of the Arts and Humanities Data Service (AHDS) which will provide a single gateway for arts and humanities scholars wishing to search for datasets across various discipline areas. Data is indexed with Dublin Core metadata, will interoperate with other databases within the AHDS and beyond, and will be available via the Web.

1. Introduction and Background

The Performing Arts Data Service (PADS) is one of a syndicate of five Service Providers appointed by the Arts and Humanities Data Service (AHDS)[1], funded by the Joint Information Systems Committee (JISC)[2] of the UK's Higher Education Funding Councils, and is based at the University of Glasgow. The AHDS's mission is to co-ordinate access to, and facilitate the creation and use of, electronic resources in the arts and humanities by offering a range of services. It will encourage scholarly use of its collections and make information about them available through an on-line catalogue.

The AHDS provides a single gateway for arts and humanities scholars wishing to search for datasets across various discipline areas. Other service providers include: the History Data Service (HDS), The Archaeology Data Service (ADS), the Oxford Text Archive (OTA) and the Visual Arts Data Service (VADS)[3]. The service providers' databases interoperate with other databases within the AHDS and beyond via Z39.50[4], and searching will be available via the Web. In order to achieve meaningful search results, data from all the service providers is indexed with Dublin Core metadata.

The Performing Arts Data Service's role within this framework is to support research and teaching in UK Higher Education by collecting and promoting the use of digital data relating to the performing arts: music, film, broadcast arts, theatre and dance. The PADS differs from the other service providers in that it has a particular concern with data consisting of and representing time-based media. The results of two recent projects have had a major influence on the system of the PADS as it stands today. The (Scottish Higher Education Funding Council funded) NetMuse Project[5] was a project developing web-based music courseware for delivery over the ATM based Scottish Metropolitan Area Networks (MAN's). This included development of a Java based audio player [Malloch and Pflicke, 1997] for streaming full CD quality music, further developed as part of the SMaTBaM project [Boehm 1997] (Serving Massive Time Based Media)[6]. The SMaTBaM project researched storing, retrieval and delivery of time-based media and was designed specifically to benefit the work of the PADS whose remit does not extend to conducting research.

The SMaTBaM project researched and set up a prototype of a system which had to be suitable for the PADS, including the means of delivery of time based data as well as the storage and retrieval issues. This prototype has been scaled up and forms the basis of the PADS system which consists of two Silicon Graphics (SGI) Origin 200...
servers: one is a media server streaming audio and video using SGI MediaBase software; the other runs an object-orientated database with a web-gateway (Hyperwave Information Server) which stores both the non-time-based data and the metadata of the material on the media server. This solution combines the demanding performance of a media server with the advanced database features required for modelling and handling big collections of data. Additional gateways have been set up to secondary remote Hyperwave servers via HGI-CSP, realtional database management systems via Netdynamics and library databases and catalogues via a newly implemented Hyperwave-Z39.50 gateway.

Thus the user, although accessing information from different locations, different platforms and different kinds of databases sees one sort of interface, i.e. a browsable webpages guiding him through the information space via navigational aids such as discipline specific and discipline independant searching templates, knowledge domain related, hierarchical browsing hierarchies, depiction of relationships between resources via metadata and other hyperlinks.

The PADS has recently been involved in a major project to provide a digital catalogue records for the Scottish Music Information Centre (SMIC)'s unique collection of scores, manuscripts and recordings, with funding from the Scottish Cultural Resource Access Network (SCRAN). The project "Five Centuries of Scottish Music" aims to digitize 1000 items and metadata of manuscripts, scores, composers' bibliographies, concert programmes and recordings of ten representative scottish composers taken from the last 5 centuries and adding an additional glossary explaining musicological relevant terms mentioned in these records. This project is near its final stage and the collection is planned to be accessible in the near future.

This paper will cover three principle areas:
- the general information systems requirements for serving time-based media over the web;
- the PADS system architecture
- a report on the experiences gained in the first major effort to make a collection of 1000 digital resources available: the SCRAM/SMIC/PADS project.

2. Information Systems Requirements for Performing Arts data on the Web

In a time where the internet becomes the platform, the browsers become the operating system, and applications become services a digital library project set in the performing arts has to define new methods of storing and distributing time-based data to be able to serve quality and quantity information across wide area networks. It also requires solutions of the more philosophical areas of research into how interfaces have to be set up and how information should be represented in order for users to handle vast amounts of data as intuitively and as user friendly as possible. In order to cope with the information increase and user capacity expected information management services will always have to deal with the "three I's": Information Structure, Information Representation and Information Access.

2.1. Nature of the data in the performing arts

A collection dealing with Performing Arts related data consists of both secondary resources i.e. materials about the performing arts, moving image and sound-based media, and primary resources, i.e. the digitised multimedia objects themselves. As data compression and transmission technologies develop in the future, it is the service's aim to facilitate the real-time access of video clips, sound files, movies, musical performances and multimedia productions - both primary and secondary resources.

It is desirable that a collection is able to be expanded by collections of other service providers holding resources in the same field but at the same time maintaining a "one-stop shop" in accessing time-based media resources. This distributed resource environment allows the option of other collection holders keep and maintain their collection physically in their own repository, while access is handled by a central access point.[7]

A performing arts resource collection encompasses a wide range of different disciplines, starting with the disciplines of music and film and stretching further toward dance, theatre and the broadcasting arts.[8] The
resources as a whole can be characterised as a) being made out of different types of data, b) containing differing complexities of data, c) possessing different relationships, and d) being time-based in their nature.

2.1.1 Different types of data

As with all multimedia related systems, all the "usual" data types are involved from sound, video, text, image and binaries. Storing them in a certain way provides us with a more complex entity of data types: html, sgml, mpeg, wav, gif, jpeg, java, etc. It is certain that these data formats will evolve further in number and content. The use of different formats in a system should therefore be a means but not a solution. In other words, to minimise the danger of storing data in standards that might not be supported in the future, much thought should go into separating the content of a resource from its presentations. To be able to store a resource in the highest quality possible, combined with the ability to convert it into formats suitable for a certain purpose, or added formats in the future, is to provide an open and flexible system with maximum compatibility in the long term[9].

2.1.2 Differing complexity of data

Whereas video and images might be stored largely as single binary data-objects, music, theatre and the broadcasting arts could involve the storing and accessing of highly structured data, presenting complex objects or 'composite objects'.[10] In some cases, it might be hard to distinguish which is the real, the original resource, and which is a composite part of it. If one accepts the fact that the content of a resource might be of complex or composite nature, then the step towards devising a way to store it as such is not far. Technologies are needed that offer the ability to depict, represent, access, store and manipulate complex structures in their complex "Gestalt". A broadcasting feature, as one resource, might encompass video data, sound data, and text data and still be one work of art.

We should accept the fact that our future data might not remain in its binary form and much of our present resources have never been in the "Gestalt" of one entity. Java Applets, Webobjects and other distributed object environments are already being used by artists to create works made out of many components and having many facades. Also the existing resources, which have been traditionally stored as metadata in catalogues, while their real content is being stored as artefacts in shelves, cassettes, or discs, are often not just one entity. In trying to devise resource systems of the next decade, it would be illogical to diminish the resources and their "real-life" manifestation by disregarding their composite character.

It was clear for achieving the above requirements, normal library catalogues and conventional relational database management systems would not be sufficient. Object-oriented or at least object-based information system technologies would have to be employed.

2.1.3 Different relationships

Assuming that we have objects stored in a persistent way, the access and search results are influenced by the context these objects are in. The mapping of content and context into a digital world means defining and storing different kinds of relationships between objects. Examples for generic implementations and standard definitions can be found in OMG's Object Request Brokers and their Relationship Service Specification for distributed objects [OMG CORBA-Relation 1997] or in the Knowledge Interchange Format of the Laboratory for Advanced Information Technology [Finin and Labrou 1997]. Relationships can be of numerous variety. For example, five basic relationships widely used in information systems are:

- *Inclusion - one object is included in another object (e.g. a file in a folder, a certain sound used in a composition, a note in a bar)
- *Inheritance - one object inherits the characteristics of another object (e.g. all service provider users have read rights, these might be inherited down towards the developers of collections, who also have write rights; or, as a third example, all sounds stored at high quality inherit the characteristic of being served out over ATM network only).
- *Association - one object is associated with another object (e.g. Mendelssohn's composition *Fingals Cave* is associated with the geographical rock formation of Staffa. Another example would be that two pages can be associated with each other in form of a sequence. One page should follow the other in a certain context as for instance a book, course, slide show, score etc.).
**Attributes** - an object contains certain attributes, or certain characteristics which describe its state of being or its internal structure (e.g. all objects in the PADS archive have the attribute DublinCore, where the DublinCore object itself has 15 further attributes defining the elements of the Dublin Core, see 2.2 Metadata).

**Web Links** - Web-links can be thought of being a realisation of a certain kind of association in a web environment. The publication of these resources involves the presenting of one resource via different types of other resources or one resource related to others. For instance, a computer-music piece may exist as a sound file, presenting the first recorded performance, as well as archived as the code of the computer program itself and the secondary information associated with this resource.

Whereas relationships belonging to the categories of inclusion and inheritance are implemented “hard-core” into the PADS system, attributes can be thought of being the metadata of the objects. Unlike normal library system in which only metadata about objects is stored, which are not held digitally or stored separately, in the PADS system attributes belong directly to the objects described by them. In order to facilitate an interdisciplinary approach of resource discovery, the PADS within the greater context of the AHDS searched for a standard way of describing resources across different disciplines, across different types of resources and across the different service providers.

During 1997, the PADS engaged in various activities to investigate and debate how best to facilitate resource discovery in an on-line setting. Specifically, the PADS looked at the metadata standard known as the Dublin Core[11] and how it could be applied as a tool to describe the time-based (sound and image) data resources that are the special responsibility of the PADS. The PADS work [PADS Metadata 1997], which formed part of a series of activities in all the arts and humanities discipline areas represented by the AHDS, was conducted under the auspices of the AHDS and the UK Office for Library and Information Networking[12] with funding from JISC. The aim of the series was to explore how different subject domains both describe and search for electronically held information and to evaluate the usefulness of the Dublin Core as common set of concepts shared across disciplines that may be used in the construction of the AHDS's integrated catalogue.

One of the attractions of the Dublin Core metadata set is its simplicity - the Dublin Core was originally intended to be used by non-specialist authors to describe World Wide Web documents. Although the AHDS workshop series[13] and other initiatives from the library and information community have proposed some fairly complex and lengthy qualifiers, and the AHDS has proposed amendments to some of the definitions, the Dublin Core consists of 15 basic elements:

1. Title  
2. Creator  
3. Subject  
4. Description  
5. Publisher  
6. Contributor  
7. Date  
8. Type  
9. Format  
10. Identifier  
11. Source  
12. Language  
13. Relation  
14. Coverage  
15. Rights

The PADS held two workshops in April-May 1997, inviting participants with a cross-section of expertise and interest in moving image and sound resources from both service provider communities (libraries and archives) and user communities (UK academics in performing arts disciplines). The groups examined the potential use of the Dublin Core for describing time-based resources, tested it against a variety of examples and critically reviewed its application. The findings from the workshops, which have been borne out by subsequent pilot applications to PADS data, were that the Dublin Core could function adequately, but there were some reservations and concerns over certain of its elements. [14] The experience gained was used to develop and implement a Dublin Core Metadata set with a data entry scheme, including additional subelements, which would work for performing arts data resources in general and for the SCRAN/SMIC/PADS project "Five Centuries of Scottish Music" specifically.

### 2.1.4 Time-Based Data

The common denominator of many prospective resources of the PADS service has the characteristic of being time-based. Storing and accessing time-based media requires special attention in storage and delivery of the objects. Solutions are needed to store information in its inherent complex form on the server side, to transmit these information packages in real-time with high-quality over a wide-area network, and to provide a user
interface able to access and use the resources intelligently. For a high-quality service four types of time-based material, all requiring real-time access, can be identified:

- **large binary data objects**: such as sound or video - streaming binary data combined with using a guaranteed bandwidth to ensure no glitches or breaks. Requires:
  - high performance networks providing high bandwidth and guaranteed quality of service;
  - client-server software tools to provide the streaming;
  - high-performance media servers, and high-end client workstations.
- **subsets of large binary data objects**: playing just a part of a sound or video
- **two or more parallel large binary objects**: such as synchronisation of multiple audio streams, requires Intra-stream and Inter-stream synchronisation to maintain the temporal relationship between multiple streams [Robertson 1998 and Robertson 1998] E.g. 'lip sync' in film and tv, where sound and vision tracks are often recorded on different media.
- **complex objects**: such as MAX music scores, more complex Java applications, or sound-sound combinations require a fast and time-coordinated access of all the composite parts of an object: the synchronisation of multiple, periodic, logically independent streams of arbitrary type.[see Flinn 1995]

In the first two instances, high-performance media servers designed specially for serving time-based media offer many solutions for streaming large amounts of data. Automatic recognition of bandwidth and consequential choice of compression and delivery means ensures that users have the best quality available to them. More difficult are the last two instances. First results to synchronize separate streams on ATM networks have been achieved through the work of George Robertson at the University of Glasgow [Robertson 1997] and are planned to be integrated into the PADS system. Several upcoming standards such as MPEG7 will hopefully further this research and development.

3. The PADS system
3.1 PADS System Infrastructure

A goal of the PADS service is to provide interoperability with other collection holders by conforming to and implementing relevant standards. To shortly sketch the status-quo situation of using multimedia digital resource collections already available, one can look towards broadcasting stations, music/video archives, record companies and libraries. It must be taken into account that collections are stored in different storage mediums, ranging from simple file systems, to relational database management systems to the growing number of object-oriented database management systems.[15] In addition, a large number of music catalogues in a variety of formats has to be also made accessible.[16]

Between library and library-like catalogues, an implementation of the Z39.50 protocol (version 3, 1995) is sufficient. For interfacing catalogues with relational databases, there will need to be a Z39.50 - SQL interface. There are very few relational database vendors who have implemented a Z39.50 support; one reason being that their "interoperability protocol" has been SQL, which has been universally accepted and implemented by almost all of the database vendors.

Discussions have already taken place to extend the Z39.50-1995 protocol with SQL.[17] From here it is logical step and a matter of time to stay interoperable with the present database generation which is based on object-oriented technologies, and has defined an object query language (OQL) and an object definition language (ODL).[18] With the prospective widespread use of digital libraries, object-oriented database management systems will become a major means of storing, accessing and using complex, multimedia data objects. [19]
Assuming a basic interoperability of different collections holding digital, multimedia objects, the underlying transfer protocol will have an influence on the performance, the quality and the representation means of the objects to be delivered. Using a stateless protocol, such as http, means that only one object can be delivered per session. Thus the connection closes after each document is delivered, losing all the information of the former session.

In devising a secure and distributed system, with collections stored in different locations, access handled from a central gateway and user access in the best case being controlled to a point of write, read and execute rights of
single objects and collections, stateless protocols can be a problem. Solutions lie in the underlying existence of user rights management, such as a database management system able to control the access of many users in dependency of objects or collection of objects, or/and the use of a stateful protocol such as Z39.50 or Hyperwave's HG-CSP.

PADS Hyperwave Information Server is able to handle these security issues, as well as offer an expandable protocol layer. Relational Database management systems are hooked up to it by Perl Database Modules (DBI:DBD-ODBC, DBI:DBD-Oracle, etc). In cooperation with the AHDS, Index Data (Denmark) and Hyperwave R&D GmbH (Germany) a generic Z39.50-Hyperwave gateway was implemented, translating incoming Z requests into the object query language used by Hyperwave. With this gateway, the requirements of being able to access library catalogues, as well as relational database management systems, as well as other object servers was fulfilled.

3.2. PADS Database and Media-Server System

In the greater context of the AHDS, a central WWW-Z39.50 gateway residing at the AHDS is responsible for incoming requests for multiple-database searches via Z39.50. Z39.50 targets, installed at each of the 5 service providers including the PADS, process the incoming requests and send the result-sets back to the AHDS WWW-Z39.50 central gateway. The PADS also has its own gateways, providing their own specific user community with specialized services relevant for time-based media. Thus gateways to a number of clients is realized, such as www browsers, media-players, Z-clients, telnet clients, etc. Direct requests for subject specific searching is possible, with or without the use of Z39.50 protocols. The PADS resources reside on several database management systems, interoperable with each other through hyper-G, CGI and SQL interfaces. Hyperwave Information Servers are responsible for controlling incoming and outgoing requests from clients and interfacing databases. A, for this project implemented generic Z39.50-Hyperwave gateway was linked to the server, transposing incoming requests into the object query language used by Hyperwave. The hyper-G protocol allows proprietary clients (such as Harmony and Mozart) to have session-based protocols with graphical browsing abilities. These graphical representations of relationships of the objects in the DBMS are also realised with the http-Web gateway through Java/JavaScript implementations. The loss of functionality in using http, a stateless protocol, instead of statefull HG-CSP, is compensated by the use of Cookie files or java variables.

As the media server MediaBase on a separate Silicon Graphics Origin 200 is used. Movie players or soundplayers, either from MediaBase or those created by the University of Glasgow are able to make direct connections over the ATM networks. These players are installed on the client machines as browser plugins. Sound and movie objects are put into Hyperwave as objects, calling the functions by scripts to establish the direct ATM connection through Java classes and or C++ classes.

The PADS uses the feature of running several different web-gateways with different presentation schemes on different ports, in different collections and on different machines. The PADS is running two general webgateways at the moment, one serving webpages out for non-java/javascript browsers, the other utilising java and javascript in order to depict dynamically the resources and their relationships with each other. For specific data entry needs another webgateway is running at locations where collections are being archived, digitized and metadata'd. A fourth one is in development, to offer additional functionality needed for usage as a digital library service.

Interoperability between the HWIS and remote RDBMS/ORDBMS is supported through a HGI-SQL gateway. For example, to hook up a MS Access database, as the PADS has with a catalogue of a Glasgow-based film association, Hyperwave's own HGI (hyper-G Gateway Interface, using HG-CSP, hyper-G Client Server Protocol) communicates with its SQL gateway, which in turn interfaces to the standard available DBI-DBD perl-gateways. These have RDBMS vendor specific modules, such as DBD-Oracle, DBD-ODBC, DBD-Informix, etc. On the Access side, the only thing required is an MS ODBC or SQL server driver.

Another way used to link external sources to the Hyperwave Information server is by using the HGI (HyperG Gateway Interface) to call upon remote objects using as an additional attribute the protocol used such as http, telnet, Java Objects, CGI programs, etc. Mediabase, the database used by the PADS to store and deliver videos, is hooked up to the HWIS through the HGI. Metadata of videos and high quality soundfiles are stored on the Hyperwave Information Server, as is the protocol used for the delivery, but the BLOBs (Binary Large Objects) of
video or sound themselves are stored on Mediabase. The user thus accesses the videos through the Hyperwave Information Server, which builds up a direct connection between the client of the user and the Mediabase Server.

With this architecture, certain specifications demanded by a service such as the PADS are answered. It is an open but secure system running on a distributed resource environment with full user administration and rights management. It has, among other gateways, a web gateway and can be expanded by future gateways, answering the need of any upcoming specialized clients. It is interoperable with RDBMS and ORDBMS through SQL, and with its own object query language it is theoretically expandable with ODMG's OQL and ODL, linking it to OODBMS and distributed objects. It has powerful indexing capabilities and additional features deriving from the OODBMS world, such as versioning, inheritance of functionality, separation of content and view, and scalability of the delivery as well as the storage system.

References

Footnotes

[7] This distribution of information has also implications regarding copyright. I.e. Institutions holding copyright of material will likely want to hold their collection physically on their servers and still be able to offer single user interfaces across remote collections. The National Preservation Office of the National Library of Australia has made this "Distributed responsibility" one of its Statements of Principles of Preservation of and Long-Term Access to Australian Digital Objects. See http://www.nla.gov.au/nla/staffpaper/preserve.html , 1998/07/01.
[9] For an example of the separation of content resource and various representational views, one might think of a picture stored in the highest resolution possible in a central resource archive, and its compression to a lower quality for web use. When using high-speed networks, one would still be able to provide a higher quality resource to appropriate users or maybe an even lower quality one due to any possible copyright restrictions. In the computing world, this separation of content and representation has one of its object-oriented manifestations in the Model-View-Controller paradigm. The model being the content, the data, or a knowledge domain, the view being one possible presentation of it. The controller can be seen as the gadget maintaining the connection between the model and the view. One musical note, for instance, could be depicted in a system by an internal, proprietary data structure. To this note, one or more views can be "plugged in" as for instance a midi representation, a sound representation, and a graphic representation. Devising new views is thus independent of the content. See also [Ossenbruggen 1994].
[10] Elementary or simple objects are objects made out of one entity or one binary (text files, bitmaps, wave format files, midi files). Composite objects consist of a number of elementary or composite objects, for instance a complex/composite music data structure. Complex objects are objects with attributes that change in size.
[14] Most of the problems related to the use of the Dublin Core can be put down to its design of describing textual documents on the web. A very clear example for this is the "author" element, which works only for written documents. It does not work for music or many other disciplines, in which there are many more and different creators, which cannot described and would be even confusing in being described as being the author. Changing this attribute to creator makes it more elegant, but does not solve other problems, as for instance: a) Subelements or schemes of the Dublin Core are not yet standardized, as are the values in their syntax. (for example date, controlled lists, etc). b) Absence of any distinction between the digital item, which is represented in the system, and the physical item it might represent. Thus digital libraries using the Dublin Core face always the question of "Which metadata are we actually using, the one representing the digital object (for instance a image of a manuscript) or the physical object itself (the manuscript). Both sets of information might be important for a specialized user, but the Dublin Core has no option for this possible double existence of the object it is supposed to describe. c) Certain basic elements are problematic in their use in an interdisciplinaty context, such as subject and coverage. For more information about the Dublin Core and it interdisciplinaty evaluation at the PADS and AHDS, see [AHDS Metadata 1997].
[16] Whilst in the academic and non-academic library world interoperability has established itself as an important topic, it is not so clear that, mainly commercial, television and broadcasting companies will want their archives to interoperate with those of their competitors. However, given that material tends to decrease in commercial value with time but increase in academic and cultural or heritage value, it is quite possible that their material will end up in such a collection and so issues of interoperability are worth addressing at the outset.
[17] See Proposal for SQL Access in Z39.50: Z39.50/SQL+, http://www.dstc.edu.au/DDU/research_news/reports/zproposal.html, 1998/07/01. It should be noted that although such plans are being discussed elsewhere, the AHDS' plans are limited to procuring specific interfaces between collection holders and Z39.50.

Abstract: The Digital Beethoven House is a digital library project of the Beethoven House Association, the City of Bonn, and GMD. It mainly consists of three parts. A digital archive contains digital copies of and catalogues about the collection of the Beethoven House and the Beethoven Archive. The Beethoven Salon is a real building which offers on-site access to the whole collection and additional visualization facilities about Beethoven's work and life. Finally it is a World Wide Web presence. This paper describes the services of the Digital Beethoven House to be implemented and the present project plan.

1. Introduction

Ludwig van Beethoven is the most famous son of the city of Bonn in the Rhineland of Germany. The composer was born here in 1770. Bonn became the center of the documentation and research about Beethoven's life. Beethoven's birthplace today contains a collection of more than 4000 original documents [Fig. 1]. They have to be preserved on one side for future generations and should be opened for the broad public and music research on the other side. Today's technology makes this possible.
2. The Digital Beethoven House

The Digital Beethoven House is a digital library project of the Beethoven House Association, the City of Bonn, and GMD. It mainly consists out of three parts. A digital archive contains digital copies of and catalogues about the collection of the Beethoven House and the Beethoven Archive. The Beethoven Salon is a real building which offers on-site access to the whole collection and additional visualization facilities about Beethoven’s work and life. Finally it is a World Wide Web presence.

2.1 The Digital Archive

Five main subjects dominate the design of the underlying database for the digital archive. The main part of the database will contain archive data concerning Beethoven’s life and work (#1). On one hand the database will comprise Beethoven’s own works like compositions, manuscripts, letters, sketchbooks, and autographs and on the other hand those documents where others dealt with his biography, the images of him, his surroundings, and working places, i.e. the whole Beethoven literature.

Additionally all the information about the Beethoven Museum of Bonn (#2) has to be part of the database including images, business hours, and all sorts of souvenirs which can be purchased. Moreover, all cultural events (#3), like concerts, exhibitions etc. are available in the database including the booking and reservation data.

Besides these informational data, the results of online working groups (#4) are saved to the database. These could for example be all the public contributions made to the forums for discussion or the examination and regeneration/restoration of musical handwritings. Finally it is in the own interest of the Beethoven House Association to organize their members (#5), the membership fees, the donations and all data concerning the advertisement in the data bank.
2.2 The Beethoven Salon

The Beethoven Salon is a real building close to Beethoven's birthplace giving access to the Beethoven House and the complete Beethoven Archive. In the Beethoven Salon people have the chance to experience the ancient world of Beethoven through audio, video, and virtual data. The digital copies of all documents in the Beethoven Archive are here. A virtual guide will lead the visitors through the Digital Beethoven House. State-of-the-art visualization technology will give deep impressions into Beethoven's life and background. Interviews with Beethoven himself can happen based on modern videoconferencing technologies. Visitors can virtually touch the contemporary instruments and objects of the Beethoven House and can have a close look at the material and the mechanics used at that time. Last but not least, online studies can be made here.

2.3 Beethoven on the Web

Living in an Internet-based information society today, a global World Wide Web presence of Beethoven is a must. People planning their trip to Bonn will find all related information in the Web like opening hours, logistics, and travel information. An online booking service allows people from abroad to book one of the limited seats in the Chamber Music Hall, in advance and in time. Online catalogues of the museum shop will offer online purchasing possibilities.

2.3.1 A Beethoven Course for Beginners and Experienced

In order to connect the city of Bonn with the name and music of Beethoven, the Digital Beethoven House site will contain a course on Beethoven's music and life, which teaches the Beethoven friend as well as the scientist. The bilingual course (English/German) will also show step by step the whole offer of the Digital Beethoven House site like Beethoven's manuscripts.

The Beethoven course aims to provide a comprehensive learning platform which is motivating, intuitive, fun, and simple to operate so the user may immerse quickly into the content by using full multimedia Internet possibilities like text, picture, audio, and video. It is planned to make it the most complete Internet offer about Beethoven worldwide.

Another advantage of the Beethoven course is its ability to connect teachers, scientists, and other learners who study Beethoven via the Internet. They can communicate and exchange information fast and easily. By this, they form online working groups and their discussion results will be saved to the database too.

Additionally, the Digital Beethoven House Web server will contain: A virtual tour of the Beethoven House, compressed, low-quality versions (thumbnails) of the exhibitions and the documents in the collection, and catalogues about the archive as such. This Web offer may attract people coming to Bonn. Additionally, the Digital Beethoven House will maintain a guide to Beethoven research worldwide [BR 98].

2.3.2 Museum Support

The normal operation of today's Beethoven Museum will be simplified and enhanced by modern technology: It will base on the contents of the digital archive and Internet technology. Newsletters for the clients and the members of the Beethoven House Association will inform about events or new manuscripts for the Beethoven collection. A CD and facsimile production adapted even to individual user's/customer's needs, be it a private person or be it a scientist and researcher, will be part of the museum shop. Permanent exhibitions will perform here.

People doing research on Beethoven or having a generic interest in his work will find the URL of the Digital Beethoven House in all search engines directly. They can search for different types of documents in the digital Beethoven archive. They may have a look at them in a downgraded quality, make a choice, fill out and sign an invoice, and immediately download and use the document needed.

2.4 Challenges

The scanning equipment must be of high-quality as there are photographs, picture postcards, 3-D-compositions, books, magazines, newspapers, and even microfilms or microfiches to scan. The valuable primary material is either available as original or as copy or facsimile and often yellowed, soiled, and even fragile.

In a first step, technical metadata have to be stored during the scan process, like e.g. date, type, format, and identifier of the material, or the quality of original and scanned documents, the number of pages to be printed etc. Finally there is bibliographical metadata that have to be captured by cataloguers (music experts) in a second step. They comprise data like the title and the subject of a document, its description, its source, or its creator, and publisher or its contributor etc. The database of the library today ('allegro') has to be integrated.
into this set-up. As the data will be accessible to other virtual digital libraries, standards for metadata, e.g. Dublin Core [DUCO98], will be evaluated against the cataloguing process.

Having digital copies of the Beethoven manuscripts has several disadvantages too. It makes it simple on one side to publish the documents but also makes it easy on the other side to manipulate the document, duplicate them or distribute them without the owner's approval. Content integrity, authentication, intellectual property, and copyright protection are the major issues here. It is technically not possible to prevent the unallowed manipulation, but it is possible to record the information about the owner, the application purposes, and the copyright in the document itself.

Watermarking, visible or invisible, is part of a solution for this problem. There is no standard method to embed and proof watermarks in digitized documents which browsers, operating systems, image processing software, and hardware devices can follow. There is no standard registration procedure for watermarks. This is needed for example for evolving search services, which have the task to find watermarked documents in the worldwide Internet, or for registries. About 20 products are on the market for watermarking with different procedures/algorithms implemented. An evaluation has to take place.

One issue in distributing digital objects is the granting of access rights to registered users all over the world ('pull technology'). Modern compression technologies and scalable coding can be applied here to limit the bandwidth usage during the transmission. More sophisticated distribution channels and policies will be implemented in the Digital Beethoven House.

3. The Project Plan

In June 1998, the budget commission of the German Parliament has devoted a large amount of Deutschmarks to the Digital Beethoven House in the context of its tourism concept for Bonn. With this decision, several activities performed by the Beethoven House Association and GMD since the end of 1996 came to a successful end [DBH 97]. The project is scheduled to start after the summer vacation period in October 1998. The plan is to demonstrate the complete Digital Beethoven House at the Expo 2000 exhibition in Hanover.

The project will start with a preparation phase where a feasibility study, a project plan, and a rapid prototype will be made. In a following design phase, a conception and a concept refinement for the Digital Beethoven House testbed and the overall system will be developed. The testbed will contain only a subset of the documents in the Beethoven House collection. In the next phase, the testbed and the overall system will be implemented. The testbed implementation will be accompanied by a scientific conduct study. Finally, after an integration of the overall system, the Digital Beethoven House will go into (pilot) operation following an operation model identified in the design phase.

Additionally, several permanent tasks have to be performed from the very beginning like project management, decision making, documentation, quality management, technology watch, and service adaptation and development.

Division of Curriculum and Instruction
University of North Florida
Jacksonville, Florida, USA

The purpose of this session is to demonstrate and discuss ongoing projects at the University of North Florida. The presenters are instructors of two courses which are offered via the Internet. Middle School Philosophy/Curriculum is a required course in an undergraduate middle school education program. Telecommunications in Education is a graduate course. This session would help to disseminate information, to gain feedback, and to establish contact with those who are working on similar projects.

Topics of discussion include, but are not limited to: Effective Lessons, Objectives, Estimating Student Time, Frequency of Assignments, Collaborating on Assignments, Measuring Technological Skills or Achievement in the Content Area, Accessibility of Technology Resources, Types of Assignments, Electronic Discussion Areas, Face-to-Face Meetings, and Streaming Video/Audio.
Web-Enabled Distance Education Environment

Christos Bouras, Petros Lampsas, Antonis Bazaios, Giorgos Tsintilas, Computer Technology Institute, Patras, GR-26441, Greece, Tel: +30 61 994318, E-mail: {bouras, lampsas}@cti.gr, {bazaios, tsidilas}@ceid.upatras.gr

Abstract: As the new network computer technology forces into every aspect of daily life, many things change in a rather rapid way, compared to what we were used to until recently. One of the most important aspects in the social activity of people, Education, could not be an exception. Advances in network infrastructures and telematics services, combined with multimedia techniques and powerful personal computers provide the opportunity to make a network-based multimedia system for distance learning (teletraining) a real fact.

Introduction

The value of accurate and on-time data and information in world-wide range towards the Information Society, has altered the needs for education. Today, instead of having “once-in-a-life” education, is more likely to follow the pattern of “life-long” learning. The concept of Teletraining is able to replace the time-and-money-consuming status of moving around in order to acquire the knowledge needed, since via computer networks the experts can give their knowledge to all that have access to the Web. Additionally, an unlimited variety of themes can be provided by a PC, in the context of a well organised, easy-to-handle, brief or detailed, continually updated lesson.

The potentials of Teletraining has prompted many Software Development Companies and Educational Institutes (Universities, Colleges) to invest and work on it. Microsoft has already developed and distributed NetMeeting, which provides the ability of working collaboration between users in different locations, using TCP/IP protocol suite. NetMeeting provides point-to-point video and audio real time communication, multipoint data conferencing and application sharing. It can also interact with other multimedia network applications provided that they support the same ITU-T standards that NetMeeting use.

Another tool that can be used for teletraining purposes is WhitePine’s CU-SeeMe 3.0, which among others supports Phone Book with Graphical Contact Cards, Directory Services for locating other CU-SeeMe users, H.323 Standards based video codec (H.263), White Board (T.120), Motion JPEG (M-JPEG) video codec for high quality and video over LANs and ISDN. However, the most significant functionality of it is the TCP/IP support for LAN/WAN conferencing, using the reflector policy, with the ability to view up to 12 participant windows simultaneously, supported by Caller ID for incoming connections and Parental Control Management.

What has been mentioned above, have inspired and motivated the research efforts that resulted in the design and implementation of a “synchronous” distance education environment using WWW, which represents the continuity of the research work that has started three years ago in the Telematics Laboratory of Computer Engineer and Informatics Department (CEID) and Computer Technology Institute (CTI). Telematic services are used for the conduction of lessons over computer networks and this environment can be thought of, as a simulation of a traditional classroom setting with the live presence of a teacher, where all interactions among students, teacher and courseware can be realised.

General Architecture of Teletraining Tool

The overall architecture is based on the Teletraining Server, that is responsible for the communication between the trainer and the trainees. The main idea of the proposed architecture is to setup a single Teletraining Server per Training Center. The concept of the Training Center is a powerful computer with a Web server and the tool’s Teletraining Server installed. All the slights needed for the lesson will be stored there and for everyone taking part in the lesson, the computer will function as a reflector for the audio, video, chat, and White Board.
data. The Server is capable of taking over multiple lectures. Furthermore, the interaction between the trainer and the trainees is performed by the Server, which implements the commands of the users. Both the trainer and the trainees are connected to the Server through custom designed Clients that provide them with the ability of interacting with the Server through a user-friendly Graphical User Interface (GUI).

The major advantages of the proposed architecture are:

♦ Interactive communication between teacher and students over the Internet, including audio, video and data exchange.

♦ Modular design in the sense that the application specific network protocols are exclusively responsible for the interaction between the Clients and the Server.

♦ The physical appearance of the trainer is not required at the Teletraining Center since he can manipulate the lesson, through the Teletraining Server, from his PC provided that there is installed the trainer’s client software, which interacts with the Teletraining Server.

♦ Uniform approach of the Graphical User Interface of both the trainer and the trainees. The different functionality of the Clients for the trainer and the trainees is implemented by means of enabling and disabling controls of the User Interface and the corresponding modules of the application.

♦ Ease of use. The user interface is designed in order to hide from the user most of the low level details that are needed for the interconnection of the various computer systems over the network.

♦ Being an opened-environment tool since it was developed in Java, in order to work independently of platforms.

♦ Reduced costs for development and administration and increased flexibility. This implies that a single Server is capable of taking over multiple lectures given by different trainers. Thus, the effective operation of the Teletraining Tool requires the setup of a single Teletraining Server per Training Center.

♦ Provision of interesting lessons incorporating JPEG, GIF images and offers a variety of tools that can be used to enhance these images with remarks and drawings, thus making the lesson material interesting and attractive.

It is obvious that the software tool can be put into immediate use through the use of TCP/IP protocol suite, and can greatly aid the implementation and realisation of the distance education service. This use can offer a number of advantages to the persons that will attend the classes, among which are the following:

♦ The trainees do not suffer from lost productive time, since they have the flexibility to attend the lessons in more negotiated time periods, even outside their work hours.

♦ The creation of friendly and continually modified lessons can instigate the interest of the trainees for them.

♦ The use of Telematics reduces the need for experts and the cost of the educational process.

A very significant characteristic of the tool is the selection of JAVA as the programming language with which it was developed. During the design phase, it was considered crucial the demand for full portability of the tool. That is, the tool should be able to be executed independently of the workstation of the user. It should be able to work either under Windows 95 or a UNIX System or a Macintosh. At the same time it should have the ability to use the Internet infrastructure for reaching every potential user. In order to achieve what was mentioned above and to build a very easy-to-use tool as well, JAVA was selected.

As a result of the above, the server of the Teletraining was implemented as a JAVA application. The server should be installed in each Training Center in the same workstation with a Web Server in which all the Web pages that a lesson would use, reside. The client of the Trainer on the other hand, is also a JAVA application that should be in each trainer workstation. It can be locally executed in order either to build and prepare a lesson and later to store it in the Teletraining server or to actually conduct a lesson in real-time.

The client package of the trainee though, is consisted of several JAVA applets. Each applet is responsible for the respective functionality (Chat, White Board, Text Editor, Audio Communication, Videoconference). All the applets resides in a single workstation and can be accessed by every trainee through a Web Browser (Internet Explorer, Netscape Navigator) as easily as they reach any other address in the WWW. The only restriction is that the trainee-user should have acquired previously a Login and a Password from the Teletraining server, using the appropriate Web pages for registration in a lesson.

In the following, a complete functional specification of the Server and the Clients will be given.
**Functionalities of the Teletraining Tool**

**Functional Specification of the Teletraining Server**

The Server of the Teletraining Tool is responsible for the interaction between the trainer and the trainees before and during the lecture. More specifically, the Server provides both the trainer and the trainees with the following services:

- **Lecture Announcement.** Once a lecture is prepared, the Teletraining Server uses the network to announce it by notifying all possible interested trainees, possibly by a bulletin board system, a WWW server, or a mechanism of distribution lists. The notification consists of a simple announcement of the lecture that calls the potential trainees for participation.

- **Lecture registration.** Trainees that have been notified, can simply register their interest in the lecture. The Server automatically registers the corresponding trainees in order to deliver the course material to them and to automatically handle the network connections during the lecture.
  - Distribution of the material for the lecture. After the registration process, the material for the lecture is distributed to all the trainees that will participate to the specific lecture. The Server is exclusively responsible for the distribution of the material, that may take place either before (off-line) or during the lecture (on-line).

- **Access to previous lectures’ material.** The Server stores previous lectures’ material so as to provide access to them to any interested trainee. Thus, the material of any previous lecture will be available to all the trainees for later review.
Lecture presentation. During a lecture, the Server will operate according to the commands of the trainer so as to ensure the proper presentation of the lecture to the trainees. Furthermore, the Server offers the following operations:

- Submission of written questions from the trainees. The written questions are transmitted to the trainer. The trainer answers the questions and both the questions and the answers are transmitted automatically to all the trainees.
- Submission of requests for oral comments. The trainees have the ability of inquiring and the trainer will either accept or reject the inquiries. In the former case, the trainer will give permission to the requester and the oral comment will be broadcast to all the participants of the lecture.
- Session management. Because of the nature of the multiple data types that have to be transmitted during a lecture, some media handlers that will take over the synchronisation and the appropriate representation are necessary, especially when dealing with audio, video, high quality images, and structured documents. Another handler will be responsible for the interaction among the trainer and the trainees.

Functional Specification of the Trainer’s Teletraining Client

The trainer’s client is meant to give the opportunity for the preparation and presentation of a lecture to a selected audience through a friendly user interface. This client interacts with the server in order to guide the lecture according to the trainer’s will. Within these directions the trainer’s client provide the following services:

- A tool for the creation of lectures. Each lecture will be prepared from the trainer with this tool. It consists of a hypermedia document that will be described in a suitable language and consisted of several slights. For all the slights of a lecture is assigned a hierarchy of dependencies which organises the notional succession of it. A similar hierarchy exists for a group of lectures comprising a seminar. Each slight might consist of text, still images and connections that would refer to others slights or files of audio or video. The tool for creating slights provide the following abilities:
  - Creation and processing of slights
  - Request and acquire information from the WWW
  - Notional succession of lectures and seminars
  - Update the lecture announcement’s board
- Off-line reading and processing of existing lectures. This functionality holds only for the trainer that created the lecture or someone who has the appropriate privileges.
- Selection of the audience. It allows the trainer to select the members of his audience from those who requested permission to attend a lecture.
- Guidance of the lecture’s flow. During the lecture, the trainer interferes dynamically in the flow of the lecture. Thus, the client interacts with the server in order to execute the wills of the trainer. As a result the following abilities are supported:
  - Interchange and annotation of the slights. That can be done by notes, underlying, natural speech and video with the face of the trainer whenever is possible.
  - Admission and answering of the possible questions by the trainees. The trainer is able to admit or not written questions or requests for oral statements. He can also respond with orally speak or by writing to any kind of a question. Moreover, he can withdraw anytime the permission for speaking from any of the trainees. Finally, he controls the flow of questions/answers to the rest of the virtual class.

Functional Specification of the Trainee’s Teletraining Client

The trainee’s client is a tool that requires only a Web browser in order to be executed. It enables the trainee to attend a lecture and to interact with the trainer through the teletraining server. It specifically provides the following services:

- Lecture’s Attendance. There exists a White Board for the slights and a space for text that accompany them.
Questions. Ability for interaction with the trainer in order to submit questions written or audio-recorded.

Display of the trainer in an embedded window (video) in the central interface of the application. Ability to disable that window if the available bandwidth is not able to support the live broadcast of the video of the trainer. A similar ability is provided for the audio support.

Store/Delete of lecture. The lectures or specific parts of them that are selected from the trainee can be stored locally in their workstations for future use.

**User Interface**

**Trainer’s Client**

The Trainer through the basic menu “Server”, “Server Location” has the ability to specify the server’s Internet address and afterwards to connect to the server pressing “Connect Server” from the basic menu “Server”. Using the “Window” menu the trainer can choose any time which of the Services (White Board, Chat, Video, Select Slights, Selected Slights, FTP, Statistics) to be on the screen. All the available slights for each lesson can be loaded from the trainer through the Select Slights Service. Successively, the trainer chooses the specific slight at the order to be displayed on all clients. Upon that slight he can add some drawings (rectangular, straight lines, consecutive lines, etc.) and text using the White Board menu. Finally using the Chat Service he can send to all trainees text messages guiding the lesson and give the opportunity to the trainees to break in the session.

**Trainee’s Client**

Every trainee can access a session using a Web browser in order to run the client’s applets. Before that, he should enter the server using his Login and Password which he should have acquired previously by the server.

![Figure 2. User Interface of the Trainee’s Client](image-url)
Entering the server with the Login and Password, the applets are executed automatically and the trainee could then choose which windows (Services) he wants to be active. In the Video window, he can watch the face of the trainer. If the network bandwidth cannot support this service the trainee can deactivate that service.

**Conclusions and Future Work**

Initially, the Web was a mechanism to retrieve distributed information, with little interaction available. Java now allows full interaction with server and discussion with other users. It also enhances the Web’s functionality by allowing a collection of Web-based documents to serve as a focus for synchronous collaborations.

In the present implementation the teletraining server controls thoroughly the lesson’s flow. That allows the trainer to manipulate the lesson according to his will. On the other hand the fact that the server operates as a reflector for video, audio streams and for the White Board and Chat data, creating one connection for each user, the bandwidth required for a large number of trainees would be prohibitively big when all services are enabled.

In order to solve the problem that is described above, we have planned for future work to make the application use the Internet’s MBONE technology, which JAVA gives the opportunity to take advantage of.

Abstract: The transfer of Hypermedia methodologies to audio in the World Wide Web is discussed introducing sonic hyperlinks. Sonic hyperlinks are links annotated within an audio stream that lead to arbitrary multimedia content. A system architecture and implementation relying on commercial WWW technology like RealMedia is presented. The system includes an authoring tool as well as the necessary presentation plugin for an Internet browser. As an example application sonic hyperlinks have been used for WWW-based teaching and training.

1 Introduction

Hypermedia methodologies like links in hypertext are an essential feature of WWW-based training courses compared to traditional media. However, hypermedia methodologies have not been applied within the audio content of WWW pages in contrast to text content (hypertext) or graphical content (imagemaps, video hyperlinks).

There are few graphic systems like [Martel 96] utilising the audio channel. The sonification systems of [Brewster 97] add sonic information on graphical interfaces. Systems for blind users [James 96] translate graphical information to sonic information. Systems without graphic output like [Stiefelmann 96] use the audio channel to give information to the user. However, all these systems do not integrate and represent hyperlink annotation of the audio stream in the audio stream itself.

Enhancing the audio channel with an intramedial hypermedia structure offers an alternative to the visual channel. This is especially important if information is not redundant in the sense that it is only provided on the audio but not on the visual channel. In some hypermedia systems a somewhat artificial solution for this problem is to show additional, isolated textual hyperlinks [Martel 96]. Relating audio information to textual hyperlinks, however, is not easy to perform for a user and distracts his attention from the actual information. Using in audio represented hyperlinks offer the advantage of a close relationship between information and annotation. Sonic hyperlinks are expected to be more intuitive as they are closer to natural communication where it is common to inquire additional information in a talk. Besides, all users are able to listen to different audio streams, and thus telling audio information from hypermedia annotation, by taking advantage of the ‘cocktail party effect’ [Arons 92]. Annotated audio streams are a non-used interaction potential on most audio-visual presentations.

2 Sonic Hyperlinks

In this section we deal with the question what constitutes a sonic hyperlink, i.e. hyperlinks annotated within an audio stream that lead to arbitrary multimedia content, and what requirements a system that support sonic hyperlink has to fulfil.

A sonic hyperlink works as follows: the author integrates the hyperlink in the audio stream and defines what happens if the user would like to follow the link. This additional information is transferred via the WWW to a user. When the hyperlink is presented to the user a certain sound is played in parallel to the regular audio. If the user reacts using a certain interaction metaphor in a certain time interval a system reaction occurs as defined by the author. Thus, these are the major criteria for the sonic hyperlink:
• The link area of the audio information that is annotated, this is the hyperlink start- and stop-time.
• Time-delay for the user reaction (delay after hearing the sonic hyperlink).
• The sound that represents the sonic hyperlink (e.g. earcons [Brewster 97]) eventually indicating different kinds of information.
• The link target of the hyperlink (e.g. URL).
• The user interaction metaphor (e.g. keyboard stroke, mouse click, voice entry).
• The hypermedia navigation metaphor (e.g. button, voice commands).
• The system reaction (e.g. target windows, presentation break, rewind of the presentation).

3 System Architecture and Realization

A first architectural decision to be taken is whether the sounds for the sonic hyperlinks are integrated in the audio stream, send in a separate audio stream or timing information is send. The first solution does not allow the user to modify the sonic hyperlink representation. Currently, however, WWW video servers and clients do only support the first solution. We chose this solution as our aim was to use a commercial Web video server with an API. Here we selected the RealMedia Web video server [Hefta-Gaub 97]. RealMedia has established itself as a de facto standard on the World Wide Web. The benefit of this Web video server is that it provides in addition visual hyperlinks on the video stream, synchronized Web-pages and a Java application programmers interface.

For authoring we conceived a graphical tool that requires start time, stop time, URL, hyperlink sound and volume from the author. The tool is implemented using the RealMedia authoring API which is able to give a Web-page a push-time relative to the presentation time of a audio-visual presentation. We mark these Web-pages as sonic hyperlink target URLs and give them two push-times: The first at the start-time, the second at the end-time of the sensitive time of the sonic hyperlink. This is stored in an RealMedia stream. The sound of the sonic hyperlink is mixed with the audio stream exactly on the sensitive time of the sonic hyperlink, the result is stored in a second RealMedia stream. These two streams are stored together in a third RealMedia stream which represents the annotated audio stream. This annotated audio stream may be linked with a video stream or pushed Web-pages to a multimedia presentation.

For transmission, the multimedia audio-visual presentation is served through the Internet via a non-modified RealMedia Web video server.

For presentation, the multimedia audio-visual presentation is received by the RealMedia Web video client. This client is controlled by a Java applet. The applet checks the server-pushed Web-pages for the sonic hyperlink mark. If it detects one it holds back the server-push, waiting for a user reaction, this until the second push of the marked page. A potential user reaction is served to the applet via its reaction interface. If the user reacts the applet pushes the Web-page. The applet stops the presentation (if adjusted) and resumes the presentation as specified.

Abstract: In this contribution we present the INTERAPIE system for counselling via the WWW. Based
on existing protocols for face-to-face treatment of traumatic or stressful life events, an application has
been developed that allows patients and counsellors to interact via the WWW. The interaction mainly
consists of patients writing essays following assignments set out by counsellors. The INTERAPIE system
uses a database in which all relevant information is stored. The WWW pages are adjusted to the activities
performed by the patients and the counsellors and are generated automatically on the basis of the contents
of the database. The INTERAPIE system is different from typical WWW applications that are often
'search-oriented'. The INTERAPIE systems supports task-execution, i.e. it provides the tools that help the
patients and counsellors to carry out activities as required by the protocol for treatment of traumatic or
stressful life events of these patients. What kind of additional constraints follow from constructing this
type of WWW applications is the research topic underlying the INTERAPIE project.

1. Introduction

Research has demonstrated the positive effect of writing assignments in the treatment of individuals
(patients) who have suffered traumatic or stressful life events, e.g. [Lange 1994, Schoutrop 1997]. Treatments
of this kind rely heavily on systematic confrontation with the stimuli. The hypothesis is that successful
treatment results in habituation to emotionally painful stimuli. This habituation facilitates overcoming of the
traumatic event. An important feature of the therapy is the largely fixed structure of the counselling procedure.
A typical treatment is organised as follows. The patient writes essays about the traumatic event. The
counsellor reads these essays and gives feedback with respect to what issues to focus on next. After a certain
number of writing sessions the patient engages in a kind of ritual. This ritual usually consists of one more
writing session followed by some procedure to symbolically remove the problem, e.g., by burning or burying
this last piece of text.

There are a number of reasons why the counsellors that we are working with want to investigate the
usability of the WWW as a communication tool between patient and counsellor [Lange and Emmelkamp
1997]. One reason is the assumption that the availability on the WWW will lower the barrier for people to
engage in a counselling situation and that thus more people will be able to get help in solving their emotion
problems. This lowering of the barrier can be explained by more then one argument. For example, as soon as
counselling can be done using the WWW people can take therapy while staying at home. So it simply takes
less effort to get started. An other issue concerns the fact that people don't easily go to a counsellor because of
the anxiety that such an activity brings about. This is mainly a social or a cognitive barrier. A second reason
for investigating counselling via the WWW follows from the fact that many people spend a lot of time
communicating via the WWW (chatting, etc.). Apparently this way of 'talking to someone' is appreciated.
There is also evidence that people 'tell more' on the WWW then they do in face-to-face meetings [Postmes
1997]. Consequently, using the WWW might be beneficiary for the therapy itself, because one of the key ideas
of the counselling procedure is to have patients write extensively about their emotional problems.

Whether the counselling procedure works, and works better using the WWW, is not part of the research
discussed in this paper. Here we focus on the design question, i.e. can we build an application for the WWW
that facilitates task-based support for counselling situations. Many applications on the WWW are search-
oriented'. Users surf the WWW in order to obtain information. Not many applications on the WWW support
the execution of a task, although there are some examples in the domain of education [Parker Roerden 1997].
The realisation of task-based support for counselling situations is complex. At each point in the therapy the
patient is required 'to specifically do certain activities' and 'may not do other activities'. The same holds for the
counsellor. This situation is further complicated by the fact that what 'must' or 'may not be done' depends on
the previous activities of the patient and the counsellor.

A second research topic concerns the difference between a task-based application on the WWW and a
more regular 'stand-alone' application. Many things are known about the latter, which is not the case for
applications on the WWW. Typically users can access the WWW when it best suites them. This is a problem
for task-based applications on the WWW when the type and frequency of the interaction between the different parties is crucial. Almost needless to mention that this is the case in counselling situations.

2. The INTERAPIE System

In this section we describe the INTERAPIE system (http://www.psy.uva.nl/interapie). This version of the system is the first full implementation and has been used in experimental try-out sessions involving real patients and counsellors. How the INTERAPIE system was developed and what kind of ideas are behind this version of the system will be discussed in the next section.

![Screen-dump: Overview Counselling Situation for Patient 3](image)

Fig. 1. Screen-dump: Overview Counselling Situation for Patient 3

When consulting the INTERAPIE WWW site a patient has two options: reading general information about the system or signing up for counselling. In the case of the latter INTERAPIE starts the screening activity. Each patient has to fill out a number of questionnaires. The questionnaires have two purposes. They are used to deny access to the system for patients that cannot be helped by the kind of treatment implemented in the INTERAPIE system. The second purpose of the questionnaires is concerned with information gathering about the patient that might be of use during the counselling. The screening is largely automated, i.e. the answers provided by the patient are stored in a database and procedures have been implemented to decide whether a patient can be allowed to use INTERAPIE. In the case of exclusion, the patient is presented a message explaining why he or she cannot be allowed to use the system. Additional information is given about where the patient may seek help instead.

Only one part of the screening is not automated. This part concerns the use of medicine by the patient. It was felt by the counsellors that this issue was too complicated to automate. In the current version of the INTERAPIE system the patient has to fill out a questionnaire about use of medicine. The information provided by the patient is presented to a counsellor who decides whether the medicine situation of the patient is problematic for the treatment as it is implemented in the INTERAPIE system.

Before the treatment may start a patient has to fill out an 'informed consent' (IC). This is a formal document including a signature of the patient by means of which the patient formally agrees to be part of the research project, and thus that the information about the patient's treatment (although anonymous) may be used for research purposes. Filling out an IC is a standard procedure in the Netherlands for doing psychological and clinical research with real patients. The handling of the IC could not be done fully automatic, because it requires a written signature of the patient.
If the screening is successful, the next main activity in the procedure is carried out by the counsellor. The counsellor has to construct an introduction ('right-arrow' icons in figures 1 and 2) for the patient. Most of the text needed for this can be taken by the counsellors from sets of pre-canned sentences, but the counsellor is free to deviate from this. Notice that, patients when they enter the INTERAPIE system are assigned to a counsellor at random, although the assignment procedure makes sure that each counsellor has approximately the same number of patients.

Next the patient has to plan the first sequence of four essay writing sessions. This activity is shown to the patient in the interface by means of a 'clock' (figure 1, top row). By clicking on the icon a new WWW page is generated that allows the patient to plan the writing sessions. The planning tool implements certain constraints. For example, two essay writing sessions have to be separated by at least one ‘free day’ whereas at the same time there is a limit in the total amount of time that the four essay writing sessions may take (two weeks).

After the planning, the counsellor has to construct the specific instruction for the first two writing sessions (illustrated by the 'loudspeaker' icon). Next the patient performs two essay writing sessions followed by feedback and new instructions for the next two essay writing sessions. This first part of the treatment finishes with a feedback constructed by the counsellors on the third and fourth essay writing session. The second part of the treatment (Schrijf-opdracht 2) smoothly follows the first part and has the same set of activities, although the instructions, feedback, etc. will now have a different content.

After finishing the second part, the patient proceeds with the ritual (figure 1, Eind-opdracht2). In figure 1 only a fraction of this third part is shown. The patient has just received the instruction specifying what to do next and is currently reading a previously written essay (nr. 8).

The counsellors may use pre-canned sentences for these activities. In fact, the counsellors that we are working with favour the use of such sentences because it improves the similarity between the treatments of different patients and thus provides them with a better situation for evaluating the usefulness of the treatment. INTERAPIE also supports the counsellors in how to read the essays written by the patients. However, none of the activities that have to be carried out by the counsellors are automated. Hence it is always the counsellor who interacts, although via the WWW, with the patient. This was also seen as an important requirement by the counsellors.

---

Fig. 2. Screen-dump: Overview Counselling Situations for Counsellor.

A number of other things are worth mentioning. The set of icons in the patient interface that illustrate the activity that has to be carried out, and those that have been carried out, grow while the treatment is underway. In the beginning there is only the introduction icon. When the patient has made the planning, and the counsellor has ‘replied’ by constructing the instruction, the related planning and loudspeaker icons appear in the patient interface, etc. So the patient doesn’t know beforehand how the treatment will proceed. Instead this is made clear to the patient, step-by-step, while following the treatment. At the left-hand side in the patient interface, five icons are shown that illustrate general issues. The topmost icon, currently showing a book and a pen, changes during the treatment, i.e. it always illustrates the activity that has to be performed. So we can infer that this particular patient has to write an essay, probably his or her final one. When clicking on the 'book
and pen' icon the patient is presented a new WWW page which is basically a full-screen text-editor. When the patient is finished with writing, the essay can be saved and the patient can go back to the overview pages. The 'essay' icon then appears next to the instruction icon, meaning that this activity has been completed.

The counsellors mainly construct feedback and instruction. For these activities a dedicated interface is available. A counsellor usually has a set of patients (C=client) he or she is counselling at a certain moment. Therefore the counsellors must have means to easily overview the different counselling situations. This is realised by the interface part shown in figure 2. In fact, this is the screen the counsellors starts with after logging on to the INTERAPIE system. As all patients go through the same protocol an overview is generated by making a kind of table matching activity to patients. The black squares under the icons show activities that have been completed. At the end of each row, the current situation is highlighted. The red circle for patient 1, 2 and 4 means that the counsellor has to do something (feedback for 1 and 2, instruction for 4). At the end of the row for patient 3 no special cue is provided, which means that the patient has to do something. Sometimes a patient runs late with respect to his or her schedule. In such situations, a special icon is placed to illustrate this being late (patient 5). By clicking on one of the rows the counsellor gets into a workspace that matches the activity that has to be carried out. Finally, at the top of the interface five icons are shown that illustrate general activities. Respectively from left to right they represent: general help, new patient who's medicine situation has to be analysed (medicijn wachtkamer), new patient who's informed consent has to be checked (IC wachtkamer), the possibility to remove a patient from the INTERAPIE system (for instance because he or she has not followed the agreed upon schedule) (verwijderen), and logging out.

3. Designing and Implementing the INTERAPIE System

The development of INTERAPIE was done using a User Centred Design approach [Preece 1994]. During the first phase (requirements analysis) interviews were held with the counsellors in order to find out details concerning the original face-to-face treatment based on writing assignments. During this period we also tried to define the requirements for the INTERAPIE system. Next a task analysis was carried out to further specify the roles and activities during a counselling period. The third major effort concerned the design of the user interface, both for the counsellors and the patients. After that the INTERAPIE system was implemented and tested.

The task analysis was very important to the development of the INTERAPIE system. During this phase the tasks that the INTERAPIE system must perform were defined. Were needed these task were further decomposed into sub-tasks, until for each sub-task a detailed data-flow was available that clearly showed how the task could be implemented. Task analysis is not just concerned with specifying the tasks. Also important is task-allocation and the construction of a data-model. The former defines for each task the agent that has to perform it. In the case of our counselling situation, three agents can be defined: the INTERAPIE system, the patient and the counsellor. The data-model provides the basis for the construction of the database. It also specifies the data types that can be input and output of the tasks. The complete task analysis consists of specifications for approximately 50 data-flow diagrams for the leaf-tasks, i.e. the tasks at the most detailed level of specification.

While constructing the task analysis a number of remarkable issues emerged. Particularly, between counsellors conflicting statements were made about how certain treatment details should be realised in the INTERAPIE system. The counsellors also had a tendency to sometimes change their ideas during the constructing of the task analysis. Both facts illustrate the fact that the counsellors were still in the process of refining their ideas on the INTERAPIE system. In fact, many of the low level details have been decided upon while constructing the data-flow diagrams for the INTERAPIE system. When following a user centred design it is the task of the knowledge/software engineer to make sure that the domain experts reach a consensus on these issues. There were no major bottlenecks in this respect. The data-flow diagrams were finalised by defining a control structure on top of the tasks. The control structure specifies the exact order in which, and conditions under which, tasks have to be executed in the INTERAPIE system. To further minimise the step towards the implementation, this control structure, was then re-written in a semi-formal language.

The next crucial step in the design of the INTERAPIE system concerns the interface design, i.e. how do we visualise the interaction of the system with the patient and with the counsellor. This was a difficult problem to solve. One discussion focused on the question whether the interface should be 'text-oriented' or use mainly graphics. It was decided that the latter was the best option. An important reason being that icons can be used to illustrate many concepts, while usually only using little space in the interface. It was soon recognised that both the interface for the patient and for the counsellor would become very full otherwise.

In order enforce that both patients and counsellors follow the activities as scheduled in the treatment protocol, little cues have been used to highlight the next activity. First, the interfaces only visualises the activities that have to be carried out next (the last icon in the row), and the ones that have been done before. The current activity is further emphasised both in the interface for patient and for the counsellor. In the case of the former an additional icon is used to point to the current activity: in figure 1 the book and pen icon
illustrating that an essay must now be written. In the case of the counsellor the current activities are emphasised by a red spiral (figure 3).

The treatment requires a strict schedule for carrying out the required activities. To enforce this regime a planning tool is used. After the plan has been constructed it is not directly visible in the interface, i.e. the patient has to click on the 'clock' icon to read his or her planning. The complexity of a plan and the planning tool made it impossible to show the results on the screen continuously. Also note that a plan is fixed. That is, after the patient has made it, and saved it, it cannot be changed anymore by the patient. If the patient gets behind on the schedule the interface will show this to the counsellor by placing the 'late' icon in the overview screen (figure 2). The patient on the other hand receives a standard text message in the case of being late.

Finally, note that the icons in the patient's interface are considerably larger then those in the counsellor's interface (compare figure 1 and 2). The main reason for the latter being smaller was lack of space. However, the idea was that for the counsellor this should not pose any problems. The counsellor spends more time working with the INTERAPIE system and is also more experienced with the set of activities within the treatment. Moreover, in the actual system the icons can be 'read' easily in the counsellor's interface.

The website of INTERAPIE was implemented using Macintosh computers. The webserver of INTERAPIE is WebStar. All the information that is used by the INTERAPIE system is stored in the relational database Butler. The interface of INTERAPIE is written in Tango. Tango is a program that communicates between the database Butler and by doing so can dynamically create HTML pages which can be sent to the webserver WebStar, and thus be made available for the outside world. For example, when a patient wants to see/read a previously written text, he or she has to click on the essay icon. This selection is presented to Tango by Webstar. Tango generates an SQL-query for Butler. As soon as Tango receives a reply from Butler it constructs a HTML page and presents this page to Webstar. Webstar puts the page on the patient's computer screen.

A difficult problem was the use of the many icons and the dynamic way in which each screen had to be constructed using a continuously changing set of these icons. Care had to be taken that the INTERAPIE system didn't take too long to put the next WWW page on the screen.

4. Experiment and Evaluation

Two experiments have been carried out. At the department of Clinical Psychology a rather large experiment has been conducted investigating the effectiveness of the treatment via the WWW. This experiment uses 24 patients and 4 counsellors. Next to this, we have conducting an experiment that investigates the functionality of the INTERAPIE system. We wanted to find out whether users encounter any problems and whether they understand the icon-language that the system 'speaks'. In general, we wanted to investigate how well the system functions as a communication mediator between the patient and the counsellor. The following situations have been investigated: patients with high degree of computer experience (2 persons), patients with low degree of computer experience (2 persons), counsellors who have no experience with INTERAPIE whatsoever (2 persons). We wanted to investigate whether experienced and inexperienced users were able to use the INTERAPIE system. Notice that each of these situations can be investigated independently from the other party, i.e. for an inexperienced patient it does not matter whether he or she is being counselled by an experienced or inexperienced counsellor. The only aspects the patient 'sees' from the counsellor are the written texts that make up instructions and feedback. This is of course independent from issues concerned with the use of the system by the patient. The same is true for the other cases.

The experiment consisted of video-taping users while using the INTERAPIE system. The camera recorded the computer screen showing the interface and the sound (spoken words) made by the user. Users were asked to comment on the system as much as possible. Particularly, they were asked to mentioned unexpected phenomena, issues that confused them or they didn't understand, and things they thought were interesting or good. Next to video-taping, users were asked questions after a single INTERAPIE session (for instance, after writing feedback). Not all sessions were recorded completely, selections were made of periods of which we were interested.

Some interesting results can be pointed out. Even though the INTERAPIE system had been tested before starting the above mentioned evaluations, some bugs still emerged during some of the sessions. One example was a limit on the number of characters that a certain variable in the program could manage. It turned out that the first instruction written by the counsellors had to be smaller than 200 words. The error was noticed only after the first 'large' message was written by one of the counsellors. Fortunately, the error could be repaired before the first patient wrote an essay. Particularly for the patients, who encounter a program error, this is a
strange and sometimes frustrating event. Imagine the situation in which a patient has been writing an essay for
almost an hour and now the machine does not want to store the text. This can be very frustrating for patients.

For inexperienced patients there are many standard computer interface issues that are unclear. If someone
has never used a computer, things such as a scroll-bar, a hyperlink, etc. are not so obvious. If you haven't
worked with the WWW before and you do not know that sometimes it takes a while for the files to appear on
your screen, you may get confused. In some case this resulted in repeatedly clicking on some icons (which
made the problem only worse). It was in this respect remarkable to notice that the general help pages were
almost never consulted by the patients. This may indicate that the system was still easy to understand and use
for them.

The counsellors complained that while constructing a feedback or an instruction they had insufficient
overview of general facts about the patient. For example, the age of a patient cannot be assessed by the
counsellor while constructing a feedback or an instruction. Although this information is available in the
INTERAPIE database, the counsellor can 'only' see/read the essays written by the patient. Counsellors also
would like to have a kind of patient specific notebook for making statements about the patient. During the
treatment the counsellors want to use this as an external memory on how they are interacting with a patient.

Each time a new patient enters the INTERAPIE system, he or she is assigned to a counsellor. In the current
version of the INTERAPIE system each counsellor can get 6 patients at the most. If at some point patient
'number 25' tries to enter the system he or she is not accepted. In the current version of the system this means
that the patient receives a message saying that the system is full. In future implementations a kind of waiting
room should be constructed in which patients can wait a few days (or weeks) until counselling space is
available.

5. Discussion and concluding remarks

While writing this paper the evaluation of the INTERAPIE system is underway, hence our results are
preliminary. Still some distinctive points emerge. First, there are errors in the program, or the supporting
software, that occasionally hampered users to use the system as planned. Two lessons can be learned from
these. The first is the impact of an error. When the system becomes unusable the situation easily runs out of
control. Because the system doesn't work it is impossible to inform the patients about what is going on.
Consequently, patients cannot access the program and may become uninterested or emotionally more
disturbed. The latter problem should not be underestimated although it depends on the problems and the
specific therapeutic phase a patient is going through. The second lesson that can be learned concerns the
importance of realistic testing during the initial evaluation phase. For example, when we were testing the
system with 'test' users, they only typed a few words instead of the lengthy pages as written by real patients.
Thus, we never discovered the problem of the system not allowing to type more then 200 words in one
message. However, testing is a problem for task-based applications on the WWW involving many users. It is
even more of a problem when the interaction lasts for several months and is continuously changing during this
period. It is not self-evident how such interactive situations can be 'speed up' for evaluation purposes while not
overlooking important details. In our specific case, system breakdown was less a problem for counsellors,
because they were fewer in number and could be informed using a phone.

Although the INTERAPIE system has continuously been debugged during the evaluation phases, and at
this moment may seem 'to be without many problems', this doesn't mean that in the end the above problem has
been solved. There may always be some reason for the required interaction between the patient and the
counsellor to be hampered. What do to if someone falls ill? At least some form of meta-communication
channel should be available next to the INTERAPIE system to inform users about the meta-problems with the
system or related issues that effect them.

Related to the above issue is the need for having a kind of super user (cf. UNIX operating system) to
manipulate the contents of the database if required. Due to different kinds of circumstances small
modifications had to be made to the database entries that the INTERAPIE system uses. For instance, re-
allocating a patient to a different counsellor, or modifying the writing schedule of the patient. In the current
version of the system changing something in the database that is outside of the scope of the counselling
protocol requires detailed knowledge on how the system has been programmed and can thus only be
performed by the system programmer. In a future implementation of the system a super-user facility should
overcome this problem.

Next to simply improving the current version of the system, plans have been discussed for a larger
INTERAPIE system that might work within a city, nation or maybe even on a world scale. Of course, this
would require solving many new problems. Language problems may not even be the most complicated ones.
Another plan for future work concerns the construction of 'INTERAPIE-like' systems for other psychological
or medical problems that can be treated using a largely fixed protocol as in the case for the treatment of
traumatic or stressful life events.

Abstract: User interfaces to WWW search engines typically present results as ranked lists of documents. Such lists give users little help in understanding document variation: we propose a richer representation of retrieval results in the search interface. Fundamental to us is the notion of document grouping. We use both stylistic genre-based document categorization and statistical content-based clustering, and organize documents along these criteria in a highly interactive visualization front-end to WWW search engines, enabling quick overview and incremental query refinement.

Introduction

The vast majority of user interfaces to WWW search engines are still based on an exceedingly simple interaction model where a linear list of hits, i.e. document items, is sorted after so-called "relevance" with inner workings and metrics hidden and all but incomprehensible to most users: “This is appealing in its simplicity, but users are often frustrated as they do not know what the results mean, nor can they control aspects of the search.” [Shneiderman 1997] Usage problems stem partly from lack of overview and means of organizing the presentation of documents. These issues are addressed in a user interface framework known as Easify [Fig. 1].

Documents can be grouped by topic as shown by Scatter/Gather [Cutting et al. 1992] or a variety of other criteria, such as site address, geographical location or title similarity. In the framework presented here, the notion of genre or stylistic variation is one of two main grouping criteria. Easify takes genre classification further than other similar tools by establishing a genre palette tailored to the typology of WWW documents, and applying automatic document classification algorithms accordingly. The second dimension made use of in our interface is statistical content-based clustering. Incremental refinement of the search process is supported by means of giving users increased control over pruning the search space through direct manipulation. Envision [Nowell et al. 1997] is another example of a search interface relying on multi-dimensional document visualization.

Stylistic Genre Classification vs. Content-Based Clustering
Stylistic items can be found on any level of linguistic abstraction: lexical, syntactic, or textual; each is of little import in itself, but taken together their variation indicates systematic differences [Biber 1989, Karlgren 1998]. We make use of dozens of items to classify documents into genres: sets of documents with a consistent tendency to make the same stylistic choices. Useful genres must be based on differences known and recognized by readers. To this end, we have created a genre palette and collected a test corpus tailored for our trial users and the WWW. We have interviewed 102 users on their perceptions of what types of material they find and interact with on-line. These impressions are used to define a palette of genres [Fig. 2] both reasonably consistent with what users expect and conveniently computable using measures of stylistic variation [Dewe et al., 1998]. Our test corpus was used to train a categorization tool. A relatively large number of textual features are calculated for each individual text and combined into simple if-then categorization rules using the C4.5 machine learning tool set [Quinlan 1993]. The features we use here are rather lexical in nature, for ease of processing; the relative frequency of certain classes of words such as personal pronouns, emphatic expressions, downtoning expressions, etc. We add more general textual and genre-specific features: relative number of digits, or average word length, for instance. Others yet are vectored specifically to the web material we have been using for training: number of images or proportion of HREF links in the document, among others. The genre determination algorithm in its current state makes sub-optimal classifications too often. Flexible genre determination would help here – a document should be allowed to fall into several genres rather than exclusively one.

Grouping of documents based on textual content, as opposed to style, is based on traditional statistical term-frequency based metrics. Since the emphasis is on a high degree of interactivity, a quick and rudimentary clustering must be used for the initial document sets. We assume that a small number of clusters in the interface is desirable. Initial clustering can be achieved by defining the first clusters on a few (10-50) randomly selected documents. The clustering itself is a variant of the standard metric: a hierarchical agglomerative group-average algorithm [Jain & Dubes 1988]. After deciding the first \( n \) clusters (with \( n \) user-adjustable) the following documents are each routed to one of them. A simple assign-to-nearest algorithm is used to decide cluster membership. Cluster headings are currently sets of significant keywords, and could definitely be improved upon.

Visualization of the Document Space

Following query submission, documents found relevant by the underlying search engine are sorted into \( nm \) slots, where \( n \) is the user-defined number of content-based clusters and \( m \) is the system-defined number of genres (currently \( m=10 \), following the results of the genre survey and viable screen real estate usage). The group of documents in a slot is presented in the shape of a “bubble” growing as search results become available. Although the number of slots may well be in the range of 30-90, the complexity of navigation is reduced through the clear two-dimensional lay-out with genre headings spelled out along the x-axis and content clusters along the y-axis (Fig. 1). When the cursor is moved across a bubble, a pop-up window is displayed with a list of all the documents contained within the group. This list can be presented using title, URL, size, date and other attributes. Clicking on a single document brings up the abstract, and double-clicking sends the URL to the default web browser to be displayed in its entirety. In order to “zoom in” on a subset of the resulting documents, bubbles can be dragged onto the “regroup” area in the top right corner of the main screen. When regrouping is applied, a second screen appears where only the documents contained in the selected groups are candidates for creating new bubbles. In the subselection, distribution according to genre remains the same as in the superset case, but the content-based clusters may differ.

Abstract: This paper presents an electronic ACT-R bookshelf, a system which supports learning ACT-R, a well-known theory in the field of cognitive psychology over the WWW. ACT-R bookshelf is a collection of electronic books on various aspects of ACT-R. The books on ACT-R bookshelf are authored and served on the WWW with InterBook system which makes most of the books on ACT-R shelf adaptive. This paper describes main functionality of the Bookshelf, provides some evaluation data, and speculates about possible extensions of Bookshelf-like systems.

1 Introduction

This paper presents an electronic ACT-R bookshelf, a system which supports learning ACT-R, a well-known theory in the field of cognitive psychology [Anderson 1993; Anderson & Lebiere 1998], over the WWW. ACT-R bookshelf is a collection of electronic books on various aspects of ACT-R. The primary role of ACT-R bookshelf is to serve as a 24-hours available information resource for Carnegie Mellon University on-campus students taking course "Production System Models of Thought". However our intention was to build a system which can be used as a resource for distance learning of ACT-R, as well as an information resource for the international community of cognitive scientists and ACT-R researchers.

A hierarchically structured electronic book (EB) is one of the most popular metaphors for representing online course material. Virtually any kind of course material can be represented as an electronic book. Currently, the bookshelf contains an ACT-R tutorial, ACT-R 4.0 User Manual, a Manual for ACT-R Lisp-based environment, and an ACT-R Glossary. These books are quite different. The ACT-R tutorial is a kind of electronic textbook. It provides a step-by-step introduction into ACT-R theory and ACT-R modeling. The presentation is linearly sequenced and augmented with multiple examples, quizzes and assignments. ACT-R 4.0 UserManual is an encyclopedia-like book for reference access.

The books on ACT-R bookshelf are authored and served on the WWW with InterBook system [Brusilovsky, Eklund & Schwarz 1998]. Unlike most existing electronic textbooks which are not more than a static electronic copy of a regular textbook: chapter by chapter, page by page, picture by picture) most of the books on ACT-R shelf are adaptive. Adaptivity is especially important for educational programs on WWW which are expected to be used by very different classes of students without assistance of a real teacher (who usually can provide adaptivity in a normal classroom). An adaptive nature of ACT-R bookshelf is based on a specific concept-based approach suggested originally in [Brusilovsky 1995] and further elaborated by the ELM research group in the process of development an adaptive Web-based LISP textbook ELM-ART [Brusilovsky, Schwarz & Weber 1996]. InterBook is the first authoring system which implements this approach.
This paper uncovers concept-based knowledge representation behind adaptive electronic textbooks on the Bookshelf, describes main functionality of the system, provides some evaluation data, and speculates about possible extensions of Bookshelf-like systems.

2. Knowledge Representation and Content Structuring for Adaptive EB

The key to adaptivity in an adaptive textbook is knowledge about its domain (i.e., ACT-R) represented in the form of domain model and knowledge about individual students represented in the form of individual student models. The domain model serves as a basis for structuring the content of an adaptive EB. We distinguish two content parts in each adaptive EB: a glossary and a textbook. This section provides some minimal...
information about knowledge representation and content structuring. Some more information could be found in [Brusilovsky, Eklund & Schwarz 1998].

ACT-R bookshelf uses the simplest form of domain model: a set of domain concepts. By concepts we mean elementary pieces of knowledge for the given domain identified by a domain expert. The domain model provides a structure for an overlay student model which is a representation of the student's knowledge of the subject. For each domain model concept, an individual student's knowledge model stores some value which is an estimation of the student's knowledge level of this concept. For ACT-R domain we distinguish for states of student knowledge of any concept: "unknown", "known" (learning started), "learned" and "well-learned".

An electronic textbook is a regular book represented in hypermedia form. In InterBook, each EB is hierarchically structured into units of different level: chapters, sections, and subsections. To make EB "more intelligent" and to connect it to the glossary, we have to let the system know what each unit of the textbook is about. It is done by indexing of textbook units with domain model concepts. Several books on the same subject form a bookshelf. All books from the same bookshelf are indexed with the same set of domain model concepts. Each terminal unit has an attached list of related concepts (we call this list spectrum of the unit). For each involved concept, the spectrum represents the name and the role of the concept in the unit (each concept can be either an outcome concept or a prerequisite concept). The system has an option to show all outcome and background concepts for the current section on a page border to the right of the section content (Figure 1).

![Production](image)

**Production**

Productions are **condition-then-action** rules which specify what to do in a situation.

This concept is introduced on these pages:

- 1.1.2 Production Rules in ACT-R
- 1.1.3 Production Rule Format
- Section 1.5: Creating Declarative Structure
- Production

Knowledge about this concept is required for:

- Section 1.6 Writing Productions
- Section 2.1: English Rules
- Selecting non-numeric elements
- Find applications

Figure 2: A glossary window showing a "page" for production. In addition to providing a description of a concept, each glossary entry provides links to all book sections which introduce or require the concept. Colored and checked balls to the left of the links and the font type of the link text provide adaptive annotation.
The Glossary is, in fact, a visualized domain network. Each node of the domain network is represented by a node of the hyperspace, while the links between domain network nodes constitute main paths between hyperspace nodes. The links between domain model concepts constitute navigation paths between glossary entries. Thus, the structure of the glossary resembles the pedagogic structure of the domain knowledge. In addition to providing a description of a concept, each glossary entry provides links to all book sections which introduce or require the concept (Figure 2). This means that the glossary integrates traditional features of an index and a glossary.

3. Functionality

Domain model-based indexing is a relatively simple but powerful mechanism, because it provides the system with knowledge about the content of its pages: the system knows which concepts are presented on each page and which concepts have to be learned before starting to learn each page. It opens the path for several adaptation techniques presented in this subsection.

3.1. Advanced Navigation

The knowledge about the domain and about the textbook content is used to provide a well-structured hyperspace. As any well-designed EB, the system supports sequential and hierarchical links for navigation:

- Each page has back and continue links which let the user go through the material by a linear way.
- The system generates the table of content where all entries are clickable links to respective sections.
- Each page provides a navigation center on the top for one-click navigation to any section of the same or upper level and for understanding "where I am" in the hyperspace.

In addition, the system uses knowledge about the concepts behind the pages to generate other types of links between the glossary and the textbook:

- The concept bar provides links from each textbook page to corresponding glossary pages for each involved concept (Figure 1).
- The system identifies concept names in the text and turns them into hyperlinks to the corresponding glossary pages (Figure 1).
- From each glossary page describing a concept, the system provides links to all textbook units which can be used to learn this concept (Figure 2).

All these links are not stored in an external format but generated on-the-fly by a special module which takes into account the student's current state of knowledge represented by the student model. This approach is not only reducing page design time but also providing room for adaptation. In particular, our approach supports two adaptation techniques: adaptive navigation support and prerequisite-based help.

3.2. Student Modeling, Adaptive Navigation Support, and Adaptive Guidance

The InterBook approach provides many more opportunities for browsing the course materials than traditional on-line textbooks. The negative side of this is that there is a higher risk for the student to get lost in this complex hyperspace. To support the student navigating through the course, the system uses adaptive annotation and direct guidance technologies. Adaptive annotation means that the system uses visual cues (icons, fonts, colors) to show the type and the educational state of each link. Direct guidance means that the system can suggest to the student the next part of the material to be learned.

The key to all adaptive functionality of ACT-R bookshelf is student modeling. The system maintains an up-to-date model of individual student knowledge on the subject. The student modeling mechanism accepts two kinds of evidence of student knowledge of a concept:

- a student have visited a page which presents some information about a concept (i.e., the page has this concept among outcome concepts).
- a student answer correctly to a test which checks the knowledge of this concept.

The latter evidence is stronger, so no "well-learned" grade can be given to a concept unless the student confirms his or her knowledge by answering a test.
Using the student model, it is possible to distinguish several educational states for each unit of EB: the content of a unit can be known to the student (all outcome concepts have been already learned), ready to be learned, or not ready to be learned (the latter example means that some prerequisite knowledge is not yet learned). The icon and the font of each link presented to the student are computed dynamically from the individual student model. They always inform the student about the type and the educational state of the unit behind the link. In InterBook, red means not ready to be learned, green means ready and recommended, and white means no new information. A checkmark is added for already visited units (Figures 1 and 2). The same mechanism can be used to distinguish and show several levels of students knowledge of the concepts shown on the concept bar. In InterBook, no annotation means "unknown", a small checkmark means "known" (learning started), a medium checkmark means "learned" and a big checkmark means "well-learned" (Figure 1). For many students, adaptive guidance provides enough support to make a navigation decision. Those who hesitate to make a choice could push the button "Teach me" and the system will apply several heuristics to select the most suitable node among those ready to be learned.

3.3. Prerequisite-Based Help

The system knowledge about the course material comprises knowledge about what the prerequisite concepts are for any unit of the textbook. Often, when students have problems with understanding some explanation or example or solving a problem, the reason is that some prerequisite material is not understood well. In that case, they can request prerequisite-based help (using a special button) and, as an answer to help request, the system generates a list of links to all sections which present some information about background concepts of the current section. This list is adaptively sorted according to the student's knowledge represented in the student model: more "helpful" sections are listed first. Here "helpful" means how informative the section is to learn about the background concepts. For example, the section which presents information about an unknown background concept is more informative than a section presenting information about a known concept. These sections which present information about two unknown background concepts is more informative than a section presenting information about one concept.

4. Evaluation

By the Summer 1998 three groups of students (one group of 10 to 20 students per semester) learning ACT-R have been using the ACT-R Bookshelf as a learning resource. Most of the students were undergraduate or graduate Psychology students. At the first lecture of the course each group of students has 30 to 45 minutes introduction to ACT-R Bookshelf and its functionality. The Bookshelf was a primary source of learning information in addition to regular lectures. No printed handouts were provided.

It was our intention to evaluate how useful are the advanced features of the Bookshelf for Psychology students. Our standard evaluation technology in InterBook is comparing performance of InterBook users with a performance of a control group which uses a system with advanced functionality disabled [Brusilovsky & Eklund 1998]. Unfortunately, the number of students taking the ACT-R course is too small to run a control group. Instead, we have used a more subjective evaluation technology - a specially developed questionnaire. The goal of the questionnaire (41 questions in total) was to check whether the users understand the advanced functionality of the system (13 questions), whether they find it useful (24 questions), and what kind of improvements they could suggest (4 questions). We have run the questionnaire with one of the groups and collected 11 correctly filled forms. Due to the lack of space we could report only some of the most interesting results here.

Our major concern was that Psychology students will not be able to understand the advanced functionality of the Bookshelf even after a 30-45 minutes introduction. To check it we have developed 13 special questions to test their understanding. The results show that adaptive navigation support, the most "intelligent" functionality of the Bookshelf, is quite clear to the students. 11 or 11 students understand the role of the "green ball" and 10 of 11 understand the role of "red ball" and "checked ball". To compare with, less than half of students were able to understand the functionality of "Search" button, which provides standard search functionality (a feature of any advanced Web site). At the same time, the students have not considered adaptive navigation support as a very useful feature. Various components of it were rated 2.5 to 3.1 on a scale where 1 means totally useless and 6 means very useful. Here we should agree with the students. Adaptive navigation support is not very useful for well-organized sequentially read textbooks like the ACT-R textbook (here the best strategy is just read all units...
Adaptivenavigation support was designed primarily for the users who need to learn selected parts of the ACT-R material and need to use "backward learning" to meet all prerequisites.

5. Prospects for ACT-R Bookshelf as a Integrated Resource on the WWW

A concept-based indexing of EB on ACT-R bookshelf provide a unique opportunity of concept-based linking of various kinds of ACT-R related information. As soon as the ACT-R domain model (a consistent and comprehensive set of ACT-R concepts) is created and all book on the shelf are indexed with ACT-R concepts, these books are invisibly linked through the glossary. Each page of any book which is indexed with a concept will have a link to a glossary entry for this concept. In turn, a glossary entry for a concept will include the links to all pages in all books on the shelf which are indexed with this concept. Currently, the bookshelf contains primary the tutorial and manual-like books. However, we consider several useful extensions of the bookshelf.

- ACT-R addressbook may list researchers working in ACT-R area providing at least annotated links to their home pages. A page inn address book may be indexed with concepts showing area of interest of this particular researcher within ACT-R domain.
- An annotated collection of ACT-R research papers may provide a number of existing papers on-line. Each page in this book may provide an abstract and a URL for one particular paper. This page may be indexed with the concepts discussed in this paper as well as with a set of prerequisite concepts required to understand it. Some papers may be represented on a bookshelf as separate books. In this case, each section of the paper may be indexed.
- The content of main ACT-R book may be indexed section by section and placed on the WWW as a virtual copy of the book. When for the copyright reasons the content could not be placed on the WWW, the page range in the actual book may be provided enabling a user easy to find a place in the book.

There are multiple outcomes of having all ACT-R resources on a single bookshelf interconnected by a global glossary as presented above. Wherever the user starts, he or she can see the concepts behind the pages and see a glossary entry for any of these concepts. A glossary entry for a concept will provide links to all relevant information which exists on the bookshelf. For an introductory-level concept, the user will be able to see book, tutorial or manual pages explaining this concept. For more advanced concepts, the user will also see a list of papers dealing with this concept and a list of people investigating this concept deeply. We hope that such an integrated bookshelf accessible worldwide will seriously contribute for the promotion of ACT-R learning and research worldwide.

5. References

Acknowledgments:

The ACT-R manual and tutorial materials were converted from Word and HyperCard format into HTML format by Valeria Brusilovsky. Elmar Schwarz, the original developer on InterBook, seriously contributed to the
development of the Bookshelf. Permanent support of Christian Lebiere, the author of the ACT-R manual was important for the success of the project.
Anticipating Information Needs: Everyday Applications as Interfaces to Internet Information Resources

Abstract: We outline work on a class of systems called Personal Information Management Assistants (PIMAs). PIMAs observe user interaction with everyday applications, and use these observations to anticipate a user's information needs. They then automatically fulfill these needs by accessing Internet information sources, filtering the results, and presenting them to the user. Essentially, they allow everyday applications to serve as interfaces for traditional information retrieval systems. In this paper, we present our preliminary work on an architecture for this class of systems, and our progress implementing such a system. Finally, we discuss our preliminary results and survey directions for future work.

1. Motivation and Introduction

In recent years, we have experienced an explosion in the amount of information available online. Unfortunately, tools that allow users to access this information are still rudimentary. Users are often forced to express their information needs in Boolean query languages, or fill out a complicated form. More, systems often offer results that are unnecessarily redundant and poor in quality—partly because the user is unable to specify his needs in terms of a query well enough, and partly because of the nature of the software servicing his query. Some intelligent systems allow users to pose their information needs in the form of a question [Burke, et al., 1997] [Kulyukin, et al., 1998]. Others allow users to search by example [Hammond, et al., 1994]. Nonetheless, these kinds of systems still require the user to make his information needs explicit to the system. Thus, while Internet search engines provide a first step at solving this information access problem, most of them not only fail to produce good results reliably, but are also hard to use. Systems that answer questions or allow users to search by example provide a solution to part of this problem, yet remain inconvenient.

In response to the problems posed by the current state of information retrieval systems, we are working on a class of systems we call Personal Information Management Assistants (PIMAs). PIMAs observe user interaction with everyday applications, and use these observations to anticipate a user's information needs. They then automatically fulfill these needs by accessing traditional information retrieval systems (e.g., Internet search engines), filtering the results, and presenting them to the user. Essentially, they allow everyday applications to serve as interfaces for traditional information systems, paving the way for us to remove the notion of query from information systems altogether.

In this paper, we present our preliminary work on an architecture for this class of systems, and our progress implementing such a system. Finally, we discuss our preliminary results and survey directions for future work.
2. Overview and Architecture

One of the main insights driving our work is that information-seeking behavior, such as posing a query to a search engine, is goal-directed behavior. In this view, posing a query to a search engine is a step in a plan that satisfies the goal of finding information about a certain topic. Given that finding information is usually in service of some goal, we can construct a library of information-consumption scripts (using “script” in the sense of [Schank & Abelson, 1977]) associated with satisfying a user’s goals. Scripts are knowledge structures that house information about highly routine situations. In an appropriate context, they serve the purpose of making strong predictions about situations and sequences of events. For a PIMA, knowledge of a user’s information-consumption scripts means the ability to anticipate information-seeking goals and the ability to automatically fulfill them.

The second observation we bring to this problem allows us to readily apply the above understanding technique. The observation is that standard information systems, the documents themselves, and the environments in which they are produced, consumed, and otherwise manipulated are highly structured and regular. To mention just a few of these regularities:

1. Within the document, gross structures such as headings, paragraphs, and titles are prevalent and have a well-known semantics.
2. Documents have a gross morphological form (e.g., letter, newspaper article, invitation, memo, etc.), that corresponds directly to the document’s function.
3. Everyday computer applications serve a particular and easily attributable function.
4. Everyday computer applications have well-formed interaction semantics.
5. Information retrieval systems have an interface that is arguably easier for a computer to use than a human.
6. Information retrieval systems are computer programs that generate regular output.

The above structure and regularity, as well as the semantics associated with the regularity of this world make it particularly amiable for a computer program. This is not all that surprising—after all, the environment, in fact, is a collection of computer programs. What is interesting, however, is that because this particular part of the world is so strongly structured, human behavior within it is also highly structured and regular. It follows that this regularity in the environment (in terms of computer programs, documents, and information systems) and in user behavior should be known and used by a PIMA to inform the task of understanding that behavior.

![Figure 1: PIMA Architecture](image-url)
We have built a prototype PIMA that observes user interaction with everyday applications (e.g., Netscape Navigator, Microsoft Internet Explorer, and Microsoft Word), and, using a very preliminary knowledge of information-consumption scripts, is able to anticipate a user's information needs. It then attempts to automatically fulfill them using common Internet information resources.

Given the requirements that it must observe several applications and that it must also use multiple information resources, we have adopted the five-tiered architecture depicted in [Fig. 1]. The user interacts with their everyday applications (shown at the bottom of the diagram), and the information management application in the middle. Through a series of adapters, the assistant application communicates with the existing software applications through the operating system’s IPC facilities. The assistant then interprets user behavior in these applications, and constructs a query, which it sends off to information sources at the top. It collects the results, and applies information-filtering heuristics that allow it to present the user a concise, high-quality list of suggestions. These suggestions are presented in a window for the user to browse. Eventually, we plan to give our PIMA a memory of user interests and expertise (c.f. [Budzik & Hammond, 1998]), as well as the ability to communicate with other users’ assistants, in order to personalize and improve the quality of the results.

3. Implementation

Currently, our PIMA observes user interaction in unmodified versions of Microsoft Internet Explorer and Microsoft Word, as well as a modified version of Mozilla (Netscape’s free-source version of Navigator). The PIMA communicates with Microsoft Word and Internet Explorer through COM (PC only), and with Mozilla through BSD sockets (UNIX and PC). We designed our architecture with the idea that application interfaces should be the only OS-dependent components. We implemented the assistant application in Java, for maximum portability and ease of development. These design decisions afford us the ability to extend the PIMAs field of observation relatively easily, without having to change the core application code.

![Figure 2: Suggesting Relevant Web Pages](image-url)
3.1 Finding Relevant Pages

The simplest of the information-consumption scripts we have identified is associated with finding related web pages. The FIND-RELATED-PAGES script is composed of the following basic steps.
1. Summarize the document in terms of a few words.
2. Pose a query to a search engine using these words.
3. Sift through the results, searching for ones that are actually related.

It is applied when the assistant anticipates the user wants more information in the subject area of the document he currently manipulating. For the two Web browsers, the PIMA recognizes when a user navigates to a new web site, either by clicking on a link, or by explicitly opening a URL. In Microsoft Word, it recognizes when a user has opened a document or changed it significantly.

There are essentially two processes associated with retrieving relevant documents: query construction and information filtering. [Fig. 2] demonstrates the user interface associated with the result of these two processes applied in sequence.

3.1.1 Query Construction

In order to retrieve relevant sites, the PIMA constructs a query based on the contents of the current web page, and sends it off to AltaVista [1]. To construct a query, the PIMA uses three techniques to decide on which words should be included: a standard stop list and two heuristics for rating the importance of a word.

</tbody>
</table>

Table 1: Output of a query generated from a page on Java standardization

The first heuristic is that words at the top of the page tend to be more important than the words at the bottom. The second is words that occur with high frequency (that are not in the stop list) in a document are usually representative of the document. The terms with the top 20 weights form the query that is sent to AltaVista.

### 3.1.2 Information Filtering

Because the results returned from AltaVista are often redundant, containing copies of the same page or similar pages from the same server, the PIMA must filter the results so as not to add to a user's feeling of information overload [Maes, 1994]. If these similarities are not accounted for, some of the more interesting pages returned by AltaVista may be missed. Moreover, we constantly face the risk of annoying the user instead of helping him. As a result, we actively attempt to reduce the amount of irrelevant information presented, and in doing so address some of the problems associated with a constantly updating interfaces (like [Lieberman, 1995]). To this end, we have designed our prototype to collect search engine results and cluster similar pages, displaying a single representative from each cluster for the user to browse.

For this task, we currently use three pieces of information that AltaVista returns for each document: the document's title, its URL, and the date on which it was last modified. For each of these pieces we have a heuristic similarity metric. The similarity of two titles is represented numerically by the percentage of words they share in common; two URLs are compared by examining their host, port and closeness in terms of directory structure; and two dates are judged by the number of days separating them. The combination of these similarity metrics is sufficient to determine the uniqueness of the documents returned.

[Tab. 1] shows a typical response from AltaVista generated by a query posed in response to a page on Java Standardization (we have deleted several long ones for brevity). Notice there are a number of mirror sites, as well as logical duplicates (they may have different URLs, but they are the same file). [Tab. 2]
shows these URLs after clustering. Instead of presenting the user with 20 sites, we present him with 10, effectively removing the duplicates and mirrors.

3.2 Exploiting Structural Cues: An Example

Of course, the more abstract goal is to find relevant resources, not simply related pages. To demonstrate both the feasibility of extending the domain of resources exploited by our architecture, as well as power of this paradigm of interaction, we have extended the PIMA’s functionality in Microsoft Word to include the ability to recognize when a user inserts a caption. The script associated with this situation suggests a different class of information-consumption behaviors we can anticipate: those that are dependent on the structural context of the active document. The FIND-RELATED-IMAGES script is applied when the user has inserted a caption with no image to fill it (and probably others—we make no claims about being exhaustive, here). It contains the following steps:

1. Summarize the desired picture in terms of a few words.
2. Send these words off to an image search engine.
3. Sift through the results and choose the best one.

In response to the above situation, the PIMA applies this script and predicts the user will require an image. It then sends off a query to Arriba Vista [2] a commercial implementation of WebSeer [Frankel, et al., 1997], an image search engine. The PIMA constructs the query using a piece of knowledge about the structure of documents, in general: that the caption of an image is a verbal summary of that image. Hence the query it constructs is simply the conjunction of the stop-listed terms in the caption. The results from the image search are presented in a web browser window, from which the user can drag-and-drop the images into Microsoft Word (see [Fig. 3]).

4. Related Work

Software that recommends web pages and learns user preferences has been the intense focus of recent research in Artificial Intelligence and Information Retrieval. A few good examples of related work follow. Letizia [Lieberman, 1995] is an agent that recommends web pages by compiling a profile and doing lookahead search in the locus of the current web page. ParaSite [Spertus, 1998] is a system that suggests relevant web pages using link topology. WebMate [Chen & Sycara, 1998] keeps track of user interests and uses them to extend queries to search engines. Maxims [Lashkari, et al., 1994] learns relationships between application events and user interaction patterns in an email package and uses them to predict and carry out common tasks. The Remembrance Agent [Rhodes & Starner, 1996] suggests related documents you've written as you compose a new document. The Shop Bot [Doorenbos, et al., 1997] queries various commercial sites for price information to aid the user in the task of comparison-shopping. Finally, Alexa [3] is a company dedicated to recommending web pages, and is responsible for the "Find Related Pages" button in the new Netscape Navigator.

Our approach differs from the above and contributes in several important ways:
1. User behavior modeling. User behavior is modeled and can be used to inform all of the assistant's tasks.
2. Search is automatic and distributed. The goal of finding relevant documents is predicted and carried out automatically using an extensive, dynamic chunk of the web. We do not require a pre-compiled index of related documents—only access to standard web search engines.
3. Search is directed. Search is directed and constrained by the content and the structure of the document at hand.
4. Results are post-processed. By applying several simple, low-cost web page similarity heuristics we were able to improve the quality of suggestions dramatically.

5. Directions for Future Research

Our initial experiment suggests that the combination our heuristics for query generation and for response clustering produce high quality, on point suggestions. Our hypothesis is that this is due to the fact that the query generation algorithm we apply to documents roughly mirrors the process of document indexing, and that the clustering heuristics are effective. While our initial results are promising, the system has much room for improvement.

Most obviously, our library of scripts is very sparse. Augmenting it so it understands more user/application interactions (and thus is able to anticipate more kinds of information needs) will be of primary concern. Tied to this is the fact that the PIMA has a very rudimentary notion of document structure. As it stands, the query construction algorithm ignores all but the most obvious structure of the documents it uses. Applying heuristics to improve the query construction algorithm based on document structure will not only improve query construction, but it will also afford the assistant the opportunity to direct its search for recommendations based on that structure. Queries frequently include terms that are of little information value to vector space information retrieval systems like AltaVista. Composing a table of term frequencies from a random sample of web documents and using this table to negatively weight terms with very high frequencies will increase the number of "quality" query terms sent to information sources. As a further improvement, we plan on adding support for more information resources and developing a vocabulary for expressing the kind of information available, as well as a means by which the assistant can be made aware of new information resources as well as filter suggestions in a task-directed way.

Finally, our prototype is reactive in the strictest sense—it has no memory, and knows nothing about what the user prefers. Giving our PIMA the ability to learn user preferences and leverage this knowledge as it attempts to anticipate information needs, select appropriate sources, and filter results from those responses is sure to improve the quality of suggestions dramatically. Clearly there is much more to be done.

6. Conclusion

In summary, we have outlined several major problems associated with contemporary information access paradigms. In response, we presented an architecture for a class of systems we call *Personal Information Management Systems*. These systems observe user interactions with everyday applications, anticipate information needs, and automatically fulfill them using Internet information sources. Essentially, they turn everyday applications into intelligent user interfaces for conventional information retrieval systems. We presented our initial work on a prototype of this kind of system, some related work, and closed with directions for future research.

Abstract:
The emergence of the Internet presents enormous opportunities and challenges to humanity. If we work to preserve its openness and diversity, we can ensure that the Net will be used to change the human condition for the better, and can prevent or mitigate its less desirable consequences.

The Internet is more than wires, computers, software, modems, routers, standards, and the applications that use them. It even encompasses more than text and pictures, and the audio and video that are rapidly joining those media. The Net is also the collective knowledge and experience of countless communities, each with its own modes of interaction, languages of discourse, and forms of cultural expression.

Certain principles must be understood and respected as we consider the more detailed daily questions that arise in the administration or governance of the Net. We believe that among these principles are the following:

1. The Net links us all together.
2. The Net must be open and available to all.
3. Net users have the right to communicate.
4. Net users have the right to privacy.
5. People are the Net’s stewards, not its owners.
6. Administration of the Net should be open and inclusive.
7. The Net should reflect human diversity, not homogenize it.

The continuing evolution of the Internet presents both opportunities and challenges. We must work to counter the political, economic, social, and technical forces that work against these principles and threaten the promise of open communication on the Internet. Failure to do so may lead to a future in which the Internet is homogenized, commercialized, and regulated to the extent that it fails to meet its fundamental mission - to serve as a medium for maximizing human potential through communication.

1. The Net links us all together.

The nature of people and their use of networking technology provides a strong natural drive towards universal interconnection. Because the flow of information on the Net transcends national boundaries, any restrictions within a single country may act to limit the freedom of those in other countries as well. The true value of the Internet is found in people, not in technology. Since each new user increases the value of the Net for all, the potential of the Net will only be reached when all who desire can openly and freely use the Net.

2. The Net must be open and available to all.

The Net should be available to all who wish to use it, regardless of economic, social, political, linguistic, or cultural differences or abilities. We must work to ensure that all people have the access to the technology, education, and support necessary for constructive, active participation. People in all walks of life should have as much right to send and receive information as do the affluent and powerful.
3. Net users have the right to communicate.

Every use of the Net is inherently an exercise of freedom of speech, to be restricted only at great peril to human liberty. The right to communicate includes the right to participate in communication through interacting, organizing, petitioning, mobilizing, assembling, collaborating, buying and selling, sharing, and publishing. The Net offers great promise as a means of increasing global commerce and collaboration among businesses, but restrictions on information exchange would eviscerate that promise.

4. Net users have the right to privacy.

Without assurances of appropriate privacy, users of the Net will not communicate and participate in a meaningful manner. The right to privacy includes at least three forms:

- Individual Network users should control the collection, use, and dissemination of personal data about themselves, including financial and demographic information.
- Network users should be free to use any available technical measures to help ensure the privacy of all aspects of their communications.
- Individuals have the right to control who they communicate with, and how they conduct that communication. The privacy implied by the decision to not communicate must be respected.

5. People are the Net's stewards, not its owners.

Those who want to reap the benefits of the shared global Net are obliged to respect the rights of others who may wish to use the Net in different ways. We must work to preserve the free and open nature of the current Internet as a fragile resource that must be enriched and passed on to our children. Individual pieces of the Net, such as wires, routers, and servers, have owners whose economic rights and interests must be respected. However, just as the ecosystem in which we live cannot be owned, the Net itself is not owned by anyone.

6. Administration of the Net should be open and inclusive.

The Net should be administered in an open, inclusive, and democratic manner for the betterment of humanity. The needs of all who are affected by the Internet - including current users, future users, and those who are unable to or choose not to be users - must be considered when making technical, social, political, and economic decisions regarding the operations of the Internet. Although administration of the Net should aim to enhance its efficiency, availability, and security, it should not do so at the cost of discouraging use of the Net. Administration should facilitate and encourage greater use of the Net for communication, rather than inhibit it in any way.

7. The Net should reflect human diversity, not homogenize it.

The Net has the potential to be as varied and multi-cultural as life itself. It can facilitate dialogue between communities and individuals that might previously not have encountered each other in a dozen lifetimes. However, the Net could also become a homogenizing force, working to suppress diversity in favor of a bland globalism. Individuals and communities should not be forced to forego local cultures and traditions in order to participate in the Net. In order to preserve the vitality that comes with a diversity of viewpoints, we should work toward helping the whole world participate as equals.

Abstract: This paper presents the main results of a survey held by de Vrije Universiteit Amsterdam and KPMG EDP Auditors, concerning Internet-related security incidents. The survey was held within Dutch organisations that are currently using the Internet. The first aim of the project was to determine the actual security risks of using the Internet. This requires insight in the percentage of companies experiencing Internet-related security incidents, the damage caused by the incidents, the way the affected companies deal with the incidents and a profile of the perpetrators. The second aim of the project was to determine the right security measures in order to prevent security incidents. This was done by (1) analysing the security incidents to find out in which way they could be prevented and (2) trying to find correlations between certain security measures and (the absence of) security incidents.

1. Introduction

As more and more organisations are connecting to the Internet, security is becoming increasingly important. The fact that security is indeed a problem is illustrated by a survey carried out by Dan Farmer, showing that over 60% of 1700 inspected sensitive Websites, such as banks, credit unions, newspapers and government agencies, could be broken into or even destroyed [Farmer 1996].

Given the high number of vulnerable sites, an interesting question is which part of the organisations using the Internet is actually experiencing Internet related security incidents. The existing surveys that tried to answer this question, such as carried out by CERT/CC [Howard 1997] and Prowatch Secure (a commercial security surveillance service) [Prowatch 1997], are usually based upon a special subset of the Internet connected organisations, such as those requesting assistance from CERT/CC or those having their network security surveyed by Prowatch. It is therefore hard to determine to which extent the resulting figures are representative for the Internet as a whole. Furthermore, these surveys also provide little insight in the amount of damage caused by the incidents to the affected organisations.

A second question is what measures should be taken in order to prevent security incidents. Although many measures are being advised for the technical as well as the organisational part of security [Garfinkel & Spafford 1996] [Roos 1996], little is known about the effectiveness of these measures.
2. Definitions

An incident is a situation in which the security of a computer system has been violated. This survey focusses on the following kinds of incidents:

- unauthorised access, whereby someone on the Internet gained access to computer systems or information without being authorised to do so;
- denial of service, whereby someone on the Internet managed to disrupt the information services;
- malicious code, such as viruses and Trojan horses, being spread by means of the Internet.

An attack is an attempt to cause an incident by trying to identify and/or exploit security vulnerabilities.

A distinction is being made between the Internet site and the internal IT-infrastructure. The Internet site consists of the information services (such as WWW of FTP) that are being offered to the Internet. The internal IT-infrastructure on the other hand, consists of the information services (possibly including Internet services such as e-mail or Web-access) offered to internal users. The main differences between the Internet site and the internal IT-infrastructure is that the users of the Internet site are located (externally) on the Internet, while the internal IT-infrastructure is being used exclusively by own employees. This also means that the internal IT-infrastructure usually contains the greater part of the business critical information. Therefore, incidents affecting the internal IT-infrastructure can have a higher impact than incidents affecting the Internet site.

3. About the Survey

The survey, a joint project between de Vrije Universiteit Amsterdam and KPMG EDP Auditors, was carried out by sending enquiries to 878 organisations that are currently using the Internet. The organisations were selected using the DNS information of the .nl domain, with a strong preference for organisations that have their own Internet system administration, as the questionnaires were to be filled in by the system administrators.

Eventually, 145 usable responses were received, obtaining a response-rate of approximately 17%. For a sensitive subject like computer security incidents, this is not a bad result. A similar survey, carried out by the Computer Security Institute (CSI) in co-operation with the FBI reached a response-rate of 9% [CSI 1996].

4. Characteristics of the Responding Organisations

The responding organisations can be described by the following characteristics:

- both small and large organisations (measured by annual turnover, number of employees and number of IT-administrators) are significantly represented;
- although several sectors are represented among the responding organisations, approximately one third of the population consists of Internet providers and the IT-sector. This is probably caused by the (earlier mentioned) preference for organisations that have their own Internet system administration;
- about one third of the population (99 organisations) has an Internet-site that is maintained by its own personnel. More than half (58%) of the organisations with an Internet site have their site for longer than one year, which is in principle long enough to be confronted with security incidents;
- about one third of the population (98 organisations) has a permanent link between the Internet and their internal IT-infrastructure (often using a firewall);
- the responding companies have serious interests in (the security of) their Internet-facilities because:
  - 53% of the responding organisations with an Internet site uses it as to generate income (at least $ 5.000 on annual base) or to provide their customers with support for delivered products or services;
  - in two third of the organisations where the personnel has one or more Internet facilities at their disposal, one or more facilities (mostly e-mail) were classified as essential, meaning that the loss of the facility would result in a immediate loss of productivity;
  - in three out of four organisations more than 75% of the employees have a workplace with computer facilities, which means that a potential security incident can affect a significant part of the organisation.
5. The Extent of the Problem

An estimate of the part of the Internet connected organisations that is attacked is hampered by the fact that organisations do not need to be aware that such attacks took place. The data of [Tab. 1] has therefore been calculated twice: once for all the organisations, regardless whether they have implemented adequate detection measures and once for the organisations that have at least implemented a minimal form of detection (a regular check of the log files). It is felt by the researchers that the latter group, although having a smaller size, provides a more realistic insight into the extent of the problem.

<table>
<thead>
<tr>
<th>Environment</th>
<th>Percentage of organisations reporting attacks (regardless of detection measures)</th>
<th>Percentage of organisations reporting attacks (organisations with regular log-checks)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Internet site</td>
<td>32% over 18 months (n=99)</td>
<td>45% over 17 months (n=51)</td>
</tr>
<tr>
<td>Internal IT-infrastructure</td>
<td>29% over 19 months (n=98)</td>
<td>40% over 20 months (n=47)</td>
</tr>
</tbody>
</table>

Table 1: Percentage of organisations reporting attacks

A similar table can be set up with respect to the incidents (meaning attacks that have broken through the security measures), as done in [Tab. 2].

<table>
<thead>
<tr>
<th>Environment</th>
<th>Percentage of organisations reporting incidents (regardless of detection measures)</th>
<th>Percentage of organisations reporting incidents (organisations with regular log-checks)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Internet site</td>
<td>12% over 18 months (n=99)</td>
<td>18% over 17 months (n=51)</td>
</tr>
<tr>
<td>Internal IT-environment</td>
<td>10% over 19 months (n=98)</td>
<td>9% over 20 months (n=47)</td>
</tr>
</tbody>
</table>

Table 2: Percentage of organisations reporting incidents

The percentages of attacks and incidents for the Internet site are based on organisations having an Internet site which is being maintained by their own personnel. The percentages of attacks and incidents for the internal IT-infrastructure are based on organisations having a permanent link (leased line) between the Internet and their internal IT-infrastructure.

6. Attacked Organisations

The attackers do not seem to be very selective when choosing their targets. The chance of an attack is relatively constant, regardless the size of the organisation or the sector it operates in.

The only exceptions are the media and the non-profit sector. These are reporting more, respectively fewer attacks. A possible explanation is that hacker ethic is to some extent keeping the perpetrators from attacking non-profit organisations (of which most of them, such as humanitarian organisations of the environment activists have an idealistic mission). The media on the other hand are likely to be extra attractive because of their high visibility and the potential amount of publicity a successful attack would generate.

7. Providers and Clients

<table>
<thead>
<tr>

</thead>
<tbody>
<tr>
<td>Providers</td>
<td>15% (n=34)</td>
</tr>
<tr>
<td>Clients</td>
<td>0% (n=31)</td>
</tr>
</tbody>
</table>

Table 3: Reported incidents by providers and clients
There is a remarkable difference in incident reports between the Internet providers and the organisations that have outsourced the technical maintenance of their Internet site to a provider. While providers are affected by security incidents concerning their Internet site, the organisations that have outsourced the maintenance of their site do not seem to be aware of it. Although the cause of this situation could not be determined, it is certainly advisable for organisations outsourcing the maintenance of their Internet site, to define clear procedures for reporting incidents in the contract with their provider.

8. A Closer Look at the Security Incidents

In the following paragraphs the incidents concerning unauthorised access, denial of service and malicious code will be dealt with. The number of reported incidents (17, 4 and 9 for unauthorised access, denial of service and malicious code respectively) is, however, not sufficient to do a thorough statistical analysis. The discussion will, therefore, be limited to the most striking trends.

8.1. Unauthorised Access

It seems that in most incidents considering unauthorised access, the impact on the operations of the affected organisation is limited. The number of affected systems is usually one (counting only the affected systems within the surveyed organisation). None of the organisations reported missed revenue, nor did the perpetrator read or modify any business sensitive data such as the personnel database or the financial records. The relatively small impact may be related to the fact that most incidents affect only the Internet site, whereas the mission-critical information is usually located on the internal IT-infrastructure.

Despite the relatively limited impact on the operations of the organisations, the incidents can be very annoying. In roughly half of the incidents, the perpetrator misused the hacked systems for spreading undesirable information (such as illegally copied software or Website hacking) or for launching attacks against the computer systems of other organisations, which can be quite embarrassing for the affected organisation. Furthermore, the system administrators spend on average half a week for each incident.

Ten out of the seventeen unauthorised access incidents were reported as caused by bugs in software. From the name and version number of the concerning software, it was determined that five incidents were caused by bugs that were well known at the time the incident took place and for which a fix was available. These incidents, therefore, are in fact caused by not timely installing security fixes. This may be related to the high workload of the responsible system administrators, as in three organisations that have become victim of incidents caused by not timely installing fixes, the pressure of work, as described by the system administrator, was high. In two cases it was even noticed that “the urgent tasks and requirements coming from the organisation take so much time that there is frequently not enough time left for necessary (less visible) maintenance.”

8.2. Denial of Service

With three out of 145 organisations reporting denial of service incidents, it can be stated that these kinds of incidents are infrequent, despite the fact that they can relatively easily be caused. Apart from being a nuisance, the incidents did not have any serious consequences, such as a significant loss of productivity or missed turnover.

8.3. Malicious Code

Despite the current attention for the security problems in Java and ActiveX, no incidents with respect to active content were reported. The incidents concerning malicious code, as reported by 9 organisations, were all related to MS Word macro viruses spread by e-mail. These viruses, however, can cause considerable damage. This was indicated by the fact that:
- usually several systems were infected (in one incident even up to 45);
- the system administrators spent much time with the handling of the incidents (sometimes several days);
there is a realistic chance of passing the viruses through to business relations, something that happened to two of the responding organisations.

8.4. About the Perpetrators

Based on the actions the perpetrator undertakes when he has gained unauthorised access to a computer system, his objectives can to some extent be deduced.

From the incidents as reported by the responding organisations, it can be stated that most intruders are not really interested in reading or modifying business-critical data. The information that was read or modified usually consisted of data like logfiles, network traffic, Webpages or system binaries. Not a single responding organisation mentions incidents whereby the perpetrator has read or modified any truly sensitive data, such as customer files or financial data.

The perpetrators are more interested in the network facilities. In approximately half of the unauthorised access incidents, the hacked computer systems were misused for activities like Website hacking, the distribution of illegally copied software or for launching attacks against the computer systems of other organisations. In some cases the intruder was eavesdropping the network traffic. The fact that eavesdropping intruders were also being reported by Internet providers means that it is certainly advisable to use strong encryption when sending sensitive data over the Internet.

Another indication that most perpetrators have few interest in gathering business critical data, is the fact that among the organisations reporting unsuccessful unauthorised access attempts, more attacks are reported with respect to the Internet site than with respect to the internal IT-infrastructure.

One of the first priorities of an intruder after having launched a successful attack is to safeguard his access. In almost half of the incidents concerning unauthorised access, the perpetrator realised new means of access; such as by adding new accounts, installing Trojan horses or reading the password file.

Most intruders can probably better be described as joyriders than as vandals or criminals. They break into a system not to gain any financial profit (the affected organisations rarely suspect any financial motives) but to fully enjoy the power of the computer system and it's network facilities.

The intruders do not necessarily possess a high level of expertise, as many of them make use of well-known techniques.

In only two incidents the intruders were prosecuted.

8.5. Additional Security Measures

Organisations affected by attacks or incidents often take additional security measures:

• almost all organisations confronted with unauthorised access incidents have implemented additional security measures. The reported measures often do not require a continuing effort nor any additional resources apart from a certain amount of man-hours of the system administrators;
• the few organisations affected by denial of service incidents all have implemented measures to prevent further incidents;
• two thirds of the organisations that became victim of malicious code incidents improved their virus checking as a result of the incidents;
• among the organisations exclusively detecting unsuccessful attacks, about half have implemented additional security measures.

It appears that most organisations are not fully aware of the risks of their Internet usage until the first attack or incident takes place. The chance of attacks is relatively high, up to 45% during 1½ year, so it makes sense to implement appropriate security measures before being confronted with the first attack.

9. Effectiveness of Security Measures

The survey measured the effectiveness of several kinds of security measures: the presence of a firewall, security policies, the presence of security audits and the quality of the system administrators.
9.1. Effectiveness Firewall

A firewall is an often-used technique to establish a secure link between the Internet and the internal IT-infrastructure. In this survey it was measured to which extent the presence of a firewall actually contributes to the security of the internal IT-infrastructure. This was done by comparing the percentage of organisations experiencing security incidents on their internal IT-infrastructure for both the group of organisations with a firewall and the group of organisations not having a firewall.

Strangely enough, the percentage of companies experiencing Internet security incidents among the organisations having a firewall is not any less than among the organisations not having a firewall.

A possible explanation is that not all firewalls are of proper quality. This was indicated by the following findings:

- one out of four organisations reported that they have implemented a policy of allowing all services to pass through the firewall, other than a few services that are explicitly blocked. The main danger of such a default permit policy is that because of the great number and complexity of network services it is fairly easy to overlook a certain kind of dangerous network traffic. It is therefore advisable to allow only explicitly authorised network traffic, and block all other traffic [Chapman & Zwicky 1995];
- one out of ten organisations having a firewall offers the possibility of inbound logins without necessarily using encryption, one-time passwords or some other means of strong authentication. The danger of this situation is that if an eavesdropper manages to intercept the password, he can logon as a normal user [Garfinkel & Spafford 1996];
- at two organisations, the firewall had been installed by an external expert without any kind of maintenance ever since.

The above criteria are necessarily incomplete and could therefore only be used to get a rough impression of the quality of the firewalls, as a more thorough measurement would be too extensive to fit into the survey.

A second explanation for the poor effectiveness of the installed firewalls can be given by a closer examination of the incidents that broke through a firewall. It was found that 5 incidents could be reduced to security holes in the firewall itself:

- in one case the services passed through the firewall were handled by software containing security holes;
- in the case of another incident the entire firewall (at least the security part of it) was out of service without the organisation being aware of it;
- in the case of three incidents the firewall did not check on incoming e-mail, causing MS Word viruses to be able to reach the internal IT-infrastructure.

One other incident concerned a computer system reported as part of the internal IT-infrastructure but located outside of the firewall. The two remaining incidents were not being reported in enough details to be able to determine the cause.

The frequent poor quality of firewalls is being confirmed by the people of KPMG doing penetration tests. They report that in one out of five cases they manage to break through the firewall. As the organisations that ask KPMG to do a penetration test often spend a more than average effort to security, it is likely that the total percentage of organisations having security holes in their firewall is more than 20%.

9.2. Organisational Aspects of Security

The survey has tried to measure the effects of the following organisational security measures, taken from [BSI 1993] and [OTB 1997]:

- a written security policy;
- an explicit assignment of security related responsibilities;
- security clauses included in the Service Level Agreement (SLA's) if the organisation makes use of them;
- a written policy with respect to the risks of the Internet connection, if such a connection is present;
- user awareness measures;
- management involvement in the selection of services allowed to pass through the firewall;
- the existence of procedures and guidelines with respect to incident response.

To measure the effects of these organisational security measures, two groups of organisations were assembled: those having implemented many measures and those having implemented few. The difference between many and few was defined in such a way that both categories contain exactly 50% of the relevant responding organisations.
Surprisingly, the group of organisations that have implemented many organisational security measures does not have any fewer incidents than the other group. A possible explanation is that, in order to have an effective security, the organisational measures must be translated into operational procedures, as few intruders will be stopped by measures like security policies, job descriptions or user awareness sessions by itself. The organisational security procedures are, therefore, only useful if they actually result in adequate operational security measures, most of which are related to the technical configuration of the computer systems.

To measure the effects of the organisational measures on the implementation of operational procedures, the emphasis was laid on one specific operational procedure: a regular check of the system logfiles. For each organisational measure two groups of organisations were formed, those with and those without the measure. In most cases it was found that the group of organisations having implemented the organisational measure did not have a significantly higher percentage having implemented a regular logcheck than the group without the organisational measure. If this trend also appears at other operational security measures not included in the survey, than it can be stated that the effect or security policies and other organisational measures upon the quality of the operational procedures is frequently insufficient.

9.3. Auditing the Security

As a significant part of the incidents was detected by checking the logfiles, special attention was being paid to the effects of a regular audit on the logfiles. It turned out that the number of incidents reported with respect to the Internet site was significantly greater with the organisations performing regular logchecks (18% reported incidents) than with organisations that check the contents of their logfiles only if there is a direct reason to do so (6% reported incidents). If the organisations without adequate detection measures are under the same pressure of attacks as the organisations that do have adequate checks, then it can be assumed that the former group is having security incidents without being aware of it. This assumption is being confirmed by a further analysis of the reported security incidents. It turns out that the "silent" attacks, where the perpetrator merely reads information without undertaking any further actions that might draw the attention on the incident, were exclusively reported by organisations that have implemented procedures for incident detection. Organisations that do not have regular security checks, on the other hand, were only reporting incidents with a relatively high visibility, such as where the perpetrator undertakes actions like Website hacking, attacks on other sites or modification of system binaries.

If organisations without proper detection measures have the same chance of being (successfully) attacked as those that do have adequate detection measures, it can be inferred that approximately 12% of the former group is having Internet related security incidents without being aware of it.

If 18% of the organisations are having incidents, while only 6% of the organisations without adequate detection measures are aware that such incidents have taken place, then the latter group has managed to detect only one third of the incidents. This however, is relatively modest compared what other researchers have found. For example, a test program by the Defense Information Systems Agency (DISA) found that 96% of the succeeded penetration tests carried out by DISA was not being detected [GAO 1996]. A research carried out by the Air Force Information Warfare Center (AFIWC) found that only 13% of the attacks was being reported [Howard 1997].

9.4. Quality of the System Administrators

Security often depends on people. The survey has tried to find out which human factors have a significant effect on the effectiveness of the security. The focus was on the system administrator, as he was the person filling in the questionnaire. From the information provided, it was inferred that the following factors are important when security is at stake:

- the level of knowledge. Because a direct measurement would be unfeasible, the level of knowledge could only be measured by indirect means. The level of knowledge has therefore been measured by asking whether or not the system administrators are members of a user group, as these are specifically aimed at the exchange of knowledge among their members;
- the level of experience with the administration of Internet services;
- the pressure of work. In 30% of the responding organisations the pressure of work of the system administrators is on such a high level that overtime is regular (more than once a week) or that the urgent tasks and requests coming from the organisation take so much time that insufficient time is left for doing...
structural maintenance. In this situation it is up to the professionalism of the system administrators to – despite the high workload – pay enough attention to important things not immediately visible to the users, such as computer security. It is, however, the task of the management to structurally improve this situation.

10. Conclusions and Recommendations

With up to 45% of the Internet connected organisations under attack, it is safe to state that security is an essential requirement for anyone connecting to the Internet. Although this threat is present for practically every Internet connected organisation (regardless its size or the sector it operates in), most organisations do not seem to be fully aware of it.

Most security incidents seem to be affecting the Internet site instead of the internal IT-infrastructure, which causes the impact to be relatively low from a business point of view. This, however, does not mean that security is irrelevant, as in roughly half the number of incidents the intruder uses the systems in a way that can potentially embarrass the affected organisation.

A significant part of the incidents concerning unauthorised access could have been prevented by timely installing security fixes.

When considering malicious code, it appears that MS-Word viruses, spread by e-mail, are currently a far greater problem than Java or ActiveX. It is certainly advisable to have virus scanning on incoming e-mail, such as being offered by several commercial firewall products.

The sole availability of a firewall does not always provide a proper protection. Without careful planning, testing and maintenance, a firewall can provide a false sense of security.

The effect of security policies and other organisational security measures is somewhat disappointing, as not every policy results in the actual implementation of effective operational security measures. The security policy should state clear procedures for measuring the resulting operational measures.

The survey added further evidence to the fact that without adequate detection measures, only a small part of the incidents will be detected. Detection measures are, however, an important aspect of security as they enable an organisation to respond to incidents in an early stage.

Human factors have a clear influence on the security. Especially the level of knowledge, experience and the absence of a high workload among the system administrators have a positive effect on the security.

Considerations in Collaborative Lesson Development on the Web

Dr. Stephen Canipe  
Director, ABC Technology Consortium, Technology Center, 425 Prescott Street,  
Greensboro, NC 27401, E-mail: scanipe@abcnet.org

Abstract: This report is work that began during the summer of 1997. The research has as its hypothesis that technology rich lessons will increase the performance of low achieving students (grades 3-8) on standardized end-of-grade tests. The lesson development has emphasized three factors that have been agreed upon by each district. The factors called for a thematic unit with each unit being developed using Howard Gardner's Multiple Intelligence theory and the constructivist theory in its preparation. The project has utilized several on-line systems including the free system from nicenet.net, the Lotus Domino server, Learning Space, and Xerox's DocuShare. This paper will describe the pros and cons of each system tried and the teachers' reactions to them. The effectiveness of on-line development as well as considerations in choosing what should NOT be done on-line but in person are discussed.

1. Introduction

The ABC Technology Consortium is an Innovative Challenge Grant funded by the US Department of Education in 1996. This grant has as its basic premise that technology rich lessons will increase the performance of low achieving students (grades 3-8) on standardized end-of-grade tests.

Part of our reason for thinking that technology-rich lessons will help students grew out of our study of constructivism. When one considers the media rich environment that today's students have been exposed to since before birth, it seems to be logical to make this assumption.

Today's infants grow up with huge woofers booming sound even prenatally. This electronic assault continues into early childhood. Children are exposed to all sorts of electronics from large screen televisions, cell phones, Nintendo, and other things we take for granted. So do the students!

Students are accustomed to instant information. They "need" to be kept wired during their learning. This perceived need presents tremendous challenge to today's teachers since educational infrastructure has changed little from its industrial era mentality. Educators doing things as groups, in order, and on a schedule - learn my way, when I want you to - seems to be the prevailing philosophy.

Media-rich lessons will, certainly, not solve all problems in student learning, but our hypothesis is that it will help. Preliminary data indicate that this approach is having some effect. One of our targeted schools has improved its writing scores by over 600%!

There are five separate school systems participating in the grant. They cover a broad geographical area (over 120 miles distance for the two districts furthest apart). There are 1500 teachers in the districts and they have committed themselves to producing a technology rich curriculum which emphasizes the creation of multimedia materials that are to be delivered on-line. The distances involved in the project eliminate easy, face to face meetings. The differences in district calendars and school days mandated an asynchronous method be used for effective lesson development.

The districts are Guilford, Person, Stokes, Surry, and Wilkes County Schools. Part of the reason for the grant selection by the Department of Education was based on the demographics of the districts.
The reported demographic data are shown below:

Demographic makeup of the districts has not changed appreciably since the grant’s inception in Spring 1996. Population has increased but the other data remain practically constant. This enables us to maintain a relevant data collection.

The lesson development has emphasized three factors that have been agreed upon by each district. The factors called for thematic units rather than just lessons. Each lesson is developed using Howard Gardner’s Multiple Intelligence theory. Also each lesson uses the constructivist theory in its preparation.

The project has utilized several on-line systems including the free system from nicenet.net and the Lotus Domino server. Several other systems were considered including Learning Space and Xerox’s DocuShare.

2. LearnNC Partnership

We entered a partnership with the Institute for Academic Technology at the University of North Carolina at Chapel Hill. The particular effort we joined is called LearnNC. LearnNC utilizes a Lotus Domino server. The strengths of using this approach are the immediacy of postings being available, the ability to selectively password protect sections, the ability to have a web presence, and the ability to enter into collaborative work in the group section.

There are many features of the Domino system that are not currently being used. A key concern of the sponsor (LearnNC) is that user difficulty be minimized. As teachers become more familiar with the system, more features might be utilized.

LearnNC provides its service without charge to every teacher and school in North Carolina. This allows for the widest possible usage. The ABC template varies only slightly from the base template which every NC teacher can use. The key differences lie in identifying the various multiple intelligences being targeted and in having a student work space attached to the lesson but also separately accessible. Since the ABC Grant is a federal grant, all lessons are fully accessible to all teachers. The URL is http://www.learnnc.org. While anyone may view the lessons, in order to post, one must have a password to access the system. A sample lesson and the template can be seen at the URL referenced above.

One possibility that we have used for collaborative lesson development is for one teacher to take the lead and post a lesson. The collaborators then check the posted material and email the original author who makes the changes. This was not an ideal solution so collaborative accounts have been set up so that each collaborator can have total access to the lesson(s) being posted. There are some potential problems with this method, but it seems the best available alternative at the moment. This shared account posting method is asynchronous at the moment but ways to make it synchronous are being explored.

Discussion forums using a threaded format make it possible for interested parties to exchange ideas and for anyone to participate in the sharing. One disadvantage to this type of discussion is the difficulty new users have in knowing where exactly to post. It is also possible to respond via email to a posted message without posting for the entire user group to see.
3. Southeast Cluster Partnership

The ABC Consortium is one of fourteen Innovative Challenge Grants to comprise the Southeast Cluster. The Cluster comprises projects in Pennsylvania, Delaware, Virginia, West Virginia, North Carolina, South Carolina, Florida, Louisiana, and Tennessee. Each project has a short description at the following URL http://www.se.ticg.jhu.edu. Several components of the Cluster site are related to sharing and posting. One of the primary components is called DocuShare that is produced by Xerox. This component is password protected on the Cluster site lending itself to private conversation between members. Not all features available in DocuShare are being used. The two, which are being used, are the bulletin feature and the folder and document sharing.

The bulletin feature allows anyone (with the requisite access) to post a newsflash or a short announcement which everyone should read. One advantage of the program is that a date tag can be added so users can check for recent news. A disadvantage is that the date stamp must be manually adjusted. Users having the proper level of access can add folders and documents. This is a very powerful feature because it is possible, for example, to get groups that cannot see the post; can see but not change; and can see and change. These levels of access can be set by the poster and do NOT require the intervention of the web guru. In our case, we have not taken the access down to the teacher level it remains at the district level for the time being.

The WebBoard program by O’Reilly & Associates allows for discussions in much the same way that Lotus Notes does. Here there are folders that can be added for holding particular discussion postings. It is possible in this section to allow selective access just as was the case in DocuShare.

Attachments can easily be added to the discussion topics. One disadvantage in that the new message tag which alerts a user when they sign on must be reset manually, otherwise users get every message as NEW now matter how many times they’ve read it. A plus is that a user can set an email notification property that automatically lets him/her know when any new posting occurs. This is helpful for busy people when the amount of posting is relatively small.

4. NICENET.ORG

Not enough good things can be said about nicenet. Perhaps the most important is that it is free! This program does not have all the bells and whistles that the commercial offerings have. It does have a discussion component, a presentation component, and the ability to link users via email.

This site is probably best used for a teaching purpose even though it is flexible enough to allow for collaborative work. Teachers who used this site liked the presentation quality but found collaboration difficult. If one has a need for an on-line cyberclassroom then nicenet should be considered. The URL is http://www.nicenet.org.

5. Basic HTML

During the first summer of the ABC project, we used Netscape Navigator Gold to produce thematic units suitable for posting to the web. Our teachers were in structured workshops that allowed them to collaborate on lessons, see the code for presenting the information, and modify the code. The group activity allowed sharing and any dispute/discussion was easily handled during the sessions.

When the lessons were done in the home schools, there was, of necessity, a need to involve a referee in this collaborative effort to look at the conflicting versions and decide which should be posted. This work required ftping documents online or by using sneaker.net. Using HTML was fine if there was a face to face meeting of the collaborators but less effective with the distances in the grant. Teachers decided rather quickly that there had to be a better way for on-line collaboration.
6. Conclusions

In using the various systems, the teachers are really enthusiastic about the Lotus Domino solution. Part of the acceptance here might be the very strong statewide push for training in this program. Nevertheless the teachers accept and use this program very well.

Second in order comes the DocuShare program for Xerox. The most ardent supporters are those with a little more technical expertise. Whether the training curve has not turned up or the program is harder to master, the rank and file teacher seems more reluctant to utilize it regularly.

Nicenet is very easy to use but teachers seem not to use it except as a learning tool. It is not used as a collaborative or discussion vehicle.

The same can be said for HTML – it is just too complex for regular use and teachers use it only for special purposes.

Little concern has developed over what should be done on line and what should be done face to face. One conclusion, which may be valid, is that since teachers are people-oriented they prefer, in most instances, human contact. Perhaps only time and experience will enable teachers to become totally comfortable in cyber-meetings and cyber-collaboration.

Acknowledgements

The author wishes to thank the following members of the ABC Consortium for all their hard work and efforts on behalf of the program: Guilford County-Zelia Frick, Dr. Chuck Morris, Michael Parrish, Donna Yow; Person County-Sandy Davis, Russell Dixon; Stokes County-Arden Browder; Surry County-Dr. Judy Flake; Wilkes County-Chuck Parker. In addition, all the teachers from all the districts who have worked on the program and provided valuable input on the various collaborative programs deserve a great thank you. Of course, the Technology Innovative Challenge Grant program which has provided the funding for the entire effort deserves accolades.
Abstract: The typical way of accessing HTML information has been the utilisation of WWW browsers. These applications have inherited their way of interacting with the final user from other common Windows applications. The use of standard toolbars, scrolling bars, buttons, etc has confined the presentation of HTML information within the limits of the browser window. The purpose of this project is to suggest the possibility of designing and presenting HTML information isolated from the constraints that the current browsers impose. This will be possible thanks to the definition of a new set of tags and parameters and a browser capable of parsing such extensions.

1. Introduction

This paper describes the object oriented design and development of an HTML browser capable of parsing a set of new HTML extensions. These extensions are intended to enhance the control of the HTML document author over the graphic interface of the visual environment where the information is being displayed. Implementations to demonstrate their behaviour have been carried out on a PC platform, on top of the Win32 API. Since we are only talking about extensions, total compatibility of both the new browser with actual documents, and the actual browsers with documents including the mentioned extensions, is guaranteed.

Our intention is to present an alternative to the current ways of showing HTML information, that is, to the browser constraints accepted by WWW users. We, of course, do not intend to assume the enormous effort required to develop and maintain a new complete browser. Our aim is to suggest a more generic visualization policy; for this purpose, we have developed a browser that interprets a new reduced set of HTML extensions, along with the most common standard ones. Such extensions are a set of ‘tags’, and their associated parameters, that mainly allow the author to control the fully independent area where the information is going to be displayed, and the way this area will interact with the platform windowing system. The available area properties currently include size, position, transparency, and movement.

HTML related technologies do already allow authors (via the use of transparencies, animations, hot areas, etc.) to design friendly user interfaces free of buttons, check boxes, scrollbars, combo boxes, and other standard graphic controls whose effectiveness for novice users is not clear. The problem is that currently all this information should still be confined into the browser frame, not only limiting the designer freedom by the constraints commonly imposed by the windowing systems, but also by the ones imposed by a the client area of a single window. The objective of the work in progress, similar to many other user interface enhancement initiatives [Grudin 93], is to give the author the possibility of showing HTML information outside the browser frame or any other frame but the screen.

2. Description

By parsing the proposed extensions, our browser (now just a small toolbar, without client area) is able to show throughout the screen bare information free of title bars, buttons, borders, tool bars, etc. Composition of different documents, either separated or overlapped, either transparent or opaque, either with full window frame or without even a border frame, allows the author to play with a series of new original possibilities. Moreover, a movement parameter makes possible to specify an initial position for the document's window, a type of movement (now just linear or circular) and a set of options to determine the trajectory of the window.
These few extensions, along with the possibility to link several URLs with a single anchor [Pimentel & Buford 96], allow sets of HTML documents to act, for instance, as virtual remotely maintained desktops covering the whole screen, or just a part of it, by simply specifying the borderless, non-moving, no resizing and transparent parameters. As a paramount part of the WWW facilities, advertising would find a new range of possibilities; for instance, Internet providers could display their animated logo in one corner of the screen (or moving around it) without disturbing the user navigation. Definitely, the appropriate combination of these tags and parameters will provide authors with much more power to design their multimedia presentations.

The syntax of these extensions is as follows:

```xml
<LAYOUT
  POSITION= x, y, width, heigth // initial coordinates for the window
  PROPERTIES = // window properties
    BORDER, // border around the window
    SIZEFRAME, // resizable window
    MOVEFRAME, // window with title bar
    OVERLAPPED, // overlapped window
    POSRELATIVE, POSABSOLUTE, // relative or absolute initial coordinates
    of the window
  TRANSPARENT // transparency of the whole window
  MOVEMENT = // window movement
    LINEAR, vx, vy // linear movement, horizontal and vertical speed
    CIRCLE, r, 1/0 // circular movement, radix, positive/negative rotation>
```

In fact, all the work we are carrying out is a much more generic approach to the currently available frames inside the browser, which is just a partial solution, in our point of view, to a real user requirement. Current status of the developments does already allow to have a clear image of the proposal.

3. Related Work

Although when we started the design of this work, we did not find any other similar idea in this direction (maybe due to the fact that requires the implementation of a new browser to effectively show it, a work that, due to several reasons, is seldom found [Verhoeven et al. 98]), it is evident that it was already evolving in the largest browser developers premises. The first actual step in this direction is the Active Desktop [Microsoft 97], recently fully implemented in the Explorer. Independently of the automatic updating mechanism that includes, the main differences are that, first, they only consider the desktop, not a generalised new approach for document visual behavior; and, second, it is the user, not the information provider, who decides the appearance (just position, not transparency nor movement) of WWW information, always just on the desktop.

High-level Database Document Specifications Using XML

K. Cardinaels, E. Duval, H. Olivé
Dept. Computer Science
Katholieke Universiteit Leuven (B)
Celestijnenlaan 200A, B-3001 Heverlee, Belgium
E-mail: {Kris.Cardinaels, Erik.Duval, Henk.Olivie}@cs.kuleuven.ac.be

Abstract: Reporting information stored in databases for use in different environments is not an easy task. Most database management systems do not provide integrated tools that can be used for, say, both on-line information browsing as in the World-Wide Web and information retrieval for static use (e.g. paper printing). The system discussed in this paper implements a flexible method, based on the new standard XML (eXtensible Markup Language), to generate database reports. XML is chosen for its processing capabilities with parsers and processors, it is not used as a replacement for HTML, so the output we serve to the WWW-clients is still in HTML.

1. Introduction

Retrieving information from databases and presenting it to users in different formats, such as for on-line browsing on the World-Wide Web or printed reports, has always been a difficult task. Most database systems provide proprietary tools to generate reports for paper printing or have special tools for information reporting towards the WWW. Examples of these tools are Oracle’s SQL*Forms, WebServer, and Microsoft’s Internet Assistant for Access. There are few integrated systems for reporting information for different uses.

Our system is developed in the Hypermedia Object Management Environment [HOME] framework. The techniques and methodologies presented in this paper were developed during the implementation of a database application for the Department of Computer Science of the Katholieke Universiteit Leuven (B). Characteristic for this department is its diversity in computer platforms and operating systems, so the systems needed to be flexible and platform independent.

Using XML [XML] as a specification language, enables us to make flexible high-level documents and generate output in different environments, such as on-line browsing on the World-Wide Web and paper printing. The system differs from other systems for database access, as it uses document templates to generate the output (HTML or other).

In this paper, we will first discuss the different high-level concepts we are using in the information templates. The presentation of these concepts is given from the viewpoint of the report-generator, so the elements we discuss might not be exactly the elements one expects in a relational database. The second part is a discussion of the DGReport document type definition (DTD) in XML, and the third part describes the report generator.

2. High-Level Reporting Elements

Looking at relational database schemes, we can discover three kinds of elements that are important in generating reports. These elements can be derived from the use of database tables while retrieving data out of the database.

We take a navigational approach to retrieve data out of the database, in contrast with SQL data retrieval where a descriptive approach is followed. During the retrieval of the information, the system always works with a specific table, the current table, from which it will retrieve some tuples. In the figure below, for example, this could be the table PERSON. All information retrieved will come at first instance from the current table, and information

[1] Postdoctoral Fellow of the Fund for Scientific Research - Flanders (Belgium)(F.W.O.)
retrieval will always start from this current table. But of course, while looking at the current table we may need information from another table if necessary, and thus change the current table.

![Relational model for employees](image)

**Figure 1**: Relational model for employees

1. The first kind of element is the simplest one. It corresponds to attributes of the current row in the current table. In Figure 1, the attributes of the current table PERSON are *Id*, *Name* and *Phone*. Attributes can be retrieved from the table and inserted in the generated document. For example in Figure 2, three attributes are represented as columns in a generated document for employees.

![Example document for employees](image)

**Figure 2**: Example document for employees

Generally, a document is made up of combinations of attributes of different tables.

2. The second kind of element is related to single values from other tables, referred to by foreign keys in the current table. During the generation of the report we may want to follow the reference to the referred table and include some columns of that table (join the current table and the referred table). Notice that we only insert one tuple of the referred table in our generated report, in contrast with the next element, discussed in 3. At this moment the current table changes to the referred table. In the example of Figure 1 we have an employment which states a relationship between a person and an institution. The table employment contains references to both the person and the institution, but we do not want the values of the foreign keys to appear in our document. Rather, we want for example the initials and last name of the person and the name of the institution. So, in this example if the current table changes to the person table, and the process can restart: attributes of the new current table can be included, and so on... The same method is used to include attributes of the institution table.

3. Using the employment example, we can discover the third kind of element when generating a report for an institution: a repeating list of values from other tables, referring to the actual tuple of the current table. One of the report elements we want to insert could be a list of employees with their name, e-mail address and phone
number (as given in Figure 2). If the current table for the document is the institution table, we insert a join with
the employment table in the document. This join returns a list of tuples according to the employment reference.
As in the previous element, the current table changes to the joined table and elements can be inserted in the
document for the new current table.

3. High-Level Element Specification

Our system uses XML to specify the information templates. We rely on XML as a template specification
language. Documents generated from the template can, but need not, be XML documents themselves. They can
just as well be ordinary HTML documents, or formatted text, or any other character-based format. At the moment
a lot of work is going on to make XML the standard language for the World-Wide Web and thus replacing HTML.
So, web-documents would be marked-up with XML tags, which can be seen as a generalization of HTML.
In contrast with this use of XML, our system uses XML for its processing capabilities. The first step in our system
is an XML parser that parses the information template and passes the parsed XML tree on to the next processing
step. The output from our system is an HTML file that can be served on the Web. It also possible to generate
XML in stead of HTML as the final output, no changes need to be made to the system, only the report template has
to be altered.

We have chosen XML for its flexibility and the number of available tools to parse and process the templates. In
addition to the three main elements described above, some additional ones have been declared. The next
paragraph describes all these elements and their use in the information server. Figure 3 shows the Document Type
Definition we defined for the information template.

```xml
<!ELEMENT dgreport (dghead, dgbody, dgfoot)>  
<!ENTITY content (#PCDATA | column | reference | repeat)>  
<!ELEMENT dghead (#PCDATA)>  
<!ELEMENT dgfoot (#PCDATA)>  
<!ELEMENT dgbody (&content;)>  
<!ELEMENT column empty>  
<!ELEMENT reference (&content;)>  
<!ELEMENT repeat (&content;)>  
<!ATTLIST dgreport table CDATA #REQUIRED>  
<!ATTLIST column column CDATA #REQUIRED>  
<!ATTLIST reference table CDATA #REQUIRED
    column CDATA #REQUIRED>  
<!ATTLIST repeat table CDATA #REQUIRED
    column CDATA #REQUIRED
    sep CDATA #REQUIRED>  
```

**Figure 3: Information Template DTD**

`<dgreport>`

Serving information out of a database always starts from a certain table or view. The name of this table must be
specified at the beginning of the template, as a parameter of the `dgreport`-element.

`<dghead>` and `<dgfoot>`

Every document can contain one header and/or footer. These two elements are processed only once for the whole
document. For the time being, the header can only contain static text, values that need be retrieved from the
database are not allowed. A more elaborated model could allow special columns to be included in the document,
which can be retrieved from a dummy table (e.g. sysdate from dual in Oracle in order to include the date the
document was generated) or summary information like totals or counting for the table.

<column>
The body of the document (dgbody) can include values that must be retrieved from the current table. For each
tuple in the main table (given in <dgreport>), the system will process the body of the document and replace all
column elements with values from the database.
For example, when we are generating a list of people, we will need the first and last name of the person and his
address. For such a report we thus add three column tags specifying that we want these values to be included (see
Figure 4).

```
<DGREPORT table="PERSON">
  <DGBODY>
    <COLUMN column="FName"/>
    <COLUMN column="LName"/>
    <COLUMN column="Address"/>
  </DGBODY>
</DGREPORT>
```

Figure 4: Information template for employee labels

In this example the three column elements will be replaced with the appropriate values for each tuple in the person
table. Figure 5 illustrates a possible result from this template.

```

Erik Duval
Celestijnenlaan 200A, B-3001 Heverlee

Henk Olivié
Celestijnenlaan 200A, B-3001 Heverlee
```

Figure 5: Person labels from the template in Figure 4

<reference>
Foreign keys can't be included directly into the document. A foreign key references to the primary key of a tuple
in another or the same relation in the database. Specifying a <reference> in the document template starts a lookup
(join) to the referred tuple: the current table changes to the referred table. After the current table switch, we can
specify which columns of the referred tuple we want to include. So, between start and end tag of a reference we
can specify a number of elements. The next figure gives an example using a reference from the employment table
to the person table.

```
<DGREPORT table="EMPLOYMENT">
  <DGBODY>
    <COLUMN column="id">:
    <REFERENCE table="PERSON" column="person">
      <COLUMN column="name"/>
      <COLUMN column="phone"/>
    </REFERENCE>
  </DGBODY>
</DGREPORT>
```

Could generate:
1. E.Duval, 327066
2. K.Cardinaels, 327660
3. H.Olivié, 327538

Figure 6: Alternative information template for employees
A repeat element corresponds to a join of two tables that can generate a list of values. For a tuple in the first table, a list of tuples is returned which all refer to that first tuple. Repeat elements are more or less similar to reference elements: with references we look for the referred element, with a repeat we look for all elements that refer to the current tuple.

Because the repeat element returns a list of values, we want that list to be returned in a formatted form. Therefor two attributes (sep and last) can be specified that handle the separation of the list elements. Consider for instance the document in Figure 7 that concerns published articles. The first element in this document is the repeating field author. The resulting report will include the authors separated from each other with a comma, as specified in the sep-attribute. Optionally, the last attribute can be used to make a distinction for the last separator in the list. In Figure 7, we use a comma to separate authors and the word 'and' to use as last separator.

```
<DGREPORT table="ARTICLE">
  <DGBODY>
    <REPEAT table="AUTHOR" sep="", last=" and " column="author_article">
      <COLUMN column="initials"/>
      <COLUMN column="Iname"/>
    </REPEAT>,
    <IT><COLUMN column="dname"/></IT>.
  </DGBODY>
</DGREPORT>
```

Could generate:

Figure 7: Bibliographic information for published articles

4. Report generation

As explained in the previous section, our system uses an XML template to generate its documents. Starting from the XML file, an XML parser parses the document and passes an XML tree to the second process in the system, that we call the XML-consumer. This second process connects with the database and generates the document, which will be given to the HTML server.

```
Figure 8: The Information Server Process
```

With this kind of implementation, it is easy to generate documents for different uses. When we want printed documents we can redirect the output to a file and print that file. For online documents on, e.g. the World-Wide Web, we use a simple servlet mechanism to redirect the output through a webserver.
A second advantage of our system is the use of text-templates. Any kind of output-template that can be written in standard text format, for example, with the ISO8859-1 (Latin-1) character set, can be processed with our information server. Of course, ASCII and HTML outputs belong to this category, but also TeX and other output formats can be generated.

5. Conclusions

While developing a database application to be used at the department of Computer Science at the Katholieke Universiteit Leuven, we ran into the problem of serving information out of the database to different media and on different platforms (both on-line and for printing). Using XML provided us with a flexible solution to generate such information. While studying the high-level design and the implementation phase of database applications we could define a document type definition for database information templates.

This method of retrieving information from databases for the Web differs from most other systems that allow database information retrieval. In comparison, we can distinguish two other methods for serving database information on the Web.

1. The first method uses non-standard extensions of the HTML-language to embed database query facilities (e.g. SQL-tags) or to allow scripting within the HTML document. Professional Home Page [PHP] and Microsoft’s Active Server Pages (ASP) [ASP] are examples of such systems. PHP is a scripting language that can be embedded in HTML documents with specific functions for accessing databases. The web server will process such non-standard HTML and embed query results in the HTML document. Also ASP allows scripting within the HTML documents, but the tools provided in this system can be more complex, such as ActiveX components that access databases.

2. The other category of information servers are specific Web-servers with extensions to access databases. This category is not exactly the same as our mechanism, as we use standard Web-servers, like Apache, with servlet extensions. Servers in this category are for example HyperWave with the Place [HyperWave] language (this system also uses a proprietary database server) and CGI-based servers that embed SQL commands in their scripts.

Most of these systems require specific servers or processors and even special databases, in comparison with our system, they are less extensible and less flexible.

The approach described in this paper fits in the 'Hypermedia Object Management Environment' or HOME framework for research in the domain of databases and hypermedia [HOME]. Our research is mainly concerned with different approaches to the application of database technology for hypermedia systems. Two extreme methodologies in our work can be distinguished:

1. In the first one, the database and the hypermedia application are developed manually. This method is mainly used for very lightweight applications, in the context of HOME-LITE.

2. The other extreme starts from the analysis phase of the application domain and generates automatically the database application, as well as Java classes that interface with the database. Client applications are then developed in the JavaBeans application development framework [Hendrikx98].

The approach presented in this paper belongs somewhere inbetween these two approaches. The difference with the first one is that we do not program every interaction with the database manually. It is different from the second one, because the information templates aren't generated automatically.

Abstract: 2nd Infantry Division's Tactical World-Wide Web (TACWEB) exploits emerging Internet technologies to provide an effective information management system on the battlefield. Using dynamic web pages and an easy-to-use interface, TACWEB provides a near real-time picture of the battlefield that allows commanders to focus on critical issues and make decisions faster than the enemy. Fusing real-time commander's situation reports and intelligence and then broadcasting this information throughout the division to key leaders, this enhanced command and control capability provides a decisive combat multiplier that will help the United States win the next war - the war for information.

Introduction

The Problem

The 2nd Infantry Division (2ID) had an information management problem. Faced with one-year tours, an extremely high operations tempo, and the 4th largest army in the world only 15 miles away, the young soldiers assigned to 2ID could not effectively use the Army's tactical command and control system, the Maneuver Control System (MCS). Despite the division running a one-week formal training course constantly, operators could pass text messages between tactical operations center at best. The software was too complex for the average soldier to understand. The hardware was specialized and few soldiers could troubleshoot or correct even simple hardware problems. Finally, the hardware requirements of the UNIX-based software limited the number of workstations within the division. There was no redundancy available and if a critical site lost its MCS, that site would be down until the remaining MCS terminals could be reallocated within the division. This reallocation would clearly be difficult under wartime conditions. What 2ID needed a simple, easy-to-use software package that enhanced operational awareness between the division TOCs and major subordinate commands and ran on a common and widely available hardware platform. Unfortunately, such a system did not exist.

Figure 1: Views of TACWEB: (a) Unit Status Report and (b) BOS Status Report

The Solution

As a result of these problems with MCS, 2ID developed the 2ID Tactical World-Wide Web (TACWEB) (See Figure 1). TACWEB is a simple, easy-to-use classified, tactical information management system that tracks the battle status of units, battlefield operating systems and other key information such as significant events, commander situation reports, weather, priority information reports, personnel status reports, and logistics status reports. TACWEB minimizes network bandwidth requirements to be highly effective over the Army’s tactical communications system, the Mobile Subscriber Equipment (MSE). TACWEB provides an effective information management system that quickly focuses leaders on issues and provides a degree of synergy previously unseen. It is a combat multiplier.

2ID TACWEB

Design Principles

TACWEB was developed using the following design principles:

- TACWEB must present information with increasing levels of detail.
- TACWEB must be easy to use.
- TACWEB must run on commercial, off-the-shelf, hardware and software that is relatively inexpensive.
- TACWEB must run effectively over MSE.

Increasing Levels of Details

TACWEB is first and foremost an information management system. It displays the current status of units and battlefield operating systems in an easy to understand format of automated, color-coded heads-up displays (HUDs). All of these displays are dynamic WWW pages – WWW pages that are dynamically built using the latest information from tactical databases. These HUDs are the gateway to additional information and consist of a series of color-coded “gumballs” (See Figure 1). Each gumball is green, amber, red, black or white depending on status. If the user moves the mouse over a gumball, a comment field automatically appears, superimposed over the HUD, with additional information on the gumball selected. By convention, all amber and red gumballs have comments. Those green gumballs that have comments have a “C” centered in the middle of the gumball. This indicates that while the system being reported is green, the commander or staff element has provided a

Figure 2: (a) Normal Unit Status, (b) Detailed Weapons Status of 2nd Brigade
comment that requires division command group attention. If the user desires more information, he or she need only click on the gumball to load an additional page that provides another level of detail (See Figure 2). Each gumball is linked to a different report depending on the topic. For example, the division commander reviews the Unit Status Report and notices the 1st Brigade is amber in weapons system. He moves the mouse over the amber gumball and automatically the commander’s assessment of weapons status becomes visible as a superimposed text box from the latest commander’s situation report. If the division commander requires additional information, he then clicks on the gumball to bring up a complete, color-coded display of the weapons status of the brigade with the number of operational weapons of each subordinate battalion as well as a total weapons summary of the brigade. Additional weapon status reports provide automatic totals of weapon systems across the entire division (See Figure 3). Thus, users can control the amount of detail visible, from division to battalion level, so as to have the right amount of information to make decisions.

**Easy to Use**

TACWEB is easy to use. Users submit information through a fill-in-the-blank Common Gateway Interface (CGI) form running on TACWEB. Users simply fill in the appropriate form for a report and click on a submit button (See Figure 3). The information is transmitted as ASCII text over the MSE network to the TACWEB server where it is automatically added to the Division’s database. When users submit an updated report, all of the information from a previous report is automatically loaded so that the user need only make the necessary changes to submit an updated report. Users can be trained to submit TACWEB reports in less than 15 minutes and to fully utilize the informational resources of TACWEB in less than four hours. Compared to MCS, it is a very easy system to use.

From the commander’s perspective, TACWEB is likewise very easy to use. The divisional database takes the data provided by users and automatically transforms it into a series of automated HUDs that track critical battlefield information. Commander’s can quickly and visually assess the status of units and BOS without reading mountains of reports. Critical information is automatically updated at set intervals so that commanders and the division staff always have the latest information to make decisions. As commander’s situation reports are received, the division staff can provide comments, linked to the situation report, with ongoing efforts to resolve issues. It quickly becomes clear what issues are being resolved and what issues have somehow been lost. With automated updates and color-coded displays, the division command group can quickly assess the status of the division and focus on those critical issues that make a difference.

The synergistic impact of this automated, real-time information fusion cannot be understated. Issues are immediately apparent. Disconnects between staff and units are likewise apparent. TACWEB users can easily assess the status of the entire division in but a single moment. TACWEB even synchronizes all of the computers accessing the server so that everyone is using the same current time. Everyone is working using the same, nearly real-time information.

Finally, TACWEB is easy to customize to fit rapidly changing conditions. The G3 can easily task organize the division and then change the task organization in the middle of an operation to meet operational requirements. The changes are immediately visible to all units. The TACWEB task organization tool also allows other units to easy use and exploit TACWEB. It is not coded so as to work only with 2ID but instead is written to work with any unit. The 82nd Airborne Division or 3rd Corps could easily install and operate the software without modifying the TACWEB software. Likewise, the G3 can easily change pacing items and weapon systems and those changes are immediately reflected on unit commander situation reports and logistics status reports. This provides the division command group the ability to track critical equipment and change what the critical equipment is as the battle progresses. For example, as the division fights defensive operations and then transitions into a counterattack and river crossing, the pacing items for subordinate units can change.

**Hardware and Software Requirements**

TACWEB requires a personal computer capable of running the Microsoft Windows 95 or NT operating system and Internet Explorer 3.02 or higher WWW browser. It performs best on Internet Explorer 4.0. There are an
adequate number of computers within 2ID capable of meeting the hardware requirements and Internet Explorer 4.0 is a free software package. As such, the hardware and software requirements of TACWEB are minimal compared to MCS.

Effective Over MSE

To be useful, TACWEB must be effective over MSE. TACWEB reports are small ASCII text transfers and as such, require limited bandwidth. The largest TACWEB report, the unit LOGSAT which is only submitted twice per day, is less than 60 kilobytes in size and most TACWEB reports are much smaller in size.

The TACWEB interface is spartan yet functional in appearance. Graphics are strictly minimized to limit network load. With the exception of the four small gumballs (green, amber, red, and black) each of which is less than 5k in size and each of which only have to be loaded once, there are no graphics in 2ID TACWEB. Every other component is HTML code, which is transmitted as ASCII text. There are no Microsoft Word documents, Excel spreadsheets, or PowerPoint slideshows. In fact, the bandwidth constraints are so low that users with STU-III telephones and the Windows NT operating system can dial in to the system and access TACWEB information. TACWEB is effective in low-bandwidth systems.

Once loaded, the information displayed is static and does require any network resources with two exceptions: the significant events frame and the marquee line update every two and five minutes respectively. Otherwise, the user must refresh the pages as needed. As a result, TACWEB places an extremely limited network load over the MSE network while providing a highly effective information system.

Lessons Learned

2ID implemented TACWEB prior to and during Ulchi Focus Lens, a major Korean simulations exercise. It was immediately successful and received command emphasis as the command group exploited the potential of TACWEB. It was also used during the next divisional exercise, WarPath II which is the division rehearsal for its WarFighter exercise. From the communicator/automator perspective, sensitivity to network outages and especially outages of the tactical packet network increased as TACWEB gained increased importance within the division. The Division Command Group perceived TACWEB as a real-time reporting system. Outages were immediately noticed and resolution of outages received increased visibility. Techniques such as dual homing of tactical data switches and increasing bandwidth available took on added significance. Switch operators had to adjust to this heightened sensitivity and aggressively monitor the tactical packet network. System Control...
likewise became very sensitive to the data network. Data, not voice trunks, became the benchmark of the MSE network. This was a fundamental shift for 2ID.

While the first exercise, Ulchi Focus Lens demonstrated the potential of TACWEB, the WarPath II exercise validated this perceived potential. The division staff and subordinate units accessed TACWEB over 400,000 times in a five day exercise and downloaded over 3.6 gigabytes of information. The average access time was approximately 4.5 seconds. TACWEB was fast and useful and as a result, units used it extensively. The success of TACWEB has continued and it has been used extensively during numerous exercises such as WarFighter, Iron WarSteed, Strike WarSteed, and WarStrike.

Numerous exercise examples illustrate the functionality of TACWEB. Twice during the commanding general's morning update, the status of units changed rapidly during the brief and division command group had the necessary information to make immediate decisions based on accurate, real-time information of all major subordinate commands. Without TACWEB, this synergistic view of the battlefield would not have been possible and the division would not have been able to react to rapidly evolving situations. External evaluators confirmed what everyone on division staff already knew: TACWEB was a combat multiplier.

The synergistic view provided by TACWEB also facilitated rapid and accurate parallel planning process. Because everyone knew the real-time status of divisional units down to how many tanks and APCs were available in each unit, units and staff elements could anticipate future operations and begin parallel planning. This was especially apparent to the Aviation Brigade and Division Artillery brigade commanders who are adept at using the TACWEB.

Finally, the linking of unit statuses with staff assessments and comments also proved to be invaluable in synchronizing staff actions to address statuses. Everyone had visibility of divisional efforts to address personnel and equipment shortcomings. The G1, G3, and G4 aggressively tracked unit statuses and responded to unit issues in a manner that had previously been impossible.

**TACWEB Limitations**

While TACWEB is an effective information management system, it does have certain limitations including:

- TACWEB is only visible to units with MSE switch support.
- Information security of TACWEB.
- Limitations of WWW technology.

**TACWEB and MSE**

TACWEB utilizes the MSE data network as its transport mechanism. As such, TACWEB is currently only visible to units with dedicated Small or Large Extension Node (SEN or LEN) support. Battalions internal to a brigade do not have access to TACWEB and as a result cannot submit reports over TACWEB or receive information. While this limits the effectiveness of TACWEB, it also limits the potential for compromise of the TACWEB system. Other units in the Army face the same problem. As solutions such as the Surrogate Digital Radio are tested and validated as part of the Advanced WarFighter Experiment, 2ID will adapt these technologies to expand TACWEB to battalion level.

**Information Security**

TACWEB provides excellent internal information security. An easy-to-use security interface allows web administrators the capability to set permissions by staff section and unit. These permissions address all possible actions on the TACWEB site except viewing. This lack of protection against viewing pages is a fundamental weakness of the system. If the enemy gains access to the system through the MSE network, the entire divisional
status is available. While this is unlikely, future revisions to the TACWEB software will address these security concerns through initial and periodic authentication requests.

**Limitations of WWW Technology**

While WWW technology is constantly improving, there are significant limitations in the underlying technology. The WWW does not support the easy presentation of briefing material in a format similar to dedicated presentation software such as PowerPoint or Harvard Graphics. Overlaying graphics to form complex presentations is simple in presentation software and very difficult with the WWW’s language, the Hypertext Markup Language (HTML). As a result, users have false expectations on the ease of generating dynamic informational displays over the WWW. For example, forming a terrain map with unit locations overlaid is extremely difficult and requires the developed of a specialized and complex JAVA applet where it is a relatively simple task in PowerPoint. Moreover, the WWW was developed for the efficient presentation of relatively static information and not the presentation of real-time information over low-bandwidth networks in a tactical environment. These limitations hinder the potential of TACWEB to replace other tactical information management systems.

**Further Development**

Additional development of TACWEB is focused on:

- Enhancing the operational security of TACWEB. TACWEB makes it too easy to compromise the status of all divisional units. Additional security measures are necessary.
- Migrating TACWEB to other Army and Department of Defense units.

**Conclusions**

TACWEB is a highly effective tactical information management system. It has fundamentally changed how the 2nd Infantry Division uses information and automation systems to form a coherent picture of the battlefield. It allows the commander the ability to make decisions faster based on more timely information and thus stay inside the enemy commander’s decision cycle. It is an easy-to-use combat multiplier that one day will save the lives of soldiers on the battlefield.

Time for Hypervideo on the Web

Teresa Chambel

Nuno Correia,
DI-FCT/UNL, Portugal, E-mail: nmc@di.fct.unl.pt

Nuno Guimarães
DI-FCUL, Portugal, E-mail: nmg@di.fc.ul.pt

Abstract: Hypermedia has proven to be a powerful way to structure and interact with multimedia information. True integration of video in hypermedia documents requires a more powerful model, defining the semantic of linking to other videos or other media, and taking into account its spatial and temporal dimensions. In this paper, we propose a model and tools for dynamic information hyperlinking or hypervideo support on the Web.

1. Introduction

Hypermedia has proven to be a powerful way to structure and interact with multimedia information. Compared to other media, video has some unique characteristics that make it more rich and interesting, and yet more complex to handle [Elmagarmid 97, Hampapur 95]. While its richness suggests the use of a powerful structuring paradigm, its complexity makes the task more challenging. This challenge becomes more relevant, as technology is making video more easy to access, store and transmit. Also, the new tendencies for media convergence and integration are transforming video into a dominant medium.

Hypervideo refers to the integration of video in hypermedia documents. So far, on the Web and almost every hypermedia system, when supported, video could only be manipulated in a way similar to a VCR, with controls to run, stop and pause, and links could only be made to or from video as a whole. True integration of video requires a more powerful hypermedia model, defining the semantic of linking to other videos or other media, and taking into account its spatial and temporal dimensions. In this paper, we propose a model and tools for dynamic information hyperlinking or hypervideo support on the Web.

2. Design Principles

The video hypermedia mechanisms should be integrated in the Web according to some design principles: a model should be defined, as an extension of the hypermedia model used in the Web and based on HTML, thus providing for a smooth paradigm integration; Supporting tools and mechanisms should provide easy production and use of hypervideo documents, and backward compatibility with existing Web documents; A model for hypervideo on the Web should take into consideration the specific properties of video information, such as its dynamic nature and the narrative process that is usually employed. Aesthetic and rhetoric properties must be taken into account, so that the resulting documents allow taking full advantage of each of the involved media [Liestol 94, Sawhney 96]. These are essentially to be considered in the authoring process, but the underlying tools should support it.

3. Hypervideo Model

In our model, links can be established between any type of media and, like any link in HTML, are unidirectional and defined at the origin. From video, space and time conditions can be defined to restrict links scope. Therefore, links can be spatial, temporal, spatio-temporal, or unconditional. The latter meaning they are always active, from anywhere on the video. When links have video as a destination, they can specify a time interval for the target sub-video. Both interval limits are optional, having the beginning and end of the video as its default values. In the current prototype, active links or hot spots representation for the new links is similar to the one browsers use for other links. Examples of this are: (1) status message with link information, when cursor moves over an active link; (2) and border color change for the video, as is usual for images, but which can change
with time, reflecting the existence of active links at different moments. In the future, we intend to explore richer solutions concerning video hotspots representation, in order to provide better indications about the link existence and destination. As for navigation, and besides from the follow link facility, a history mechanism with back and forward operations is provided for the new types of link.

4. Implementation

To support the model described above, extensions were made to the A, AREA and MAP elements, through the inclusion of new attributes. These refer essentially to the type of link and temporal information, mentioned in the description of the model. Maps provide the support for the spatial nature of the images, to which they can be associated, and were used in a similar way for spatial hyperlinking in video. For spatio-temporal hyperlinking: (1) the MAP element is extended to consider time, the period in which the map is active for the video it is associated with; (2) a list of maps can be associated with each video, because spatial characteristics change with time. All these extensions are supported by a set of scripts that are generic, reusable, and almost transparent to the author of the hyperdocument, except for the inclusion of an extra line in the header. The authoring process is done in a declarative way in "extended" HTML. The current prototype is based on Dynamic HTML and uses VBScript language and ActiveMovie technology [Simpson 97].

5. Related Work

Other approaches to the integration of video with other media in different environments have been described [Correia 97, Liestøl 94, Sawhney 96], but they refer to proprietary applications. A language for the integration of multimedia objects into synchronized presentations in the Web was recently proposed [W3C 98] and the specification is in progress.

6. Results and Future Work

These tools are being tested and validated in a project, UNIBASE, on interactive multimedia for open and distance learning, where video plays a central role. We are working on its tuning and extension. Main issues concern: the usability of the system; the support for the authoring of hypervideo documents, including the application of video processing techniques [Correia 96, Elmagarmid 97] to index and annotate video, in order to help and find the anchors for which to establish links; and full support for the functionality found useful and adequate for the integration of different media and interaction modes, to accommodate different styles of learning.

JAVA Technology and Its Applications in Teaching

Li Chao, Computer Science & Math, University of Houston-Victoria, U.S.A.
chaol@cobalt.vic.uh.edu

Abstract: The ease of learning Java, its reliability, and its portability make this programming language more and more popular among students and faculty. It has gained much attention through its power of multithreading, networking, and computer graphics. Java is publicly available for everybody (it is free). As an assistant in classroom teaching, Java has the flexibility needed to develop classroom demonstrations, web-based databases and Internet enabled client-server applications. The objective of this paper is to present several projects used in classroom teaching. The projects include:

1. Interactive JAVA Project to Demonstrate Mathematical Concepts

In this project, Java is used to develop the graphic user interface such as menu bars, buttons, and frames. Geometric concepts such as lines and planes are also presented by using Java. Java is good at providing interaction, so that a student is able to use the mouse and keyboard to participate in hands-on activities with math objects through the World Wide Web. Java can also provide sounds and images to go along with the math learning process, which makes the learning of math more lively and interesting.

Among the Java projects we have developed, Visualization of Least Squares' Principle is the one that has been used in the Linear Algebra class. A least-squares problem is to find a vector of coefficients $\mathbf{x}$ so that the error $\mathbf{y} = A\mathbf{x} - \mathbf{y}$ is minimized where $A$ is an $m \times n$ matrix. In the case that $m = 3$ and $n = 2$, $A \mathbf{x}$ is a vector that is in the column space of $A$ and the column space is a plane in $\mathbb{R}^3$. By the geometry interpretation, the $\mathbf{y}$ is a vector that is not in the column space of $A$. Thus, a way of looking at the least-squares principle geometrically is to minimize the length of the error vector $\mathbf{y}$. This can be achieved by choosing vector $\mathbf{y}$ such that $\mathbf{y}$ is orthogonal to the column space of $A$. By taking the advantage of the Java's capability on handling computer graphics, the vectors $\mathbf{x}$, $\mathbf{y}$ and the column space of $A$ can all be painted on an Java applet. To make this Java project interactive, the connection point of the vector $\mathbf{y}$ and the projection of the vector $\mathbf{y}$, the vector $\mathbf{p}$, can be dragged around on the column space plane by using a mouse. As the mouse moves around, the length of the vector $\mathbf{y}$ and the angle between the vector $\mathbf{y}$ and the vector $\mathbf{p}$ are calculated and are displaced on a Java applet. In such a way, students can visualize the relation between the projection angle and the length of the error vector $\mathbf{y}$. A graphical user interface is also developed so that students can choose various projects from the menu bar.

2. World Wide Web Database Project with JAVA

Database development is one of the key courses in a computer science or information systems curriculum. Connecting to databases from the World Wide Web enhances learning and teaching. Students will be allowed to develop, modify, discuss and submit database projects over the Internet. With the Java interface, the Web-based database projects allow interactivity by providing a graphical user interface. Through the graphical user interface, students can test their SQL queries, add and delete records in a database table, and search for specific records in a database. By using the Web database, students are able to develop applications such as online shopping systems, online registration and discussion, tracking stocks online, and many other Internet applications.

One of the projects we have used in teaching Corporate Intranet Development class is the Company's Sales Information database. The database contains information such as products, descriptions, costs, units sold and etc. The database is developed by using Microsoft Access. To run the database on the company's Intranet or World Wide Web, the Access ODBC is installed on the Web server. The Java program instantiates the JDBC/ODBC driver which is used to query the database. The Java program also provide the graphical user interface with the textfields, panels, and buttons. With these panels and buttons, a student can select a specific database to work with. Over the Intranet or World Wide Web, students can view and search the database, add or delete a salesperson's record, modify a field, such as the field of working hours, and redesign a table interactively. Students can even test a query for a selected database on Web. Once their work is completed, students can submit their homework through the Internet.

3. Real World applications

Java programs are not only a great convenience as teaching tools, they also provide the first hand experience on developing real world projects. Nowadays, as the Web becomes a more and more important tool for doing business, the work that students have done by applying Java in problem solving processes makes them ready for Web related jobs. Helping students prepare for real world jobs is part of the goal of classroom teaching. Java is an ever more popular vehicle for achieving this goal. Many students have developed various real world Java-based applications. The education majors have developed Java projects such as English-Arabic Dictionary and math learning tools for the Algebra 1 class. In the English-Arabic Dictionary project, an English word is represented by an icon. Once the icon is clicked, both
English and Arabic pronunciation are given. It is a great tool for those who want to learn foreign languages. In the math learning project, algebra equations with various colors flying around on a computer screen, a student uses a mouse to catch the equations. Once an equation is caught, the student has 1 minute to solve the equation. If the answer is right, the student is awarded with higher score and music. The projects developed by the business majors are as good. They have developed projects such as dynamic stock watch which gives stock figures and charts instantly. The graphical user interface allows the user to choose stocks. Among other business applications, pizza delivery system is the interesting one. It has a city map on the pizza ordering applet. When a customer clicks the street where he/she lives, the street information is passed to the pizza delivery person, so the person will know how to find the customer.

Java’s portability makes it an ideal tool for implementing a client-server system over the World Wide Web. Once Java programs are developed on one platform (such as Microsoft Windows NT on a PC) and then they can be run on many other platforms (such as Macintosh, Sun Workstation with Solaris) without modification. Java’s applets can be included in the instructional materials. They can also be downloaded from the instructor’s server to the students’ home computer. It does not require students to have a specific platform on their home computers. Even if a browser is not suitable for hosting the instructional materials, the student can still run Java applets by downloading and using a free Java Development Kit package to run them. The main attraction of Java-based teaching materials is its ability to build executable content into the instruction materials, so that students can conduct their own experiments over the World Wide Web. Java has provided a bridge between faculty and students. It makes faculty more available to students. The interactive and dynamic learning materials implemented by using java applets will make the distance learning easier.
An Exploration Of Web Users' Internal Experiences: Application Of The Experience Sampling Method To The Web Environment

Abstract: In this paper we report our investigation of Web users' internal experiences by employing a digital implementation of the Experience Sampling Method (ESM) to elicit Web users' hidden experience. The computer application we created, functionally equivalent to the ESM, allows us to capture users' situated perceptions and internal experiences at given moments. How we transformed the ESM for the Web environment is reviewed and what we have learned from our data analysis and our approach is discussed.

1. Introduction

Human beings' experience can be divided into two aspects: external behavior and internal behavior. The external aspect of experience refers to how a person at a certain time, in a certain place engages in activities, encounters people or faces some situation. Internal behavior refers to how a person feels and thinks during specific moments in his perception of self and the world. The experience of "being" in the world helps a human being build him or her "self" through the interaction of the aspects.

As computers and networking technology increasingly penetrate our daily lives, a study exploring human beings' experiences becomes more and more important for at least two reasons. First, the information technology provides human beings with an unprecedented opportunity for distributed communication. Indeed, the growth of interactions on the Internet indicates that people are taking advantage of these opportunities. Communicating in a distributed environment itself probably generates some unique experiences. Second, human beings now live in an information-intensive world which creates some impacts on human beings' experiences. We believe there is an emerging need for an in-depth exploration of human beings' experiences in this "information age."

Over the past several decades, either quantitatively or qualitatively, social science researchers have tried in labs or in the field to observe and analyze human beings' internal and external experiences. Potentially understanding human beings' experiences can provide us with more knowledge about ourselves as human beings and can inform us about how to effectively employ emerging technologies. To understand human beings' internal and external experiences, different research methods and observing schemes have been developed. Depending upon one's orientation, quantitative measurement may be seen as an appropriate tool in measuring external experience and qualitative research methods may be a better idea for studying internal experience. However, some behaviors (particularly internal) have not been effectively observed, some of these behaviors are not available for analysis and replication or are not suitable for systematic analysis. For these situations, traditional research methods may not provide researchers with reliable and valid data for their studies.

There are a few concerns about measuring internal experience in daily life. First, in general, measuring the same individual repeatedly at different times or occasions may provide the optimal approach to studying experience [Stone & Kessler & Haythornthwaite 1991] [Wheeler & Reis 1991]. The quality of the data and the amount of information in a single questionnaire may not provide enough data for researchers to explore.
subjects' inner world over time. Second, data collected over extended time periods are subject to substantial
distortion, especially it is the inner experience in question. Several studies have already demonstrated that recall
accuracy decreases linearly over time [Conrath & Higgins & McClean 1983] [Bernard & Killworth 1977]
[Bernard & Killworth & Sailer 1982]. Therefore, the data point measured should be as close as possible to the
occurred event in question. Third, in order to study internal experience in its naturalistic environment, for the
purpose of ecological validity, the measurement of internal experience should occur in actual situations and in
the natural environment, not in laboratory setting. Fourth, internal experience in daily life is a completely
subjective inner experience situated in different time and place and is not directly observable without further
inquiring respondents directly by using questionnaires or self-recording techniques. Therefore, needed is the
research method of self-recording, which requires subjects to introspect and monitor their inner and external
experience through self-reporting instruments.

In this paper we investigated users' internal (or perceived) experiences in the Web environment. We
employed a digital implementation of the Experience Sampling Method (ESM) [Larson & Csikszentmihalyi
1983] to elicit Web users' internal and external experiences while engaged with the Web. In the following
sections, we will first introduce the ESM and its functions, and then discuss how we transformed the ESM for
the Web environment by creating an "auto-ask" application. In the last section we will discuss what we have
learned from our data analysis and our approach.

2. The Experience Sampling Method

The purpose of the Experience Sampling Method (ESM) is to capture the main dimensions of
consciousness. It has been more than two decades since the ESM was developed at the University of Chicago in
1976 [Csikszentmihalyi & Larson & Prescott 1977]. The original format of the ESM consisted of providing
respondents with an electronic pager and a questionnaire booklet. The researchers randomly activated the
pagers several times a day. Upon receiving a signal on his pager, the respondent would fill out one sheet of the
booklet. By the end of the study, usually lasting from one to several weeks, the booklet contained a systematic
description of the person's life in different situational contexts at different given moments, including external
experiences and internal experiences. The external experiences might have included the activities performed,
places visited, people encountered at given moments. The internal experiences might have included the activities performed,
places visited, people encountered at given moments. The internal experiences might have included perceptions
when the signal activated, such as emotions, cognitive efficiency, motivational states, challenges encountered
and skills brought to the situation [Csikszentmihalyi & Csikszentmihalyi 1988].

There are a few reasons that make the ESM an appropriate and useful tool. First, the randomness of
signals sent out from the researcher to subjects' pagers over time makes the random sampling of subjects' experiences possible. Second, the ESM is a general-purpose research tool which is not limited to any specific research question or domain. It can be used to diagnose a wide variety of topics by redesigning the self-report booklet appropriately [Kubey & Larson & Csikszentmihalyi 1996]. Third, the richness of the data collected from subjects tells researchers at given moments what respondents' internal and external experiences are. Researchers can then reconstruct the situational context at every given moment and diagnose the situation. Fourth, the ESM creates an opportunity to overcome constraints of other methods by "combining the ecological validity of field methods with a variety of measurement techniques" [Kubey & Larson & Csikszentmihalyi 1996]. Fifth, the ESM can provide highly detailed insight into changes in perceptions in everyday life. Since an ESM study usually lasts from one week to a few weeks, it becomes possible to diagnose changes over time.

For years, various versions of the self-report booklet were developed and several different types of
signaling equipment were employed, such as programmable watches and laptop computers. Originally, the ESM
was developed for the purpose of studying the concept of "flow" [Csikszentmihalyi 1975] in the field of
psychology but more recently this method has been accepted by researchers in diverse fields, such as
geography, sociology, education and communication. As a general research tool, the ESM has been employed
to study different research topics, such as thought content, cognitive disorders, emotional experience, self-image
and self-awareness, adjustment to change in drug use and rehabilitation, and the behavior of gifted children or
disabled children.
3. Exploring Web Users' Internal Experiences

How is the ESM useful to scholars interested in Web phenomena? Why should scholars interested in Web phenomena be concerned with this particular method? The advantage of the ESM is that it provides a systematic examination of subjects' internal experiences over time. The concept of internal experiences applied to Web navigation refers to a Web user's overall subjective feelings during interactions within a distributed, multi-media environment. An individual's subjective experience in a Web environment is usually bounded by specific points in time, in a specific place, i.e., the experiences are "situated." Therefore, to tap dimensions of Web users' internal experiences, it is important to focus on the users' inner experiences situated in the behavior of Web navigation.

Traditional research methods, such as interviewing or surveying, have been a useful tool when a researcher tries to diagnose a subjective dimension of experience from subjects' memory. However, when a researcher wants to elicit a sequence of events relying on subjects' memory, the results may not be satisfactory due to three reasons. First, memory is not exact and recall may not be complete; respondents may not remember. Second, by reconstructing the events and consciousness through recall, subjects may not be able to put themselves into the same situational context where the events actually occurred. Third, it becomes difficult for subjects to separate between actual event as it occurred in a situational context and the personal wishes or social expectancy that may influence its retelling [Csikszentmihalyi & Csikszentmihalyi, 1988]. The problems with interview and questionnaire data collected outside the context in they were experienced have been long known for their validity problems.

With these methodological constraints, we argue that traditional approaches which study objective, external concepts or demographic variables are not appropriate for internal, situated behaviors [Dervin 1983] [Dervin & Nilan 1986]. We need a better observation tool which would allow us to see how users perceive and construct their personal experiences in a situational context and how they build their pictures of reality during their Web navigation process. In our study of Web users' perceived experiences, we argue that the ESM would be an appropriate research tool.

4. Auto-ask and Our Study

To apply the ESM in the Web environment, we needed an application which could record users' navigation activities, such as the time of the movement between Web pages, titles of Web pages and the URLs of visited pages. Information about users' navigation activities allows us later to track users' interactivity within the Web environment. Like the ESM, the application we created is able to activate a questionnaire according to a random schedule, popping up on the computer screen on the top of users' Web browsers to capture their situated perceptions. Each time that the questionnaire is activated, the respondent fills out the questionnaire based upon the situational context. The questionnaire was designed to elicit users' dimensions with open-ended items as well as eleven-point Likert numerical scales. We call this questionnaire popped up at random interval a "loop," the unit of analysis of this study because it constitutes a situated observation which is repeated several times for a given respondent. The data collected from each loop represents each user's inner experience during specific moments in their Web navigation. By studying these data points for Web users, we can then begin to reveal their inner experiences and the results can help us understand Web users' subjective experiences during the navigation process.

The computer application we created is called "auto-ask" which is functionally equivalent to ESM. It allows us to capture users' perceptions at given moments which are advantageous for two reasons. First, the very randomness of the sampling of users' perceptions during subjects' Web navigation provide results which reveal the general quality of subjects' Web experience and changes over time. We believe this gives us good coverage of the range of users' experiences. Second, by interrupting the subjects' navigation several times, we are able to catch their subjective experience at specific moments, i.e., our observations are situated.

In order to observe users' subjective experience during their Web navigation, we integrated the auto-ask
computer application into the Web environment. Data were collected from 100 individuals in a northeastern university who were using the Web as part of their day-to-day experience. Subjects who were browsing on the Web in the computer clusters during the research period were asked to participate this study. With subjects' consent, the auto-ask ESM software was installed onto subjects' computer and started. Subjects then continued their navigation behavior as usual. Like ESM, the application activated a questionnaire according to a random schedule with a time interval from five to seven minutes. After three loops, subjects could press a button to quit their participation and send the data to researchers through the Internet automatically. A total of 201 loops (n = 201) were collected for this study.

The questionnaire asked about subjects' inner experiences with both open-ended items (e.g., What make you feel challenged?) as well as numerical scales (11-point Likert scales) that indicate the intensity of these dimensions (Where would you place yourself on the following scale for the Web page you were just looking at?). This allowed us to capture users' perceptions at given moments in a situated context of one or more Web pages. The data collected from several loops during users' Web navigation help us understand users' perceived and subjective experiences during their navigation process.

For each loop, we asked the following questions:

1. What is your purpose on the Web right now?
2. Do you know exactly where to go next to get what you want? And what makes you feel this?
3. Were you paying complete attention to the Web page you just visited? What makes you feel this?
4. How would you describe your feeling about time passing? Too slow, O.K. or too fast?
5. How would you describe your orientation to the web page you were just looking at? Interest, fun or curiosity? What make you say this?
6. Do you feel challenged by the Web page you were just looking at? What make you feel this?
7. Do you feel you have adequate skills to deal with the Web pages you were just looking at? What make you feel this?
8. How do you feel (from the Web page you just visited) about the possibility to communicate with the designer of that Web page? What make you feel this?

5. Discussion

This was an exploratory study employing the auto-ask ESM to users in the Web environment. We will summarize our preliminary findings and then we discuss what we have learned from this study.

The data we collected by employing the auto-ask ESM tool to the Web environment is very rich and we can only present very limited results here due to the size limitations. We found out there is a higher proportion of Web surfers than we had expected and their navigation activity usually is not goal directed. In addition, their goals change frequently during their surfing, and sometimes users abandon their original goals and become pure surfers. Since the Web pages provides a very friendly user interface, some subjects reported that they have become lost because Web pages either do not provide clues telling users where they are and where they can go, or the Web pages simply had organization problems. However, most of our subjects believed the Web pages they just visited offered an effective communication channel between Web master and themselves.

In our study, we also try to elicit subjects' internal experiences. For example, most subjects reported that their attentions were focused on the Web itself and extraneous thoughts were screened out completely. Some even reported that time passed faster than they thought in part due to their attentions being focused on the Web. Many subjects reported high levels of enjoyment, fun and interest. However, when subjects were not able to find what they wanted, they began to feel high levels of challenge from the navigation itself. When their confidence levels were high, subjects reported high attention and high enjoyment in their responses.

As discussed above, the auto-ask ESM application allowed us to elicit Web users' experiences at given moments. By popping up a questionnaire window on top of a subject's Web browser, we forced our subjects to stop their navigation behavior and answer the questions regarding their experiences. In general, we think the
auto-ask ESM is applicable to the Web environment. By eliciting subjects' situational contexts and their experiences, we were able to reconstruct subjects' internal and external experiences during their interaction with the Web. By not relying on subjects' recall or the constant intrusion of talk aloud protocols, we believe our data revealed relatively accurate descriptions of users' experiences. By interrupting subjects' navigation behavior both physically and cognitively, we were able to capture subjects' fresh, situated memory at given moments.

However, there are some negative aspects of using this approach. First, some subjects complained that the questionnaire popping up was very annoying and too intrusive. Even though our application had been programmed to minimize the possible intrusion, some subjects felt uncomfortable when they had to stop Web surfing to answer the questionnaire. Second, we also received some negative feedback about the length of questionnaire and the time they needed to spend on answering questions. Third, from a pilot test before this exploratory study, we found out that in general Web users do not have enough patience to read a long explanatory text. This may be due to the impulsive nature of the current Web environment, e.g., intensive interactivity and distributed hyperlinks, which force users to proceed and not to stay at a given spot too long. Thus, we shortened our questions to short sentences. This may have reduced the reliability of the study.

As with other observational tools, the ESM, as well as our auto-ask ESM version of it, has its limitations and is definitely not a panacea. First, it is not conducive to random sampling of respondents. Usually, it is limited to the convenience samples because you need to access to the sample physically before the study can be started. Second, the study usually is restricted to a specific geographical area because the signaling equipment must be physically installed for subjects although our auto-ask version can be deployed over the Web itself. Third, the signaling equipment is considered too instructive to subjects. Fourth, ESM is a good tool for studying some day-to-day experiences and not an appropriate tool for a specific activity with an ephemeral occurrence.

In this paper, we argued that there is a need to explore human beings' external experiences as well as internal experiences in the information age. By employing more traditional research tools which depend solely upon subjects' recall, talk aloud protocols, etc. we believe the essence of subjects' inner experiences is difficult if not impossible to reveal thoroughly. Studying Web users' navigation behavior and surfing experience, we need a better approach which can help us understand users' feelings and thoughts. Therefore, we propose that the ESM can be a more appropriate tool in the Web environment. The exploratory study we described in this paper provides important evidences that the ESM is useful and promising for exploring Web users' perceptions. We would like to take what we have learned at this stage to refine our approach and our auto-ask ESM tool in order to conduct more systematic research in Web environment.

Abstract: Social interaction is an integral part of collaborative learning. In this paper, we introduce StarWalker — a unique 3-dimensional virtual environment for social interaction. Our design explores the notion of discourse-context mutual coupling in order to characterise social interaction in semantically organised virtual environments. Our aim is to support social interaction for collaborative learning.

1. Discourse-Context Coupling

Social interaction is an integral part of collaborative learning. In this paper, we describe our ongoing research in the development of an innovative three-dimensional multiuser virtual environment called StarWalker to facilitate focused and domain-specific social interaction. StarWalker is accessible on the WWW. The notion of discourse-context mutual coupling is a key concept in our design. It highlights the role of a virtual environment as a medium in which discourse is mediated. The design of StarWalker explores the notion of discourse-context mutual coupling in order to characterise focused and domain-specific social interaction in semantically organised virtual environments. Our principal design rationale is that the visualised structure of a subject domain will provide a natural and stimulating context for collaborative learning.

People from distributed places can visit and share the virtual world. They may engage in some in-depth and scholarly conversations with peers on specific topics in the given subject domain. Currently, StarWalker is structured according to a salient semantic structure derived from papers that appeared in the recent three years ACM SIGCHI's conference proceedings. StarWalker enables concurrent visitors to chat with one another. StarWalker is originated from our work in information visualisation and visual information retrieval, namely the Generalised Similarity Analysis (GSA) framework [Chen, 1998a; Chen 1998b]. The StarWalker virtual environment is expected to provide a means of exploring some fundamental aspects of collaborative learning, such as social construction of knowledge, situated cognition, and a mutual coupling between learners' activities and their meaningful context.

2. Structures of Social Action

As in the real world, social interaction in virtual worlds is influenced by many factors. People's behaviour is often associated with their social, cultural, and historical backgrounds. Subject matters, the medium of communication, and environmental characteristics influence the way people communicate. There are a large number of signals that people can pick up from the immediate environment and organise their course of action accordingly. These cues of a context are known as contextualisation cues [Gumperz 1982]. Social experiences have been studied in terms of frames [Goffman 1974].

We are interested in the mutual coupling between these contextualisation cues and the structure of discourse, and how the design of a virtual environment can take advantage of such mutual connections so as to provide a stimulating environment for collaborative learning. Works in the social construction of knowledge, situated cognition, and the activity theory have all emphasised the mutual connection between social actions and a meaningful context. A grasp of the characteristics of the context is necessary for people to understand and make sense of behaviour and actions of others.

1 http://www.brunel.ac.uk/~cssrccc2/vrm12/starwalker/
Dourish and Chalmers have classified information navigation into three distinct types: spatial navigation, semantic navigation, and social navigation [Dourish & Chalmers 1994]. For example, the social navigation may include information seeking by following the clustering of like-minded individuals in a spatial framework. However, the link between the discourse and context in virtual environments is yet to be fully understood.

Our ongoing work aims to explore the possibility of combining social clustering and semantic clustering within the same environment so that the connected clustering process will reinforce each other and lead to high-quality and focused conversation regarding a specific subject domain. We are starting to observe and analyse the structure of discourse taking place in StarWalker and to study empirical evidence that the structure of discourse is in fact shaped by the visualised semantic structure in the background.

In our work, a semantic space is visualised and rendered in Virtual Reality Modelling Language (VRML). The semantic space is constructed based on a galaxy model. The semantic space is embedded into a 3-dimensional multi-user virtual environment. Users are able to share the visualised domain structure, to communicate and engage in social activities within the virtual environment. The affordances of the virtual world are partially reflected in its name — StarWalker.

3. Ongoing Work and the Future

We expect that the knowledge structures of concurrent users may converge over a period of extensive use of the virtual environment, and that their discourse structures will be strongly influenced by the knowledge structure visualised in the background.

The significance of our approach lies in the tighter coupling between the spatial model of the underlying semantic structure and discourses associated with the virtual environment. Users' navigational behaviour within the spatial framework becomes relevant to the content and the knowledge structure of an underlying information space.

As a result, navigation patterns of a user become meaningful and interpretable with reference to the spatial-semantic relationships. Not only can a visitor make sense of what is happening in a populated virtual environment, but extract contextual and situational cues from others' behaviour and thereby adapt their search and navigation strategies accordingly.

Finally, the significance of the work is due to its unique and profound paradigm of supporting social interactions on the top of a variety of interaction metaphors and enabling techniques, namely information visualisation, information retrieval, virtual reality, and multi-user chat rooms.

Abstract: The University of Houston System is working with Anlon Systems Inc. to provide its four campuses with one hundred instructors’ accounts to automate the instructional and administrative process for professors. In July, Anlon provided a two-day workshop for about one hundred faculty and staff members from all four U of H campuses who wanted to put instructional materials onto the World Wide Web. During the Q&A session, the instructors expressed the extra features that they would like IntraKal to have. Although these recommendations were made based on the current version of IntraKal, and these improvements may not be technically feasible with today’s technology, yet they can well be the features the general school teachers have dreamed of for an ideal Web-based test system. As observers of the collaborative discussion, we have collected a list of their wishes.

Introduction

The University of Houston System is Texas' largest metropolitan university. It is composed of four major campuses, including University Park, Downtown, Clear Lake, and Victoria. Information technology requirements and capabilities vary widely. Some of the faculty has access to the cutting edge resources of electronic classrooms, while others have only passing acquaintance with computer word processors and e-mail. The World Wide Web is fast becoming a technological equalizer between these two extremes. Web-based education is made easier on the four campuses thanks to a pervasive network infrastructure and a well-developed IntraKal Web-based course system (http://www.courses.uh.edu). Faculty and staff may create Web pages for themselves, their courses, their research field, or their departments on the system.

IntraKal is a commercially available academic Intranet package developed by Anlon Systems Inc. (http://www.anlon.com) for colleges and universities. Anlon is working with the U of H system to provide its four campuses with one hundred instructors’ accounts to automate the instructional and administrative process for professors and students and increase access to higher education. The package, written in Perl and Javascript, is currently housed at the University Park campus on a Windows NT server with 256 MEG of RAM and 6GIG of hard drive. Each professor is allotted a minimum of 10 MEG of hard disk space.

In early July, Anlon provided a two-day workshop for nearly one hundred faculty and staff members from all four U of H campuses who wanted to place instructional materials onto the World Wide Web. In the workshop, the Anlon representative demonstrated these features that already implemented in IntraKal:

- Online Testing
- Post-test Analysis
- Course Bulletin Board & Chatroom
- Course Material Publishing
- Academic Honest Checking
- Online Calendaring
- E-mail and WWW Connectivity
The demonstration was followed by a Question and Answer session, allowing the software company representative and users to communicate and interact. During the Q&A session, the instructors expressed opinions about the extra features that they would like IntraKal to provide. Shortly after, the dialog shifted gear focusing on the Web-based testing feature. The attending faculty vigorously joined in on the brainstorming of what improvement they wanted to see for the IntraKal Web-based testing feature. The Anlon representative dutifully took note of their suggestions, promising to relay the information to the Anlon technical staff. Since Web-based test became the focus of the discussion, the following paper will concentrate on comments and suggestions by the professors and staff for Web-based testing.

People may jokingly say that it is almost impossible for one hundred professors to agree on any specific topic. However, by eagerly participating in the Q&A session, they are endorsing the potential of Web-based test system in the classroom, at least in a higher education environment. Therefore, it was an interesting experience to watch these faculty and staff members contribute on what they wanted out of a Web-based test system. As observers of the collaborative discussion, we have we have collected a list of their wishes.

The Wish List

Support Issues

- Print-based manual, online help, and a 7x24 800 technical support line should be provided.
- Minimum system configurations need to be published online and on documents.
- The system must be accessible to most Internet browsers.
- The Web-based testing system must be accessible at standard Internet connection.
- Instructors need to be able to export their entire courses from the Web.
- The Web-based test should provide documents on how to extract administrative student data and import it.
- The import module for Scantron scoring should be implemented in the Web-based test.

Scoring Issues

- On the electronic answer sheets, the instructor should be able to list keywords in the answers and can enter model response for automatic scoring.
- The instructor should be able to make comments at the beginning, middle, or the end of the student’s answers.
- The instructor should be able to leave some questions ungraded or unscored.
- The Web-test should be able to show scores individually and the class as a whole.
- The questions should be able to carry different weights.
- The electronic grade book should provide automatic score analysis features such as standard deviation, class average, etc.
- The electronic grade book should be able to curve scores based on the performance of the whole class. For example, A’s for the top 10%, B’s for the top 20%, etc.
- The instructor should be able to grade a certain essay question for the whole class all at once so that the scores given will be fair.
- For the electronic grade book, the instructor should be able to assign a grade not taken through the Web-test system.
- The electronic grade book should provide the flexibility of assigning negative scores to accommodate situations such as mandatory attendance.
- The Web-based test system should be able to prepare a list of students who gave the second best answers to a question. These students can then be given partial credits.
• The instructor should be able to import/export the grade book from the Web-based test system to their PCs and vice versa.

Test Creation

• The e-mails sent out to the student’s after the test should be able to include test questions, the students’ answers, model responses, and instructors’ comments, etc.
• The instructor should be able to randomize the test questions, including each individual question and different question banks.
• The instructor should be able to copy questions from the test banks provided by textbook publishers and paste over to the Web-based test template.

Test Management

• Adding students to the system should be easily accomplished.
• Teaching Assistants should be granted limited access to instructors’ accounts.
• In the test report, the IP addresses of where the student have taken the Web-test should be listed. If the test is supposed to be taken in the computer lab, any IP address other than the lab addresses should be able to be identified.
• The time spent on the test should be able to be logged. Instructor should receive an e-mail about when each individual question has been answered to see whether the student has spent too much time on a test or a specific question. The instructor can then fairly deduct scores.
• Receipt confirmation messages should be able to be displayed on computer screen and be sent through e-mails to the student after submitting responses.
• If the student attempts to go to another site while taking the test, the Web-test system should be able to block the student out. The block should be released only when the student has obtained the special security reentry password from the instructor with approval.
• The Web-based test should provide side-by-side comparison of students’ answers for academic honesty.
• Instructors should be able to terminate student accounts at a predetermined time.

Security Issues

• The Web-based test should provide virus checker to check the answers provided by the students through document attachment.
• The system should zip attachment so that it is not susceptible to virus attack.

Summary

Although these suggestions were made based on the current version of IntraKal, some of them are probably the same as what the general classroom teachers have dreamed of as an ideal Web-based test system. Some of the items on the wish list, especially the ways the faculty have envisioned for creating tests, and the ways they wanted the test to behave, may not be technically feasible with today’s technology. However, in a way, by participating in this activity, the involved members are acknowledging the potential of Web-based test system.
Website News: A Website Tracking and Visualization Service

Yih-Farn Robin Chen
Eleftherios Koutsofios

AT&T Labs – Research
Florham Park, NJ 07932
{chen, ek}@research.att.com

Website News is a website tracking service. Currently, we track about 20 Internet and telecom companies on a daily basis. A spider wakes up at about 2am every morning to visit these web sites, analyze their html pages, and store the analysis information in a database. A difference database is then created for each website to store the differences between today's version and the last archived version. Another spider collects new links from these difference databases and then prints newspapers for the telecom and Internet industries on a daily basis. Users can also query these databases through a web interface and view the results in HTML or graph views. For more information about Website News and to experiment with the service, visit http://www.research.att.com/~chen/web-demo.
A Survey On Online Education

Abstract: A survey has been conducted to investigate the current state of online education. About 1,500 websites of 8 different groups were randomly chosen from the Internet for study. It is interesting that the survey result shows that virtual universities, although contribute to a very small portion of the sample data, perform better in many aspects as compared to other groups. In general, the result also indicates that the technology is mature enough for online education and it is the appropriate time for universities to consider offering such courses, but to remain competitive, more need to be done.

1. Introduction

The growth of Internet has been tremendously fast. The use of World Wide Web (WWW) and multimedia technologies on teaching has a great impact on the mode of education [Neilson et al. 1996]. The traditional class room teaching is supplemented by online lecture notes, multimedia animations, and computer simulations [Kann et al. 1997]. More importantly, a new mode of education has evolved which is known as Online Education. Roughly speaking, by online education, we mean that the learning material is present on the network and the learner can log on the network at any time to retrieve the material for studying without the presence of the instructor. This mode of education has changed or enhanced the way distance learning courses [Peraya 1994] are delivered. At present, there are already more than 30 virtual universities around the world which offer online courses through this mode of education and the number of distance learning courses is expected to increase rapidly [Lewis et al. 1997]. Breaking the barriers of distance and time, online education will become a major mode of education in the future.

The most common way to achieve online education is to make use of WWW. In order to find out the current state of online education, a survey has been conducted on about 1,500 websites which are related to education. Due to the limitation of space, the paper will only give an overview of what has been done. Interested readers, please refer to http://www.cis.hkuspace.org/~olea for a complete set of survey statistics.

2. Sample Data Distribution

About 1,500 sites have been visited. Among these sites, more than a half are universities. Others include online courses provided by individuals and software development organizations (See [Fig. 1] for the distribution). In [Fig. 1], “Univ. (N)” are universities which do not offer online course while “Univ. (O)” are those universities which offer online courses. “Org. (O)” are organisations which provide online courses. “Org. (SW)” are organisations which develop software for online education but do not offer online courses, while “Org. (SWO)” are those organisations which develop software for online education and also offer online courses. The category “Others” refers to the web-sites which are related to online
education but do not belong to any of the other categories, for example, sites providing forums and discussions for online education.

Figure 1: Sample Data Distribution

3. Criteria for Comparisons

In the survey, the sites are evaluated based on some aspects such as overall design, technologies used, and the response speed. Refer to http://www.hkuspace.org/~olea for the set of criteria used in the comparisons.

4. Survey Result and Conclusion

From the survey result, universities which provide online courses show a quite normal distribution with most of them perform moderately in almost all aspects, while virtual universities outperform other universities in some aspects. One reason may be that offering online courses is not the main stream in normal universities. Resources and support may be limited. In other words, if a university wants to offer online courses, and remain competitive, more should be done.

Correlation between different aspects is also investigated in the study. There are some interesting results. For example, both groups of normal universities show a stronger correlation between the overall design and the technology usage than the group of virtual universities. One possible reason may be that in normal universities, website designers are usually technical persons. It is likely that they will try to use more advanced technologies. While this is not the case in virtual universities. However, the exact reasons need further investigation. It is also the appropriate time to investigate other related issues of online education such as the social implication of the online education, the change in roles of the instructors, the cost and resources requirements of running an online course, the alternative way for online education, for example interactive TV. Please refer to http://www.hkuspace.org/~olea for more details about the survey.

Abstract: The hot topic in security circles these days is Marcus Ranum's Network Flight Recorder,[1] which is normally thought of as a tool to track attempted break-ins. The NFR software is designed to sit on a separate computer from your server and analyze network traffic. Like a flight recorder, NFR survives even if your system doesn't. It can recover or monitor online transaction records, keep historical statistics about how the network grows, and generate detailed breakdowns of how your network services are being used and by whom.

The great strength of NFR lies in its configurability. You can choose to track only HTTP packets, and then you have a tool for validating HTTP log consistency. Because NFR is not connected with your Web server, issues with virtual hosts are easily tracked, and you are not filling up space on your Web server or using valuable CPU cycles for log analysis. Tracking unique IP addresses is more important in Web usage analysis than hit count, and NFR is ideally suited for this. Once you have reached an understanding of potential problems in HTTP serving, it can also serve as a tool for heading off those problems before they cause user complaints.

Sniffers and Security - the design intent behind NFR

The Internet is based on TCP/IP, which is a packet switching protocol. This means that all data to or from computers on a shared local network go across the same wire, taking turns. Each packet is labeled with a header telling which computer sent the packet and which computer should receive the packet.

Fig. 1 Data Packet

<table>
<thead>
<tr>
<th>Header</th>
<th>Data</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

A packet has a header with address information followed by the data.

Each computer on a network has a unique address, and the packet switching system permits multiple pairs of computers to communicate across a shared network by dividing each conversation into small packets and arranging for computers to take turns sending packets. Normal IP stacks ignore packets that are not for their address. [2] A network sniffer is a device, hardware or software, that is attached to your network in promiscuous mode, meaning that it keeps track of all the packets going by on the network, not just those with headers saying that they are for it.
Sniffers were developed to track network problems, and are good for that, but for a long time, network "sniffers" weren't exceptionally helpful to people working with Web servers. You could certainly use tools such as Network General Sniffer or a Unix box running snoop to dump the network data coming along your interface into a file. If you had a good deal of knowledge about how TCP/IP worked, you could stare at data after the fact and make some general determinations about your network. But until recently, it's been very difficult to apply sniffer data toward a particular network protocol, like HTTP or SSL, in any meaningful way. The tools just weren't there, or were prohibitively expensive and complex.

Enter Network Flight Recorder (NFR) and other intrusion detection systems:
The NFR uses a promiscuous packet interface to pass visible traffic into an internally meta-programmed decision engine which routes information about packets and their contents into statistical or logging backends. In addition to packet analysis and collection, the NFR's internal architecture permits network managers to sample interesting portions of network traffic for logging or statistical analysis. The NFR programming language is simple, but powerful enough that you can perform reasonable analysis on traffic before choosing to record it. For example, you might analyze SMTP transactions but only choose to record those relating to a user who is sending spam or abusive E-mail. The analysis language includes a capability for generating alert messages which the rest of the system queues, multiplexes, and delivers. A simplified hypertext interface allows extensive browsing of the NFR's stored datasets and statistics from any Java-enabled browser. [4] 

Network Flight Recorder fills an important void in the security tool arena. It is a general purpose network traffic recorder. It is perfect for sites that need to verify their security measures. NFR has a meta-programmed decision engine that is extremely flexible. The NFR N-code language is designed to deal with streams of network traffic, with data types like "source IP address" and "url" along with more general purpose programmatic functions. The NFR inserts your N-code into a high performance filtering engine. For example, one of the simple programs included with NFR is "Watch what clients send to web servers". The user can get different reports by simply filling out an on-screen form, or perform more advanced reporting by changing the N-code. The N-code implementation is shown below.

Figure 4: filter N-code for showing Web client requests

#
# This filter serves two purposes: to record client requests
# made to your web servers, and to serve as example in the LISA paper.
#
watchservers_schema = library_schema:new { 1,
[ "time", "int", "ip", "ip", "str" ], scope() };

# list of web servers to watch. List IP address of servers or a netmask
# that matches all. Use 0.0.0.0:0.0.0.0 to match any server
my_web_servers = [ 0.0.0.0:0.0.0.0 ];

# gather data the client sends to a web server. This will only see
# web servers on port 80. If I had web servers on other ports,
# I would make this more elaborate. (coming soon?)
filter watch tcp ( client, dport: 80 )
{
    if (! ( tcp.connDst inside my_web_servers ) )
        return;
    declare $blob inside tcp.connSym;
    if ($blob == null)
        $blob = tcp.blob;
    else
        $blob = cat ( $blob, tcp.blob );
    while (1 == 1)
    {
        $x = index( $blob, "\n" );
        if ($x < 0) # break loop if no complete line yet
            break;
        $t = substr($blob,$x+1,1); # look for \r at end of line
        if ($t == \"\r\")
            $t = substr($blob,0,$x+1); # tear off line
        else
            $t = substr($blob,0,$x);

```
# save the time, the connection hash, the client, 
# the server, and the command to a list
record system.time, tcp.connHash, tcp.connSrc, tcp.connDst, 
$t to watchservers_list;

# keep the remainder of the blob for the next pass
$blob = substr($blob, $x + 1);

# keep us from getting flooded if there is no newline in the data
if (strlen($blob) > 4096)
$blob = "";

# save the blob for next pass

watchservers_list = recorder("/bin/list packages/web/watchservers.cfg", 
"watchservers_schema");

NFR is free for noncommercial and research use. It can be installed[5] on an Intel-based server running Linux or BSD, or a Sun server running Solaris. In addition, NFR, Inc. promises to keep the source code freely available. It is a great addition to the security administrator's toolkit.

In their efforts to create tools to do post-mortem analysis of hacker attacks, the authors of NFR have also created better tools for network monitoring that have some intelligence about the protocols they monitor, are more programmable, and have nice visual interfaces to help show you data that's important to you. The marriage of this emerging technology to the Web can lead to new tools to qualify and quantify Web behavior.

The Web Connection

I. HTTP log integrity: If you want to make sure that the logging mechanisms for your particular httpd are correct, or that you're seeing particular behavior, or if you're an ISP that bills by number of hits, it'd be convenient to have additional logging mechanisms to insure the integrity of your data.

Typical log analysis tools like Analog [6] allow you to make the common log format into something easier to read, but can only track what an HTTP server can log.

Figure 5: Typical HTTP access_log

199.221.88.74 - - [22/Mar/1998:22:12:50 -0500] "GET /stilyagi/about.html HTTP/1.0" 200 16499

Using tools like NFR, it is possible to do much more. For example, you can look at all traffic on your network on the basis of port number (for instance, port 80, the default for HTTP), list all web servers on your network (by scanning all TCP traffic for HTTP headers), and look at all HTTP requests going across your network on port 80. These functions can be combined to show all web traffic on any port. Any sniffer could give you this data, but NFR combines ease of use with a variety of output formats, including useful graphics such as bar charts, histograms, etc.

At this point, it may be worth mentioning that cookies are readily viewed by NFR or any other sniffer. Personal data is often stored in a cookie for the purpose of personalizing a page, listing a stock portfolio, or saving login and password information. Even if the cookie is encrypted, it may be vulnerable to electronic privacy invasion.[7] To check for a privacy invasion, you could log what goes into httpd as well as what comes out of httpd and compare.

II. Logging ephemeral data that might not otherwise be logged: Most Web traffic is so short that it fits in the TCP/IP socket buffer. This makes it very difficult to determine if even the small answers to Web server requests actually made it to the other end. You could make the TCP/IP send buffer smaller, but then your Web server has to do more work. Answer: use an NFR to see what kind of bandwidth your WWW server really takes.
Fig. 10 Where NFR Tracks Data

Whereas the WWW log tracks information between httpd and the kernel, NFR tracks information between the Web server and the client.

With NFR, you can visualize data that isn't going to be obvious with some of the WWW logs. You can see how much of that 1.5GB JPEG the user with the 14.4k modem really downloaded before getting impatient and canceling the download. You can see 'dropped' connections. You can look for retransmits. In general, you can see what kind of bandwidth your WWW server is really using, data which won't be obvious by just counting transactions within the httpd logs.

III. Finding Web servers on your local network on ports other than 80: Many people run Web servers on ports other than port 80 for a variety of reasons. They don't have root on their Unix box and can't run on ports greater than 1024, they want to hide a massive archive of pictures or an old, insecure web server running CGIs. You might be interested in recording who's running a Web server on your network, but may not want to set off alarms and waste cycles by beating every TCP/IP port on every machine with SATAN or an old, and hoping that the banner the Web server uses identifies itself as a Web server. How can you tell if a given service is actually a WWW server? Use a NFR which looks for real HTTP traffic.

</tbody>
</table>
You may simply want to log a list of version strings of Web servers used on your network to inform the machine owners of when new httpds come out to fix holes (www.trouble.org).

IV. Finding out what your Web client sends: Some people are still surprised that the Web browser emits things like what kind of browser you use, HTTP_REFERER by default. You may want to know if your so-called "encrypted session" really is sending out credit card numbers -- for that matter, you may want to know if you have users who are inadvertently emitting credit card info using an unsecured WWW channel. NFR and similar programs can help you find out that information.

V. Doing the analysis on a separate box: HTTP logs can become unmanageably huge very quickly; a common problem in log analysis is simply getting the logs off of the server onto another box which has to spend more time running the analysis than it takes to build up another huge set of logs. Because NFR is not running on your Web server, this problem is easier to manage. It is extremely easy to tell NFR to track all HTTP accesses (that is, accesses on port 80) for a particular machine, or an entire network, and graph it as you like.

Figure 12: NFR graph of Web traffic from a single server
VI. Tracking problems with your Web server: When users are constantly canceling a page during loading, because they are frustrated with the wait, the Web server administrator should take some action - but it is relatively difficult to determine when that is happening, and really unusual to do that kind of tracking with current tools. This leads to some really interesting ideas... the author of NFR read an earlier version of this paper and suggested tracking packet timing issues and actually using NFR to find out what bandwidth your users have, and the latency of the connection. Determining user bandwidth is something of a "holy grail" in Web circles, because with that information (which is often impossible to determine without asking the user directly) you can decide what size graphics are appropriate, and whether to use graphics and Java at all! When a robot is out there causing problems by inefficient or inappropriate searches, or something has hung on your network, you would want to know this, and NFR can be a tool to make you aware before the user complaints start coming in.

VII. Network attacks: Of course, it doesn't hurt to use NFR technologies for their intended purpose. There may be malicious folks trying all sorts of network-level attacks on your WWW server, or people trying to send bogus information to CGI scripts, just waiting to exploit some bug or another than compromises your system.

Conclusions

In actuality, the best part about the technologies that are emerging is that they're flexible and extendable, and have good visual tools so you can take that sniffer data and put it in a WWW page fairly easily. The whole purpose behind this paper isn't so much about specific applications for modern sniffers as much as raising awareness of their existence, that they are free to the academic community, and have the potential to be a great research tool.

[5] The installation of NFR is not difficult, if the system administrator performing the install has a good understanding of IP, MAC addresses, and web server configuration on your system. See the NFR Mailing List Archives for help with the install, at http://www.nfr.net/nfr/mail-archive/. Using NFR does not require a technical background, once it is installed.
[8] There are many such archives on the Net, from http://abc.com:1234/ to http://xyz.edu:6789/. If you find one which is particularly interesting, please email the authors.
Abstract: The Internet has great potential for educational purposes. In 1997, the Software Engineering Laboratory at PUC-Rio implemented a first version of AulaNet™, a web-based educational environment. This year, some of the teaching staff will be using this environment to offer regular term disciplines through the Web. This paper introduces Quest, a tool for quiz generation and automatic correction incorporated into AulaNet™. Its purpose is to support the educational assessment process through the Web and to grab the results of this process.

Introduction

With the fast emerging of the Internet, the Web has become an increasingly interactive and dynamic medium for sharing information. The Web provides an opportunity to develop new learning experiences for the students not possible previously [Alexander, 1995]. It has been increasingly popular to move away from the traditional model of education and move towards a more interactive, computerized system [Carbone and Schendzielorz, 1997].

AulaNet™ is a project in development at the Software Engineering Laboratory (LES) to deploy an environment for the creation and maintenance of Web-based courses designed for the layman. The objectives of AulaNet™ are to adopt the Web as an educational environment; to foster a workable transition from conventional classrooms to virtual classrooms, giving the opportunity to reuse the existing educational material; and to create knowledge communities [Lucena et. al., 1997].

Quest is a quiz generator and assessment tool incorporated into the core package of facilities provided by AulaNet™. It would be desirable for an interactive Web-based learning environment to have a Web-based way of assessing the students, instead of using a paper-based assessment.

Assessment

Assessment is defined as a direct measure of what has been learned as a result of instruction on particular subjects [Gagne et. al., 1988]. Assessment for distance learning has not yet been thoroughly researched [Dirks, 1997]. Some of the principles of the common paper-based assessment made in the conventional classrooms do not apply in distance assessment, such as reporting feedback and security.

However, the Internet shall be used to create environments that facilitate an active and customized process of learning, supporting cooperation. In such a cooperative environment, assessment may not only involve measuring the students' ability to remember and repeat ideas, but should also make people think about problem situations and new solutions to them [Cox and Clark, 1996]. The strategy of Quest is to provide a simple multiple choice-like assessment tool that can be used not only to test the students but also to enhance the learning process.

In structuring a quiz it is important to work with a theoretical framework of learning. There are several learning objective taxonomies as can be seen in [Imrie, 1995], [Gagne, 1982]. Bloom's Taxonomy of Cognitive
Levels [Bloom, 1956] divides students' abilities into six different levels, which are: knowledge, comprehension, application, analysis, synthesis and evaluation. Using Bloom's taxonomy, a teacher can make a deeper evaluation on the students' performance, instead of only checking their grades.

Description of Quest

The main goal of Quest is to serve as the Web-based assessment tool of the AulaNet™ learning environment. Its other goals include:

1. Lowering quiz costs: the process of creating, correcting and reporting student results in a paper-based system, of a large number of students, is very time consuming [Tinoco et. al., 1996]. This whole process requires time, money and staff that must be handled and administrated.
2. Making extensive reporting: Quest records all the information about the answers given by the students to make a comprehensive report of results for the teacher.
3. Giving feedback to students: instead of recording the results just for the teacher, Quest gives automatic feedback to the students, so they can have all the information about their performance on the fly, instead of asking the teacher.
4. Enhancing the cognitive aspects of assessment: while editing a question, the teacher tells which cognitive domain (from the six outlined by Bloom) he wants to assess. Thus, writing an evaluation must be planned, enriching its educational value.

There are other assessment tools available, such as QUIZIT [Tinoco et. al., 1996], CADAL Quiz [Carbone and Schendzielorz, 1997] and QuizSite [University of Indiana, 1996]. However, they do not provide a graphical interface for question editing. These systems require that the teacher learn some tag language to create a quiz. Quest provides a graphical interface to make editing questions easier, without demanding any kind of computer knowledge being necessary. Other features of the tool include:

a. Three question presentation styles: Quest is a multiple choice-like assessment tool, but provides three question presentation styles for question editing: multiple choice (with up to five answer choices), true/false and fill in. Later, it may offer matching and listing.

b. Editing Facilities: the tool offers quiz editing facilities such as moving the position of the questions, removing questions and insert questions between existing ones. This is done automatically due to the graphical interface (non-textual) provided by Quest. Quest provides an easy way to reedit created quizzes, with a "save as" option, for the teacher not to loose the original one.

c. Question qualifiers: while editing a question, the teacher should give it some qualifiers, for example, the topic of the instructional material it will cover, the cognitive domain level it will test and its value. These qualifiers will be useful when displaying the statistics generated by the automatic correction of the quiz, giving richness to these statistics.

d. Automatic correction: the process of quiz correction is done automatically by the tool. The teacher only needs to specify the correct answers at the time of editing; thus, giving him more time to interact with the students. The correction mechanism stores all the data needed to make the statistical results provided to the teacher and the performance information handled just in time to the students.

e. Results displayed to students: since Quest is a self-assessment tool, it is fair the students need not be dependent on the teacher to send them an e-mail to know about their performance. Carbone and Schendzielorz [1997] argue that this would increase cheating. Yet, as self-evaluation serves to indicate to students, and not to the teacher, if they are doing well in the learning process, it is important to the students to have a feedback. Thus, when a student cheats, he is aware that he is just trapping himself.

f. Storage of results for the student: usually, the results of an assessment are stored for the teacher, so he can have a way of bringing back at any moment the information about any quiz on the course. Quest also stores the information to be displayed at any time to the students. This information includes: grade; total quiz points;
number of questions in the quiz; number of questions the students answered correctly; number of questions answered incorrectly; time elapsed during the quiz resolution; the topics enclosed in the questions of the quiz; the topics of the questions the students answered incorrectly and an option for the students to revise the quiz, comparing the right answers with those they gave. This last feature was included in the tool to provide a source of help material for further studying, as these results are formatted to show the problems the learners faced.

g. **Detailed statistics for the teacher:** the teacher can have plenty of information derived from the correction of a quiz. The main idea behind the statistics provided to the teacher is that he must have a way of seeing the students' learning development, to trace where they are facing difficulties and to compare the performances of the group as a whole, not, one by one, individually. These statistics include:

- **List of grades:** this list serves to see the grades of each student with an option to revise the answers given by all the students. This is the way it is done in the conventional classroom.
- **Statistics based on topics:** a result displayed as a list of topics gives the teacher a way to know the points of the instructional material the students are having problems with. The topics are atomic instances of the course, and interpreting these statistics can be useful to see if the material delivered by the course fits the needs and objectives of the students and those of the course itself.
- **Statistics based on cognitive domain:** these statistics show if the students are constructing their knowledge correctly. It exposes the cognitive abilities in which the students show more difficulty. After this verification, the teacher can reshape the contents of the course to solve these problems, really helping the students to: remember an idea; understand it; put it into practice; verify its component parts; use it to build another idea and evaluate its usage.
- **Statistics per question:** statistics showing the troubles the students had in solving each of the questions in the quiz. This can be used to see the average difficulty of the questions, and like a cross-reference of the two previous statistics it will show whether the students had problems in understanding a topic, or applying it or evaluating the usage of another one, for example.
- **Standard scores:** standard scores involve calculating average scores and information about how much these vary from high to low—the standard deviation. Average scores should be concluded with their standard deviation, and listing of the highest and lowest scores possible as well as the highest and the lowest scores actually received. It would end with a sentence like this: "There were 35 students who took the quiz. The possible scores ranged from 0 to 100, with the students actually scoring from 32 to 95 (average score: 72, standard deviation: 6.1)."

**Architecture and Implementation Issues**

The architecture of Quest is based on the Web, where its entire interface is developed, using CGI programs to provide all its functionality. The figure below shows the tool's architecture.

The architecture has a presentation layer, which is the user interface. It is basically composed of HTML templates that help the teacher to create, edit and maintain all the quizzes. There are also some tips to help the teacher during the process. For example, if a teacher wants to create an analysis question, the tool offers him a list of verbs that are commonly used to write analysis questions. Another task of the presentation layer is to make input validation, i.e., verify if the teacher did not leave a field in blank, if he miswrote a date, etc. This feature makes Quest a distributed tool, with part of the processing resident in the client machine, due to JavaScript code.

The application layer is responsible for all the functionality provided by the tool. It is composed of CGI programs written in CGILua [Hester et al., 1997]. It uses Lua objects [Ierusalimschy et al., 1996] to perform the handling of questions, the generation and display of quizzes, automatic correction and the feedback statistics of the results for both students and teachers.

The Lua objects layer offers all the functionality needed to allow for the exchange of data between the CGI programs within the application layer and the data layer. It accesses the tool's database engine and also allows for the writing and maintenance of the HTML quiz files.
The data layer is composed of two databases and a file directory. The first database is a Microsoft Access database used to store the data related to questions and quizzes. The Lua objects of Quest only access this database. The second database refers to the data of the course maintenance environment, which describes the courses and the students who will use the tool. The file directory contains all the HTML files of the quizzes generated.

**Example of Usage**

The AulaNet™ environment has two distinct modules: the course creation and maintenance module, for the teachers and the course attendance module for the students. In the course creation and maintenance module, the teacher can configure his course to have the service Exam. Since a teacher configured his course to have this service, he will be able to create quizzes using Quest.
The main screen of Quest is divided in two parts: the options menu and the main area [Figure 2]. In the options menu, is listed the edition facilities provided to the teacher. The main area displays the tracking of the quiz under edition. The edition of a question is done in a float window [Figure 2]. When the teacher is done editing he finishes the quiz and the tool generates its HTML file.

Then, a student, in the attendance module, takes the quiz and submits it to automatic correction [Figure 3]. Right after correction, he receives feedback showing his performance. The teacher, in his module, gets detailed statistics collected in the results of the assessment process.

Conclusions

The Internet has great educational potential [Eales and Byrd, 1997] and Quest is a tool for generating quizzes and assessing materials on the Web. The process of creating and editing questions is made on a graphical Web interface, thus making the tool completely Web designed. It also aims to help teachers assess all the cognitive abilities of the students, not only their ability to memorize information. This tool delivers statistics both to the students and the teachers so that they can see if the material offered on the course meets all their purposes and needs.

An Integrated System for Multilevel Secure Compound Documents

Kuen-Feng Chu, Wen-Guey Tzeng, Ping-Jer Yeh, and Shyan-Ming Yuan
Department of Computer and Information Science
National Chiao Tung University
Hsinchu 30050, Taiwan

Abstract: For computerized information, multilevel security of digital documents is necessary for many applications. However, traditional multilevel key encryption systems do not consider the key-expiration and time-bound problems. Therefore, we propose and implement a scheme that allows users to edit and browse compound documents of multimedia data. Each component in a compound document is assigned a security class separately. Only legitimate users with equal or higher clearances can browse the document component. Our scheme includes a time-bound feature, which is suitable for many applications.

I. Introduction

In a computerized society, people use computers not only to compute, but also to record and communicate information in many forms, such as texts, images, voices, animation, etc. Because of versatility of the World-Wide Web, we can design many applications on it, for example, electronic newspapers, digital libraries, electronic commerce, etc. However, there are occasions that we need retain secrecy for digital data. For example, parents want to keep children away from violent and pornographic publications. Furthermore, there are occasions, for example, that a company may allow an employee at a certain clearance to read secret documents at certain security class only. Therefore, we need multilevel security in controlling access to digital data. We illustrate this by a paid electronic newspaper subscription system as follows. A newspaper publishing company provides electronic newspapers to subscribers. The company allows a subscriber to subscribe his interested categories, such as sports, business, etc. To save the bandwidth, the company broadcasts everyday newspaper to its subscribers. However, the company would like a subscriber who subscribes the category of sports can read the sports category only, while a subscriber who subscribe the whole newspaper can read all. Furthermore, the company would like the subscribers to read the newspapers that are within their subscription period only.

In this paper we provide a solution for the above, that is, we design and implement a time-bound multilevel security system that allows users to edit and browse compound documents of multimedia data. In our system, each component of a compound document is classified into a security class by its sensitivity. Each security class C at time T has a secret (cryptographic) key \( K_{C,T} \) and a component in a security class is encrypted with key \( K_{C,T} \), where T is the time that the component is added. To access components in a compound document, a user need to have the corresponding keys. However, we don't want a user to have a lot of keys since it is hard to manage them. We design a cryptographic scheme such that each user has only one secret information. In particular, if a user is at security class \( C \) between time \( t_1 \) and \( t_2 \), he is given a secret information \( I(C, t_1, t_2) \) so that the secret information can be used to derive secret key \( K_{C', t} \) if \( C' \) is lower than or equal to \( C \) and \( t \) is in between \( t_1 \) and \( t_2 \).

We now see how the subscription system works. When a subscriber pays for the category \( C \) from time \( t_1 \) to \( t_2 \), he is given the information \( I(C, t_1, t_2) \). In some day \( t \), he receives an electronic newspaper \( N \) from the publisher. If \( t \) is in between \( t_1 \) and \( t_2 \), the subscriber decomposes \( N \) to get the components \( M \) of class \( C' \). The subscriber then use \( I(C, t_1, t_2) \) to derive the key \( K_{C', t} \) to decrypt \( M \) and reads it. Since \( I(C, t_1, t_2) \) can only derive keys \( K_{C', t} \) where \( C' \) is lower than or equal to \( C \) and \( t \) is in between \( t_1 \) and \( t_2 \), the subscriber can only read the subscribed categories within his subscription period.

The distinct features of our system are: (1) It can edit and browse compound documents with time-bound multilevel security. (2) Compound documents are accessible through networks, but only a user with a legal key can read the component that he is authorized to. (3) Each component is encrypted and stored...
once and suitable for different security classes and time. (4) Each user has only one secret information, which is independent of the number of security classes.

A. MIME Mechanism

We use the MIME (Multipurpose Internet Mail Extensions) [Borenstein and Freed 93, Moore 93] mechanism to include various kinds of multimedia data into a compound document. MIME allows multipart textual and non-textual message bodies to be represented and exchanged without loss of information. It provides facilities to include multiple objects in a single message, to represent body text in character sets other than US-ASCII, to represent formatted multi-font text messages, to present non-textual materials, such as images and audio fragments, and to facilitate later extensions for defining new media types for cooperating mail agents.

We extend the MIME mechanism for our security scheme. This extension is capable of handling our time-bound multilevel data security requirements as well as compatible to the existing MIME mechanism. We define new types for encrypted parts. Each part is associated with a module name, a security class, and a publishing time. Only the legitimate users who are with the same or higher clearance and with the correspondent secret information (about the security class and publishing time) can open up the encrypted parts and read the information on our browser.

For the editor module, users can edit textual and non-textual data, assign each part a corresponding security class and publishing time, and put them together as a compound document. After all are done, our editor module composes and encrypts them accordingly.

As for the browser, we use a parser to preprocess MIME-compliant documents. The browser provides a user-friendly interface that helps the user to browse the authorized components that the user is entitled to. Besides, we embed the transmission ability into our browser so that the browser is able to access or download from the document databases distributed over the networks. We use HTTP (Hypertext Transfer Protocol) protocol for the transmission protocol, which is commonly used to retrieve files in the World-Wide Web. A user simply types the desired URL (Uniform Resource Locators) address in a dialog box; the browser does the rest.

I. Time-Bound Multilevel Data Security

The multilevel data security problem in the form of cryptographic key assignment was first studied by Akl and Taylor [Akl and Taylor 83]. The multilevel data security problem takes place in many occasions. For example, in the military organization, data are typically classified as top-secret (TS), secret (S), confidential (C), and unclassified (U), where TS is the highest security class and U is the lowest security class. Officials in the security class TS can read all documents, while officials in the security class S can read documents in the security levels S, C and U, but not those in TS.

Formally, a multilevel security system can be expressed as a partially ordered hierarchy where users and data are grouped into a number, say \( m \), of security classes \( C_i \), 1 symbol 163 \[ "Symbol" \ s 10 \leq \ i \ s 10 \leq m \]. These security classes (or classes for short) are partially ordered such that data in class \( C_i \) can be accessed by users in class \( C_j \) if and only if \( C_i \ s 10 \leq \ C_j \). We augment multilevel security to time-bound multilevel security with motivation as described in [Introduction]. We need the Lucas function first. Let \( V_0(x) = 2 \) and \( V_1(x) = x \). Then for \( n \) symbol 179 \[ "Symbol" \ s 10 \leq \ n \geq 2 \]

\[ V_n(x) = x \ s 215 \ s 10 \ s 10 \cdot V_{n-1}(x) - V_{n-2}(x) \]  

For given \( n \) and \( x \), it is computationally feasible to compute \( V_n(x) \).

Our time-bound multilevel security (time-bound cryptographic assignment) [Tzeng 98] is as follows, where \( z \) is the maximum time.

1. It has a key center (KC) for time-bound key generation.
2. KC randomly chooses four primes \( p_1, p_2, q_1, \) and \( q_2 \), and lets \( n_1 = p_1 q_1 \) and \( n_2 = p_2 q_2 \).
3. KC chooses two random numbers symbol 97 \[ "Symbol" \ s 10 \alpha \) and symbol 98 \[ "Symbol" \ s 10 \beta \), where \( 1 \ s 97 \ s 1 \ s 10 \alpha \) and \( 1 \ s 97 \ s 1 \ s 10 \beta < n_2 \).
4. KC assigns each class \( C_i \), 1 symbol 163 \[ "Symbol" \ s 10 \leq \ i \ s 10 \leq m \),
a number \( e \), relatively prime to symbol 102 \( \text{if} \symbol{102} \text{is} 10 \phi(n_1) \) and computes \( d \), such that \( e, d \mod 102 \text{if} \symbol{102} \text{is} 10 \phi(n_1) = 1 \).

5. KC computes \( K_i \) symbol 163 \( \text{if} \symbol{163} \text{is} 10 \leq i \) symbol 163 \( \text{if} \symbol{163} \text{is} 10 \leq m \), as

\[
K_i = \alpha \prod_{j \in \mathcal{C}_i} d_j \mod n_1.
\]

6. For the time period \( t \), 0 symbol 163 \( \text{if} \symbol{163} \text{is} 10 \leq t \) symbol 163 \( \text{if} \symbol{163} \text{is} 10 \leq z \), the KC chooses two numbers \( f_1 \) and \( f_2 \) and computes

\[
w_t = V_{f_1^{-1} f_2} (\beta) \mod n_2.
\]

7. KC chooses two numbers \( g_1 \) and \( g_2 \) relatively prime to symbol 102 \( \text{if} \symbol{102} \text{is} 10 \phi(n_1) \) and computes \( h_1 \) and \( h_2 \) such that \( h_1 g_1 \mod 102 \text{if} \symbol{102} \text{is} 10 \phi(n_1) = 1 \) and \( h_2 g_2 \mod 102 \text{if} \symbol{102} \text{is} 10 \phi(n_1) = 1 \). The key for class \( C_i \) at time \( t \) is

\[
K_{i,t} = H(K_i^{h_i} h_1, w_t),
\]

where \( H \) is a one-way hash function.

8. The public parameters are: \( n_1, n_2, e \), 1 symbol 163 \( \text{if} \symbol{163} \text{is} 10 \leq i \) symbol 163 \( \text{if} \symbol{163} \text{is} 10 \leq m \), \( g_1 \) and \( g_2 \).

For a user with security class \( C_i \) between \( t_1 \) and \( t_2 \), he is given the secret information \( I(C_i, t_1, t_2) = (x, y) \), where

\[
x = K_i^{h_i} h_2^{-1} \mod n_1 \quad \text{and} \quad y = V_{f_1^{-1} f_2} (\beta) \mod n_2.
\]

To derive a key \( K_{i,t} \) for class \( C_i \) at time \( t \) with \( C_j \) symbol 163 \( \text{if} \symbol{163} \text{is} 10 \leq i \) symbol 163 \( \text{if} \symbol{163} \text{is} 10 \leq i \) symbol 163 \( \text{if} \symbol{163} \text{is} 10 \leq t \), the user uses his secret information \( I \) and public parameters as follows. He first computes

\[
x = g_1^{h_j} g_2^{-h_i} \prod_{i \in \mathcal{C}_j} d_i \prod_{j \in \mathcal{C}_i} d_j \mod n_1
\]

\[
= \alpha \prod_{i \in \mathcal{C}_j} d_i \prod_{j \in \mathcal{C}_i} d_j \mod n_1
\]

\[
= \alpha \prod_{i \in \mathcal{C}_j} d_i \prod_{j \in \mathcal{C}_i} d_j \mod n_1
\]

\[
= K_j^{h_i} h_2^{-1} \mod n_1,
\]

and

\[
V_{f_1^{-1} f_2} (\beta) \mod n_2
\]

\[
= V_{f_1^{-1} f_2} (\beta) \mod n_2
\]

\[
= V_{f_1^{-1} f_2} (\beta) \mod n_2
\]

\[
= w_t.
\]

Then, he computes \( K_{i,t} = H(K_i^{h_i} h_1, w_t) \).

If a user knows the secret information \( K_i \) and \( w_t \), he can compute \( K_{i,t} \) efficiently. However, for an attacker who does not know the secret information, it is difficult to compute \( K_{i,t} \) because of the following two reasons: (1) Computing \( K_i \) is equivalent to breaking the RSA cryptosystem [Rivest 78]. (2) The security of \( w_t \) is guaranteed by the Lucas function since the Lucas-function-based cryptosystem is generally considered as secure as the RSA cryptosystem. Furthermore, even if the attacker knows \( K_{i,t} \), he can not compute \( K_i \) and \( w_t \) because one-way function \( H \) is applied on them.

I. The Integrated System

A. Document Format
We follow the MIME mechanism to encapsulate the different parts into a single document. In the MIME format, multipart of different data are embedded into one single message by specifying their characteristics in the header that precedes each part of the message.

To meet the security requirements, we make extensions to the original definitions in the standard by creating new content types. That is, we append a "-encrypt" postfix to each content type. For example, we add image/gif-encrypt for image/gif and text/plain-encrypt for text/plain. So, a body part in a MIME message with the following header

```
Content-Type: image/jpeg; name="uno.jpg"
Content-Transfer-Encoding: base64
```

has a corresponding header that specifies an encrypted data in our system as:

```
Content-Type: image/jpeg-encrypt; name="uno.jpg"
Content-Transfer-Encoding: base64
```

Therefore, when the extended MIME parser identifies an encrypted message, it invokes the base64 decoding function to produce the ciphertext for later use.

To support time-bound multilevel data security, three additional lines are appended at the beginning of the decoded data. The first line tells the name of the security module, for which the encrypted data is intended. A security module can be a company, a publication, a government department, etc. Each security module is further classified into several security classes or security levels, and the intended security class of the data is specified in the second line. The third line specifies the publishing time of the data. For example, the following three lines tell that the data published in October 1997 is intended for the organization NCTU and its security class is 5.

```
Security-Module: NCTU
Security-Class: 5
Publishing-Time: 9710
```

Only a user in this organization who has an equal or higher clearance with time period containing the publishing time can open this part with the corresponding key derived from his secret information.

A. System Components

Our system includes three major modules: an extended MIME parser/composer, a MIME browser/editor window to edit and display the documents, and an HTML browser.

1. The Parser/Composer Module

The secure compound document preprocessor, or the extended MIME parser, syntactically analyzes a compound document according to the headers preceding each part of data. The data may be a plaintext, which can be directly displayed in the text viewer, or a piece of information encoded with several different algorithms, like the base64 or quoted-printable. Therefore, the parser should invoke the corresponding decoding function to generate the right information. Furthermore, if the parser identifies an encrypted data, it needs to first decode the data with the base64 decoder, extracts the security information, and then decrypt the ciphertext. Of course, if the user does not have the correct secret key, the preprocessor cannot decrypt the information and just ignores this part of data.

The composer, on the other hand, encapsulates the body parts by necessary encoding and attaching appropriate headers specifying the properties of the data. If the data is sensitive, the composer would first invoke the DES function to encrypt it with secret keys. The multilevel secret keys can be generated by the information-provider through the dialog box embedded in our editor and distributed to the intended users or information-subscribers.
I. The Browser/Editor Window

There are a narrow URL bar and two child windows in the browser/editor window. The URL bar is for the user to assign the location of a compound document. Documents are downloaded via HTTP from a remote document server, and then the control flow passes the raw data to the parser. The main textual data in the document is shown in the upper child window and the other accessible attached parts are shown as small icons in the bottom child window. The user can invoke corresponding viewers to browse the attached parts that he is entitled to, that is, he has the corresponding decryption keys.

We can also use the browser/editor window to edit the documents. Textual data are edited or modified in the upper child window, or the text window. Attachment is created by first selecting the content type of the component and specifying the filename through the window menu, which creates a new icon in the bottom child window, or the attachment window. Users can then double-click the icons to invoke the applications specified in a setup dialog for further editing or browsing the components. Removal of attachments is also done simply by deleting the icons in the attachment window. After all editing work is done, users can then click the components and assign their security module and class. When the file is to be saved, system will then pass the document information to the composer for final and necessary processing.

Other features, such as dialogs for bookmark management, viewer locations, security settings and key generations, can be invoked through the window menus.

I. The HTML Browser

Our system also supports HTML formats. It can browse HTML files. It can also invoke an independent WWW browser, such as, Internet Explorer of Microsoft and Communicator of Netscape.

I. Conclusion

We have designed an integrated system for editing and browsing compound documents with the feature of time-bound multilevel security. The compound document can handle many types of multimedia data and is compliant with the MIME mechanism. If unknown MIME formats are received, our system offers a convenient way to handle it. The system provides a useful prototype for an information provider or organization to control access of information if hierarchical access control is necessary. Our solution is based on a cryptographic method. It can protect information against network pirates with theoretical soundness. Therefore, the system can ensure security and profits of information owners if they need.

We can still improve our system. For example, when new keys are computed, we need to distribute them to legal subscribers in a secure way. Therefore, we may need to incorporate secure mail and secure authentication modules for key distribution.

Abstract: In this presentation we describe and compare three online courses by looking at design features using general principles of situated learning and by assessing the "fit" between instructional design features, the general "type" of students registered in the courses, and differences in content between courses. Three conclusions are: 1. The more constructivist principles that are embedded in a design, the less re-designing is needed, 2. Implementing an appropriate design takes advantage of student diversity, and 3. Although content and students may differ, courses would benefit with the implementation of some principles of constructivism.

Introduction and Overview

Finding ways to enhance pedagogical aspects of teaching and learning in the computer-based medium is quickly becoming a new priority. The field of cognition and instruction offers a rich resource of empirically grounded theories and models of learning suitable for instructional design of online courses. We are currently exploring the potential for using constructivist theories in hypermedia learning environments, particularly "situated learning" theory with its emphasis on collaborative learning in "authentic" instructional settings. The fundamental assumption of this theory is that truly meaningful learning arises from students' active engagement in shared learning experiences that are anchored in tasks, activities, or settings that reflect realistic situations students are likely to encounter [Brown, Collins and Duguid 1989] [Lave 1988]. The close integration of theory and practice reflected in the situated model of learning neatly captures the dynamic nature of interactions between the cognitive and social dimensions of learning. The conferencing capabilities of interactive technologies are ideally suited to support the creation and management of shared learning opportunities for students studying online. In this presentation we describe and compare three online courses in two ways: First, by looking at design features using general principles of situated learning adapted from the work of [Salomon and Perkins 1995], and second, by assessing the "fit" between instructional design features, the general "type" of students registered in the courses, and differences in content between courses.

Principles of Instructional Design

Principle 1. Effective learning requires that learners engage actively in manipulating the target knowledge, thinking and acting on the basis of it to revise and expand it (p.116). Principle 2. The hallmark of understanding something is being able to think with what you know about the something; understanding is acquired through engagement in activities that call for such thinking(p.117). Principle 3. Understanding something involves building a rich and broad semantic network of relationships in which the target knowledge sits, with links supportive of kinds of thinking pertinent to the target knowledge(p.118). Principle 4. The learning of individuals
gains from patterns of social interaction that support the construction and distribution of knowledge and understanding (p. 119). **Principle 5.** Effective learning needs to occur in social and activity settings that have authenticity as settings of learning and as gauged by later potential applications (p. 121). **Principle 6.** Through processes of diverse practice or active abstraction, useful general knowledge can be drawn from and applied to particular contexts (p. 121).

1. **Designs for Learning: Writing**

The overall online design of the course, *Designs for Learning: Writing* [Mamchur 1997] is organized around three basic tenets of the situated learning model. Much of what is learned is specific to the context in which it is learned; the construction of knowledge takes place in social settings; learning occurs through situated and authentic tasks [Good and Brophy 1995]. These tenets are reflected in the basic premise of the course, that is, in order to write creatively and to teach writing, one benefits most by learning to write well, for and with others. During the design phase the six principles of constructivism were incorporated by integrating, enhancing and expanding opportunities for students to acquire skills through collaborative writing, reciprocal teaching, and classroom practice activities. These are illustrated as follows both within and across course units and in the "authentic" contexts of students' actual classrooms.

**Organization and Structure**

The course is presented in two modes -- print, comprising course materials, and online via FirstClass Systems conferencing, where all instructor and peer teaching activities take place. Thus individual, small group, and applied tasks converge in the conferencing medium and the various conferences for each unit of the course are designed according to the activities specific to the unit. Because writing skills development builds incrementally over the duration of the course, conference design captures activities across units as well. There are four units covering four key writing themes. Each unit contains three instructional strands through which knowledge building activities take place: 1. Writing, where students are introduced to and practice the skills through discussion and modeling activities provided by the instructor, 2. Collaborating, where students work together providing peer feedback on writing samples, share information from course tasks, and edit one another’s work, and 3. Teaching Writing, where classroom materials are designed and first tested through reciprocal teaching and then in the teacher’s respective classrooms.

**Implementing Constructivist Principles**

All threads are set out according to the general organizational and interactive principles of constructivist learning presented above. Although each thread is reflected in all of the principles, some are more prominent than others in certain of them as the following description illustrates. What emerges is an instructional design matrix of threads within and across units.

**Principle 1** primarily informs design of the “Collaborating” strand of activities. This is the section is where students are expected to do tasks singly, then in combination with a partner, small group, or whole group that are based on information and illustrations from strand one. Students engage in peer feedback and peer editing on a variety of tasks, revising their work, and enhancing or expanding both unit specific writing tasks and sections of more comprehensive work.

**Principles 2 and 3** primarily informs design of the "Writing" strand of activities where students are introduced to important concepts, associated writing skills, and how to make informed choices about, and begin their own writing selections. Strand one provides the foundation knowledge upon which the course is constructed. **Principle 3** addresses the incremental nature of knowledge and skill building over the duration of the course.
Building broad and rich semantic networks of information occurs primarily through collaborative activities organized within and across the strand two which, in turn, is based on the information presented in strand one within and across units.

*Principle 4* underscores the interactive nature of teaching and learning which permeates this course. The conferencing medium is ideally suited for this purpose as students, all working professionals, are free to participate as often as their time constraints allow. The foundations of knowledge building and the acquisition of skills take place throughout the course, but primarily within and across strands two and three. Social learning activities and the resultant distribution of knowledge and skills occurs between partners, in small, and in whole group conferencing sessions. Here, the instructor's role is initially prominent but then fades as students are encouraged to assume responsibility for their own and other's learning.

*Principles 5 and 6* highlight the importance of the need for students to work in "authentic" learning situations. Throughout strand three students are designing activities that incrementally reflect the mastery of the skills, teaching strategies, and conceptual understanding gained in the other two strands. These activities are implemented in the students' own classrooms after a trial period in the conferencing groups. Feedback from the classroom setting is reported back to the conference participants and necessary changes and adjustments are then made.

**Reflections on Design**

Overall, this course was so successful that students continued to network long after the semester was completed. This phenomenon continues with each offering of it and students from earlier semesters will sometimes "drop in," with permission, to work with or assist those currently registered in the course.

2. **Issues in the Information Society: Software Design**

The *Issues in the Information Society* course addresses communication technologies from a variety of perspectives [Tiessen 1995]. This course provides a unique opportunity to apply a situated course design by involving students in the authentic task of using educational technologies in an educational setting to critically examine the influences of software design from an interdisciplinary perspective. Students assess the effectiveness of Virtual-UTM software as a communication medium for accomplishing their collaborative work, and as an educational medium for online course delivery. In addition to performance and technology issues in software design, class discussion pertaining to the social implications of online education are situated in the context of taking an online course. A further dimension is that the design of the students' interactions supports the same educational principles of active and collaborative learning, multiple perspectives, and knowledge building, which inform the design of Virtual-UTM.

**Organization and structure**

The course combines face-to-face meetings and networking activities. Face-to-face meetings deal with organizational aspects of the course such as coordinating student project groups. The online component is fully into the course design. The course is organized into three phases. Phase I is a general orientation to issues of an information society and an introduction to Virtual-UTM software in the context of these issues. Phase II involves group investigation into the design of technology for the information society, and Phase III involves a team design project incorporating the interdisciplinary perspectives researched during Phase II. To illustrate how [Salomon and Perkins 1995] principles of situated learning are incorporated into the design of this course, each phase is described below.
Phase I (4 weeks) Here, several aspects of situated learning design are woven into. Orientation to issues of the information society is achieved by combining whole and small group discussions. Brief reports prepared by small group participants are shared with the whole class to compare understandings. This engages students in a process of thinking about elements of software design, then using that knowledge to come to a shared understanding of the broader context of social and psychological consequences of design (principle 2). In addition, a clear purpose for these activities is held in common throughout Phase I. Students become aware of their background knowledge, learning needs, and interests, to better determine their fit into the design teams to be formed during Phase II (principle 5). Since participation in the design team environment requires a clear understanding of expectations within that context, Phase I sets the stage for later work in Phases II and III.

Phase II (5 weeks) During Phase II students organize into five design teams to develop expertise in each of the following design perspectives: Human-computer interactions design, educational software design, group communication and computer conferencing design, collaboration and groupware design, and hypermedia systems and tools design. Throughout Phase II students are encouraged to use conferencing groups as much as possible. This serves two purposes: Students experience first-hand the potential and limitations of the communication technology under review, adding to the authentic nature of the task (principle 5), and the process of group work is made explicit to assist class members in reflecting on their educational experiences in using the technology. In other words, students are able to use examples from immediate experiences to illustrate shortcomings of the software under review. Scheduled team meetings with the instructor during Phase II provide a focal point requiring students to articulate their own progress as a group. The structure of these meetings model authentic interdisciplinary design team environments.

Phase III (4 weeks) Project teams from Phase II are recombined into five new groups using a jigsaw method where membership in each new design team includes an "expert" from each of the earlier project teams. Each team is assigned the task of producing a design for Virtual-UTM software. This conferencing tool continues to be used by teams to coordinate group activities. However, face-to-face meetings are necessary during Phase III because this conferencing tool does not lend itself to design tasks that typically require shared space, drawing objects, and asynchronous communication. The jigsaw model creates a pattern of social interaction requiring that each member share expertise throughout the process of constructing new understandings (principle 4). This new knowledge is then applied to the particular task at hand, the design of virtual space for educational purposes (principle 6). Students also reflect on experiences of using the virtual space to accomplish their assignment during Phase II (principle 1).

At the end of Phase III students publish their final work for other class members to view and each group presents a design for the Virtual-UTM supported by the five design perspectives. The collaborative efforts of students in the course are expanded by inviting members of the Virtual-UTM design team and interested faculty to the presentations. Functioning as software design teams, students are required to creatively and succinctly articulate their designs and theoretical support for their decisions, and defend their work through open questioning by other class members and visitors.

Reflections on Design

The constructivist principles reflect the design of this course in several ways: 1. Students engage in authentic activities in terms of both course content and process, 2. Critique and design task activities contribute to shaping of communication tool design, 3. Students are aware of the importance of their role, 4. The structuring of design teams to accomplish these tasks is equally authentic since effective design requires that the team advance beyond the sum of the pieces, and 5. Group dynamics and activities are structured according to authentic interdisciplinary software design environments, and expectations within that working context are modeled by the instructor.
3. Introduction to Statistics

Introduction to Statistics is a required course for many students from a wide range of disciplines and acquired levels of education. The course emphasizes "the collection, description, analysis and summary of data, including concepts of frequency distribution, parameter estimation and hypothesis testing" [Weldon 1997]. The intention of placing an introductory statistics course in an asynchronous collaborative environment is to give students the freedom to work at their own convenience and to develop an understanding of statistical concepts and strategies through discussion and work with other students.

Organization and Course Structure

Presentation of the course is in two modes -- offline, consisting of printed course materials and required access to a statistical software package, and online via the Virtual-UTM conferencing system. All instructor, Tutor-marker (TM) and student interaction takes place in several conferences: private study group conferences, cafeteria conferences, the test and exam conference, the online classroom which houses feedback from the Instructor or TM, the Instructor/TM office hours, and a help conference. The course is designed to direct small study groups to discuss the most important issues and to report the outcome of the discussions to the TM and Instructor. At the beginning of every week (for 13 weeks), the session plan is posted in the online classroom. In every weekly session, individual studying tasks are to be completed before students take part in online discussions. Three contributions are expected from each student and, on a rotating basis, a student from each study group moderates the discussion and reports to the Tutor-marker at week’s end. Feedback on moderator reports, marked assignments, and an introduction to the proceeding session is made in a public conference. The next section presents the instructional design of the course in terms of constructivist principles of learning. This is followed by design considerations.

Implementing Constructivist Principles

Principles 1 and 2: The weekly assignments and tasks address these principles by having students perform individual tasks, then bring their understanding to a group. The group discussions enable students to provide feedback and assist each other in analyzing and reporting data. Though opportunities are made for students to gain a rich understanding of statistics through work with others, groups differ in how they handle this intent. In some groups, students work on separate parts of the group assignment and the moderator is responsible for pasting the pieces together, while in other groups, more time is allowed for feedback, refining, and discussing topics. However, discussions tend to focus on completing the group assignment rather than providing mutual support or completing individual assignments.

Principles 3 and 4: The collaborative environment itself did not seem to contribute to the building of a rich and broad semantic network of information. Though many conferences contain numerous messages, the quality of the messages show that many discussions did not draw on individual areas of students’ own expertise and understanding. Messages appear to lack depth and students had difficulty in supporting the construction and distribution of knowledge and understanding through their collaborative work.

Principle 5 and 6: Discussion and responses to text-based and conceptual questions form the basis of evaluation for group assignments. Individual assignments consist mainly of text-book questions, with the exception of a project where students are asked to collect, explore, analyze data and write a report on the process and findings. Students are provided with opportunities to learn effectively through authentic settings in that the conferences allow them to share ideas and understandings with their fellow "researchers". Furthermore, students practice in
exercises that assist in the drawing of general knowledge and application to other contexts. The individual project is valuable as it provides an authentic setting where students perform a complete research study.

Reflections on Design

While the use of an online environment for this course does embody many of the situated learning principles, students do not appear to take full advantage of these opportunities to enrich their learning. The variability between student backgrounds may contribute to difficulties relating to one another. Furthermore, the maturity level of students may be a factor. First-year students are less experienced in learning in a group environment and in taking responsibility for their own learning. Online discussions could be improved through explicit instruction on working together, in addition to tightening the direction of group discussions, increasing motivation, and having students understand the purpose of the group discussions.

The current structure of group assignments could perhaps benefit from more direction in working together. For example, in lieu of weekly group assignments, students could be assigned projects where data would need to be collected, discussed, analyzed, and reported. The advantages of this are: 1. students could build upon the knowledge and understanding the students gained from individual work, 2. students could take advantage of the diversity in backgrounds and thus produce very interesting studies and improved group dynamics, 3. group projects could then be mounted and shared with the entire class, and 4. students would be drawing upon the general knowledge gained from their individual studies by applying it to an authentic situation. Some students are anxious about taking a statistics course. Improved interactivity would not only bring deeper understanding of the material, but it would also benefit students by allowing them to converse with and obtain support from their peers.

Conclusion

The three courses are different in content, presentation and student types: working professionals participated in an online writing course, fourth year students in a hybrid course focusing on software design, and students from a range of disciplines and educational levels in an online introduction to statistics course. Course designers should consider all of these variables when using this very flexible medium. Upon reflection on the course designs, it seems that the more constructivist principles that are embedded in a design, less re-designing is needed. Implementing an appropriate design takes advantage of student diversity and although content and students may differ, courses would benefit with the implementation of some principles of constructivism. Looking at design features using general principles of situated learning that assess the "fit" between instructional design features, the general "type" of students registered in the courses, and the nature of the content is a productive approach to online course design.

Abstract: The major purpose of this study was to compare the learning effects of four courseware versions, namely, animation+text, animation+voice, animation+text+voice, and free choice. Subjects' personal characteristics: FI/FD learning style, gender, and math achievement were also examined in this study. Study results indicated that subjects performed significantly better on the posttest in the animation+text+voice version, which was also the favorite interface design chosen by most of the subjects. It was also found that the animation+text+voice interface effect was only strong for FI subjects, males, or students with low math achievement.

In a relatively short period of time, computer technology has been increasing its impact on the ways of teaching and learning. Benefit from the technological advancement, the instructional softwares developed and used in computer assisted learning have achieved great improvements. One of the most significant changes is the widespread using of computer animation. Integrating text, sound, and computer animation into instructional softwares, the presentation effects are maximized.

Dual-code theory provides theoretical support of the uses of verbal (such as text) and nonverbal (such as animation) codes in lesson presentations. Studies performed by Mayer & Anderson (1991,1992) and Mayer & Sims (1994) confirmed the dual-code theory. Their studies revealed an instructional implication that computer animation and oral narration are most effective when they occur contiguously in time or space. Some other studies also verified the positive learning effects under certain circumstances concerning the use of computer animation in a courseware (Park & Gittelman, 1992; Rieber, 1991; Baek & Layne, 1988; Baggett, 1984). However, there are still some questions remain to be answered.

Although previous studies indicated that the learning effects were better when combining computer animation with text or oral narration, few studies were conducted to examine these three factors simultaneously. The truth is that we do see lots of applications of computer animation, text, and oral narration altogether as major presentation strategies in current multimedia coursewares. Thus, the first question tried to be answered in this study was: What was a more effective way in terms of the using of text, voice, and computer animation to conduct the learning content? Text only? Animation only? Text plus animation? Voice plus animation? Text plus voice and animation? Which one will contribute more to the understanding of the knowledge content and therefore enhance the learning outcome? In other words, the first purpose of this study was to compare the learning effects among three major presentation methods, namely, animation plus text, animation plus oral narration, animation plus text and oral narration in a computer assisted instruction courseware.

The second question this research tried to answer was: To whom the presentation effects was maximized? The study of Mayer & Sims (1994) revealed that the contiguity effect (computer animations and oral narrations presented simultaneously) was strong for high- but not for low-spatial ability students. What about other individual characteristics? The current study tried to examine more individual differences which affect students’ learning from visual and verbal instruction in a computer environment. The following three personal characteristics: FI/FD learning style, gender, and math achievement were examined in this study. Thus, the second purpose of the current study was to find out if significant differences of learning effects existed between FI and FD subjects, between males and females, or among subjects with different math achievement in a multimedia learning environment.

Most of the previous studies concentrated on the issues of learning effects of various presentation interfaces. Few of them examined the subjects’ affections toward the various interfaces. Therefore, the third purpose of the current study was to find out what kinds of interface designs were the subjects’ favorite.
METHODS

SUBJECTS And INDEPENDENT VARIABLES

The subjects were 175 7th grade students who came from 8 classes of a rural junior high school in Taipei county of Taiwan.

Before the experiments, an embedded figure test was administered to roughly 330 students of the 8 classes to determine their FI/FD learning style. Students whose embedded figure test scores were within top 25% of each class were identified as FI subjects. Those with test scores within the lowest 25% of each class were identified as FD subjects. Totally, 175 students were selected to participate in this study.

Among the 175 subjects, 89 subjects were in the FI group (50.86%). Their average score of the embedded figure test was 11.73. The FD group consisted of 86 subjects (49.14%), and their average score of the embedded figure test was -1.68. Significant difference of the average score was found between the FI and FD groups from an ANOVA analysis (F = 705.63, p<.001).

Based on the math final grades of a previous semester, subjects were divided into three groups with different math achievement. Students whose math scores were among the top 25% of each class were classified into the high math achievement group. There were 50 subjects (28.57%) in this group with an averaged math score of 85.32, based on a 100 scale. Students whose math scores were within the lowest 25% of each class were classified into the low math achievement group. There were 57 subjects (32.57%) in this group with an averaged math score of 27.02. The rest students of each class were classified into the average math achievement group. There were 68 subjects (38.86%) in this group with an averaged math score of 63.79. The average math scores among these three groups were found significantly different (F=346.29, p<.001).

Among the 175 subjects, ninety students (51.43%) were males, while eighty-five students (48.57%) were females.

LESSON CONTENT And COURSEWARE VERSIONS

The instructional content of the experimental courseware used for this study was "Forces" and "the Resultant of Forces" in Physics domain. Forces and the Resultant of Forces were knowledge with traits such as motion, trajectory, and abstractness. Understanding of these kinds of concepts could be enhanced by the implementation of computer animation in a courseware (Park & Hopkins, 1993; Rieber, 1991). The lesson material was divided into five major parts: 1) Force Equilibrium, 2) the Motion of Forces, 3) the calculation of the Resultant of Forces, 4) the introduction of the resultant of forces by using a parallelogram, and 5) review and practice questions. All instructions were presented at an introductory level. Approximately thirty minutes were needed to complete the lesson.

Four courseware versions were created for the purposes of this study. These four versions were: 1) animation+text, 2) animation+voice, 3) animation+text+voice, and 4) Free Choice version. For the Free Choice version, subjects were able to choose their favorite interface design from the three versions stated above. Differences among the four versions were only on the using of presentation media. The instructional contents were the same for all versions.

In this study, computer animations were mainly used to explicit the moving trajectory of a stationary object when pushed by two forces either in the same or in the opposite direction. For example, one of the instructional screen was that when an object was pushed by two unequal forces from opposite directions in a line, the object would start to move toward the direction of the larger force.

Subjects from the eight classes were randomly assigned to one of the four lesson versions in the experiment.

DEPENDENT VARIABLES

A ten-item paper-pencil type of posttest was administered to subjects to measure the learning outcomes. A questionnaire developed by the researcher were used to collect the data concerning subjects' affection toward the interfaces. Subjects took the posttest and filled the questionnaire immediately after they completed the instructional lesson. It took about 10 to 15 minutes to finish the posttest and the questionnaire.

RESEARCH QUESTIONS
Four research questions were issued in this study. They were:
1. Were there significant differences of learning effects among groups of four courseware versions?
2. For each courseware version, did a) FI, FD subjects, b) males and females, or c) three groups with different math achievement differ on the posttest scores?
3. For a) FI subjects, b) FD subjects, c) males, d) females, e) high math achievement students, f) low math achievement students, or g) average math achievement students, did their posttest scores have significant differences among four courseware versions?
4. What was the favorite interface design for the subjects?

RESULTS AND DISCUSSIONS

A significant effect was found for the presentation interface, F=4.20, p<.01. Subjects in the animation+text+voice group scored significantly higher on the posttest (Least Square Means, LSM=71.47) than those in the animation+voice (LSM=64.01) or the animation+text (LSM=59.72) groups. No significant difference was found on the posttest scores between the animation+text+voice and Free Choice (LSM=69.40) groups. When subjects in the Free Choice group were asked, “During the lesson, which type of presentation interface did you use most of the time?” Thirty-two out of forty-three (74.4%) subjects indicated that they used animation+text+voice type most of the time. Which might be the reason that no significant difference was found between animation+text+voice and Free Choice groups. Based on the results stated above, it could be concluded that among the animation+text, animation+voice, and animation+text+voice interface designs, the animation+text+voice type achieved the best result in terms of learning effects. Table 1 presented the results of ANOVA analysis on the learning effect for different groups of subjects.

Dependent Variable: Posttest Score
*reach a significant level

The study results shown in Table 1 indicated that FI/FD learning style was an effective factor on the posttest. It was found that FI subjects scored significantly higher than the FD subjects on the posttest, F=7.27, p<.01. However, as shown in Table 2, for the FI and FD subjects, their posttest scores only differed significantly in the animation+text+voice version (F=4.13, p<.05), or Free Choice version (F=9.74, p<.001). No such difference was found either in the animation+text version or in the animation+voice version. Study results shown in Table 3 revealed that for FI subjects, there were significant differences on the posttest among four courseware versions, F=3.11, p<.05. FI subjects in the animation+text+voice group or in the Free Choice group scored significantly higher than those in the animation+text group or in the animation+voice group. No significant presentation effect was found for the FD subjects. Since most subjects in the Free Choice group chose animation+text+voice as their major presentation interface, it could be concluded that the animation+text+voice presentation effect was only strong for the FI subjects, but not for the FD subjects. The Least Square Means of posttest of each subject groups in the four courseware versions were presented in Table 3.

*The posttest scores of this group subjects were significantly different among four courseware versions

Significant differences on the posttest score were found between males and females, F=7.36, p<.01, as shown in Table 1. The male subjects performed superiorly to the female subjects. However, only under the animation+text+voice interface, the posttest score differences were existed between males and females. No significant difference on the posttest scores between males and females was found either in the animation+text, the animation+voice, or the Free Choice versions. Study results also indicated that only for males, the significant differences on the posttest among the four courseware versions were found, F=3.00, p<.05. Male subjects in the animation+text+voice or the Free Choice versions performed significantly better on the posttest than those in the animation+text or the animation+voice versions. There was no significant difference of the posttest score for female subjects among the four courseware versions. It was concluded that the animation+text+voice interface effect was strong only for the male subjects, but not for the female subjects.

Significant differences were also found on the posttest among the three various math achievement groups, F=15.07, p<.001. Subjects with higher math achievement also had better posttest scores. However, such results were only found in the animation+text or animation+voice versions, but not in the animation+text+voice or the Free Choice versions. From the data shown in Table 3, it was noticed that
only subjects with low math achievement had significant different posttest scores among the four courseware versions, F=5.79, p<.01. No significant posttest score difference was found either for subjects with high math achievement or for subjects with average math achievement. Low math achievement subjects performed significantly better in the animation+text+voice or the Free Choice versions among four courseware versions. Apparently, the animation+text+voice interface effect was only strong for low math achievement students but not for high or average math achievement students.

Given every possible combinations of the presentation methods among text, voice, and computer animation, subjects in the animation+text, animation+voice, and animation+text+voice groups were asked: "If you could possibly choose the presentation interface, what is your favorite design?" Seventy-six out of the 131 students (58%) indicated that they preferred animation+text+voice type. Thirty-five subjects (26.7%) said they would choose animation+text as the presentation interface. In the Free Choice group, subjects were entitled to change their interface during the lesson. However, only one out of 43 persons said that during the lesson, he changed the presentation interface frequently. The rest forty-two subjects chose one presentation way and stuck with it throughout the lesson. Thus, it was not surprising to find that 83.7% (36 out of 43 subjects) of the subjects indicated that they didn't appreciate particularly the choice of freedom of the presentation interfaces in an instructional lesson.

GENERAL DISCUSSIONS

When investigating animation effects in learning, lots of studies focused on the comparisons of the learning effects of computer animation (with or without text) to the static graphics (Rieber, 1996; Park & Gittelman, 1992; Rieber, 1991; Rieber, 1989; Baek & Layne, 1988; Rieber & Hannafin, 1988). Some researches studied the presentation order between computer animation and verbal narration (Mayer & Anderson, 1991,1992; Mayer & Sims, 1994). The present study examined three media factors, namely, text, voice, and computer animation because it is more conformed to the current presentation strategies applied in CD titles nowadays. Results of the present study revealed that concurrent using of text, voice, and animation together in an instructional interface had significant better learning outcome than the using of animation with text or animation with voice. Animation+text+voice design was also the favorite interface chosen by most of the subjects in this study. On the practical side, these findings are worthy of consideration when integrating multimedia into the presentation interface of a computer assisted instruction lesson.

For the question, "To whom the presentation effects were maximized?" the results of this study indicated that the animation+text+voice effect was strong only for FI subjects, males, or students with low math achievement, but not for FD subjects, females, students with high or average math achievement. All the subjects had low prior experience with the instruction content. The findings contribute a fuller understanding of the learning in the multimedia environment.

It was unexpected to find from the present study that few subjects preferred the free choice of presentation interfaces. Due to the limited choices of interface designs provided by this study, further research is recommended to clarify the issue.

The results of this study also indicated that the subjects in the animation+text+voice version got the highest posttest scores. Besides, FI students performed better than the FD students. Male subjects scored higher than female subjects. In addition, students with higher math achievement had better performance on the posttest than those with lower math achievement. However, careful generalization should be concluded because of the nature of the knowledge content instructed in the experimental lesson. Traditionally, Physics is a more spatial and male oriented field. Subjects’ learning outcomes may be influenced by the knowledge domain. Therefore, further researches of different fields of learning content are also recommended.

Using Web Conferencing to Promote Ownership in Distance Education Coursework

Abstract: Distance education has traditionally been most effective with students who show exceptional levels of motivation, self-confidence and autonomy. But the real challenge for distance educators is to encourage these qualities in more typical learners. By adding a web-conferencing component to our longstanding rural distance education program, we are able to promote a greater degree of interaction and ownership among the teachers who take our courses. The article describes our use of Alta Vista Forums in our courses and highlights the ways this technology helps improve the level of participation and control exercised by class members.

One of the most important developments in education in recent years is a shift in focus from what teachers are doing to what learners are doing. Increasingly, educational research and practices are moving from a didactic model of instruction toward a student-directed model. Wagner and McCombs [1995] described student-directed instruction as "a conceptual framework for describing how a learner understands his or her world and approaches the process of learning inside and outside of school." A basic principle of student-directed learning is the fundamental importance of students' taking ownership for their own learning. Promoting ownership--encouraging learners to make choices and take responsibility for the direction of their own education--is an essential component of effective instruction [Langer & Applebee 1986].

Ownership is closely linked to "students' sense of personal goals and products" [Langer & Applebee 1986]. Many terms have been used to describe the attributes of ownership, such as goal setting, self-monitoring, self-regulation, learner control, critical thinking skills, intrinsic and extrinsic motivation, communication skills, and personal autonomy [Honebein et al. 1993, Oliver & Reeves 1996, Pintrich & DeGroot 1990, Risenberg & Zimmerman 1992, Savery 1996, Steinberg 1989, Zimmerman & Schunk 1989]. Whatever the specific focus of each of these terms, their application to learning shares a common premise: understanding and optimizing the factors that support and encourage students to learn for themselves is a crucial element of successful instruction.

A strong sense of ownership is an especially critical factor for students in distance education settings. Learners who are not in close physical proximity to their instructors must often work more independently than students in traditional settings [Kember 1995]. In fact, many distance educators attest that independence and a strong sense of ownership are essential predictors of success in distance education students. As Riddle [1994] has observed, instructors describe the type of students likely to be successful in distance education settings as adults who are comfortable with less personal attention from instructors. Such students can more easily overcome the discomfort caused by the lack of direct instructor contact by means of their own intrinsic motivation to succeed [Riddle, 1994; Wagner & McCombs 1995].

But distance education must also cater to the needs of students who may not have such a strong natural inclination to ownership and self-sufficiency. Students who enroll in distance education courses do so because of considerations of schedule, location or availability, not because their learning styles or motivation make them good candidates for distance learning. Thus, instructors and instructional designers must make a deliberate
effort to promote and encourage ownership among students, especially for those who may be used to teacher-directed instruction where they make few choices for themselves. The ability of a program to build ownership may well mark its ultimate success or failure among the learners who do not present exceptional levels of independence and self-sufficiency.

Web-based conferencing is an internet tool that has enormous potential for increasing ownership and self-sufficiency among students, as it helps move course content from teacher-focused technologies such as two-way video to a cooperative learner-centered environment. We are incorporating web-based conferencing into our long-running distance education program to improve the participation and self-direction of students who have traditionally felt isolated or uninvolved in remote courses. In the next section we describe our program and discuss some of the obstacles and limitations involved in promoting ownership in courses we deliver at a distance. Then we describe the use of a web-conferencing tool, highlighting some features that are critical to promoting ownership.

Description of the Collaborative Teacher Education Program

For the past ten years the Collaborative Teacher Education Program (CTEP) at Indiana University has been offering distance education coursework to in-service teachers in rural communities throughout Southern Indiana. Cohort groups of 15-35 teachers meet for weekly classes at a central location, usually in a local high school or school corporation building. The instructors in CTEP remain at the university and provide real-time coursework through distance education technology. Over the years, the communication technologies we have used have advanced from speakerphones and the U.S. Postal Service, to computer-based audiographics and fax machines, to multi-point videoconferencing and e-mail. But one challenge that has remained constant is building ownership and personal involvement among the students in our classes.

From the start, our program has made an effort to make coursework learner-centered and applicable to teachers' everyday work situations. Teachers in our classes participate in weekly practicum activities in which they apply course concepts to the needs of students at risk in their own schools. We encourage teachers to work in school-based teams or partnerships to build a support network that does not rely on the presence of the instructor. We have structured class sessions to be learner-directed whenever possible, having teachers act as on-site facilitators to lead discussions and present material from the text rather than having the campus-based instructors do these tasks. A typical class period involves several small-group work and discussion activities, with remote instructors acting as consultants more than as presenters.

Despite such practices, many in-service teachers in our program still feel a greater degree of isolation than they are used to in campus-based coursework. Without the opportunity for casual talks with instructors after class or in the hallway, or for face-to-face consultation during office hours, the teachers at remote sites often have difficulty expressing their needs and obtaining assurance and guidance about the work they are doing. More importantly, some teachers feel isolated from their peers, especially when they do not come from the same school districts as others in the class. Without the chance to meet with others outside of class to go over homework and discuss ideas, these teachers are unlikely to fully engage the course content and often do work that is cursory or misdirected. In fact, unless they quickly establish social relationships with others in the class, the teachers tend to drop out of the program altogether. For learners who do not adapt well to such circumstances, distance education can be a frustrating and disappointing experience.

Web-based conferencing offers a powerful tool for creating a more interactive and less isolated experience for distance learners. Because it promotes content-based discussion among students, it allows learners to share their concerns and develop their ideas in a low-stress environment that they can control themselves. By adding this technology to our distance education courses this year, we are able to expand and deepen the role that teachers in our program take in directing their own learning.
A Web-Based Conferencing System

Alta Vista Forum is a WWW-hosted, asynchronous, text-based conferencing system that incorporates two key elements for discussions: "forums" and "teams." A forum is a collection of related information or resources that allows learners to interact on key issues and course concepts with other members of the class. There are three types of forums: "Discussion and document sharing," "Newsstands" and "Calendars." Newsstand and Calendar forums are well suited for sharing group information and scheduling class events, as they allow learners to post news items and web pages and to coordinate meetings and other events with the entire group. Discussion and document sharing forums promote content-based discussion. Learners post discussion comments and electronic documents inside hierarchical folders, each of which can contain other folders, continuing on for many levels. This allows learners to create many levels of categorization and enables each folder to be dedicated to a specific topic.

A team is a shared environment in which a select group of class members can work together on designated tasks. Team members interact through a "Team Vista" page, which contains forums and other resources available exclusively to team members. From the team vista page, learners can also launch "chat" for synchronous text communication over the internet. Learners can be a member of more than one team: they may belong to small work teams of 4-5 learners as well as a large team that includes the whole class. In our class we have teachers grouped in small discussion teams that change every few weeks to provide a variety of contacts as well as in project teams that stay the same throughout the semester. We also have a whole-class team that we use occasionally for larger group work.

Many of the capabilities Alta Vista Forum offers for learner interaction are especially useful for distance education. Students can post their projects, ideas, or questions from formal class sessions. They can comment on others' work and answer questions, rather than limiting such feedback to instructors. Students can also make changes or additions to the topics being discussed, or propose new issues or conversation areas. At the same time, instructors can observe learners' contributions to the discussion and make determinations about their progress and needs. Or they may comment on students' works, answer questions, or interject new questions to guide and coach problem solving. The conferencing system thus offers the opportunity for students to have out-of-class interactions in which they have a good deal of control over the direction of their learning process. Unlike e-mail, which typically facilitates communication between instructors and learners, the conferencing system ensures that learner-learner interaction is also encouraged. This interaction diminishes the isolation of distance learners by allowing them to develop a continuing relationship with instructors and peers between class sessions, just as campus learners do.

Furthermore, because it is asynchronous and text-based, Alta Vista Forum is in many ways preferable for the needs of distance learners to more sophisticated web products that offer visual and voice communication in real time. As distance learners are often non-traditional students who work and raise families in addition to going to class, they can benefit from the lack of scheduling needed for an asynchronous forum. And the simple technological configuration of a text-based web product insures that it is available to learners who may not have ready access to the latest computer equipment.

Applying Web-Conferencing to Distance Education

To take advantage of these benefits, we are integrating Alta Vista Forum into the CTEP coursework this year to provide a supplement to the live class sessions we offer by two-way video. All discussion on the conferencing system is directed toward existing course content and practicum projects: rather than using this opportunity to create extra work for learners, we use it to help improve their understanding and application of the work they do. To structure discussions, we require students to participate in three kinds of interaction each week: posting examples from their assigned projects, discussing course content, and consulting with peer teams. For all three types of discussion, the asynchronous environment provides the opportunity for instructors to observe and evaluate the contributions of class members without interrupting or influencing the interaction.
unless necessary.

Posting Work Samples

An important disadvantage distance learners face is the lack of examples or models for the work they do outside of class. By having teachers post their work we give them access to a much wider variety of ideas and approaches than the instructors alone can provide. In addition to the benefit of seeing the work of others, the teachers also benefit from posting their own work: when displaying projects to peers as well as instructors, learners tend to monitor their learning process more carefully and to take more responsibility for their presentations.

Each week we have teachers post examples from their projects to a conference site. Teachers begin to work with their own project team members to discuss and select examples. Then, they post their examples in a whole-class discussion and document sharing forum. This format allows the teachers to build their own ongoing database of coursework examples, which any of them can check to see how to complete a worksheet, to find ideas for teaching one of their students, or simply to measure their progress against that of their peers.

Group Discussion

The second type of interaction is a weekly group discussion of course content. Exploring ideas outside of class and without the active presence of instructors allows learners to develop their own understandings of course concepts and procedures, rather than relying on instructors' explanations [Duffy et al. 1998]. In addition, this type of web-based discussion is likely to prompt thoughtful and deliberate comments, as participants are able to reflect upon their ideas as long as they want, in contrast to live class discussions, which require participants to be rather bold and quick to contribute.

To structure these discussions, we ask students to address specific questions or issues relating to the course content or to their practicum activities. We divide the class into small discussion teams that change frequently to allow teachers to interact with everyone in the class over time. Each week the teachers begin discussion in these teams, exploring the issues for that week and fleshing out preliminary ideas. At the end of the week, the teams post their ideas in a large-group discussion and document sharing forum, and they respond to the ideas posted by teachers in other teams. This forum in turn provides a springboard for in-class discussion at the beginning of the following week.

Cooperative Projects

The third kind of interaction also involves small groups, but in this case the teachers work in teams throughout the semester. Project teams are formed according to shared interests or circumstances, grouping teachers by school, grade level or areas of expertise. In this way the teachers in each team are able to provide helpful suggestions or experiences to other team members. Each team has its own discussion space in which members work on assignments together, share copies of their work, ask for and receive advice, or relate the week’s events and offer support. The format of this interaction is decided by the group according to its own needs: instructors offer suggestions, but no requirements. The only demand is that each teacher participate actively in the team each week.

Conclusion

Distance education coursework has traditionally been more successful with students who exhibit a
strong sense of ownership: students who are independent, who are highly motivated, who have a high degree of self-efficacy, and who wish to have a high degree of personal control over life's outcomes [Riddle 1994]. The challenge for distance educators has long been to build this kind of ownership in students with all types of learning characteristics. Educational research consistently indicates that all learners benefit from instruction in which they are motivated, in which they exercise control over their learning experience, and in which they are accountable for their own learning outcomes [Wagner & McCombs 1995]. Web-based conferencing offers a strong new approach for promoting these variables among distance learners. By offering a range of options for interaction outside of class time, web-based conferencing can encourage students to develop a higher degree of ownership, enabling them to direct the discourse of the class, to establish ongoing relationships with instructors and peers, to make informative decisions together, and to take greater responsibility for the learning process.

A Generative Approach to Active Information Assistants

Antonio Cisternino, Maria Simi
Dipartimento di Informatica, Università di Pisa, Italy,
E-mail {cisterni, simi}@di.unipi.it

Abstract: We propose a general model and associated language to specify the behaviour of an electronic assistant. The range of applications we have in mind are those tasks where the system acts as an assistant for active information exchange in both directions. Examples are interactive story telling, database querying, self-evaluation or evaluation tests, collection of user profiles, intelligent tutoring, product configuration assistants, diagnostic systems or other kind of interactive expert systems. A restricted version of this model was used as the basis for a tool to generate configuration assistants.

1. Introduction

A well-known problem of the Web is to keep large quantities of data consistent and up to date. A standard approach to this problem is to reduce data redundancy and to maintain a minimal subset of the data, together with the ability to automatically generate Web pages from this compact representation. A further step in this direction is to extend this approach to generate, together with the data, applications and graphical interfaces to manage those data. As a prerequisite, a meaningful set of applications where a similar generative approach can be exploited has to be identified.

A common task for organisations is to provide users with the required information and optionally collect useful data during this interaction. Computers may play the role of assistants in this information exchange, especially in the Internet where information can be made available to customers all over the world. We propose a general model and associated language to specify the behaviour of an electronic information assistant. This model can be used to generate graphic interfaces, data and programs for specific applications, thus addressing the problem of reducing the amount of data to manage and the time required to develop a new application.

We have adopted a restricted version of this model as the basis for a tool to generate configuration assistants, a special kind of information assistant. This experience has shown that these kind of assistants can be easily generated from a suitable representation of the configuration process [Attardi et al. 98, Cisternino et al. 97]. We believe that this model and approach can be generalised to deal with other application domains.

2. Active information assistants

The metaphor we have in mind is a dialogue between two persons finalised to information exchange. One of them acts as the information assistant, the other one as the customer. If the purpose of the exchange is to inform the customer, the assistant must present information according to the customer’s needs and, to this end, he may pose questions to decide exactly which information is useful. On the other hand, if the purpose of the exchange is to collect information from the customer, the assistant has to ask the relevant questions in order to gather the information conveyed with the answers. In any case the assistant takes the initiative.

We can identify two sorts of questions in this dialogue: general questions for deciding the strategy to follow in the information exchange, in order to assess the customer’s needs and preferences; specific questions whose purpose is to make the user provide specific data which are to be collected.

The metaphor of information exchange is quite general and can be found in many different domains: salespersons, information desk employees, and teachers, all engage in these sorts of dialogues in the role of assistants. Computer systems play this role in many information service applications. Here are some examples:

1. Database querying: the system helps the user in the formulation of the correct query.
2. Interactive story telling: the system may prompt the user intervention in deciding how to proceed.
3. Self-evaluation or evaluation tests: the system proposes questions and suggests a number of possible answers; according to the answers the skills of the user are assessed by giving back a score or an evaluation.
4. Intelligent tutoring: the system displays educational material, proposes exercises or questions and suggests a number of possible results; depending on the answers, additional material is presented which matches the level of the pupil.
5. Collection of user profiles: more or less direct questions are posed to collect user’s profiles; an obvious use of this is electronic commerce and marketing.
6. **Configuration assistants:** the user is guided through simple configuration tasks, such as product assembling and customisation or study plans generation; the goal is to assemble a product out of a set of predefined parts according to problem specific constraints and user requirements.

7. **Interactive expert systems:** questions are posed to collect information on the specific case, like symptoms in a diagnostic expert systems; the goal is to combine these collected data with background knowledge of the domain of expertise to produce expert advice.

### 3. The generative approach

The model relies on a representation of the strategy that the information assistant uses to request and present information to the customer. A rooted directed acyclic graph, called choice graph (CG), is introduced, which can be seen as a representation of the assistant’s strategy in posing questions to the customer. Each node of the graph represents a possible knowledge state that is reached as the result of a set of general questions posed by the assistant. Successor nodes represent further alternatives in the information gathering strategy. Each node has associated specific questions that the user is prompted to answer; depending on the application, the answers can be selections from a set of items or solicited input data.

The choice graph is a suitable representation of the information exchange strategy for generating a graphic interface for the information assistant. A node of the graph is displayed as a single hypertext unit; selection buttons correspond to available options which the user is prompted to select, input boxes are displayed for data required to be input; links to other pages lead to successor nodes.

An additional component of the model is custom functions associated to the nodes of the graph. Their purpose may be different depending on the application: they could update a database with the new information provided, check the new information for consistency or compliance to predefined constraints, activate forward reasoning in expert systems and so on. The last, optional, component of the model is a database of items, objects with structure like class instances in an object oriented model. They can belong to different classes: the only requirement is that they have a unique name so that they can be identified in the choice graph. They constitute the pool of objects that can be referred to in the information exchange.

The declarative language we use to define information assistants is essentially a way to describe choice graphs. The language supports the definition of choice blocks, corresponding to nodes in the choice graph, which include text components and interaction components. The form of text component is simply a string that will appear as is in the graphics interface. A selection component appears as follows:

```
[<cond> =>] <fun-name><item list> [(<pars>)]
```

i.e. a custom function applied to an item list, a list of items from the database identified by their unique name, optionally followed by a parameter list. For example “Exactly[CPU1, CPU2, CPU3] (1)” could be used for prompting the user to select exactly one item out of a list of the three items corresponding to different CPU models. The selection can also be subject to some condition on the current state, which is dynamically tested. In a configuration application, for example, a choice block can be defined as in the computer example below.

```plaintext
Personal computer
{Nec [Motherboard, Case], /1/ 
Exactly[CPU 200, CPU 333](1), /2/ 
Atleast [8MB RAM](2), /3/ 
OR(Game PC, Multimedia PC) => /4/ 
Nec [CD-ROM, Sound card, Speakers, 
3D Video Card], /5/ 
CHOICE(CRT monitor, LCD monitor) /6/ 
Max cost(3000); /7/
```

This block description includes selection components, corresponding to constraints that are to be checked in this particular domain, specifying items that are necessarily needed and items that are needed depending on the state, i.e. the presence of other items or previous choices.

We can automate the process of generating a specific class of assistants by a means of a compiler, taking as input the item database, the dialogue description in the form of a CG, and a definition of the custom functions.

The generator, written in Java [Gosling 96], produces the application programme (a Java applet), the graphical interface for interaction with the user (a set of HTML files), and a compact encoding of the CG and the database (data structures in Java), which are interpreted at run time.

jsledge@getty.edu

Abstract: An American Strategy Draft Mission Statement -- America's cultural heritage resides in countless resources in nature and in museums, in libraries and in archives, in architecture and in dynamic performance. Stewards of America's national collections have long contributed to the protection and perpetuation of this country's cultural heritage by their actions to collect, preserve, and interpret this rich abundance. Advances in information technology now open up a new threshold of opportunity for the federal stewards of cultural heritage to offer far greater access to cultural heritage information to a much broader American and international public by linking their digital information resources together and providing deeper intellectual access. This collective action, of cooperatively connecting federally-held cultural heritage information and making it broadly available as a public good, is called American Strategy.

Introduction

A situation has arisen that offers new opportunities for collaboration to all institutions in possession of collections of materials concerning the cultural heritage of the United States of America and the access of the American people to it. For the first time in history, our museums, archives, and other institutions can, through collaboration, greatly improve access to the materials involved not only for researchers, but for the educational community, including elementary and secondary schools. The collaborations discussed here go beyond institutional participation in joint exhibits or travelling shows. These collaborations, for the first time in history, propose to join collections from a variety of institutions seamlessly along thematic, chronological, geographic, or any other lines that the organizers decree or that the user requires. These efforts could only be accomplished with the help of the technologies which we now have at hand. This extension of access through the digitization of cultural assets will enable people of all walks of life to view objects of their heritage heretofore hidden from view. More importantly, projects which include an educational component will assist teachers and researchers to make good use of objects, many of which have lain unused for many years. This paper describes the process of one of the largest undertakings in this area and gives a historical background for its development by briefly describing previous and existing joint extended access and digitization projects. The word process, here, is highly important, as it means that this paper will not only disclose what the project is about, but how it is proceeding. This means that the project will be able to be replicated on large or small scale by local or state level agencies desiring to do so.

Background

284
If this paper is to be helpful to other local and state level agencies in developing their own collaborative digitization projects, it is important not only to highlight this one project, but also to give a sense of history to the development of digitization projects in general. A description of several notable collaborations follows. One of the best resources for information regarding collaborative projects of this nature is an Occasional Paper of the American Council of Learned Societies. Paper Number 41, entitled "Computing and the Humanities: Summary of a Roundtable Meeting", describes a meeting held in 1997 at the National Academy of Sciences in Washington, D.C. for the purposes of examining the reasons, procedures, and outcomes of interdisciplinary collaborations for sharing of digital resources [ACLS 1997]. Participants included representatives from the Computer Science and Telecommunications Board of the National Research Council, in collaboration with the Coalition for Networked Information, the National Initiative for a Networked Cultural Heritage, and Two Ravens Institute. It was an attempt to bring together computer scientists and humanities scholars to discuss how collaborations to improve access to digital items concerning our common heritage could be brought about. At the American Strategy meetings, issues like this are taken for granted because all of the institutions represented are cultural agencies that are already networked and familiar with computer applications relevant to their own operations. However, the National Academy of Sciences' meeting was an historic one because it began the cooperative discussion of these issues and produced a summary document that can be referred to for historical or developmental research purposes.

The National Academy of Sciences meeting described a number of digital access collaborations. One of these was the American Memory initiative, a project of the Library of Congress. It provides access to the Library's collections of American historical information and to those of other libraries throughout the country. During the meeting, mention was also made of the ARTFL Project. This is a cooperative project of the Centre Nationale de la Recherche Scientifique in France and the University of Chicago. They now have online over 2,000 thirteenth to twentieth century French texts in the arts and sciences. ARTFL is a subscription web site. A free digital library of resource material concerning ancient history is the Perseus Project of Tufts University. The Perseus Project has produced a commercially available CD-ROM set which contains multimedia historical resource materials; however, many of their texts, maps, and photographs are available for free on the Web. One collaborative effort to produce a digital library, as well as to develop standards for one, was underwritten by the Mellon Fund. Cornell University and the University of Michigan have worked together not only to put material online, but also to involve other institutions in developing common methods and protocols for the storage and retrieval of digital material. Their collection of social history resources documents the mid-nineteenth century in the United States. The last initiative mentioned in Occasional Paper 41 is of particular interest because it was begun by the forerunner of the Getty Information Institute in collaboration with MUSE Educational Media. This project tested a method of sharing licensed material across closed networks between seven museums and seven universities. Obviously, the Getty Information Institute has experience in the area of organizing and opening access to digital cultural resources.

The name of the new project described herein is the American Strategy. This initiative may shape the future of public access to information about America's cultural heritage. American Strategy is a public-private partnership, the aim of which is to give everyone multi-media access to world cultural heritage, beginning with that of the American peoples. The project will link federal departments and agencies in exploring ways to create a prominent, coordinated electronic gateway for cultural heritage information. The digital holdings of a variety of federal cultural institutions will be melded into one vast heritage resource site through the use of educational navigation tools. "In Willard McCarty's words, the Web 'is a mechanism to publish documents to be used actively by people, certainly by humanists who are compulsive publishers.' An associated need is increased awareness of digital content, which can itself be supported with information technology." [ACLS 1997:38]

Rationale

In [ACLS 1997] Edward Ayers spoke of how it is easier to produce electronic content than to effectively disseminate it. This is especially true where digital education resources are concerned. Another problem
arises, as well. The means to access digital information remain not only expensive (although the e-rate now may make things more accessible to K-12 educators) but also mysterious to many. Ayers said "... if we cannot get this (electronic resources) into the hands of people who want to touch the cultural heritage of the past, then I do not think it is worth the trouble. But when you have people out there with thirty students clustered around one computer on a 14.4 modem waiting for these pieces of the past to materialize before them, we are running into serious problems. And when it does materialize, if we have not equipped the teacher to point out what it might mean, then we are actually creating problems at the same time that we are supposedly creating potential." Obviously, it is necessary to provide both training and navigational tools for educators to use these cultural resources. Facilitating access to and use of the heritage resources for educators are main agenda items for the American Strategy project.

Cultural heritage, being the complex resource that it is, needs context as well as content. This is one of the most difficult things to provide on the World Wide Web, and providing that context is one of the greatest challenges which has been taken up by the American Strategy. It is essential to see this project as an attempt to build multiple levels of access to information containing myriad points of view and open to endless interpretations. This will be more than a basic inventory and gateway of digital resources not only because of its educational component, but because it will cut across many government levels and institutions. This, in itself, is highly innovative, as the interagency cooperation required is enormous. However, representatives from a large number of federal agencies have been meeting since mid-1997 for just such purposes. The point is that because a wide variety of federal agencies are involved in the preservation of objects and information regarding our cultural heritage, a large number of agencies must collaborate to provide access to our comprehensive cultural heritage. One of the most important things about this project is that it is flexible and continues to evolve as the directions it needs to take become apparent. There was an original idea, but it continues to be adapted and refined as advice and counsel is considered. The project has become a process. The history and framework of that process is discussed within this paper.

Project History

The Getty Information Institute plays an active role in a number of international projects such as the G7 Multimedia Access to World Cultural Heritage. The Institute has also been active in representing cultural heritage interests in the formulation of American policy for a national information infrastructure. Playing a catalytic role to support the federal departments and agencies to come together to consider access to heritage collections is a concern of the Institute. With that in mind, in 1997, Jane Sledge of the Getty Information Institute, began contacting individuals from a number of federal cultural institutions in Washington, D.C. Ms. Sledge attempted to interest representatives from a wide variety of federal resources in attending a meeting to discuss the possibility of a collaborative project regarding the digital preservation of our comprehensive cultural heritage. The goal, however, was not merely to host a meeting to coordinate efforts to improve access to federal information about American heritage. The goal was to develop a process to improve access to federal cultural heritage information.

Unlike some other seemingly similar projects, this was not to be a millennium project. The scope of this project would be much too large to be accomplished in such a short time. The original plan called for a demonstration project which would then be fleshed out over the next ten to twenty years. To that end, a meeting was held in mid-1997. This meeting included representatives from major cultural organizations in Washington, and was co-convened by the Getty Information Institute and the Institute for Museum and Library Sciences. The meeting facilitators made suggestions to stimulate participant follow through. It was decided that instead of focusing all efforts into simply holding another discussion meeting, a process could be developed which would reveal not only the larger scope and mission of the project, but also the impending necessity for a collaboration like the proposed one. This approach would also encourage continued commitment to the proposed collaboration. The process, as then generated, had five distinct components:

1. Articulate the vision(s) for an ideal strategy to position American cultural heritage;
2. Discover the opportunities and needs associated with achieving this vision;
3. Detail the challenges and impediments to achieving the vision;
4. Develop the strategies to bring the vision to fruition; and
5. Gain commitment to implement the strategies.

It was agreed that separating the strategy development meeting from the presentational and commitment meeting would allow for strategies to be developed, discussed, and, if necessary, revised before they were presented to a larger group of agency and department representatives. To carry the vision through to fruition, it was necessary to build a structure for relationship and collaboration among the participants. More time needed to be given to creating a common ground for collaboration and structuring people's and institution's relationship to the project. A much better understanding of the key issues, the problems which needed addressing, the specific needs and opportunities for which strategies might be developed, the potential stakeholders, and the guiding values for maintaining the process with integrity was necessary. These values might include working with the whole system and exploring the key issues in the largest sense. It was agreed that these first steps might best be undertaken through a facilitated meeting of an Advisory Committee.

The action stemming from this conversation was an invitation to members of federal cultural institutions to attend a facilitated meeting of an Advisory Committee to develop an understanding of the common ground and to articulate a vision statement. The Institute of Museum and Library Services, the Getty Information Institute, and the American Association of Museums hosted the meeting, an essential first step in articulating the challenges and opportunities for coordinated online access to federal collections and for developing strategies for action. The meeting was held at the American Association of Museums on Monday, December 15, 1997. Choosing this venue set the tone for the meeting. The A.A.M. is an umbrella organization of approximately three thousand institutions. Of the top 175 art museums in the USA, 95% are members. An interesting point is the interdisciplinary nature of the organization. The chair is held by a science museum. Even more relevant is the fact that education is at the heart of their mission. Clearly, this was an organization to stimulate progress on this project.

Attendees included representatives from the National Gallery of Art, the National Park Service, the Library of Congress, the National Archives, the Smithsonian Museum, the Armed Services, and many more. Most of the major players in the federal cultural scene were represented, as well as the Getty Information Institute. This meeting included an overview of the joint vision of the major convenors, the Getty Information Institute and the Institute of Museum and Library Sciences. Also, case studies of representative agencies' digital projects were presented by the National Archives and Records Administration about the Civil Rights Advocate Web page, the Library of Congress regarding the National Digital Library Project, and the Smithsonian Institution on the Smithsonian without Walls, "Revealing Things" project. A framework of questions about the case studies was provided to stimulate discussion about four main ideas embodied in the case studies. These ideas highlighted the importance of providing context, the need to navigate any quantity of information, issues surrounding intellectual property rights, and infrastructure for collaboration. During this meeting, two draft vision statements were produced by working groups and an agenda outline was generated for a two-day meeting, set for January 22 and 23, 1998.

Instead of having the January meetings be high level, it was decided to build upon the previous discussion by involving more people at the mid-management to senior level to elaborate upon the vision and to articulate possible strategies to bring the vision to fruition. A series of sub-groups (international positioning, partnerships, and public access) at the January meeting was charged with three tasks: to identify short and long term goals that the American Strategy would try to accomplish, to specify strategies to achieve the goals, and to propose tasks and collaborative undertakings. The groups also suggested players, key people. The framework for recommendations was structured to include a short term goal, a strategy, one or more tasks, and one or more key players. The recommendations would be discussed at a third meeting.

At these second meetings, the basic direction which the project would take was defined: it would layer resources from the participating institutions and join them via a gateway site enhanced by curriculum materials which would maximize their usefulness to all educators. A lengthy discussion took place wherein
the attendees talked about what they had and did not have to contribute to the project. Many types of organization were discussed, although the educational model prevails. During this meeting, participants also drew up a preliminary work plan. The process to achieve the goals of this plan also began to be defined. Tasks were brainstormed and research tasks were assigned. A pilot project was discussed and it was decided that a web-based effort was what all would agree upon. At that time it was hoped that the launch, or unveiling, of the demonstration project would be held in June, 1998. In an important decision regarding the launch, the committee agreed to seek White House support for the project. Another meeting was scheduled for late February at the headquarters of the American Association of Museums.

The third meeting, held on February 25, 1998, drew together senior management to review the strategies and recommendations and to make commitments for undertaking the strategies. At that meeting, the American Strategy members began to define how member organizations would cooperate to digitize and link federally-held cultural heritage resources. The members would be divided into six working groups: briefing materials, demonstration project, gateway home page, public-private partnerships census of digitized resources, and executive order. The working groups are chaired by a cross-section of the general membership who, in turn, make up the Steering Committee. The members of the working groups are contributing digitized information and staff resources to a Demonstration Project, originally planned for June, 1998, but now postponed until December, 1999. The members are also to help define infrastructure needs among agencies. For this meeting, three tasks had been delineated:

1. The group should make sure in re-examining the January meeting that its desired outcomes had been reached.
2. The group should agree upon an agenda for further action. This action would lead up to the event in June, 1998 (since postponed) and lay plans for the completion of the project in subsequent years.
3. The group should develop a structure for implementation of the plans.

During this meeting, one representative addressed the mission statement. It was pointed out that this statement looked outward and was for people outside of the committee. It was something that would explain our purpose to everyone. However, there would be cooperative “inward principles” which would guide how we worked together. These would assist with the pre-launch “political choreography” necessary for a project of this scale and scope, as well as the post-launch implementation phase. The launch was planned for a venue in Washington, D.C. and would attempt to garner as much publicity, and hence support, for the project as possible. As it was felt that an international perspective is necessary, since it is hoped that the project will expand beyond our borders, it was decided to include members of the international press. A number of issues had to be dealt with in addition to the demonstration project itself. There was an obvious need to orchestrate an early buy-in by agency heads before the event. Long discussions centered around how to get support from the administration. A schedule of general meetings was planned. Task groups planned to meet between the general Steering Committee sessions. During the Steering Committee meetings, each task group reports on the status of the efforts and discuss what lies beyond the launch for that work group.

**Project Future**

Since those original meetings, the project has evolved enormously. It has been realized that a properly orchestrated launch could not be effected by June, 1998 and the postponement has given the committee time to create an overall structure for American Strategy. At this time, both a business plan and a communications plan are being developed by professional consultants. A meeting will be held on July 23 to move the business plan forward. On September 17, a participants' meeting will be held to review the demonstration project, the gateway home page, the business plan, the communications plan, and other achievements. By that time, the working groups should be refined and moving towards new projects. Before Fall, 1999, the demonstration projects will have been unveiled, revised by the participants and, hopefully, publicized in both news and Web media. At this time, it is hoped that broad discussion will be initiated around the demonstration project and that corporate support for project hosting in D.C. and beyond will have been secured. Further, it is hoped that
the departments and agencies will declare continued commitment and, as such, American Strategy will begin to be reflected in some federal agency budgets. Beyond a hope for Executive Branch support, it is desirable that Congress be informed and supportive of the project and that some members will champion the project. Another important issue to be resolved will be the development of a framework to deal with any rights management and legal issues. In an effort to present a uniform face, a general presentation will be developed so that all are speaking from the same script.

By June 3, 1999, American Strategy should have identified funding strategies and developed "magnet projects" to attract foundation and corporate support. Media partners will also have been identified. Most important, though, will be the gateway which will link all departments and agencies that participated in the early meetings and, even more so, the development of enhanced cultural search and retrieval tools. American Strategy will continue to seek solutions to the problem of integrating collections databases. It will do this within the U.S.A. by beginning to involve the states in the American Strategy partnership and, later, by seeking relationships with other national infrastructures.

Summary:

As the Executive Summary of the American Strategy briefing materials states [AS 1998]:

"American Strategy is a national leadership initiative that will:

• demonstrate the commitment of national cultural organizations to encourage and facilitate public access to America's cultural heritage resources;

• emphasize the invaluable investment America's citizens have made in the preservation of their national heritage, so that people throughout the world have the opportunity to enjoy and appreciate our cultural and natural heritage;

• represent the great breadth and depth of this country's cultural and natural heritage that resides in national collections;

• respond to the public demand for access to rich and meaningful information via the Internet, ensuring ease of use and enhanced awareness of national cultural resources, for the elementary school student to the life-long learner; and

• produce an electronic gateway to related cultural information that will continue to evolve, incorporate additions to the national collections and new interpretations of our history and heritage, and break down the organizational barriers that inhibit associations among disparate cultural resources."

The State of Technology in U.S. Schools:  
Making Counts of Technology, Making Technology Count

John R.B. Clement  
Education Statistics Services Institute, USA  
jrclement@air-dc.org

With widespread support from nearly all sectors of society, Federal, state and local governments and the private sector have committed to support a massive national effort to put computer hardware in the schools and get students on the information highway. The costs amount to a significant fraction to school budgets; and, given that they largely represent budget lines that heretofore did not exist, are likely to force a reallocation of resources upon the school system. Such reallocation amounts to a policy of school reform, if largely an unconscious one.

As with all infrastructure, these are far from one-time expenses. Even if we ignore the constant race to upgrade the hardware and speed up the networks, this is one infrastructure that has very substantial maintenance costs. It is not enough to donate computers to the schools, not even if they are connected by local-area-network cabling and linked to the Internet. The provision of technology infrastructure must include plans for sufficient equipment to address real student and teacher needs; software for both instructional and administrative uses; the provision of training and support for users; and equipment maintenance and replacement. Policies and plans to provide technology may not ignore these matters, if policymakers and administrators want to avoid misuse and neglect of the system and abuse from taxpayers.

In order to estimate the size of our investment, to rationally allocate our resources, we need to know where we are in this process. Policymakers don’t know enough about what is going on. In one sense, we have plenty of information. National surveys of schools by the National Center for Education Statistics’ Fast Response Survey System (FRSS) in 1995, 1996 and 1997 have shown a pattern of constant increase. The latest data suggest that over two-thirds of the nation’s schools have some form of connection to the Internet, and nearly every school has at least one computer [NCES 1998]. And there are spot-checks, surveys and snapshots galore, as well as compilations of reports and anecdotes. As an instance, Education Week published in November of 1997 a special issue, "Technology Counts," with a substantial amount of information including state-level profiles [EW 1997]. There are also a number of reports by experts and blue-ribbon panels of diverse sorts.

But what the plethora of surveys and anecdotes mask is that we lack consistent and detailed information about many things we claim to know, and there is much of great importance for policy that we don’t know at all. For instance, even in the area of counting hardware, which might be viewed as relatively straightforward, we largely lack information about where computers are located within the schools – and this information makes a difference for instruction. For another example, we are woefully ignorant about the extent of in-service training for teachers, and we don’t know enough about the provision of maintenance and support.

As a nation, we are most concerned about these areas of ignorance because we fear that not enough is being done, and that so much effort that is going into the provision of hardware, software and networked resources is wasted because teachers don’t know how to use the equipment for instruction.

Beyond general policy concerns, there are a number of government groups who have an urgent need for consistent, well-structured data on computers and networking infrastructure in schools. We consider here just two.

The Schools and Libraries Corporation – or whatever entity succeeds it – is facing a problem. The Corporation is tasked with the transfer of Universal Service Fund monies to the schools’ service providers, in the form of discounts of up to 90% for telecommunications hardware and fees. They must do this by approving proposals
from educational organizations at all levels; they will have to do this year after year. Over the years, they must
know what equipment and infrastructure the schools have, what they were funded to do last year, and what
upgrades and improvements it is reasonable to ask for given what schools already have. They need data on each
school to manage their program, much less evaluate its impacts.

The states and localities themselves are having to assess their own progress. An examination of state data
collection efforts in this area indicates that over thirty states have collected some data in areas related to
technology and networking in schools [AIR 1998]. This is a very strong base of policy interest and experience
upon which to build. In many states, technology is being provided by state mandate, for a variety of reasons.
Another trend is that the states are under strong pressure to report what they are doing in all areas to their
citizens. Thus, an increasing number of states are issuing report cards on the performance of districts and
schools on all sorts of measures, including finances, student performance and, in a couple of cases, technology.
This sort of accountability can only be expected to increase.

One of the most interesting developments is the growth of private-sector (especially business, and most
especially technology-intensive businesses) pressure to do more about providing equipment and software for
schools, and to collect and report better and more complete information about what equipment there is. The
Milken Exchange on Education Technology (http://milkenexchange.org ) has devoted itself to this cause,
bringing people together from the Federal government, the states and from corporate America, and also funding
publications -- cosponsoring, for instance, the abovementioned November 1997 issue of Education Week. The
CEO Forum on Education and Technology, (which includes CEOs from technology-intensive firms as well as
the chiefs of both the National School Boards Association and the National Education Association), in October
1997 published the "School Technology and Readiness Report." Among other things the report calls loudly for
"...additional school and classroom data on hardware and connectivity as well as content and professional
development [FORUM 1997]."

These efforts are to be welcomed; the attention to the issues and the support for action that they bring with them
can only help the national debate. But the concern with private-sector efforts is that they will collect and report
whatever data they can find, and not spend the time and effort it takes to coordinate state forces and collect the
data that are needed carefully and consistently.

It is early yet to say how data collection needs will be addressed. One potential solution is to establish some
basic data definitions and coordinate data collection efforts by the states, acting on a voluntary basis. Another
possibility is to engage the help of private sector education data collection entities, since there is so much
private sector interest. Yet another is to engage the Federal government. So far, NCES has relied upon sample
surveys to tackle parts of this issue; it may be time, at least for matters of hardware, software and networking, to
systematically collect data on the population rather than on samples.

Abstract: Viewing high-resolution images on the World-Wide Web at a level of detail necessary for collaborative research is still a problem today, given the Internet's current bandwidth limitations and its ever increasing network traffic. ImageEyes is an interactive display tool being developed at Utah State University that addresses this problem by integrating caching, compression, and transmission techniques and performing global optimization across these techniques. Although much of ImageEyes is based on existing technology, it employs several innovations, including a three-dimensional, hierarchical cache and a data striping technique that tolerates lossy transmission without significant degradation to the user's view.

1 Introduction

The advent and popularity of the World-Wide Web (Web) has created an effective medium for scientists to collaborate among themselves and disseminate information to the public. Applications that require ad-hoc inspection of high-resolution images, however, are still not feasible because of current bandwidth limitations and increasing network traffic. One such application involves on-line examination of x-ray images. To be useful, doctors must be able to examine any part of an x-ray image in as much detail as the original film would allow. Ideally, when accessing an x-ray, a doctor should first see a high-level view of the whole image and then, in near real-time, be able to zoom and pan through the image, examining minute details like hair-line fractures. Other applications include on-line study of biological specimens, historical documents, artwork, and satellite photographs.

Most of the images on the Web today range in size from one to several hundred kilobytes. Although such images can fill a standard computer screen, they do not provide enough information for inspection of fine details, like bone fractures. Simply using higher resolution images, which can be several hundred megabytes in size, does not solve the problem. Current Web protocols are based on full-image transfers, irrespective of transmission speed, the resolution of the user's screen, and the availability of local storage [HTTP 1998]. Not only can full transfers require an unacceptable amount of time, but users may not have enough local storage space to hold the image data. In addition, why should the local system even try to retrieve and store that much data when only a small fraction of it can be displayed at any given time.

One possible approach is to cut a high-resolution image into smaller views that focus on predetermined areas of interest within the picture. For example, a high-resolution image of a plant might be broken down into separate views that focus on leaf venation, leaf arrangement, and its reproductive parts. Although this approach keeps the data requirements and transfer times within reasonable limits, it severely constrains the user's ability to freely explore the original image. For collaborative research, it is critical that users be able to explore areas of an image that may not have been previously considered interesting. Furthermore, extracting predefined views from high-resolution images takes significant effort and requires those who prepare the views to have an in-depth knowledge of the subject area.

Many of the restrictions and decision-making problems of the prior approach can be eliminated by fully and automatically partitioning the original image into sub-images at some zoom factor and then repeating...
this process for each sub-image until all available detail is fully exposed. This would result in a complete hierarchy of views. Each level in the hierarchy would represent the full image at a specific zoom factor. Zoom operations would be implemented as hyper-links between views on different levels, whereas pan operations would be implemented as hyper-links between views on the same level. Although this approach allows exploration of the entire image, it has several serious drawbacks. One problem is a potential for excessive data transfer, even when the user's Web browser has a local cache. This problem stems from the way browsers treat image files as autonomous entities. They cannot reuse bits and pieces of previous images. For example, if a user is looking at the edge of a leaf and then zooms out to see the whole leaf, the browser requests the transfer of a whole new image, even though a portion of that image was just on the screen. Another problem is that extensive zooming and panning of an image would eventually fill the browser's cache and thereby render the cache useless as soon as the user leaves the image. Finally, since the zoom and pan operations are implemented with hyper-links, the backtracking feature (the Back button) available in most browsers would cause the operations to be played in reverse, which can initiate additional unnecessary data transfers.

ImageEyes is an interactive image display facility that will allow Web users to explore high-resolution images in near real-time without upgrading their computers or networks. This paper describes an overview of its design and operation and the status of work in progress.

2 ImageEyes' Architecture

Figure 1 shows a high-level view of the ImageEyes' architecture. The boxes labeled Web Server, Web Browser, and Fast CGI Interface and the interconnecting lines represent existing Web components and protocols [Connelly 1998, HTTP 1998, NCSA 1998, W3C 1998]. ImageEyes will use this existing technology for displaying entry-points and initiating image viewing sessions. The remaining boxes and ellipses represent the ImageEyes server and client. At the core of their design is an integrated strategy for global optimization, across its image processing, compression, communication, caching, and display techniques. The basic idea is to use observed conditions in one area to tune performance in another. For example, noisy transmission might cause ImageEyes to alter how it packages and compresses individual blocks of data prior to transmission.

The ImageEyes client software is responsible for interacting with the user, sending image requests to the server, coordinating responses, managing a local cache, and displaying the current view. We have
implemented version 1.0 of the client in C++ as a stand-alone application running on HP-UX® with Motif 1.2®. Future implementations include plug-ins for Netscape® and Internet Explorer® and a Java applet. Because some of these variations are intended to be downloaded at run-time, our approach is to keep the client software as lightweight as possible. For this reason, all decision-making and optimization logic resides in the server.

The client's user interface displays a view of the image and allows the user to navigate through the image with various zoom and pan operations. The request generator optimizes the navigational requests and send them to the server via a communicator. Each request includes information about the contents of the client's cache and current network conditions. The server uses this information to decide the minimum amount of data that has to be sent back and to optimize the packaging and compression of that data.

The client's cache is a hierarchical scheme consisting of logical layers, each representing the entire image for a different zoom factor. At any given time, a layer may contain no data, disjoint blocks of data, or a complete image. The top layer, which corresponds to a 1x-zoom factor, is always completely in memory. Lower layers have higher zoom factors, and therefore, represent the image at higher resolutions. The zoom factors can increase either linearly (e.g., 2x, 3x, 4x, etc.) or exponentially (e.g., 2x, 4x, 8x, etc.) Space for new data is allocated from a free list using a first-fit algorithm. Cache data blocks are replaced using a modified Least Recently Used (LRU) algorithm. Like standard LRU algorithms [Tanenbaum 1992], ImageEyes' replacement algorithm uses a queue structure to track the order in which cache blocks were last used. However, instead of using the first-fit block from the queue, the algorithm tries to preserve blocks containing data that overlaps with the requested region in the current operation. It does so by placing "in-use" locks on all such blocks. In finding space for a new data block, the replacement algorithm first releases and coalesces blocks without locks. After this process, if there is still insufficient free space for the new data, it splits locked blocks based on their potential value to the current operation. Blocks at the same layer as the current operation and with the smallest overlapping region are chosen first. When a locked block is split, the overlapping region is placed in a new block and marked as "in-use". The remaining portion is released and coalesced with other free blocks.

The client's cache can reduce the amount of data that is needed for zoom and pan requests in two ways. First, when a user moves to a new region and there are pieces of that region in the cache at the desired level or lower (higher zoom factor), then those pieces do not need to be transmitted. Their display can be computed directly from the cache. Second, when cache contains data at a higher layer for the requested region, the client only needs delta values, which are the difference between the aggregate color values of the higher layer and the exact color values for the requested layer. In many cases, these delta values fall into a small range, e.g. -15 to +16, and therefore, can be packaged and compressed into fewer transmission packets.

The server's image processor is responsible for interpreting an incoming request and deciding the minimum data needed to satisfy that request. First, depending on the contents of the client's cache, it breaks the request up into non-overlapping sub-regions. Then, for each sub-region, it chooses how to package and compress the data. More specifically, it decides whether to send delta values or absolutes values. If the image processor decides to send delta values, it also determines how they should be striped, i.e. broken up in to smaller incremental values. Sending striped delta values allows for lossy image transmission and, in many cases, actually requires fewer transmission packets than sending absolute value. Sending striped delta values also results in a nice fade-in effect on the user's display, which gives the illusion of a quicker response time. Sending absolute values, however, is more appropriate when the delta values cover a large range and do not fit a normal curve.

The ImageEyes server is designed to support different storage formats for the high resolution images through format-specific file I/O handlers. At this point, we have only implemented a file I/O handler for Raw PPM, but plan to build handlers for JPEG, GIF, and TIFF in the near future.

3 Operational Overview

With the stand-alone ImageEyes client, the user starts a viewing session by executing the client program with parameters that specify a host machine and the name of an image. The client connects directly to the ImageEyes server running on the host machine and sends it an open request. The server returns some startup parameters directly to the client. With a web-based ImageEyes client, the user simply clicks on an ImageEyes link in their web browser. This causes an open request to be sent to the ImageEyes server via a FastCGI interface [ Fig. 1 ] The ImageEyes server initiates a new session and returns the startup parameters to the web server, which in turn, sends them to the browser. The browser uses this information to activate the
client software. From that point on, the client software interacts directly with the ImageEyes server just like the
stand-alone version.

Consider, as an example, a user who starts a viewing session for an image of a plant against a plain
beige background. Although there are very few sharp edges in the image and the contrast is low, it contains
sufficient detail to show hairs on the edges of the leaves. After opening the session, the server sends the client
an initial view of the entire image at a 1x-zoom factor. The client displays this data and stores it in the top layer
of the cache. Next, the user zooms into the top-left corner of the image. This causes a request to be sent to the
server for this region at a desired zoom factor, say 4x. The request also tells the server that the client's cache
only contains the top-layer data. The server interprets the request, reads the necessary data from the stored
images, and decides on the best processing strategy. Because of the low contrast and lack of sharp edges, it
would likely choose to use delta values, striped into increments ranging from -7 to +8. Assuming that the
network conditions are relatively good, it would also choose to use standard compression parameters and follow
a transmission protocol that tolerates a small amount of loss before retransmission requests are issued.

Just after the client sends the request to the server, it starts computing the display based on the
information in the cache. So, in this case, the user will immediately see a course-grain blow up of the top-left
corner. The first 4x4 group of pixels will have the same initial value as the top layer's first pixel; the next 4x4
group will have the same initial value as the top layer's second pixel; and so on. The client can receive the
response packets from the server at any time and in any order, as long as the request hasn't been superceded by
a subsequent request. Since the packets contain delta values, the client simply adds them to the display and
updates the cache. To the user, it appears as if the image is coming into focus.

Suppose the user now decides to pan a quarter of the display width to the right. The client creates and
sends a new request to the server. The display is again updated based on the information in the cache. This
time, the left portion of the image that is to be displayed is already in the cache at the correct layer. The right
portion of the image is filled in with a course-grain blow up of the top layer in a fashion similar to the previous
request. Because the request included the contents of the client's cache, the server knows that it only needs to
send delta values for the right portion of the image. The server computes these delta values relative to the top
layer and sends them to the client. The right portion of the image is filled in as the client receives the packets.

The user makes a final request to zoom in to the image. The display is updated from the contents of
the cache so as much detail as possible is showing. Some portions of the image may contain data at the second
layer while other portions may contain data at the top layer. Suppose that the client doesn't have enough free
space in the cache to hold all of the data coming from the server. Some of the cache contents will be replaced
based on the algorithm discussed earlier. The least important blocks are removed or split and the cache is
updated with the new data.

4 Performance Evaluation

We will evaluate the performance of ImageEyes from several different perspectives. First, we will
examine it on its own merits by testing both normal and worst-case scenarios for various kinds of images. The
scenarios will consist of sequences of zoom and pan operations. The images will vary in size, number of
colors, regularity (repetition of patterns within an image), and clarity. For each scenario and image, we will
record the requests generated by the client and the sizes of the data blocks returned by the server. We will not
measure transmission time, since it depends on other variables, like bandwidth and current network traffic.

Second, we will compare ImageEyes to several existing techniques, including non-interlaced images,
interlaced images, predefined views, and fully partitioned images. Since the zoom and pan operations do not
apply to all of these techniques in the same way, we will rate the relative effectiveness from a user's
perspective. More specifically, we will look at the following issues:

- How much data is required before the user gets a glimpse of the image?
- How much data is required before the user has a complete overview of the image?
- How much storage space is required on the local system to view the image?
- What kinds of delays occur between zoom and pan requests?
- Was backtracking natural and effective?
5 Related Work

Much research has been done over the past few years on topics related to the ImageEyes project, including caching schemes, image compression, and image transmission. However, most of the work has focused on a specific area, like caching, and not on global optimization across multiple areas. Caching schemes have been extensively researched for operating systems and their properties are relatively well understood in this context [Tanenbaum 1992]. However, there are some significant differences between caching data dominated by sequential access patterns and caching images when there are three degrees of freedom in the movement through the data. Although the principle of locality of reference [Tanenbaum 1992] still applies, it is manifested in different ways. Nevertheless, common replacement algorithms, like LRU and NRU, and allocation algorithms, like first-fit and best-fit, can be adapted.

The areas of image compression and communication are also mature. However, current research efforts deal primarily with compression and transmission of entire images and therefore don't take into account cached data. Danskin, et al., describe an approach to image transmission that tolerates lost data with minimal distortion [Danskin et al. 1995]. Surveys of image compression techniques can be found in Introduction to Data Compression [Sayood 1996] and Data Compression: Methods and Theory [Storer 1988].

The most similar product to ImageEyes is one marketed by Hewlett Packard under the name OpenPix Software Suite® [OpenPix 1998]. This viewer is based on the FlashPIX™ file format [Lee 1998], which stores pre-defined views at different zoom levels. The OpenPix viewer is similar to the ImageEyes client in that the user can interact with a high-resolution image and avoid transmission of the entire image at one time. However, OpenPix seems to lack the kind of global optimization that is at the heart of ImageEyes' design. HP’s application allows users to zoom in and out, but only at the layers stored in the FlashPix file. It also appears that OpenPix does not take advantage of client-side caching techniques. Zooming in and then back out results in retransmission of the original image, which leads us to believe that the data transferred from the server to the client are absolute values and not relative values based on a client's cache.

6 Summary

Because ImageEyes uses an integrated solution for caching, compression, communication, and display and because it works with existing Web technology, we believe that it will provide an effective means for viewing high-resolution images on the Web. For typical images and usage scenarios, ImageEyes should dramatically reduce the amount of information that needs to be transmitted, and thereby, provide near real-time image zooming and panning. Its worst case behavior should be at least as good as the full-partitioning approach described in the introduction.

To date, we have implemented version 1.0 of the server and client. This version includes the hierarchical caching and lossy data transmission schemes as well as an intelligent data compression technique. We are currently collecting test data to evaluate and optimize the performance of the ImageEyes system.

A CHEMISTRY WEB-BASED COURSE SUPPLEMENT

Dr. Leon L. Combs
Department of Chemistry
Kennesaw State University
Georgia, U.S.A.
lcombs@ksumail.kennesaw.edu

Abstract: A web-based supplement for a chemistry class is described which assists the students in preparing for a lab course and in writing the lab reports. A pre-lab lecture for each experiment is available from the web site as streaming video and pre-lab tests are accessed from the web site with answers sent to the instructor’s e-mail. A system of bulletin boards allow each student group to complete their reports with each person in the group having a particular responsibility in the development of the report. Completed reports can then be given to the instructor in written form and on a web site.

1. Introduction

Kennesaw State University is a 13,000-student commuter university located about 20 miles north of Atlanta on I-75. It is part of the Georgia University System and offers B.S. and M.S. programs in a variety of disciplines including Business and Nursing. The Chemistry program offers a B.S. degree certified by the American Chemical Society. There are about 100 majors in the chemistry program. The average age of the students at KSU is 27 and almost all of them have jobs outside of the university.

Two of the courses that have been rather difficult to offer at our university over the years are the physical chemistry labs. There are several logistical problems associated with both of the labs.

One of the problems involves giving pre-lab lectures. Because of the expense of the instrumentation involved, we cannot have enough equipment so that the labs consist only of one experiment being done at a time. Thus there may be seven different experiments being conducted at each lab period and a pre-lab lecture is not feasible. One solution to this problem is to videotape lab demonstrations. A couple of years ago we had prepared video taped demonstrations of all of the experiments in the laboratory class. Two chemistry majors had worked with the professor to videotape crucial elements of the experiments and techniques required to satisfactorily conduct the experiments. We then had been requiring the students to view the videos in the library before coming to lab. However the students all work and planning to have time before lab to view the video tapes was sometimes quite difficult.

Another problem involved giving a pre-lab test to all the different groups after they have seen the video but before they come to lab. Since they all work, it was difficult to arrange for the pre-lab test before coming to lab so as to maximize the time spent in lab on the experiments.

A third problem involved helping the students to write the lab reports for each experiment. The students work in groups of two to three and since they also work, getting together to work on the reports and to discuss the material for the reports is very difficult.

A solution to these problems of teaching the labs is the purpose of this presentation.

2. Lab Demonstrations

A web page for the course is being written which is linked to streaming video presentations of the lab demonstrations. The videotapes are being put onto a central server and then streaming video will be used for viewing. The students can then view the demonstrations whenever they have time and wherever they have a
web connection. They can view them at home after getting off work at 2:00 a.m. or they might be able to view them at work during a break.

3. Lab Pretests

The web page is also linked to a set of lab pretests which they then take after viewing the demonstration and studying their lab manual. The tests may be taken at any time and are submitted to the e-mail account of the professor as soon as they are completed. The tests must be submitted at least 24 hours before the lab is to be done so that the professor can have the grades before the lab begins.

So now the students are prepared to come to lab to do the experiments. They come to lab, do the experiments, and arrange the data for data manipulation and plotting. Now they have to write the lab reports in their groups for submission to the professor.

4. Lab Reports

Now another problem is how do the students interact in the writing of the report since they all work and have very different schedules? The web page for the course is linked to a platform called Web Course-in-a-Box (WCB) which is developed at Virginia Commonwealth University. WCB has a section called Learning Links which, among other things, can be used as bulletin boards. WCB allows as many bulletin boards as needed and allows each to be open or restricted. The professor sets up the bulletin boards for each set of students and then sets up a different bulletin board for each experiment under each set of students. The students can then post messages, exchange files, and carry out discussions as they develop their lab reports. The final lab reports must be written in MathCad, which allows for easy mathematical manipulation and plotting of the data. Having their discussions asynchronously on the bulletin boards allows them to develop the reports and then prepare them using MathCad.

5. Other Web Connections

WCB has a section allowing all students to exchange e-mail messages and even to e-mail everyone in the class. Another section of WCB has a place for announcements that the students have to check at least weekly to see if the professor has posted something required for the labs. WCB also has sections allowing for posting of any sort of information related to the course, a section allowing the students to make their own web pages (required for the course), and areas for adding links to URL’s of interest to the course.

6. Conclusion

Thus the web course supplement consists of a home web page for the course with the links to streaming video and tests and a link to WCB. Portions of this development have been used already and seem to allow the labs to proceed very efficiently. The students come to lab well prepared and the reports are among the best we have seen. We are contemplating having similar web page supplements for other lab courses. We have also begun work on having the entire lab manual – with videos and pre-lab tests – as a web manual. All video pre-lab lectures are also being put on CDs as temporary solutions to problems involving slow internet connections by some students.
COLLABORATIVE LEARNING IN WEB-BASED INSTRUCTION

Patricia Comeaux, Ph.D., Department of Communication Studies, University of North Carolina at Wilmington, USA, COMEAUXP@UNCWIL.EDU

Richard Huber, Ph.D., Department of Curricular Studies, University of North Carolina at Wilmington, USA, HUBERR@UNCWIL.EDU

James Kasprzak, Ph.D., Information Resource Management College, National Defense University, USA, KASPRZAKJ@NDU.EDU

Mary Anne Nixon, JD, Business Administration and Law, Western Carolina University, USA, NIXON@WCU.EDU

Abstract

Scholars and proponents of computer supported learning advocate the use of collaborative learning as an important component of Internet courses. Advocates claim that computer supported collaborative learning (CSCL) is an instructional strategy that can help instructors avoid the pitfalls of Internet correspondence courses that rely on information acquisition and regurgitation of rote answers that reflect low level learning. As educators transition their course from a traditional to an Internet learning a paramount concern is maintaining the essentials of a collaborative learning environment. After a brief theoretical background of collaborative learning as an instructional strategy, the panelists will describe the use of collaborative learning in three different educational contexts:

1. an environmental education program for middle school science teachers in North Carolina;
2. a graduate project management course for individuals working full time in organizations throughout the United States; and,
3. a graduate course in applications of information technology for military personnel throughout the world.
Introduction and Literature Review: Panelist: Comeaux:

Collaborative learning (similar to cooperative learning) is a well-established instructional strategy in the traditional classroom. Research suggests that collaborative learning increases student motivation and achievement, promotes greater use of higher-level reasoning strategies and critical thinking, creates a sense of social cohesion and creates a productive learning environment [Abrami et al., 1995; Johnson et al., 1991; and Slavin, 1991].

Effective collaboration involves much more than students working together; they must value and perceive the importance of working actively with their peers in an interdependent structure. Effective collaboration means students think and act in ways that promote their own learning and that of others. Collaborative learning is enhanced when students are fully engaged in the activities of the class, are engaged with each other and the subject matter and take risks.

Scholars and proponents describe the essentials of collaborative learning as positive interdependent purpose and cooperative goal structure, interdependent division of labor and resources, individual accountability, and equal distribution of rewards. Students working together should know why (purpose and goals), how (procedures and tasks), with whom (group composition), the ground rules (interpersonal and group skills), and be held accountable to the group (Abrami et al, 1995, Johnson et al, 1991 and Rothwell, 1998).

Similarly scholars and proponents of computer supported learning advocate the use of collaborative learning as an important component of Internet courses. Furthermore, advocates claim that computer supported collaborative learning (CSCL) is an instructional strategy that can help instructors avoid the pitfalls of Internet correspondence courses that rely on information acquisition and regurgitation of rote answers that reflect low level learning [Dede, 1996; Harasim, 1993; Pea, 1993; and Savard et al., 1995]. As Pea [1993] argues “combinations of new computer technologies that facilitate collaboration and communication among learners can support and enhance learning, particularly distance learning” [p 288]. Dede [1996] claims that “computer-supported collaborative learning (CSCL) enhances team performance through tools for communicating each person’s ideas, structuring group dialogue and decision making, recording the rationales for choices and facilitating collective activities. … Such ‘telepresence’ enables mentoring across distance and provides a social context that reinforces and motivates learning, in addition to preparing students for telecommuting roles in the business environment” [p. 13].

As educators transition their courses from a traditional classroom to an Internet learning environment, a paramount concern is maintaining the essentials of a collaborative learning environment. The following applications all use collaborative learning in web-based or web-enhanced instruction. Huber describes a middle school environmental education teacher training program that uses collaborative learning as an essential component in their “Students as Scientists” project. Kasprzak describes the use collaborative learning in an Internet course for training military personnel throughout the world. Finally, Nixon describes an Internet course for graduate students in a Master’s of Project Management degree program that capitalizes on the essential components of collaborative learning.

References

The "Students as Scientists: Pollution Prevention through Education" is a three year teacher training program offered through the Watson School of Education, University of North Carolina-Wilmington for middle school science teachers throughout North Carolina. The specific objectives of this teacher training project are: (1) to update teachers on environmental issues affecting North Carolina, particularly water pollution prevention; (2) to engage teachers in collaborative learning and problem-solving methodologies they can use in their classrooms; (3) to provide teachers with environmental monitoring equipment and training in the use of this equipment, (4) to educate a cadre of teacher leaders who will educate other teachers in their districts; and (5) to teach the teacher leaders to learn to use the World Wide Web and the distance learning network so that, after the institute, they can continue information gathering and networking. The project will create Web Pages that teachers may use collaboratively; they will be able to download curricular information and environmental monitoring data from the web to use with their classes.

During the summer 1997 workshop teachers from New Hanover County Public Schools conducted environmental monitoring activities on the Cape Fear River. Working with University of North Carolina-Wilmington scientists, they performed water analyses and determined dissolved oxygen and solid levels, salinity, temperature differences, and pollution indicators. Participants graphed their data using spreadsheet software and compared their data to the river monitoring activities of the Cape Fear River Project, a consortium of local industries, environmentalists, and state environmental department experts. Guided by project staff, they learned to locate environmental science resources on the Internet. Discussions focused on presenting the project's activities in lessons that reflected the national and state science education standards. Participants developed lessons that incorporated cooperative learning strategies, hands-on science inquiry, and student discourse on river use.

During the following academic year, the teachers and their middle-school students spent one day per week on the Cape Fear River replicating the summer's monitoring activities and recorded their measurements on the project's World Wide Web site. The students learned how to graph their results, use environmental science terminology to describe their activities, and analyze local environmental conditions and water-quality tests performed by the state environmental department.

During the summer 1998, teachers from Clay and Graham County Public Schools and Charlotte Public Schools, as well as additional New Hanover County teachers, attended the workshop. After completing the same objectives as outlined above, these teachers will conduct water monitoring activities on waterways in their regions with assistance from Western Carolina University and University of North Carolina-Charlotte scientists and environmental education faculty. Participants and their students will enter their data on the project's Web site and compare their results throughout the year. In summer 1999, new teachers from the four school systems will participate thus completing the three-year project funded by Glaxco foundation.

The "Students as Scientists" project emphasizes hands-on science activities which require higher order thinking and problem-solving skills. The project challenges teachers to learn to use their surrounding physical environments and real problems as teaching tools. This expertise allows teachers to better implement the new State Science Curriculum (1994) and improve their students' State Science Test scores.

The students targeted for this project are a unique group. They are constantly searching to define themselves and the world around. They must interact with their environment to learn; simply sitting passively in a classroom does not stimulate their maturing intellectual curiosity. They flourish with hands-on activities, group projects, field trips and discussion groups. Their idealism is high; they want heroes and causes and will recognize saving the water, air and land as a goal for their generation. The activities and instructional methods in this project will promote high degree of collaborative learning.

The WWW provides a forum for the presentation of environmental education concepts. "Students as Scientists" created a number of interactive web pages where teachers track the project's development and growth, and participate by using interactive forms for the posting of data to the project's home page. Furthermore, the WWW component includes modules of information that can be downloaded by teachers for integration into the curriculum and for working collaboratively with other teachers in the project. Thus, it will be possible for teachers around the world to share "Students as Scientists" with their classes.
Collaborative Learning in Military Distance Education: Panelist: Kasprzak

The Military have long been supporters of "group", "team" and other highly organized collaborative activities. The "staff" system was devised by military thinkers, and "war rooms", and "crisis action centers" are collaborative organizational structures based on military models. As electronic communication networks have developed, training and exercises have also been conducted in collaborative modes. For example, the War Gaming and Simulation Network of the Department of Defense allows military colleges, schools and training centers to conduct large simulated military exercises, with each Center playing the technical, support or leadership role that its personnel might actually fulfill in a real battle or crisis.

As distance education modes of learning are increasingly employed by colleges and universities, it is understandable that military personnel (and civilians employed by the military services) readily accept collaborative learning techniques that they already employ in varying forms in their work surroundings. At the University of Maryland University College, originally founded to support military and diplomatic personnel overseas, and at the National Defense University, the highest educational institution of the Defense Department, different collaborative learning techniques are being employed, using the Internet, video teleconferencing and educational television.

As bandwidth becomes less expensive and more readily available, the schools are conducting more experimentation with Internet video, Internet radio, Internet TV and even more exotic delivery mechanisms. Techniques include role-playing, production of group products, controlled group interactions, group study, and group use of resources.
Collaborative Learning in the Master's of Project Management Distance Learning Degree Program: Panelist: Nixon

The Master's of Project Management degree program has been offered in the traditional classroom in Western Carolina University's College of Business since 1987. The College is fully accredited by the International Association of Management Education, AACSB and the Project Management Institute (PMI). Prospective students wishing to pursue this specialized degree are usually full-time employees in business or industry, have family obligations, and live outside of a reasonable commuting distance from the WCU campus. Transitioning the traditional program to the Internet format met the educational and the personal needs of these students and industry.

The issue of maintaining high quality, student-centered learning activities, involving small group interaction and experiential learning was of utmost importance. We did not wish for this to become an Internet correspondence course. Inherent in this process is the assumption that a conscious effort be made to assure collaboration among students and faculty.

One of the most difficult tasks at first was rethinking how pedagogically sound teaching and learning concepts could be transformed into distance learning. The old adage "garbage in, garbage out" applies to this transition. If the existing course activities do not facilitate active learning, if they rely totally on the passive "talking head" lecture method, "spoon feeding" information, and regurgitation of rote answers, the technology of Internet delivery will not translate into quality teaching and learning.

Activities that have limited interaction student to student, professor to student, and student to professor have a limited value in either forum. As a graduate course, curriculum and course design processes involve rapid transition to a higher cognitive level of activities. The level and type of activity designed for the Internet was structured according to Bloom's Taxonomy of Learning Objectives. As an example, the lower-level knowledge-based, "students will identify the phases of the project lifecycle" became a higher-level evaluative activity in restating the activity as "students will read the scenario, determine the phase of the project lifecycle in which the activity is taking place, and justify that determination."

We used the WebCT classroom setup and tailored it to include the following:
- assignment page with professor introductions to lessons
- chat rooms divided into password protected "study groups" for students to synchronously discuss activities
- bulletin board with password protected "study groups" for teams to asynchronously post information, cites, material, etc. for others in the group. This included posting "hot links" to relevant web sites and on-line materials
- presentation area, a general posting area for all final group work products to be posted for all classmates to read and comment upon if desired or required by the professor.
- Microsoft NetMeeting or CU-See Me software for synchronous video and voice streaming discussions/communication
- e-mail messages and attachments
- library reserves and electronic research
- fax
- telephone
- snail mail"

The technology provided the tools to enable a higher and more consistent level of communication and interaction. Additionally, individual student input into collaborative learning activities is easily monitored...no where to run and no where to hide. Every log-in and every contribution to group activities is recorded. To date, the professors have reviewed the posted student resumes and assigned students to study groups. This is done to ensure diversity in the teams: an even distribution of experienced and inexperienced students, a mix in various industries in which the students are currently employed, a mix of nationalities, genders, and ages. This also avoids total chaos of student self-selected teams and promotes international and cross-industry interaction.
A Simple Web-based Network Management System

Enrico Commis
Dipartimento di Matematica, Università di Catania,
Viale Andrea Doria 6, 1-95125 Catania, Italy
E-mail: enrico@dipmat.unict.it

Abstract
In this paper we present a software prototype for a simple Web-based Network Management System. The system has been used in practice to monitor the TCP/IP network of the University of Catania. Although there are several dedicated machines for network monitoring and management at the University of Catania (which use copyrighted software such as OpenView), we had the need for a fast and easy retrieval of the status of the University's TCP/IP network from any network access point via a web interface. The system is able to generate the status of the overall MAN subnets in less than two seconds and to report the hosts of a selected IP subnet which are up or down in less than 15 seconds. All the information is generated on the spot without data storing and extra CPU load from the server.

1. Introduction

In [Commis and Gentili 1997] a Software Prototype for a Monitor System (SPMS) for fast and efficient retrieval of traffic load on network-links from the routers of a Metropolitan Area Network (MAN) is described. All the information is accessed and visualized inside a HTML compliant browser. SPMS offers immediate graphic representation (GIF images) of the traffic of the monitored network connection, embedded into webpages which can be viewed from any network point, with proper authorization, inside of any web-browser. In addition to a daily view, SPMS is able to create visual representation of the traffic seen within the last 24 months as well as to generate a monthly traffic summary. SPMS has been used in practice to monitor the traffic load on network links at the University of Catania MAN.

SPMS left open the problem of a large number of network access points being installed without any kind of Network Managing control, due to the fast growing of the University MAN. This produces a large number of accesses to the network which are not registered on the local or central Domain Name System (DNS). In order to control the fast growing of Local Area Networks (LANs) and avoid unauthorized access to the MAN, we investigated the possibility of a simple network management which will then be accessible via a web interface.

In this paper, we describe a software prototype for a Simple Web-based Network Management System (SWNMS) which has been used to monitor the TCP/IP network of the University of Catania.

2. SWNMS Architecture

As TCP/IP was being developed (see [Stallings 1996]), little thought was given to network management. Up to the late 1970s, there were no management protocols. The only tool that was effectively used for management was the Internet Control Message Protocol (ICMP). ICMP provides a way for transferring control messages from routers and other hosts to a host, and for giving some feedback about problems in the environment. ICMP is available on all devices that support IP. From a network management point of view, the most useful feature of ICMP is the echo/echo-reply message pair. These messages provide a mechanism for testing whether communication is possible between entities. The recipient of an echo message is forced to return the contents of that message in an echo-reply message. The most notable example of this is the widely used ping (Packet Internet Grouper) program.

Much alike the ping program, SWNMS uses the Internet Control Message Protocol (ICMP) echo request to determine whether a host is up or a subnet is reachable. Unlike the ping program, instead of checking one host at a time until it timeouts or replies, SWNMS sends out a ping packet and move on to the next host in a round-robin fashion. If a host replies, it is removed from the list of hosts to be checked. If a host does not respond within a certain time limit and/or retry limit it will be considered unreachable.

The University of Catania has a large TCP/IP network with over 1000 assigned IP addresses and over 40 IP subnets. With such a large number of IP addresses being used, it has become extremely time consuming to
check which IP addresses are actively in use, and which critical machines (routers, bridges, servers, etc) are reachable. Checking hosts (99% of which are unreachable) via ping can take hours. SWNMS was written to solve the problem of pinging N number of hosts in an efficient manner. By sending out pings in a round-robin fashion and checking on responses as they come in at random, a large number of hosts can be checked at once. SWNMS is able to check the reachability of all the MAN subnets in less than two second and to verify the status of the subnet hosts in less than 15 seconds.

SWNMS has been implemented in Perl5 (see [Wall and Schwartz 1992]) and C language. SWNMS requires an ASCII file (ConfFile) as input. Such a file must contain some relevant information of the MAN IP subnets to be managed. Each line of ConfFile refers to a specific IP subnet and contains the following fields of information

<table>
<thead>
<tr>
<th>Subnet-IP-address</th>
<th>Check-point</th>
<th>Description</th>
</tr>
</thead>
</table>

where:
- **Subnet-IP-address** is the IP address of the subnet to be managed. This field can be left blank for subnets which are not local;
- **Check-point** specifies an IP address used for testing the reachability of the subnet (generally the IP address of a router's interface);
- **Description** is a logical description of the subnet (generally the name of the building and/or the institution to which the subnet has been assigned).

3. Using SWNMS on the Web

Most World Wide Web (W3) servers provide one or more Application Program Interfaces (APIs) for integrating new and existing applications. The most well known of these APIs is the Common Gateway Interface (CGI), and although some servers additionally provide a specialized API, CGI is currently standardised and supported by all major W3 servers.

We now describe our experiences of using CGI API to deploy visual representations of the TCP/IP network status of the University of Catania on the Web.

- The *application front-end* is simply a Web browser and a CGI Perl5 script (*front-end script*) that gives back to the client a HTML page document containing the list of all the TCP/IP subnets of the University MAN and their status.
- To determine subnets reachability the *front-end script* quickly pings the associated *Check-point* IP addresses specified in ConfFile, marking with a green bullet the reachable subnets and with a red bullet the unreachable ones. The *front-end script* authomatically refreshes every two minutes. MAN subnets status is generated *on the spot* in less than two seconds.

</tbody>
</table>

Figure 3.2: Subnet's hosts status.

All hosts (the ones that are up as well as the ones that are down) of the selected IP subnet address are reported using their Fully Qualified Domain Names (FQDNs) and are respectively marked with green and red bullets. Hosts which are up but not officially registered in a local or central DNS are reported using the IP address effectively in use. This will allow the user/operator to discover unauthorized accesses to the MAN. The Subnet status is generated on the fly in less than 15 seconds.

4. Conclusions and future work

In this paper we described a Simple Web-based Network Management System. The system has been used in practice to monitor the TCP/IP network of the University of Catania. Although there are several dedicated machines for network monitoring at the University of Catania (which use property software such as OpenView), we had the need for a fast and easy retrieval of the status of the TCP/IP network of the University from any MAN network access point via a web interface. SWNMS is able to generate the status of the overall MAN subnets in less than two seconds and to report the hosts of a selected subnet which are up or down in less than 15 seconds. All the information is generated on the fly without data storing and extra CPU load from the server. For the future we plan to implement a grafical interface using Java applets.

Abstract

This paper discusses Socrates project involving team teaching on the Internet in Business Management courses. The project exploits the connectivity of the Web to collaboratively develop online teaching materials with embedded knowledge resources, and create electronic learning communities of learners, academic experts and corporate managers. It shows how the Internet can be a potent tool for team teaching and learning.

Introduction

The Internet is opening up new possibilities of connected learning. The connectedness of the Internet makes it possible to easily communicate across organizations and geographical spaces. It makes possible a highly connected form of education. The Socrates electronic learning environment specifically uses four types of Internet connectivity in a global team teaching process. The current focus is on business management education.

Connectivity to WWW resources: In the pre-Internet world, education was largely dependent on flat text (books). Now any text can be augmented with the hyper-textual connectivity offered by the Web. Socrates ties together many information resources relevant to business students to deepen their understanding of specific topics.

Connectivity between learning peers: The Internet makes possible extended and instantaneous connectivity between learning peers, be they students in a class or managers in a multinational firm. Learners can easily communicate with each other and learn from each other (via email, listservs, bulletin boards, chat rooms) even when they are not in proximity to each other. Socrates uses these tools for learning and sharing of information to foster collaboration among teaching faculty and among faculty and students.

Connectivity between learners and external experts. The Internet makes possible access to expertise beyond what is typically provided in traditional educational systems. Learners can easily reach out to external experts (manager, community leaders, voluntary organization members, government officials at home and abroad) for guidance and expert advice. Socrates makes possible mentoring, subject matter guidance, and problem solving help from outside experts.

Connectivity between learners and instructors: Finally the Internet allows learners to engage instructors in meaningful dialogues even when they are not in the same location. This opens up possibilities of distance learning from instructors in different places. It makes possible bringing the "best" instructor learners wherever they may be located.
Socrates Web-based Learning Environment

We have been involved for over two years in the program to create the Socrates Web based learning environment that exploits these features and seeks to operationalize the Socratic method of critical questioning in Business Education. Socrates is system for creating Web based teaching. It allows faculty to quickly and easily create teaching Web sites for their courses. These sites have embedded into them 750 business education resources such on the WWW, and communication tools such as threaded discussion Bulletin Board, class email listserv, and Web based quizzer with automatic grading. Faculty can create their course Web sites without any knowledge of programming, in a few hours. They can communicate with and manage interactions among learners and outside experts. It does not need any special hardware or software, or prior experience with the Web.

Socrates also offers online teaching materials in some business areas such as international business, management, marketing, and strategy. These materials exploit the hypertext capabilities of the Web by linking each topic under discussion to multiple relevant WWW resources. The materials are cast in the form of questions that evoke critical thinking and learning. By designing learning communications strategies that are inclusive of diverse perspectives (racial, ethnic, international, gender, etc.), instructors can foster very unique and rich interactions. Sample Socrates sites can be visited at http://www.esocrates.com/cgi-bin/socrates.cgi?coopm001 and http://www.esocrates.com

Team Teaching

In Fall 1998, business faculty from over a dozen Universities and four countries (USA, Canada, Holland, England) are participating in developing teaching materials and team teaching with these materials. The courses covered include:
- Business Policy/Strategic Management
- Introduction to Marketing
- Environmental Management

Each course has 15 to 25 short modules contributed to by participating members. A module is much like a chapter of a textbook focused on a specific topic. Modules have clear and focused learning objectives, hot links to relevant WWW resources, and quiz questions.

Each teaching faculty has a Socrates Web site with an electronic Bulletin Board. Faculty and students from different classes can visit each other's bulletin boards and post messages. The level of engagement is decided by each individual faculty and can vary from no engagement to joint student projects via the Internet. Faculty can also invite outside experts or corporate managers to provide inputs on course materials.

Based on our early experiences we have learned several lessons.
1. Interactivity between learners and experts or faculty needs to be carefully managed. It will not happen automatically, simply because the technology is present. Managing interactivity requires preparation, clear postings, seeding responses, follow-up reminders and evaluation.
2. Team teaching can be effective only with highly self-motivated learners and facilitators. It cannot be forced onto unwilling or unprepared participants.
3. With high degree of automation and a good collaborative development process, the time needed to develop teaching material can be reduced significantly. This makes it possible to develop materials in many different areas at a very low cost.
4. Virtual teams offer a strong bonding potential for participants. Many of the characteristics of physical teams can be replicated in virtual teams. Virtuality is not necessarily a liability in team management.
5. Team cultures emerge over time as a function of the team leader/facilitator. In virtual teams there is high dependency on the leader for coordination services. So the leader becomes a key source of cultural values and work practices.
These lessons are offered as tentative conclusions and should be interpreted with great caution. These are not definitive findings since the project is still in progress. We are sharing these as work-in-progress, and to encourage other projects into virtual team collaborations.

In the coming months several expansions of this team teaching approach are planned. First, there are plans to create teams for developing teaching materials in International Business, Introduction to Management, Human Resources Management, Accounting and Finance etc. Eventually all courses in business curriculum will be included. A related expansion is to reach out to faculty in different countries to incorporate multiple cultural and national perspectives in teaching of business issues. Socrates also plans to add online chats with authors of books, and CEOs of companies in the news to enhance the interaction among learners and experts. Other ways of incorporating innovative interactivity are constantly being sought.
The LearnShare Consortium: A Model for the Future

Mr. Rick Corry
LearnShare, L.L.C., 136 N. Summit Street, Suite 212, Toledo, Ohio 43604
Tel: 419-327-4160, Fax: 419-327-4169, E-mail: info@learnshare.com

Abstract: LearnShare is a consortium of non-competing companies who share training expertise and innovative practices. Evolving from CEO Rick Corry's concept of a collaborative approach to training, LearnShare combines the best training practices and programs of the partners with leading-edge distance learning technology. The result provides LearnShare members electronic access to proven training materials and enables them to participate in and benefit from research and development opportunities in multimedia and distance learning practices.

1. Introduction

The decentralization of organizations, rapidly evolving workplace technologies, and expanded information/skills requirements, are moving corporate training initiatives toward more flexible, highly specialized training delivery systems. This requires the design of interactive, customized, self-paced programs that use a wide range of communication technologies. How can a training organization meet these evolving needs on an ever-tightening training budget?

Fourteen non-competing Fortune 500 corporations found an answer to this question. They formed a training consortium to share training expertise and innovative practices—and, by so doing, improved the quality of their training while reducing their individual costs.

LearnShare, the consortium these companies created, is dedicated to sharing resources for the enhanced development of technology-based learning modules. Its members - diverse companies with proven expertise and innovative practices - enhance their competitive advantage through access to learning technologies and an effort to share their respective strengths.

Through “share sourcing” the consortium provides its members with the help they need to expand into the global marketplace. The consortium offers such assistance via the following benefits:

- cost-effective training curriculum that shares best practices
- reduction in cycle time from learning to action outcomes
- opportunities to leverage technology
- an expansive content library
- improved employee performance
- enhanced customer relationships
- extensive partnering with premier companies.

2. Background

At a vendor presentation in May of 1995, a training professional attendee asked why organizations continued to invest in training programs that they would not own and for which they continued to pay licensing and per-use fees. Other attendees expressed an interest in his concern and asked him to devise a plan. The training
professional presented his idea to his organization's management and received preliminary funding to explore the concept further with other non-competing corporations.

In October 1995, eighteen non-competing corporations were invited to attend a meeting to discuss establishing a collaborative training consortium. During that meeting, many of the attendees recognized the commonality of their training issues, and believed that a consortium could lower their training costs, expand their owned curricula, and improve the quality of their training. Moreover, they believed that they could fund this consortium themselves with the expectation that it would be self-sustaining in a few years.

Encouraged by the meeting, the training professional who initiated the consortium idea received additional support from his organization in the form of office space, equipment, and personnel. Officially created in October of 1995, the LearnShare consortium was established as a limited liability corporation in order to ensure that only non-competing organizations became members. In September of 1996, nine non-competing companies agreed to join the consortium as funding partners: each would contribute $100,000 a year for two years and would receive a seat on the Board of Directors. The idea originator (the training professional) was selected as General Manager.

At LearnShare's establishment, the consortium developed the following goals:

- to identify and partner with major corporations that have first-class training and performance practices in place
- to create a new competitive advantage for consortium members through the use of learning technology and state-of-the-art content
- to include universities, state and federal agencies, and other resources to maximize impact and output
- to achieve measurable cost savings in business education at many levels throughout the corporation

Next, the vision created by the consortium embraced not only the member's priorities, but also the needs of individual employees and the role to be played by their vendors and consultants. The consortium's vision for the year 2000 is to:

- extend learning into the workplace and home
- make learning accessible anywhere in the world, 24 hours per day
- ensure that learning applies to all individuals (at all levels and in all geographic locations)
- use leading-edge technology to deliver training
- focus learning on performance and the achievement of business goals and strategies
- foster the delivery of training in smaller segments, on demand, and with immediate applications
- improve performance through the full range of development alternatives including, but not limited to, training
- use uniform training and development tracking to both evaluate individual progress and to drive decision making
- use needs assessment to drive learning priorities and reallocate resources effectively
- ensure that learning occurs on individual, team and organizational levels
- establish partnerships with key vendors and consultants
- ensure that synergy occurs across businesses in all aspects of the learning process and in the use of resources

According to the general manager of the LearnShare consortium, "the fundamental purpose of the consortium is to serve as a clearinghouse for leading-edge employee training, and to eventually set the standard for customer training as well. The consortium will be a dynamic organization that will continually seek new partners, evaluate its effectiveness, and reconfigure accordingly.

LearnShare's culture encourages communication and trust among its members and partners. This results in the open sharing of existing training and development materials, human talent, and corporate-wide resources. Share sourcing enables the members to share existing programs, the cost of creating new materials, and solutions to common challenges. It also allows its members to collaborate on both training and non-training issues by tapping into their collective expertise and experiences. The culture is defined by a structured operating agreement.
and nurtured by frequent meetings, a highly collaborative project management process, and a sophisticated communications system.

LearnShare is usually introduced into member companies through their human resources, training and development, and sales and marketing departments. These departments are the first subscribers to the process and the disseminators of information about the value of the process to other departments. Widespread member use of the consortium’s programs is then promoted by linking LearnShare’s web site to the companies’ web sites. By accessing LearnShare’s web site via its own web site, each business unit within the member companies can preview the programs and can place orders to receive training programs. As a result, the member’s internal departments - financial, health and safety, manufacturing, and management - have become involved with the LearnShare concept.

3. Process

Starting its third year, LearnShare has followed an established evolutionary trajectory. Initial enthusiasm and support carried the idea forward, in rapid succession, from conception to discussion, collaboration, implementation, and funding. Once the board of directors was established, further phases of curriculum exchange and development began. Additionally, the board began the planning required for the consortium to become self-sustaining (through grants and access fees from members’ customers) within two years.

The consortium exists to advance learning based on the best available technology. At the core of the consortium’s strength are best practices and shared experiences, which provide the vitality to keep the organization moving forward. Beyond the financial and structural commitment to the consortium, each member organization freely shares its best practices and expertise.

The original purpose of the consortium - to improve the quality of training and reduce overall training costs - now includes an effort to better business education by using an innovative sharing process to improve content, technology, and delivery, including multimedia and distance learning opportunities. To achieve this objective, the consortium enlisted the assistance of the educational community. LearnShare added to its membership three universities with expertise in multimedia, distance learning, and evolving technologies that could be used for training delivery and that could significantly bolster the consortium’s efforts.

The consortium’s member organizations are leaders within their respective industries that have demonstrated innovation in an array of skill areas. Each member organization contributes the expertise of its training professionals, as well as $100,000 per year for two years to fund the consortium’s initial work. These contributions resulted in membership revenues of $1.8 million: the consortium’s first two-year budget was $1.1 million. Major cost categories in the budget have been in program development and staffing.

All participating organizations agreed to the consortium’s operating agreement and to provide a representative to the board of directors. The fourteen companies of the consortium employ 2.2 million people and have revenues in excess of $400 billion.

The consortium’s member organizations systematically share and develop educational materials. In addition, university faculty research teams interact with inter-company program development teams as they share and create world-class training materials. Members reduce their training costs through joint funding of common learning needs and maximum use of existing resources. The consortium’s size provides an advantage in negotiating volume-discount purchase rates and provides them with greater flexibility in the design and use of vendor-developed products.

LearnShare developed an organizational structure that consists of six levels: 1) Board of Directors; 2) General Manager and Administrative Support; 3) Strategic Planning and Research Support; 4) Project Manager, Sales and Marketing Manager, and Technology Manager; 5) Resource Manager and Technical Editor; 6) Project
Teams.

The board of directors consists of one representative from each of the consortium member organizations. The board meets three times per year, and each board member has a single vote. Board responsibilities include, but are not limited to, setting policies, prioritizing training projects, and approving the operating budget.

The general manager reports to the board of directors and is responsible for developing consortium membership and for maintaining its focus. The general manager's functions include development of relationships with the member organizations; leadership of the investigations of state-of-the-art delivery options; joint development of world-class skill modules; and exploration of federal, state and local government participation in and support of the process. The administrative assistant reports to the general manager, provides administrative and secretarial support, and functions as the office manager.

The director of strategic planning and research reports to the general manager and works with representatives from Arizona State University, Fairleigh Dickinson University, Ohio State University, and all other schools deemed appropriate by the board. This position helps coordinate the research and external funding initiatives established by the board.

The senior project manager also reports to the general manager. This position manages each LearnShare project team, supervises the building and maintenance of the resource library, manages the project innovation process, and coordinates the work of the member universities with LearnShare's member companies.

The sales and marketing manager reports to the general manager as well. This position manages the development and implementation of the internal marketing plan for launching LearnShare within member organizations, and also handles all negotiations with outside vendors for the LearnShare member companies.

The technology manager reports to the general manager and is the liaison between LearnShare, the consortium member organizations and vendors for all technical issues.

The resource manager reports to the manager of sales and marketing. This position manages the LearnShare resource library, directs order fulfillment, maintains resource data and provides direct product support to LearnShare members.

The technical editor reports to the senior project manager and edits all LearnShare library materials, oversees compliance to LearnShare product standards, conducts research, and negotiates copyright releases.

The project teams are managed by the senior project manager. Each project team consists of representatives from LearnShare's member organizations, an appropriate subject matter expert, and an online developer. The team members are selected from member organizations according to their skills, abilities and initiative. Each project team is responsible for the development of a specific program, identified and prioritized by the board of directors.

Headquartered in Toledo, Ohio, the consortium has branches in many other locations. The headquarters office provides a focal point for the strategic development, collaboration, warehousing, and dissemination of a full spectrum of training and development products and services to participating organizations.

The consortium management is responsible for: ensuring the strategic linkage of each team activity to organizational goals; monitoring deliverables development, timeline/milestone achievement, and budget expenditures; and, adjusting team activities to be responsive to members' needs, competitive challenges, or other factors.

The Consortium staff conducts industry analyses to determine the needs of each partner and provides accurate analyses of available products and services to meet those needs. They serve as a clearinghouse for available
products and services; provide information, orientation and demonstrations; and maintain a catalog of currently owned products and services. Initially, most of the files in the consortium’s content library were text based, but the entries have been expanded to include multimedia resources and CD-ROM materials. This format allows for easy conversion to online training as new technologies emerge. Additionally, members have access to an expanding library of training resources, and by choosing programs designed in partner organizations, members have the opportunity to see the topic through another’s eyes. Shared programs offer users new ways to look at challenges and to increase their expertise.

The staff helps participating organizations to acquire and implement the desired products and services or to create high-quality, low-cost alternatives. They also spearhead new product and service research efforts between corporate and university partners. Further, they seek external funding through grants and other opportunities and coordinate the use of the consortium’s installed base of technological hardware.

LearnShare has established a web site that lists all available training, and includes a directory of high-quality suppliers and vendors. The site also provides information about training news and events, a chat room for individual employee input, and a “request for help” area.

The consortium is a model for integrating and aligning multiple learning and development approaches and practices designed to achieve aligned outcomes. It was designed to address an ever-expanding series of learning needs in a way that takes advantage of a uniquely networked group. The Consortium accelerates the development of learning technology through the immediate expansion of resources and provides efficient, effective design, development, and delivery of training. Its unique structure enables it to meet current learning needs and to adapt itself quickly to meet future needs.

The consortium is continually revised as it experiments with ways to integrate it’s design structure with extenuating factors and to produce high-quality products.

The use of leading-edge technology to facilitate the training and development process is central to the Consortium’s value to participating organizations. It’s design enables it to use its members’ considerable technology infrastructure and the consortium’s educational partners to develop and deliver the most innovative training and development products available. Decisions about the selection and use of new technologies are driven by the research results from the university and consortium members. Research teams have been formed and are charged with:

- Determining the training and development needs of Consortium partners
- Identifying organizational learning objectives
- Defining training and development program content
- Determining content delivery methodologies
- Coordinating the program delivery
- Conducting post-program evaluation and feedback

Examples of the targeted technologies the Consortium uses or will be using include:

- Existing databases of training and development products and services
- E-mail, Internet, Intranet, and other communication channels
- Live video-conferencing technologies at members’ sites coordinated through the university partners
- Person-to-computer links to key members via e-mail, computer conferencing, video conferencing, Lotus Notes, and other emerging technologies
- Beta-site testing through university partners to evaluate future products and services for consortium members

Members’ immediate access to LearnShare resources provides them with leading edge technology for real-time electronic access, and it’s electronic library provides information in text form, CD-ROM and photo CDs for downloading through the Internet. Moreover, the consortium is exploring ways to provide “smart” interfaces so that a training manager can be directed to specific materials that fit their particular requirements. This will
provide electronic access that has been expanded beyond simple delivery to provide on-line assistance in the development of individualized training materials.

LearnShare’s available training modules include components inherent in all corporate environments and additional modules are created within the dynamic curriculum as the need arises. Any one of the consortium’s training managers has access to modules within existing programs to create a program tailored to the needs of his or her audience. In addition, training managers who design their own courses from these materials can then offer these programs back to the library as enhanced material. The smart interface could also be used by individual learners to tailor their instruction by selecting modules that best meet their personal training objectives and essentially designing their own individualized courses.

4. Impact

Critical success factors established by the consortium at its inception include:

- Membership that boasts world-class organizations supporting the consortium concept
- Sharing of best practices by members
- Technologies shared by members
- Development of a market for consortium products
- Open sharing by members of individually developed and individually held training programs
- Establishing shared priorities for training programs
- Maintenance of a strong working relationship between consortium members and university partners
- Grant support obtained by the consortium to develop, implement, and disseminate program innovations

Additionally, consortium members developed a list of objectives to be met that would reduce member’s capital investment through:

- Developing a critical mass of world-class partners committed to sharing resources and best practices
- Efficiently producing world-class training modules
- Providing access to world-class training modules through a digital library and state-of-the-art distance-learning technologies
- Joint funding of common training materials
- Maximizing the use of existing resources, facilities, and technologies
- Securing volume discount purchase/licensing rates
- Reducing cycle time from learning to action outcomes
- Achieving improved employee performance
- Securing greater leverage with training vendors resulting in more flexibility in the design and use of vendor-developed products and services
- Exchanging best practice training content and delivery methodologies
- Developing training program evaluative mechanisms
- Developing innovative training delivery strategies

The consortium has developed a quarterly report of all projects and initiatives to be distributed to member organizations. It includes the following information:

- All current projects
- Projects under consideration for next quarter
- Progress-against-plan report from each team
- Strategic analyses from the General Manager addressing the consortium’s contribution back to member organizations

The consortium’s educational partners are also responsible for validating the quality of its programs.
Although it is too early to quantify the results of the consortium’s efforts, there are indicators that the goal is being achieved. One member organization estimates it is saving 30 to 50 percent on the purchase of new training materials. Another partner estimates that it has access to over 40 new programs, which - if the partner had developed them in isolation - would have cost the organization $30,000 to $50,000 each. “We recovered our investment in the first 90 days,” he said. For one consortium member, curriculum developers available through the consortium have become his department’s development arm.

Member relationships are key to the consortium’s success, and members have commented on increased trust and a rising participation level. Members have developed a list of courses they need and are prioritizing their courses’ development based on urgency. The members also have extended their relationships to include benchmarking in other business areas.

According to its members, the consortium’s e-mail system is an excellent means of gaining access to information and training materials, usually within minutes or hours rather than weeks or months. By “talking” with trainers in other organizations via e-mail, employees have shared training methods, modules, and books, including those housed in the consortium’s library or loaned by other members.

The increased interest in membership expressed by companies outside the consortium is another measure of its success. The consortium now looks not only for new members among non-competing and leading-edge companies, but also for value-added additions to the collective whole, and now asks potential candidates to indicate what unique qualities they can bring to the consortium to enhance the contributions to members.

5. Shared Learning

At its earliest stages, the need to create an organized, legally defined structure for the consortium became apparent. Once the consortium institutionalized all rules and procedures that defined LearnShare, participants became more comfortable with the concept, and the definition process helped the consortium focus on its purpose and direction. This also led members to realize that they needed a system to develop priorities that would allow for both democratic voting power and factors that influence choices (such as available funding and long-term benefits).

Another lesson learned was the significance of gaining acceptance and support from the highest levels of every organization involved. The visible encouragement of high-level managers strengthened the consortium and encouraged participation from individuals and their member organizations.

The original mission of the consortium focused on achieving results for its members, yet as the consortium has evolved, it continues to define what best practices are and how the consortium can serve as a model for other collaborative structures. Additionally, as the consortium takes advantage of technology that allows it to distribute its educational materials worldwide, the market for its products and services has become global.

6. Conclusion

The consortium model developed by LearnShare has tremendous potential for improving the quality of education and training in the workplace, government operations, school systems, and other organizations. The State of Ohio, a school district in Las Vegas, Nevada, and the federal government have all expressed an interest in the consortium’s model. By collaborating on the design, delivery and distribution of member best practices, the consortium has created opportunities for people to become better employees through improved workplace learning and performance.
The consortium's success changed its member corporations' approach to the purchase and use of interactive training materials. What had started as a simple idea to share resources blossomed into a model for future instructional design, development and delivery.

The synergy of partnering creates timely and effective training at a lower cost, with measurable results, and with significant benefits for participants. Each member brings new ideas and new ways of looking at existing situations that are then shared with the entire LearnShare organization. The level of trust among members grows with the activity of the organization. Formerly isolated, members now feel comfortable sharing best practices and, in return, they can augment their own resources with the best practices learned from others. The wealth of information the consortium has garnered regarding organizing and succeeding as a non-competing collaborative unit can easily be shared with others through presentations and interactive opportunities.

Leadership and outcome-based interventions, combined and multiplied throughout the consortium, provide the curriculum basis for the consortium's virtual classroom of the future. This classroom can access training modules derived from leading-edge research inspired by the consortium's business and education partnerships, and it will deliver them to its participants through existing and emerging technologies. The combination of LearnShare's state-of-the-art realities and future plans will enable the consortium to create for its members the best virtual universities possible.
THE BIBLE AS LITERATURE: ELECTRONIC TEXT

Jeanie C. Crain
English Department
Missouri Western State College
USA
Crain@griffon.mwsc.edu

Abstract: Imagine teaching the Bible as literature in a classroom equipped with the latest in technology. What power! The Bible is open electronically; CDs are at hand to provide sound and visual effect. All of the Web exists for research. Of course, all the old standbys are still available: VCR and large screen projection, full audio for movies and tapes. What does it all mean? Today, as never before, the student of the Bible can conduct almost instant searches of the entire Bible, hear difficult names pronounced, walk in the streets of Jerusalem and tour its museums; review histories, cultures, and religions. It's all there—at the click of a button or switch.

Actual Class Session

How, though, would this translate into an actual class session? Students in my Bible as Literature class this semester found themselves on the Web the very first day of class. They accessed my home page which links to several other pages. The syllabus to the class, in fact, was accessed by the Web. On the first day of class, we looked at several points made in essays readily available to them: "The Bible as Literature" http://griffon.mwsc.edu/~crain/biblelit.html and "Five Reasons to Read the Bible" http://griffon.mwsc.edu/~crain/bible2.html. I then took them to an outline providing an overview or approach to the Bible: http://griffon.mwsc.edu/~biblelit/Overview1.html. These essays, in themselves, were a full first day introduction.

Second Day

Following the first day, I have ready at hand outlines which I am placing on the Web for student access http://griffon.mwsc.edu/~biblelit/ These outlines exist in PowerPoint format, but I saved the outlines as HTML files and posted them to the Web. More often than not, I use the outlines rather than PowerPoint, but if I wish to slow down the process and present more formally, then the slides are available, too. I experimented with putting PowerPoint slide presentations online but chose finally not to do so because more storage space is required. Still, should I want to do so, I can click from a link on a home page and open up an actual PowerPoint presentation. The outlines provided are generally interpretive outlines of books of the Bible rather than chronological ones. Since the use of the Web for storing data for class use is a developing area for me, I'm well aware I have not tapped its full potential. Colleagues of mine are now creating carefully crafted, framed pages with multiple links that make mine look quite amateurish, but even at this level, I'm impressed with what can be stored, accessed readily, and linked to other powerful data.

Stepping into the World Beyond Classroom

I can easily step out of an outline into a Bible search engine or visit a map of the Old Testament world; through CD and Web, I can allow students to explore artifacts and current archeological sites. I can get to study guides of the Greek and Hebrew languages and mnemoics, multiple and parallel versions of the Bibles in language of choice as well as other sacred books such as the Koran or Book of Mormon, and research from all directions and levels. My home page lists King James and Revised Standard versions of the Bible with the link leading to the University of Virginia's Electronic Text page: http://etext.virginia.edu/frames/bibleframe.html This source is useful in that it also, followed, will bring students to the complete Online Library of Electronic Texts in English,
Choosing one of the languages, the student arrives at listings from A.D 1500 to present with 1,588 titles and 6,699 manuscripts. I've set up other pages that will lead, for example, to Bible history http://griffon.mwsc.edu/~crain/history1.html or ancient religions http://griffon.mwsc.edu/~crain/Ancient_Religion.html. These are, of course, just the beginning of what is possible.

Other Resources

Anyone using software today realizes the wealth of resources available on one CD at affordable prices. I keep DesktopBible by CompuWorks on my computer for simple and fast access. Another usable CD is Jerusalem by Multimedia Corporation CDC. This disk tours Jerusalem using Islamic, Jewish, and Christian guides. I also use The Deluxe Multimedia Bible, SoftKey's The Bible: A Multimedia Experience, and Expert's Bible Explorer. As for programs, I use Kirkbride's HyperBible. Parson's also has out Greek and Hebrew language tutors.

Conclusion

The truth is that today's world offers more for students and teachers of the Bible than any time previously. The difficult act is planning and balancing what is to be accessed and studied within the one class session. While I can move easily among technological media, I have to keep human beings in mind—and pace myself accordingly. The real joy—apart from richness of sound and vision—really lies in what can be archived and accessed. Probably the tool of choice is the search engine on the web and the search program on CDs. In class, for example, a student asked why the tribe of Dan was not recorded in Revelation; in minutes, we had seven pages of reference to Dan and the last Old Testament record: Amos 8:14: "They that swear by the sin of Samaria, and say, Thy god, O Dan, liveth; and, the manner of Beer-sheeba liveth; even they shall fall, and never rise up again." This is power that never before has existed at the fingertips!
Web-based Support for Technology Integration

Sylvia J. Currie
Teaching Support Lab, Centre for Distance Education, Simon Fraser University, Burnaby, BC, Canada.

Stephanie T.L. Chu
LohnLab for Online Teaching, Centre for Distance Education, Simon Fraser University, Burnaby, BC, Canada.
E-mail: stephanc@sfu.ca

*please direct all correspondence to S. Chu.

Abstract: Two Lab facilities to support faculty and teaching assistants integrating online technologies into their teaching are currently in place in the Centre for Distance Education at Simon Fraser University. This poster session presents a model to expand on the existing support provided in the Lab by introducing a web-based environment for sharing resources, ideas and experiences.

Our goal is to produce a showcase of exemplary online course designs and other related work undertaken at SFU, and provide a means for instructors to participate in shaping and sustaining this environment. This model would enable faculty and teaching assistants to investigate and explore a variety of online teaching strategies, benefit from broader and more flexible instructional support than we will be able to offer with increasing interest in online education, and participate in the advancement of online pedagogies and new technological developments at Simon Fraser University.
Adapting Teaching Strategies in a Learning Environment on WWW

Instituto de Informatica - Universidade Federal do Rio Grande do Sul - Brasil  
E-mail: [carmenbd, adriana, geyer, rosa]@inf.ufrgs.br

Abstract: This paper describe the application of personality theories, in especial, the Jung's theory for adapt teaching strategies to the learner. It has been used the learning and teaching environment AME_A[ D'Amico et al 96, 97] to validate these ideas. This environment works at World Wide Web( WWW) and was defined as a multi-agent system[Jennings & O'Hare 1996]. The information in the learner model are mapped in a set of methods and teaching process by neural networks.

1. Introduction

AME_A has in his architecture a set of functional agents; these agents have the ability to control their own problem solving and to interact with other community members. The interactions typically involve agents cooperating and communicating with one another in order to enhance their individual problem solving and the better solve the overall teaching and learning problem.

One of our goals was to adapt teaching strategies to the student. To accomplish this goal many agents collaborate: Drive_Learning, Drive_Practice, Control_the_Results, Select_Strategy, Learner_modeling and the own Human_Agent( student). The name of the agents indicate their functions.

2. Contents of the Learner Model

There is the initial model of the individual learner which is to be regularly updated in the course of her interactions with the system. Some information carried within this model will, however, be stable or relatively stable and not subject to regular updating. Based in[Benyon & Murray 1993], we can identify three different groups of information contained in the Learner Model: Profile Model( personal learner details), Student Model( proficiency), Cognitive Model(preferences in the learning).

Table 1 outlines some characteristics which have been identified under each category and provides information on the possible value types of the attributes, how and when these values are acquired, and whether the values are static or dynamic.

In order to update the learner model, information are transmitted by the agents in the teaching process. In this phase, the Select_Strategy agent, analyze the information received and use a neural network to choose the more adequate way to teaches the learner in that conditions.

Since the study of personality began, personality theories have offered a wide variety of explanations for behavior and what constitutes the person. Jung developed a personality typology that has become so popular. It begins with the distinction between introversion and extroversion. He also defined the functions: sensing, thinking, intuiting and feeling. Katharine Briggs and her daughter Isabel Briggs Myers found Jung's types and functions so revealing of people's personalities that they decided to develop a paper-and-pencil test. It came to be called the Myers-Briggs Type Indicator, and is one of the most popular, and most studied, test around.

In the first interaction the learner answer a few questions related with the learning process and some questions that was selected from the test( Myers-Briggs Type Indicator). The system has a neural network to identify the learner's personal characteristics. Based on the results we stand the
more adequate strategy for the individual learner. Then the learner process is stated. In this phase the learner's behavior is observed and the model's information are modified.

4. Conclusions

Backpropagation [Freeman & Skapura 1991] was the neural paradigm used by us to map the learner's characteristics in teaching methodologies. It is a good alternative when the definition of heuristics isn't so easy and there are much information in the learner model used to define such methodologies.

References

Abstract: The aim of our work is to study the effects of animations used in educational software. The domain chosen for this study is Physics, more specifically concepts that are crucial to understanding pendulum movement. The aim of the pilot was to investigate the feasibility of the software designed for the study as well as the methodology chosen for the test situation. Initial analysis indicates that there does not seem to be a problem with understanding that an animation can be a representation of a non possible situation. We also found that minor adjustments in the instructions for the test is needed.

1. Background

The WWW supports a number of techniques for different kind of multimedia (Shockwave, QuickTime, animated JPEG's etc.). There is much common-sense argumentation regarding the effectiveness of multimedia for educational purposes, but there is not much empirically validated knowledge. The usual argumentation follows the “more is more” path [Scaife & Rogers, 1996], that is: a picture is better than (a thousand) words, an animation is better than a still, sound is better than silence, etc.

In many computer-based instructional products animations have become popular. Unfortunately, the animations are often used to impress rather than to teach [Rieber, 1990a].

Rieber [Rieber, 1990b] shows that animations facilitate learning for children (under certain conditions) but not for adults [Rieber, Boyce, & Assah, 1989]. On the other hand there is the study by Mayton [Mayton, 1991] which suggests that the use of animations in computer-based tutorials can be beneficial for adults.

Although results from the research on animations in instructional material are mixed to some degree, there still appears to be significant potential for the use of animations in computer-based instruction [Milheim, 1993].

2. Current Work

We want to look into the effects of animations used in educational software. So far we have studied the effects of animations on university level (the principle of equivalence, a part of Newtonian physics) and found indications of a less than expected benefit from animations contra non animated illustrations [Dahlqvist, 1997]. The present study stays within the domain of Newtonian Physics but this time the students are younger (13-14 years). The part of Physics taught this time concerns the pendulum and the fact that it is only the length of the pendulum and not its weight that has an effect on the time for a period.

A program was constructed. It consisted of two parts, a short tutorial and a test. In the tutorial part short texts about the pendulum were accompanied by several related animations, illustrating the phenomenon in the text. In total there were 5 animations. The animations were all short and due to the repetitive nature of the pendulum movement the animations could simulate a longer period of movement by repeating the animations. This kept the files small, which could prove to be useful when there is a slow network connection. The texts with its accompanying animations were presented dynamically in a linear fashion, one pair after the other. The student controlled progression with an “OK”-button.

The test consisted of multiple-choice questions of different kinds: ‘transfer’, ‘repetition’ and ‘true/false animation?’. The ‘transfer’ question was about a grandfather clock that was too fast and the language used was deliberately different from the one in the tutorial. The ‘repetition’ required ‘only’ that the student could reproduce the text from the tutorial. In the last questions the students were asked to verify if the animation shown was describing an authentic situation or not. One of three animations was correct and the other two described impossible situations (e.g. two pendulums of equal length but with different time for a period). Each question was to be rated regarding difficulty of problem and confidence in giving the correct answer.
At the time of writing we have conducted a pilot with 16 subjects. The students worked in pairs and were encouraged to discuss with each other during the session. During the session the subjects were video-recorded from two angles: from the back (to see the screen and where they were pointing) and from the front (to see facial expressions and body language).

The main purpose of this pilot was to verify the software design and detect problems associated with the test situation.

3. Initial Results

At this point in time there are only some preliminary results from the pilot. Initial analysis indicates that there does not seem to be a problem with understanding that an animation can be fake. The subjects thus seem to be used to computer games and the fact that they do not mimic realistic situations, but rather a made up artificial world. We had some concerns about the subjects believing that all of the animations in the last questions were correct, but we stand corrected to the point that one of the subjects stated: "No, they just made that up!" (translation from Swedish) about the animations in the tutorial.

One set-back was the obvious belief among the subjects that they were to be graded on their performance. This resulted in high estimations of how easy they believed the problem to be and how confident they were in their answers. An alternate interpretation is that since subjects worked in pairs, and tried to impress one another, they might very well have boosted the ratings regarding their confidence in being right and also rated the difficulty of the problems lower than was actually the case.

Another problem detected was a little halt in the pendulum movement when the animation came to an end and started over again. In cases were the animation was too short this little halt came about too often and disturbed the subjects' perception of the motion. When this halt came about just once in a while it did not seem to disturb the subjects that much, and was probably seen as a normal glitch in the computer. This interpretation of course presupposes that subjects had computer experience, i.e., they know that these things can happen.

4. Future Work

After a complete analysis of the pilot we plan to revise the software and perform a full-scale study comparing animation with still illustrations.

In revising the software we will reformulate questions that were unclear and in some cases ambiguous. An additional rating regarding the subjects experience from different computer programs (games, word-processing, edutainment etc.) will be added. Further, instructions given in the "test" part will be made more explicit since language problems in some cases made it difficult for the subjects to follow the instructions.

In the full-scale study subjects will interact with the test program one at a time. The interaction with the test program will be logged and results saved to a file. Subjects will also be encouraged to think aloud and be given an exercise in thinking aloud in the beginning of the test.

Introduction

The use of web-based instruction (WBI) is exploding in PK-12 and university programs (Rasmussen & Northrup, 1997). Many questions need to be addressed to allow educators to use this emerging technology effectively and efficiently. This study explores issues surrounding types of collaboration that can be facilitated among teachers and learners. This paper concludes with sample strategies for developing collaborative cohorts in distance education learning communities.

Background of Study: Collaboration/Mentoring

In WBI teaching and learning processes, participants may be collaborators; traditional roles and relationships among instructors and students are altered. WBI requires participants to be visibly active in the learning environment. Students become equal partners with the instructor and collaborative efforts provide opportunities for mentoring novice technology and distance education users by matching novices with experts to help bridge initial WBI problems (Gray, 1997; Jennings & Dirksen, 1997).

Method

This case study explored how students and instructors collaborated in a graduate-level course, Trends and Issues in Instructional Technology which was delivered through the WWW. Class discussions were facilitated through electronic mail and informational material was available through the class home page. Online chat sessions were available to some learners. The research question for the study was: What type of collaborative relationships develop among learners and instructors in WBI? Design and development of the class was conducted by two instructors in graduate programs at two regional institutions. Course topics included: History of Instructional Technology/Instructional Design, Critical Issues, Instructional Design, Research, Evaluation, Technology, Business and Industry, Public Schools, and the Military.

The Setting

Classes at two regional universities participated in the study. Both courses were conducted during the Spring Terms in 1997; with one beginning in January on a semester schedule and the other beginning in April on a quarter schedule. The two courses overlapped during the month of April. Class 1 ended in April; class 2 ended in June, 1997. Instructor 1 had had prior experience in the design, development, and delivery of WBI. Instructor 2 had had prior experience in using the WWW, but had not facilitated WBI. Class 1 was comprised of
20 masters and doctoral students in an IT masters program or a Educational Management Doctoral program. Class 2 had 15 masters and doctoral students in an Instructional Design and Development program. Students had a wide variety of prior computer and telecommunications experience. Students at the two institutions did not know each other; many were acquainted with their own classmates. Instructors were unacquainted with students at the remote institution. The first week of each class was devoted to familiarizing students with class protocols. Intensive class work and discussions began during week two.

Data Collection

Data were collected from the following sources: student demographic information, online student discussion and assignments, online personality measurement, student interviews, student questionnaires, problems and solutions log, and online "observations" of all student and/or instructor interactions. Data was triangulated where possible, to limit potential bias and data anomalies.

Results/Discussion

All learners experienced anxiety at the onset of the class. Few had participated in a course at a distance and were unsure as to their role and responsibilities. However, students were excited to be participating in a class that was different from the norm that permitted them to work at their own schedules and convenience. Initial strategies to build class cohorts included sharing of personal biographies, personal course expectations, requiring minimum numbers of contact and comments, providing initial learning and web-searching strategies, and matching technology novices to experts for group projects. Students in Class 1 were comfortable with WBI by the fourth week of class, as evidenced by increased participation, in-depth responses, and non-related class e-mail "chatter." One student commented in week 4 that they could finally relax and enjoy the class. Results for Class 2 and the interaction between Class 1 and 2 followed a similar trend; however, comfort levels for Class 2 appeared to develop in fewer weeks, primarily due to a face-to-face initial meeting. In addition, students in Class 1 mentored students in Class 2, by answering their questions, providing strategies for distance learning, and working with Class 2 students in small groups.

Strategies for Developing Collaboration

Strategies used to facilitate development of a distance learning community included: group activities with changing membership each week, encouraging learner self-direction and exploration, forced numbers of responses, and modeling of teacher behavior through discussion leader assignments. Face-to-face meetings, when possible, also appeared to help learners develop relationships with one another and their instructor. Using a variety of strategies assists students in developing personal, teaching, and learning relationships with one another, adding to the complexity and significance of the learning environment.

Conclusion

Teaching and learning at a distance requires different strategies than traditional education. Instructors need to develop varied technological and design skills that facilitate learner success and performance. Strategies can be employed by both instructors and learners to facilitate transition to a web-based learning environment that results in meeting the needs of learners and instructors. These strategies provide a foundation that permit the successful use of WBI for varied learning environments, today and tomorrow.

Knowledge Sharing over the World Wide Web

John Davies, Scott Stewart & Richard Weeks
Knowledge Management Research
BT Laboratories
Ipswich
IP5 3RE
UK
e-mail: john.davies@bt-sys.bt.co.uk

Abstract: Large and increasing amounts of information are now available both on the Internet and on corporate intranets. With the availability of these vast networked information resources comes a requirement for tools to manage the information and provide users with the information they want, when they want it.

In this paper, we describe a system which facilitates and encourages the sharing of knowledge between groups of users within (or perhaps across) organizations. KSE (Knowledge Sharing Environment) is a system of information agents for organising, summarising and sharing knowledge from a number of sources, including the World Wide Web (WWW), an organization's internal intranet or from other users. Users are organized into closed user groups or communities of interest with related or overlapping interests. Such groups could be members of a project team, students studying the same subject (perhaps at different institutions), members of an organizational department, and so on. As well as sharing explicit (codified) knowledge, the sharing of tacit knowledge is encouraged via the automatic suggestion of and support for contact between people with mutual concerns or interests.

1. Introduction

There are now more than 60 million documents on World Wide Web (WWW) servers. Every day millions of people trawl the Internet for information using any one of a dozen or more different search tools. But whether they find what they're looking for sometimes depends not only on their skill, but also on their luck. Studies indicate that many existing search engines do not meet the needs of users [Pollock & Hockley 1996].

Recently, we have seen increasing interest in the use of Internet technology within organizations and the emergence of intranets [Cochrane 1997]. More and more information is being stored in intranet networks and this has led to the realization that these intranets are valuable repositories of corporate knowledge. Organizations are increasingly realising the importance of using knowledge and information residing in their networks for competitive advantage. It is forecast that annual spending on corporate intranets will top $2.1bn in the UK in 1998; for western Europe the total is expected to be over $7.7bn (Inteco Corporation 1997).

Key to the usefulness and viability of both the public Internet and corporate intranets, however, will be the ability to manage the information and provide users with the information they want, when they want it.

Of course, raw information in large quantities does not by itself solve business problems, produce value, or enhance competitiveness. Knowledge solves a problem. Knowledge is information transformed into a capability for effective action: that is to say, it produces competence leading to effective action. Thus today we see a great emphasis on the development of methods for turning information into knowledge. Information as a growing part of a company’s asset base is often inefficiently captured, stored and sometimes simply lost. Knowledge management [Nonaka & Takeuchi 1995] is a strategy that turns an organization’s information into greater productivity, new value, and increased competitiveness.
The first step in implementing a knowledge management solution is to provide seamless access to an organization’s entire collection of information. Many organizations have begun this process through the provision of an intranet. The logical progression for organizations that have implemented intelligent information access software will be to extend it to deliver additional value to knowledge workers. Organizations need to look beyond their formal organizational structures to recognize communities of interest—informal networks of people with common interests who can share knowledge across departments, as well as perhaps continents and time zones.

In this paper, we describe a system which facilitates and encourages the sharing of information between communities of interest within (or perhaps across) organizations and which encourages people—who may not previously have known of each other’s existence in a large organization—to make contact where there are mutual concerns or interests.

KSE (Knowledge Sharing Environment) is a system of information agents for organizing, summarizing and sharing knowledge from a number of sources, including the World Wide Web (WWW), an organization’s internal intranet or from other users. Users are organized into user groups or communities of interest with related or overlapping interests. Such groups could be members of a project team, students studying the same subject (perhaps at different institutions), members of an organizational department, and so on. KSE extends and enhances our earlier work on the Jasper information agent, [Davies, Weeks & Revett 1995]. The Jasper agent automates the sharing of WWW-based information among a community of users with related interests. The additions and enhancements embodied in KSE, described below, are informed by the concerns of the knowledge management community and by the results of trials of the Jasper system.

2. Storing & Organising Knowledge in KSE

KSE agents are used to store, retrieve, summarize and inform other agents about information considered in some sense valuable by a KSE user. This information may be from a number of sources: it can be a note typed by the user him/herself; it can be an intra/Internet page; or it can be copied from another application on the user’s computer.

Each KSE user has a personal agent which holds a user profile based on a set of key phrases which models that user’s information needs and interests. As we will see below, KSE agents modify a user’s profile based on their usage of the system, seeking to refine the profile to better model the user’s interests.

Given the vast amount of information available on WWW, it is preferable to avoid the copying of information from its original location to a local server. Indeed, it could be argued that approach is contrary to the whole ethos of the web. Rather than copying information, therefore, KSE agents store only relevant meta-information. This meta-information is then used to index on the actual information when a retrieval request is made.

When a user finds information of sufficient interest to be stored by KSE, a 'store' request is sent to KSE via a menu option on his or her WWW client. KSE then invites the user to supply an annotation to be stored with the information. Typically, this might be the reason the information was stored and can be very useful for other users in deciding which information retrieved from the KSE store to access. The user can also specify at this point one of a predefined set of interest groups to which to post the information being stored.

In the case of WWW-based information the URL of the WWW page is then added to the KSE store. Similarly, when the user wishes to store some information from a source other than WWW, he or she can enter the information in a text box on their WWW browser and can again supply a relevant annotation. The information thus entered could be from a document in another format or might be a note or snippet of knowledge which the user wishes to enter directly themselves. This information is converted to a WWW HTML page on the user’s KSE server and stored as before.

Essentially, the KSE store is a simple term-document matrix M, wherein:
At storage time, KSE agents perform four tasks:

(i) an abridgement of the information is created, to be held on the user's local KSE server. This summary is created using the ProSum text summarization tool. The summarizer extracts key theme sentences from the document. It is based on the frequency of words and phrases within a document, using the technique of lexical cohesion analysis [Davies & Weeks 1998]. Access to this locally held summary enables a user to quickly assess the content of a page from a local store before deciding whether to retrieve remote information.

(ii) the content of the page is analysed and matched against every user's profile in the community of interest. If the profile and document match strongly enough, KSE emails the user, informing him or her of the page which has been stored.

(iii) the information is also matched against the storer's own profile. If the profile does not match the information being stored, the agent will suggest phrases which the user may elect to add to their profile. Thus KSE agents have the capability to adaptively learn their user's interests by observing the user's behaviour.

(iv) for each document, an entry in the KSE store is made, holding keywords, an abridgement of the document, document title, user annotation, universal resource locator (URL), storer name and date of storage.

In this way, a shared and enhanced information resource is built up in the KSE store. Given that users must make a conscious decision to store information, the quality of the information in the KSE store is high - it is effectively pre-filtered by KSE users. Furthermore, each user leverages the assessment of the information made by all the other users.

3. Tacit & Explicit Knowledge in KSE

3.1 Sharing & Retrieving Explicit Knowledge in KSE

We have seen in the section above how KSE allows a user to store information of interest using an enhanced, shared bookmark concept. This facility goes well beyond the bookmarks familiar from WWW browsers such as Netscape Communicator, in that in addition to the reference to the remote WWW document, a summary of the document, an annotation, date of storage and the user who stored the information are recorded in a shared store. Furthermore, KSE can be used to store and organize information from many sources and in many formats (rather than only WWW-based information).

In this section, we discuss the various ways in which KSE facilitates access to and the automatic sharing of the knowledge thus stored.

Email notification

As described above, when information is stored by a KSE agent, the agent checks the profiles of other agents' users in its 'local community' (the set of users who contribute to that particular KSE store). If the information matches a user's profile with a score above a certain threshold, an email message is automatically generated by the agent and sent to the user concerned, informing the user of the discovery of the information. Thus in cases where a user's profile indicates that they would have a strong interest in the information stored, they are immediately and automatically emailed about the appearance of the information.
Keyword Retrieval – Accessing Information and People

From their KSE home page, a user can supply a query in the form of a set of key words and phrases in the way familiar from WWW search engines (see Fig. 1). The KSE agent then retrieves the most closely matching pages held in the KSE store, using a vector space matching and scoring algorithm [Salton 1989] as follows:

\[
\text{sim}(q,d) = \frac{\sum_{i=1}^{n} (t_{iq} \cdot t_{id})}{\sqrt{\sum_{i=1}^{n} t_{iq}^2 \cdot \sum_{i=1}^{n} t_{id}^2}}
\]

where \( t_{iq} \) is the \( i^{th} \) term in the query \( q \)
and \( t_{id} \) is the \( i^{th} \) term in the document \( d \)
and \( n \) is the number of unique terms in the combined profiles of user u1 and user u2.

In addition to these pages from the KSE store, the agent can also retrieve a set of pages from an organization's intranet and from the WWW. The agent then dynamically constructs an HTML page with a ranked list of links to the pages retrieved and their abridgements, along with the scores of each retrieved page. In the case of pages from the KSE store, any annotation made by the original user is also shown. Note that the user can ask their agent to search for other users by selecting the appropriate check box (see Fig. 1). We will have more to say about this capability to identify other users as well as information in section 3.3 when we look at accessing explicit and tacit knowledge using KSE.

What's New

A user can ask his KSE agent "What's new?" The agent then interrogates the KSE store and retrieves the most recently stored information. It determines which of these pages best match the user's profile. A WWW page is then presented to the user showing a list of links to the recently stored information, along with annotations where provided, date of storage, the storer and an indication of how well the information matches the user's profile.

In addition, a series of buttons are provided so that the user can:
(i) add their own comment or annotation to information stored by another user;
(ii) indicate interest or disinterest in a particular piece of information – this feedback will be used to modify the user's profile;
(iii) examine a locally held summary of the information before deciding to download all the information;
(iv) ask their KSE agent to identify other users with an interest in the information under consideration (see section 3.2).

This What's New information is in fact displayed on the user's KSE home page, so that whenever they access the system, they are shown the latest information. A typical KSE home page is shown in [Fig. 1].
Interest Groups

As mentioned above, when a user stores information in KSE, he has an opportunity to specify one of a predefined set of interest groups to which to post the information. Interest groups gather together pages of related information. KSE users can visit interest group pages which are dynamically constructed from the pages which have been posted to them and consist of a list of links to the pages and their abridgements, along with any annotation provided by the original storer of the page. Interest groups are similar to the 'list of links' pages found in many WWW locations, with the important extensions that multiple users can contribute to the list (automatically via the storage process) and that abridgements of the information and annotations by the original storer of the link are also available.
3.2 Adaptive Agents

We have already mentioned that KSE agents adapt to better understand their user's interests over time. There are two types of event which trigger the profile adaptation process.

As discussed above, when a user is storing some information, if the profile does not match the information being stored KSE will extract the main themes from the information using a unique theme extraction algorithm [Davies, Weeks & Crabtree 1998]. The user's agent then suggests to the user new phrases they may wish to add to their profile. The user can accept or decline these suggestions.

Similarly, when information stored by another member of the community is retrieved by a user using one of the methods described in section 3.1, a feedback mechanism is provided whereby the user can indicate interest or disinterest in the information by clicking on a button (indicated by $\oplus$ or $\ominus$ as shown in Fig. 1). Again, the agent will suggest to the user phrases which should be added to or removed from the profile.

3.3 Finding People & Tacit Knowledge in KSE

In the section 3.1, we focused on the technical aspects of KSE and on explicit knowledge. We now turn to the social aspects of the system and tacit knowledge.

A large amount of the knowledge within an organization may of course not be codified: it may be personal, context-specific and difficult to write down. Such knowledge is referred to as tacit knowledge [Polyani 1966]. When tacit knowledge is difficult to make explicit (codify), we need to find new ways of transmitting the knowledge through the organization. Failure to do so can lead to loss of expertise when people leave, failure to benefit from the experience of others, needless duplication of a learning process, and so on.

One way in which a system such as KSE can encourage the sharing of tacit knowledge is by using its knowledge of the users within a community of interest to put people who would benefit from sharing their (tacit) knowledge in touch with one another automatically.

User profiles can be used by the KSE system to enable people to find other users with similar interests. The user can request KSE via their WWW client to show them a list of people with similar interests to themselves. KSE then compares their profile with that of every user in the store and returns to the WWW client for viewing by the user a list of names of users whose interests closely match their own. Each name is represented as a hypertext link which when clicked initiates an email message to the named user. Profiles in KSE are a set of phrases and the vector space model can be used to measure the similarity between two users $u_1$ and $u_2$:

$$\text{sim}(u_1, u_2) = \frac{\sum_{i=1}^{n} (t_{i1} \times t_{i2})}{\sqrt{\left[\sum_{i=1}^{n} t_{i1}^2 \times \sum_{i=1}^{n} t_{i2}^2\right]}}$$

where $t_{i1}$ is the $i^{th}$ term in the profile for user $u_1$, and $n$ is the number of unique terms in the combined profiles of user $u_1$ and user $u_2$.

A threshold can then be used to determine which users are of sufficient similarity to be deemed to 'match'.

This notion is also extended to allow a user to view a set of users who are interested in a given document. When KSE presents a document to the user via their WWW client using the "What's new?" facility (see above), there is also a hyperlink presented which when clicked will initiate a process in the KSE system to match users against the document in question, again using the vector cosine model. KSE determines which members of the community match the relevant document above a predetermined threshold figure and presents back to the user via their WWW client a list of user names. As before, these names are presented as hypertext links, allowing the user to initiate an email message to any or all of the users who match the document.

In addition, as we have already discussed in section 3.1, a user can carry out a keyword search on other users and thus identify users with an interest in a particular subject.
In this way, KSE, while not claiming to actually capture tacit knowledge, provides an environment which actively encourages the sharing of tacit knowledge, perhaps by people who previously would not otherwise have been aware of each other’s existence.

4. Conclusions

We have described KSE, a tool for encouraging the exchange of tacit and explicit knowledge amongst a community of interest. KSE builds on our earlier work with the Jasper system and incorporates a series of extensions including:

- the ability to store information from multiple sources (rather than simply WWW pages);
- the facility for multiple users to annotate information;
- the ability to search for other users (as well as information) in a variety of ways;
- the facility for users to provide feedback on retrieved information in order to modify their profile.

[Fig. 2] shows the main features of the KSE system of agents, people and information: users can create, store and organize information; they can locate relevant information stored by others in their community of interest and they can contact other users with overlapping interests.

![Figure 2: The KSE](image)

In his seminal article, Bush [Bush 1945] describes a tool to aid the human mind in dealing with information. He states that previous scientific advances have helped humans in their interactions with the physical world but have not assisted humans in dealing with large amounts of knowledge and information. Bush proposed a tool called a 'memex' which could augment human memory through associative memory, where related pieces of information are linked. Trails through these links could then be stored and shared by others. WWW itself fulfils Bush's vision in some respects: Bush's associative memory can be seen in the hyperlinks of WWW. What is lacking is a way of organising this vast 'memory' of WWW pages into coherent 'trails' which can be saved and communicated to others. Currently, only relatively simplistic bookmarks and menus are available.

KSE goes some way to addressing these problems by providing agents which, as we have seen, can store meta-information about WWW pages which can then be used to retrieve relevant pages quickly and easily and share the information contained in those pages with other users with the same interests. In addition, KSE can put users
in touch with other users who share their interests in general or who share their interest in a specific document. In this respect, KSE is moving into the area of tacit knowledge in the sense that it is suggesting useful person-to-person interactions wherein tacit knowledge can be exchanged. So as well as addressing the issue of how best to search WWW for information, KSE is an attempt to address the complementary problem of how best to store information once it has been found and how to share information with others with the same interests. KSE is a step along the road towards the original vision for WWW [Berners-Lee 1991] as a network which supports fully co-operative working and the sharing of knowledge.

Abstract: We have developed a document system that enables multiple format versions of the same document on the WWW, as well as a user-friendly interface for non-linear navigation of the formatted document. We have efficiently applied the system to provide LaTeX documents on the WWW. In addition, we have developed a hyperlink network that allows efficient presentation and non-linear navigation of LaTeX content incorporating JavaScript. This type of multi-targeting is quite significant for allowing posting of a document on the WWW in different formats, so that multiple users can navigate into formats they individually understand. A printable version of the document is also obtained by converting the LaTeX file to a PostScript one. Hence, we obtain two versions, one optimized for display and one for printing, by editing a single original document. The documentation medium that allowed us to implement this multi-targeting is the Automatic Site Markup Language (ASML) developed in the DEVLAB [DEVLAB 98].

Introduction

Document multi-targeting is the ability to author, present, and maintain closely related document content in multiple formats with minimum manual effort. This ability is useful in many applications where content may be altered or refined and needs to be used or adapted for different conditions or users. In this paper, an extension of the Automatic Site Markup Language (ASML) site level authoring system for the World Wide Web [Owen et al. 97, Owen 98], is described and is shown to be useful for multi-targeting content for the World Wide Web. Multi-targeted documents should have the following features: (1) permit easy-to-make changes with centralized facilities; (2) minimize the duplication effort; (3) enable document production without knowledge of scripting languages and (4) avoid custom programming need. ASML provides a tool for this process.

LaTeX is a widely available, sophisticated, and powerful document generation language used extensively in many academic environments [Lamport 86]. By implementing ASML templates, we have designed a system that allows user-friendly editing of LaTeX documents on the WWW that permits viewing LaTeX content as a hierarchical structure of hyperlinks. This allows users to post their LaTeX documents on the Web so that others can derive and save their own updated versions, while leaving the original document intact. Further, establishing a hyperlink network for LaTeX content allows efficient non-linear navigation of the LaTeX content. This navigation has been implemented in JavaScript.

Once LaTeX documents have been downloaded through the system, users can obtain printed versions by converting them into PostScript. Thus, the system presents a Web-based displayable form of a document while preserving a version designed for printing. The operational flow of the system is illustrated in Figure 1.
Figure 1: Operational flow of obtaining a displayable and a printer version of a document

Related Work

The usual approach to multi-targeting is to author in one distribution environment, then convert to the other formats. ASML can be compared to HTML conversion utilities (though it has many more features). An example is authoring in LaTeX, then converting the LaTeX to HTML using the LaTeX2HTML tool [Drakos 94]. Such tools are primarily designed to facilitate conversion of existing content. Because the mechanics of the target format (such as HTML) are not available in the alien environment (as they are in ASML), conversion tools limit the designer's flexibility. Converters exist for a wide variety of environments include most commercial word processors and page layout programs. All of the above mentioned conversion approaches lack the ability of editing an original document once, whose further compilation displays the file on the WWW in different formats.

Object Oriented Modeling of LaTeX documents

In Figure 2, we illustrate a representative physical structure of a LaTeX document.

\end{center}
\end{document}

Figure 2: A sample of the physical structure of a LaTeX document.
In the logical structure hierarchy of a LaTeX document, called an article, a LaTeX document is composed of child components. For instance, we have a title, an abstract, and chapters with sections as children, each of which themselves have subsections as children, and which can further have figures as children. Hence, one can realize a hierarchical container relationship of the entire article. We further consider that a LaTeX document provides the following content class types: Title, Abstract, Chapter, Section, Subsection, Math, Figure. This implies the following logical structure hierarchy of an article, as it appears in Figure 3.

Figure 3: Logical structure hierarchy of a LaTeX document.

We further consider each content class to be derived from a virtual HTML page class, which further allows the user of the system to present any content of the article through non-linear navigation.

Implementation of a Web-based LaTeX Presentation System

Exploiting the power of ASML templates allowed us to develop a component-based system for editing LaTeX document on the WWW that uses the logical hierarchy of Figure 3. It represents this structure by constructing a network of hyperlinks.

The system is composed of the following components, called packages:

- Macros Package: Defines LaTeX environments, commands, TeX definitions.
- ControlDocument package: Defines grouping of textual LaTeX content objects (e.g., chapters, sections, etc.)
- DocumentConfig package: Defines boxes, fonts, page size width, as well as, any kind of information relevant to the appearance of the article.

This system architecture allows the user to include only the packages necessary to the composition of an article. In Figure 4 we give a sample of ASML templates from the ControlDocument package.

```latex
{define name="title"}
  \{\huge\bf\{tName\}\} \\\\\ <br>
  <a name="{start}"</a><br>
{/define}

{define name="subtitle"}
  \{\LARGE\bf\{stName\}\} \\\\\ <br>
{/define}

{define name="subsubtitle"}
  \{\Large\bf\{sstName\}\} \\\\\ <br>
{/define}

{-- we assume numbered chapters --}
```
Figure 4: A sample of the ASML ControlDocument package for LaTeX document

The network of hyperlinks is implemented by the writing of anchor names with proper syntax; e.g., for a section there is an anchor name of the form `sec(cNum)_(sNum)` . This is an exact realization of the logical structure hierarchy presented in Figure 3. This hierarchy is shown again with only the hyperlink communication between parent-children in Figure 5.

![Diagram](image)

**Figure 5:** A hyperlink network on the logical content hierarchy.

**Example Site**

A prototype Web site created using this templated system is shown in Figure 6 [Sasles 98]. A Web-based graphical-user interface facilitates the presentation of the multiple-format document. The example source document chosen was a section of the documentation of ASML. The GUI presents the source document in a window, supplemented by a browsing access utility displayed constantly in a separate frame. This utility includes incremental chapter and section buttons for chapter-by-chapter browsing, as well as a jumping mechanism to access any given chapter and section non-linearly. The crucial part of this system's multi-targeting nature is its ability to switch between formats easily. A dropdown list is used to offer the user the choice between viewing HTML or LaTeX formats, as well as the option of split-screen viewing, where the document is displayed and navigated synchronously in both formats.

Also included is a figure-browsing utility that allows the user to skip to each figure incrementally throughout the document (See Figure 7). Using this utility, the user may browse through the selected material in HTML or in LaTeX, switching between the two formats as he or she chooses and saving whichever format is desired, according to his or her needs. A user might browse the HTML version until she finds what she is looking for, then access some other part of the file to satisfy her own needs, e.g., saving in some specific format or printing.
Figure 6: A dropdown list is used to offer the user the choice between viewing HTML or LaTeX formats, as well as the option of split-screen viewing.

Figure 7: Figure-browsing utility that allows the user to skip to each figure incrementally throughout the document.

The GUI for this project was implemented using JavaScript. JavaScript is widely accepted (a crucial aspect of making this system accessible was using “lowest-common denominator” tools) and allows fully functional frame-based Web browsing, an accepted modern standard on the World Wide Web.

Conclusion and Future Work

We have described the prototype of a system that allows display and non-linear navigation of a LaTeX document accompanied by its HTML version. In addition, we described the steps of obtaining a PostScript version of the original document for printing. A future enhancement of this approach is to manually or automatically add links to the HTML version to improve navigation within that version, and in the process, facilitate navigation for all associated formats.

A very powerful enhancement would be the support of built-in tags that perform C++ function calls; since ASML has been developed in C++, this would permit use of C++ programs in Web site development. This could enable ASML as an alternative to HTML with Java applets. Additionally, such a feature would allow users develop their own content retrieval systems that could, for example, selectively cluster existing content of a document, from which he/she could compose a new one. In other words, ASML could become the computational intermediate system for melding multi-targeting and document content retrieval.

Adaptive Hypermedia on the Web: Methods, Technology and Applications
(invited talk)
Prof. dr. Paul De Bra*
Department of Computing Science
Eindhoven University of Technology
Eindhoven, The Netherlands
Email: debra@win.tue.nl

Abstract: World Wide Web lets information providers (potentially) reach millions of people located all over the world. These users form a very diverse crowd. No single presentation of the information an organization wishes to distribute will be suitable for all types of users that organization wishes to address. Adaptive hypermedia techniques make it possible to provide each individual user with the information and presentation he or she needs, based on an internal representation of that user, called the user model. The user's goals, preferences and needs may change over time. An adaptive Web-site observes these changes, updates the user model on the fly and uses it to adapt the presentation to the changing circumstances.

This paper gives a very brief overview of some existing adaptive hypermedia methods and techniques. Both the (textual or multimedia) content of pages and the links between them can be adapted. The paper indicates which Web technologies are (sometimes or typically) used to realize adaptive Web sites. This includes both technical hacks to make it work and authoring tools intended for subject-matter experts who are not (necessarily) very computer or hypermedia savvy.

Through examples of applications we show reasons for making a Web site adaptive in certain ways. Adaptivity must be used with caution in order to avoid Escher effects that might turn browsing through an adaptive Web site into an adventure game instead of making it easier and more effective.

keywords: adaptive hypermedia, adaptive Web sites, user modeling, adaptive presentation, adaptive navigation, adaptive authoring tools.

1. Introduction
World Wide Web is a great medium for potentially reaching millions of people located all over the world. This potential has been exploited by thousands of companies, research organizations and educational institutes. Web sites have been created for informing customers and business partners, research colleagues, students, visitors and many other categories of users. More and more Web site builders are beginning to realize that one uniform Web site cannot offer the information these millions of different users need, and certainly not offer it in a way that is best suited for each individual user. This is where adaptive hypermedia comes into play. Using an internal representation of a user, called the user model, a hypermedia system or Web server can change the information and its presentation according to a user's individual goals, preferences and/or needs.

Adaptive hypermedia (or AH for short) is a research and development field which has its roots in the crossroad of hypermedia and intelligent tutoring systems. As a result, a majority of adaptive hypermedia systems (or AHS), beit Web-based or not, are used for educational applications, and especially for interactive course texts that allow access to more advanced learning material as the student gains knowledge. However, as the Web is

* Paul De Bra is also affiliated with the University of Antwerp and the "Centrum voor Wiskunde en Informatica" in Amsterdam.
being used more and more by companies for promoting and providing information about their products and services, the need arises for providing each individual user with the most appropriate information, in the most desirable form. For instance, browsing through a paper mail-order catalog can be done much faster and more effectively than browsing through an electronic version of that catalog. However, most of the catalog is of no interest to a particular user, and it is time consuming to find the appropriate offerings among the wealth of irrelevant stuff that is also for sale. When an electronic catalog knows what the user's interests are, and possibly what goal the user has during a specific browsing session, it can present the appropriate information very efficiently, thus saving the user some valuable time, and not distracting the user in a way that may lead to no purchase at all. Companies have been formed, and more are coming, that specialize in gathering a lot of information about an individual user, so that this rich user model can be used for adaptive access to Web sites. In this paper we concentrate on techniques that are used for creating adaptive Web sites. We ignore the obvious social and legal privacy issues that arise when user models are exchanged between Web sites (of different companies) or requested by authorities for tracking an individual's Internet activities.

The Web was not designed with adaptive hypermedia in mind. As a result, the standards defined for Web technology, including HTML and HTTP, sometimes hinder the creation of adaptive documents. In the future, dynamic HTML (or DHTML for short) may offer a solution to the need for alternative presentations of content. Since DHTML involves a combination of "pure" HTML, Style Sheets (using CSS) and Javascript or VBscript code we will need sophisticated authoring tools for generating DHTML automatically, as it is impossible for non computer scientists to write DHTML documents manually. HTTP is also lacking some feature(s) that are needed to make adaptive presentation work under all circumstances. We will describe possible ways to program around the Web's shortcomings in order to realize adaptive Web applications.

This paper is structured as follows: Section 2 [Classification] gives a classification of adaptive hypermedia techniques. Section 3 [User Modeling] describes how systems may store information about users in order to do adaptation. It also relates this representation to the issue of authoring. Section 4 [Implementation] shows how adaptivity can be achieved on the Web.

2. Classification of adaptive hypermedia methods and techniques

Adaptive hypermedia (AH) is a term used in different meanings throughout the hypermedia literature. To avoid any confusion we distinguish:

- **Adaptable hypermedia systems** allow the user to explicitly set preferences, or provide a profile through filling out a form. This information is stored in a *user model*. The presentation of the information is then adapted to that model, which is only updated upon explicit request by the user. Some systems may have very elaborate user models, while others only distinguish between a few stereotype users such as "beginner", "intermediate" and "expert", or "student", "employee" and "visitor".

- **Adaptive hypermedia systems (AHS)** build a *user model* by observing the user's navigation through the information space, and in educational systems also by means of (mostly multiple-choice) tests. The presentation is adapted to the user model, and the user model is constantly updated as the user reads the information.

Most AHS are also adaptable, because they need a way to initialize the user model, or to allow users to explicitly adjust that model. However, we shall concentrate on the adaptive features of the systems and applications.

In his overview article Brusilovsky [Brusilovsky 96] describes which AH techniques exist. We briefly recall this classification and refine it as was previously done in [De Bra & Calvi 98]. We also indicate sample applications or application areas where such techniques are (potentially) useful.

**Adaptive presentation** is the general term for all techniques that adapt the content of a Web page according to the user model. Brusilovsky [Brusilovsky 96] distinguishes:
Adaptive text presentation: the textual content of Web pages is altered depending on the user model. Technical terms can be avoided for beginners, and additional explanations added. Likewise, additional details can be provided for advanced users who are capable of understanding them. Three techniques for creating adaptive text presentation are:

- **page variants**: several (or a few) different versions exist for a given page. This technique fits a stereotype-based AH system, in which the variation is limited.
- **fragment variants**: different versions of fragments of a page exist. Fragments can be as small as a single word (like a technical term which can be replaced by a common term which means almost the same), and as large as a whole page. (Thus, page variants are a special case of fragment variants.) The number of variations of a page can be large since each fragment can be adapted to different variables in the user model.
- **frame based techniques**: using natural language techniques pages are assembled from small information items like words and parts of sentences.

Adaptive multimedia presentation: although this term suggests that multimedia content elements might be adapted to the individual user, current implementations are limited to media selection. Unlike with text, the content of an animation, audio or video fragment is not adapted.

Adaptive navigation is the term for techniques that manipulate the links that are available to the user (at any given moment in time). Brusilovsky [Brusilovsky 96] and De Bra and Calvi [De Bra & Calvi 98] distinguish:

- **Direct guidance**: a link is provided to whichever page the system considers to be most appropriate for this user to go to next. The repeated use of such a “next” button is like following a personalized guided tour.
- **Adaptive sorting of links**: instead of providing a single “best” link this technique provides a list of links, in descending order of relevance. Information retrieval (searching) systems typically provide this kind of list of links. But in educational AHS an adaptively sorted list of links can also be provided to provide guidance as to which pages to read to learn about a certain concept. In [Weber & Specht 97] adaptive “curriculum sequencing” was found to reduce the number of navigation steps a user needs to learn a concept.
- **Adaptive link hiding**: in order to avoid an abundance of links the AHS hides links to currently non-relevant information by making the link anchor (the text which is normally underlined and/or displayed in a different color) indistinguishable from normal text.
- **Adaptive link removal**: this technique removes the link anchor for non-relevant links. This can only be done when the surrounding text still makes sense after removing the link. In a list of items one can easily remove items. In [Brusilovsky & Pesin 95] experiments with ISIS-Tutor are described, where links to non-relevant items were removed. While adaptive link removal is effective in reducing the number of navigation steps, preliminary evaluations [Calvi & De Bra 97] show that users dislike this technique.
- **Adaptive link disabling**: the link functionality is removed but the link text remains. This technique is often combined with link hiding, because if the appearance of an anchor remains, but the link does not “work” the user may think there is a system error. Users dislike adaptive link disabling [Calvi & De Bra 97] but still prefer it over adaptive link removal.
- **Adaptive link annotation**: links are annotated to indicate their relevance. This can be done by changing the presentation (e.g. color) of the anchor itself or by providing another visual cue like a colored dot or arrow. Several systems developed by Brusilovsky, together with others, use adaptive link annotation, combined with other techniques. These systems include ISIS-Tutor [Brusilovsky & Pesin 94], ELM-ART [Brusilovsky et al. 96a] and Interbook [Brusilovsky et al. 96b]. Experiments (see e.g. [Eklund & Brusilovsky 98]) have lead to the conclusion that adaptive link annotation is helpful in reducing the number of navigation steps and in improving comprehension of the learning material.
- **Map adaptation**: a few hypertext systems provide graphical overviews of the link structure of a hyperdocument. This map can be adaptively filtered to present a manageable overview of the parts of the hyperdocument that are relevant to the user.

In [Calvi 98] there is a discussion about the benefits and drawbacks of some of these adaptive linking techniques. Experiments and preliminary evaluations (see e.g. [Eklund & Brusilovsky 98] and [Calvi & De Bra 97]) lead to inconclusive advice: the goal to increase user satisfaction can be served through adaptive link annotation, whereas for improving the efficiency of navigation link removal and/or disabling work better.
3. User Modeling in AH

AHS need an internal representation (or approximation) of the user's state of mind in order to adapt the presentation and navigation to that user. The AHS needs to know the user's goals and task, background, experience in the subject matter, experience in hypermedia navigation, preferences like media, verbosity, etc. Some of this information, namely preferences and sometimes also goals and task AHS from the user's browsing behavior.

Information about the user's state of mind is typically implemented through an overlay model. The user's state is compared to a set of variables. Because of the focus of the field of AH on educational systems these variables are often called concepts. We shall also use this terminology, but keep in mind that these variables can have any meaning and use, other than representing the user's knowledge about a certain concept.

We distinguish three (sub)types of knowledge representation, differing in the data type used for the concepts:

- **In the Boolean model** there are two possible values for each concept: true and false, which could be interpreted as known and not known. However, the values may actually mean something completely different, like verbose and terse to indicate whether a user wants a lengthy or short version of each page. Some AH courseware developed by this author uses the Boolean model.

- **In the discrete model** there are a small number of values for each concept. (The Boolean model is a special case of the discrete model.) Systems like ELM-ART [Brusilovsky et al. 96a] and Interbook [Brusilovsky et al. 96b] use a discrete model with four values, meaning not known, learned, well learned, and known. A concept becomes learned when the user has read about it while she was not ready for it; it becomes well learned when the user has read about it while she was ready for it, and it becomes known when the user has passed a test about the concept.

- **In the continuous model** there is a range of values, e.g. the real numbers between 0 and 1. Values can be interpreted as how much a user knows about a concept, or alternatively as the chance that the user knows a concept. The model used by Pilar da Silva [Pilar da Silva 98] comes close to being a continuous model. Instead of values between 0 and 1 it uses percentages (between 0 and 100), thus providing many more possible values per concept than any other discrete model.

It will be clear that the possibilities for adapting a hyperdocument to each individual user are greater in the continuous model than in the discrete model or the Boolean model. However, in order to exploit these possibilities the author (and authoring software) must be able to deal with such a rich value set. In hyperdocuments authored for the Boolean model there is typically a one-to-one relationship between concepts and Web-pages. The user learns about a concept by reading a (single) page. The discrete model may relax this constraint a little bit, for instance by associating a Web page and a test with a single concept. Both techniques lead to a fine grained user model, with many detailed concepts. In the continuous model it is possible to associate may pages with a single concept. Each page contributes towards the knowledge of that concept. The concepts may be coarse grained, meaning that they represent fairly global knowledge items. This makes it easier to export the knowledge from one AHS to another, assuming that other AHS may not be able to interpret the detailed distribution of knowledge over a large set of (small) concepts.

Authoring AH documents requires that the writer first construct a global map of how he wants the knowledge to be presented to the user. This means determining which concepts will make up the user model, and how these concepts depend on each other or maybe contribute towards knowledge about each other. While it may help the author a bit when the system provides a (graphical) tool for editing this concept map, the main benefit of such a tool is that it helps the system in automating the dependencies. In order to use the concept map each concept must be tied to the pages dealing with that concept. To some extent this could be done automatically through word frequency techniques used in information retrieval, see e.g. [Golovchinsky 97]. However, it will be mostly the author who gets to decide how pages relate to concepts. Determining exactly what the contribution of a single Web-page is to a concept for which there are many pages is difficult.
4. Implementing AH on the Web

In order to provide AH on the Web the server needs to be able to generate Web-pages (in HTML) that are adapted to each individual user. This is typically achieved through a server-side scripting technique such as servlets or CGI-scripts. In the sequel we call the Web-server plus its scripts the AH engine. The source for the pages, as written by the author, need not necessarily be HTML. The AH engine can translate different source formats to HTML on the fly. This is especially useful for authors who are not used to writing HTML documents. However, the difficulties in creating adaptive hyperdocuments are the same regardless the source language:

- Most Web-pages contain links to other pages. The author must indicate which links are subject to adaptation and which are not. The AH engine manipulates the adaptive links using one of the techniques from [Classification]. In Interbook [Brusilovsky et al. 96b] for instance adaptive links are annotated by means of a colored ball or arrow (which follows the link anchor), while in AHA [De Bra & Calvi 97], [De Bra & Calvi 98] the link anchor text is displayed in blue, purple or black depending on the relevance of the link. (The link is thus annotated or hidden depending on the situation.)
- Some systems provide additional guidance through an annotated table of contents or a textual or graphical representation of (part of) the user model. Such information is often generated automatically, but the author needs to be aware of what information will be displayed. An author who knows this generated information can avoid to repeat it unnecessarily in the information pages.
- The content of the authored Web-pages may need to be adaptive as well. Technical terms should be avoided for users who have not studied their definition. Additional details may be provided for users who have enough experience in the topic at hand. Variations can be achieved by using the fragment variants technique, described in [Classification]. This technique requires that the authoring environment provides a facility for indicating which variation of each fragment is displayed, depending on which condition on the variables in the user model.

Currently, tools for authoring adaptive text presentations in an easy way are still lacking. AHA [De Bra & Calvi 97], [De Bra & Calvi 98] for instance uses “if statements” encoded as HTML-comments. This technique is convenient for authors who are familiar with authoring HTML and with logic. The majority of authors of Web-pages will most likely not be able to use such an authoring environment.

Implementing an AH engine is also non-trivial. In an AHS it is common that when the user revisits a page the appearance of that page may (need to be) different. Links may be sorted or annotated differently, text fragments may have changed, a “next” button may point to a different location, etc. While the changes are usually subtle, in order to avoid Escher effects, the architecture of the Web makes it difficult to offer even small variations to pages: the HTTP standard (version 1.1) states:

By default, the Expires field does not apply to history mechanisms. If the entity is still in storage, a history mechanism should display it even if the entity has expired, unless the user has specifically configured the agent to refresh expired history documents.

(quoted from RFC's 1945 and 2068, which define HTTP/1.0 resp. 1.1)

Unfortunately, the “agent” (meaning the Web-browser) is not required to offer the option of refreshing expired documents when going back to them. Luckily the two most popular browsers (Netscape Navigator and Microsoft Internet Explorer) do request expired documents from the server each time they are revisited. (However, due to a bug in Netscape Navigator, it may be necessary to disable the browser’s memory and disk cache when going through a proxy gateway. This adversely effects the overall server load and browser performance.) Older browsers, including NCSA Mosaic for X (the browser that made the Web popular, long before Netscape Navigator and Internet Explorer existed) may refuse to revisit pages that are available through the browser’s history mechanism.
When a Web-based AHS uses HTML frames (a presentation technique introduced by Netscape and later incorporated in the HTML 4.0 standard), following a link within one frame may result in the other frames no longer corresponding to the actual user model. In order to update the other frames, a small piece of Javascript or VBScript code must be added to each page, requesting the other frames to be updated if needed. The two most popular browsers support Javascript, but some others may not.

Adaptive link annotation, and link hiding, can be done by changing the color of the link text. This requires the use of HTML style sheets, a technique introduced with the HTML 3.2 standard. Again, not yet all browsers support style sheets.

5. Conclusions and final remarks

There exist many different techniques for adapting the presentation of information and the navigation between pages on the Web. Several applications have been evaluated and show the benefits of the different adaptive hypermedia techniques. However, there is no evidence that the findings of these experiments can be generalized to all applications that use these techniques. In fact, the process of constructing a user model, determining dependencies between concepts, and tying concepts to Web-pages is not yet automated. While adaptive hyperdocuments can be created that are easier to use than static equivalents, the techniques can equally well be used to make navigation through a hyperdocument more difficult. There currently exist no (software) tools for verifying the usability of adaptive hyperdocuments. Therefore, user evaluation remains the most important way to determine the effectiveness of adaptivity for a particular application.

Using adaptive hypermedia for Web-based education

Paul De Bra
Eindhoven University of Technology, The Netherlands

Peter Brusilovsky
Carnegie Mellon University, USA

Adaptive hypermedia (AH) techniques are used to adapt Web-sites to each individual user (or user group) in order to provide (links to) the most relevant information for that user. The tutorial "Adaptive Hypermedia and its Implementation on the World Wide Web" provides valuable (but not strictly necessary) knowledge for attendees of this tutorial. It explains all different methods and techniques used in AH systems. During this tutorial we will demonstrate the creation of adaptive Web sites using two different AH systems:

- An adaptive hypermedia engine "AHA" was developed at the Eindhoven University of Technology, by Paul De Bra. Adaptive hyperdocuments in this system consist of (standard) HTML pages. Authoring the pages for AHA-hyperdocuments is easy. AHA can be used with any standard Web server. It consists of CGI- or FCGI-scripts written in Java. The presentation can (and must) be determined entirely by the author. This includes the choice of an optional frames structure and the (JavaScript) code to keep frames synchronized. A choice of link colors determines whether adaptive link hiding or adaptive link annotation is used. During the tutorial AHA will be used on a PC with Windows'95, but AHA can be used in the same way on Unix workstations.

- Interbook was developed by Peter Brusilovsky. It provides tools for generating guided tours for users who have a specific goal, as well as adaptive navigation for users who with to explore the whole adaptive hyperdocument. Interbook uses a frames presentation structure which is kept synchronized by the system itself. It provides information on the concepts a user has learnt and concepts still to learn to achieve a given goal. Interbook uses a Lisp-based Web server and software. During the tutorial an adaptive Interbook document will be developed on a Macintosh.

Attendees of this tutorial should have some experience with creating (static) Web pages. They will learn how to create adaptive Web pages in general, and get a demonstration of authoring for AHA and Interbook.

Abstract: This paper's purpose is to present a functional description of a groupware-type application that controls the environmental management process [Michelis] [Dix 1996]. The application, named SIGMA, was developed for PETROBRAS and has three main objectives: to provide the users information on the process of environmental licensing; to help users conduct this work and allow a better interaction between them and the community concerned with a given environment – either PETROBRAS workers or not – , and to disseminate information in a differentiated way according each user's profile.

1. Introduction

The Brazilian legislation regarding the environment determines that any project that might have a high-degree impact on the environment must be submitted to a specific process of environmental licensing.

PETROBRAS (Brazil's petroleum company), through COEMA (Environmental Engineering Coordination), an agency belonging to SEGEN (Engineering Services), had the need to implement an information system that allows the management of the licensing processes of the corporation's enterprises that have an environmental impact.

The SIGMA system provides communication resources that allow, in an easy way, information sharing, negotiations in cases in which divergences may appear, and experience exchange among members of the community involved in environmental licensing processes.

On the other hand, the corporation wished the enterprise to start in the shortest possible date, hence the need to accelerate as much as possible the conduct of the process. Thus, an important requirement is to establish automatic controls aiming to avoid unjustified delays, taking into account that fast information broadcast means expense economy to the corporation.

Despite the system's wide covering, it devotes maximum attention to information security, regarding both access to it and its integrity. For this, different kinds of users and different kinds of access to the information were defined, making the system available in a differentiated way according to the user.

2. Monitoring Mechanisms

The environmental licensing process consists in obtaining licenses with the competent agencies. This requires the development of several activities: (a) Preliminary Analysis Study; (b) Definition of the Reference Term, in which the scope of the environmental studies to be made is presented; (c) Environmental Study Elaboration; (d) Revision of the studies by the competent agencies, dissemination of information and public hearing when required; (e) Issue of the Previous License; (f) Issue of the Installation License, which allows the corporation to begin the construction stage; (g) Construction Stage; (h) Environmental Hearing; (i) Elaboration of Emergency Action and Risk Analysis Plans; and (j) Issue of the Operation License.

For this monitoring, the application was divided to two parts. The first one is identified by the inclusion, for each project, of cadastral data, of the dates corresponding to the activities, of the people responsible for them and of the restrictions involved. PETROBRAS has created three kinds of projects: ducts, industrial units, and production units. The projects concerning the ducts refer to the implantation or enlarging of ducts for the transportation of products such as gas, petroleum, oils, etc. The projects concerning the industrial units consist in the construction or enlarging of refineries, while the ones concerning the production units correspond to the construction or enlarging of platforms or terminals.

In this stage, the phases with their respective activities are selected. Each project has a set of particular phases/activities that might be different from another project's or not. This selection is made by means of the
fulfillment of the dates related to the activities, estimated and/or accomplished. It is also here that the
information on the evolution of the management process are updated.

The set of phases available in the inclusion part follows a standard. The system doesn't allow the
inclusion of new phases yet, but phases that will not be used in a given project could be excluded. There is also a
default set of activities for each phase. In this case, the system allows the exclusion and/or creation of new
activities in each phase. The exclusion of phases and/or activities and the creation of new activities are only valid
for the specific project. Each project has its own set of information, all of which are stored in a data base and are
recovered in real time when the user navigates through the application's pages of a given project.

The second part of the application refers to monitoring the environmental management process. There,
the pages of the project, of the monitoring of phases/activities, and of the schedule are presented.

Schedule Charts

The schedule can be analyzed according to two concepts: the bar chart and the block chart, developed
by TeCGraf (the Catholic University of Rio de Janeiro's computer graphics development team). The bar chart,
presented in Figure 1, refers to the GASBOL project, which is the duct responsible for transporting natural gas
from Bolivia to the South and Southeast regions of Brazil. It lists all the project's phases, being also available to
each phase. The access to the bar charts is also made through the links existing in the block chart in the page of
products being licensed or in the product's page.

In the project's abbreviation there is a link to the project's page. There are also links in the name of
each phase, leading to each one's bar chart.

![Figure 1: Bar Chart](image-url)

The block chart presented in Figure 2 has two purposes: to present the project's situation, and to present
the situation of the phases that constitute the project. Both cases inform the user about the situation of the project
or phase by means of a graphic feature, detailed in Table 1, which allows a quick identification of the situation of
the project or phase.
Below is the description of each symbol and its meaning. A particularly important one is the alert state, represented by the yellow ball in Table 1, which aims to inform the person responsible for the environmental management process that the final date of the activity is approaching.

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Green ball</td>
<td>The Phase/Activity is concluded</td>
</tr>
<tr>
<td>Red ball</td>
<td>There is a delayed phase/activity</td>
</tr>
<tr>
<td>Red lozenge</td>
<td>There is a non-started phase/activity whose schedule has expired</td>
</tr>
<tr>
<td>Blue ball</td>
<td>There is a phase/activity in progress, in time</td>
</tr>
<tr>
<td>Yellow ball</td>
<td>There is a phase/activity in progress, in time, whose end date is approaching</td>
</tr>
<tr>
<td>Gray ball</td>
<td>There are project/phases/activities yet to be initiated</td>
</tr>
</tbody>
</table>

Table 1: Symbols from the block chart

The monitoring of each activity is made through the project's page, shown on Figure 3 for the GASBOL project. This page presents information on the projects according to their kind. They include the entities involved with the people responsible for them. For each entity, there may or may not be a list of the ones responsible for the project.

The top of the page presents the project's block chart, in which the links to the bar chart and to the details of the phase selected are available.

The vertical frame to the left is called general index. It presents the links to recurrent themes when navigating through the application, such as sending an e-mail to the webmasters or consulting the system's user guides.

The second vertical frame (beside the general index), in Figure 3, is called contextual index. It shows the list of activities belonging to the selected phase.

The central frame is called main frame. It presents information to be consulted or for the forms to be filled by the user.

The system works with text files, such as environmental reports, study letters forwarded to Environmental Agencies, etc. In this case, the system makes available pre-defined files which serve as a base for the creation of new text files. The access to these documents is made by means of links that activate text editor MS Word, the one used by PETROBRAS.
The documents received, including the licenses (Previous, Installation, Operation), will be associated to their corresponding projects. They will be scanned, treated, and stored digitally, becoming available in the system to be accessed by those interested and authorized. The documents will be scanned for any area, and, by means of upload, will be included into a specific area of documents for each project. In this case, the system automatically defines each document's name.

3. Communication Mechanisms

Communication mechanisms are the features through which the users can make notes concerning the project. In the note pages the users register comments during the execution of the projects under their responsibility, which become available in the system to be accessed by the people involved in the environmental management process, according to their profile. These notes are classified as individual, public, pertaining to a sector, pertaining to a project’s community, and pertaining to the managers.

Access permission to the notes available in the projects is defined by the kind of note together with the kind of user that is trying to access. Based on this combination, the users might have access to the notes or not, both for reading them and for creating them.

The individual notes may be created by any PETROBRAS employee involved in the project, and may only be accessed by the person who created them. This kind of note aims to allow the users to write reminders or to make observations for themselves.

The notes pertaining to a sector may be created and accessed by the users belonging to the same entity of the person who made the note. Their purpose is to disseminate information on the project, so that those working in the sector involved in the project may be kept informed on what is going on.

The notes pertaining to a project’s community may be created and accessed only by the users related to the project. It is one of the mechanisms that aim to maintain an interaction between the people responsible for the environmental licensing process and those relat to it.

The notes pertaining to the managers may be created by the users who are responsible for the project. These information is only accessible to those working in the high administration (superintendence and board of directors).

Public notes may be created by people from entities like COEMA, Enterprises, Coordination of Works, and Division of Projects related to the project. They may be accessed by any person belonging to the environmental community, either a PETROBRAS employee or not.

SIGMA also has links to consult other organizations, making available access to information from environmental agencies.

Beside the above mentioned communication mechanisms, electronic mail is also available to provide direct communication among the people involved in the process.
4. Access Mechanisms

Due to the security needs demanded by the users regarding access to the system’s information, differentiated visions were defined according to their profile. The users are divided into: COEMA, Enterprises/Coordination of Works/Divisions, Operational Agencies (the clients), Superintendents/Directors, PETROBRAS’ intern public, and PETROBRAS’ extern public. For each of these users there are different levels of access.

The access level informs how users have access to the information specifically available for him. Level A allows the user to include and update the information concerning the projects under his responsibility, and to create any kind of note. Level B allows the user to consult the information regarding the projects under his responsibility, and to create and access specific notes according to the entity that he belongs to. Level C allows the user to consult cadastral information about all projects and specific notes according to the entity that he belongs to.

5. Conclusion

Groupware is a technology that allows corporate work between two geographically distant groups, propitiating a better and wider interaction among themselves [Khoshafian 1995] [Ostwald].

SIGMA is a groupware application. It enhances the interaction among those belonging to the environmental community, allowing them to exchange ideas, to share information, and to actually control the environmental licensing process of PETROBRAS’ enterprises by means of three mechanisms: monitoring mechanisms, communication mechanisms, and access mechanisms.

Abstract: We describe the functions and internal architecture of the GLOBE Visualization server. The server generates maps and graphs of environmental data for GLOBE, an international science and education program. Users can modify the visualizations to show any date, location or dataset, and users can customize the interface itself based on browser capability, native language, and familiarity with the system. Wherever possible, all options are self-generating to avoid separately-maintained content areas. We describe the system from the user's point of view. We then discuss how it is implemented on the server side, describing the interface, imaging, and database components.

1. Introduction

The GLOBE Program is an international program of science and education involving students, teachers and scientists. Nearly 5,000 schools in over 60 countries participate. Students in grades K-12 perform measurements of environmental parameters such as temperature, precipitation, water quality, soil characteristics, and vegetation, and report them to the GLOBE Student Data Server. Teachers receive training on measurement protocols and Internet use, and return to their classrooms to oversee data collection by students [Soloway 1996]. The instructor can integrate GLOBE activities into the curriculum in whatever way is most appropriate for that school and country. The measurement types and techniques are defined by scientists affiliated with the program.

The GLOBE Visualization server at NASA Goddard Space Flight Center provides scientific visualizations for GLOBE. We use student measurements, and data and forecasts from other sources, as the basis for maps and graphs used by GLOBE students and by the public. The imagery is created on demand to the user's specifications. This paper describes the visualization system and its architecture.

2. Visualization Products

The GLOBE Visualization server provides maps and graphs. Maps show the geographic distribution of measurement values and are available at scales ranging from full-earth to 25x25 km in a series of discrete steps. As the user zooms in, additional context is provided by political boundaries, bodies of water, towns, and railroads. Maps are in spherical projection except for the full-earth Mollweide (equal-area) projection. The central latitude and longitude of the spherical maps is arbitrary and may be selected by the user to focus on the area of interest.
We display GLOBE data atop these maps. Student measurements are taken at specified locations in the vicinity of each school. The data values are displayed as colored glyphs centered at the measurement station and colored in accordance with a scale appropriate to the quantity shown. Some measurements may legitimately be interpolated to estimate values in areas between the stations; those data types can also be displayed as colored contours over the map. We also display reference (non-student) data for comparison purposes. Those maps are based either on numerical weather prediction model forecasts or on satellite estimations.

Besides maps, we also provide graphs of student data as a function of time. Each graph can display up to six parameters for a single school, or up to six schools for a single parameter. The time spanned by any graph is adjustable from the entire program period (April 1995 to date) down to a single week.

3. User Interface

The normal means of requesting visualizations from our server is via a set of HTML-based user interfaces (UIs). Two primary goals have driven the overall design of the system: allow fine-grained access to the data's space and time dimensions, and make the visualizations accessible to all users regardless of physical disability, bandwidth limitations, native language, and previous familiarity with the system.

Navigation

Fine-grained access means that we allow the user to zoom in on any map location and any graph week, to create maps for any single date, and to create graphs for any individual school. [Fig. 1a] shows a sample map interface. The top half of the page contains the map and the controls to make a new map. HTML menus are provided to change the map type, the dataset, the date, and the image size. Geographic navigation is accomplished by clicking on the image containing the map cut, annotation, and icons. The active areas are the map of data on the right (click to zoom and/or recenter to new latitude and longitude), the smaller locator map and surrounding arrows at top center (pan horizontally at the same zoom level), and the zoom bar in the center (zoom in or out at the same lat/lon). The lower half of the page contains links to related products such as a page showing the image by itself for printing, a legend explaining symbols on the map, and a facility for comparing two maps side-by-side. Below that is a GLOBE-wide navigation bar for access to parts of GLOBE besides the visualization server. (GLOBE comprises multiple servers at NOAA and NASA.)

The graphs have fewer parameters (datasets and start/end dates) than the maps, so the interface is correspondingly simpler.

UI revisions based on user feedback are continuously implemented. A new step-by-step option for beginners that progressively builds up the interface has been developed. Also, we are considering using Javascript to trap potential user errors on the client side.

Customization

To satisfy the goal of universal access, we offer several means of customizing the interface itself. The tunable parameters are graphical/text display mode, language, and help message display. These options are handled internally within each script; in particular, we do not have separate text-only and graphical content areas because they would tend to diverge with time. The state describing the user's preferences is encoded in the URL of the document [Iyngar 1997]. These interface options are user-selectable using hypertext links in the page footer (see [Fig. 1a]); we do not test for the myriad possible User-Agent request headers, nor do we use content negotiation as defined in HTTP/1.1 [Fielding 1997]. The default parameters are graphical display, English language, and no help messages. The footer also presents a list of mirror sites to choose from. We have duplicate servers on the East and West coasts of the US and in Germany; servers in Australia and Japan are in preparation as of this writing.

Text-Only Mode

Although our primary product is imagery, we are committed to allowing access to that product by text-only or
speech-enabled browsers. This goes beyond merely adding ALT attributes to images or omitting icons when text-only mode is selected, because geographical navigation is customarily performed by clicking on an image as described Section 3. Hence, we offer an alternative navigation scheme. When text-only mode is selected, the current page and map are replaced by a page containing (1) an anchor which references the bare image that had previously been displayed within the page, (2) new control widgets to select latitude, longitude, and zoom level, and (3) all the other controls previously available. Users can thereby type in the coordinates and construct the desired image without using the click-to-zoom procedure. Text-only mode also benefits users with graphical browsers because it allows direct access to a known location without generating images at intervening zoom levels.

Figure 1: (a) Screen shot of the map interface, showing the map image itself, the widgets to modify map parameters, and links to related pages, the GLOBE navigation bar, and display customization options. (b) Conceptual diagram of the system architecture.

Translations

Because GLOBE is an international program, we are committed to offering content in languages besides English. We presently offer French and Spanish; Russian is under development. Each menu item, help message, or image annotation displayed with the imagery is represented in the software by a string variable instead of by a hardcoded phrase. For each language, we create configuration files that provide appropriate values for each string. Users select language via a link in the footer of every page, and the software reads the appropriate configuration file(s) at runtime.

Embedded Help Messages

To assist novice users of the interface, each script offers a help option. Rather than rely exclusively upon external help pages, which may become out of date and which cause the context to be lost when they replace or hide the page which caused the confusion, we have embedded the capability for each script to display its own help. In help mode, explanatory messages appear beside each widget or control. The interface remains
functional, but the page is somewhat lengthened by the additional text. Thus, the user maintains context and can immediately follow the instructions. The messages remain enabled if the form is submitted to create a new map, and the user can explicitly turn off the help when ready. A set of more detailed external help pages is also available.

4. Technical Information

We now discuss the technical details of the implementation. As sketched in [Fig. 1b], the principal components are the user interface, a visualization engine, a data repository, database update, and raw data ingest. These pieces are written in a combination of Perl, IDL (Interactive Data Language), and C. We use SGI machines running Irix 6.x; mirror sites run Sun or HP machines. All sites happen to use the Apache HTTP server, but none of the code is Apache-specific.

Space limitations in this conference paper preclude going into complete detail. A more specific paper on the technical details of the system is forthcoming [de La Beaujardière et al. 1998].

UI Layer

The UI is generated by a set of Perl CGI scripts. Perl 5 is required. The primary scripts are used to generate the home page, the interface for one map or two maps, the graph interface, and the form to select schools for graphing. Additional scripts process and display static HTML template files and perform other miscellaneous tasks. This section will focus on the map interface; the implementation of the graph interface is conceptually similar.

A shared set of configuration files lists machine-specific options, defines all of the available datasets, provides language-specific phrases, and sets miscellaneous variables. These files are read as needed at startup time by each script using Perl's require() function. A collection of Perl files provides shared subroutines which are read as needed.

All CGI code was written from scratch, with many reworkings since early 1995. The code has evolved from standalone scripts which generate a collection of static pages [de La Beaujardière, Mitchell, & Hasler 1995], to CGI scripts which generated HTML dynamically while displaying a collection of static images [de La Beaujardière et al. 1997], to the present system with both HTML and imagery created on demand.

The CGI scripts accept data from HTTP GET requests in the usual manner. GET is used to allow hypertext linking or bookmarking of any page; the URLs are not long enough to require POST. The basic philosophy is to always show a map and the user interface to change it, so defaults are supplied if the user does not provide enough parameters. For maps the default is to show a small map of student maximum temperature, for the current day, showing the entire world, annotated in English. The CGI communicates with the database and the visualization engine to request an image, and when ready displays the image along with interface elements.

In HTML, the UI is implemented as a <FORM> with the visualization itself being the submit button (<INPUT TYPE=IMAGE>). The ACTION attribute of the form is the same script that displays the form, so the form essentially submits data to itself. When the user clicks on the image the x,y coordinates of the pixel are sent to the script, which determines whether the user clicked within the map area, one of the other active areas, or an inactive area. An active area functions as discussed in Section 3. An inactive area generates a map at the same location and zoom level. A click on the map itself requires a call to the visualization engine (described below) to translate the pixel coordinates to a latitude and longitude. The text-only option replaces the submitting image with <INPUT TYPE=TEXT> elements and a normal submit button.

At present we do not pre-start the CGI scripts using FastCGI, nor have we incorporated the software as Apache modules. The startup cost of the CGI scripts is much less than the time required to actually make the image, and server load is modest, so such optimizations have not yet been necessary. The CGI script for map display runs
in about one second. Image times are given below.

Visualization Engine
The visualization engine is written in IDL (Interactive Data Language), a high-level scripting language well suited for manipulating arrays and scientific data. Map-making functions are built into the language. There is substantial overhead associated with starting up a new IDL session, so we initialize a batch of IDL servers which await requests. We typically run 40 IDL servers at once. IDL version 5.0.3 is required.

The CGIs communicate with IDL using an RPC (Remote Procedure Call) interface written in C. Arguments are passed to the RPC driver, which chooses one of the available servers at random, issues the IDL request, and returns the name of the image just created. Images are cached until invalidated by a database update, so IDL first checks whether it has already made the desired image.

IDL uses its built-in routines to perform the transformation from pixel coordinates to latitude and longitude, which are then used to determine the new map center. When a particular flag is set in the request, IDL responds not by making an image but simply by declaring what the coordinates would have been. This allows us to query an existing map (say to find the schools near a point) without making a fresh image.

Besides displaying GLOBE data on a map, IDL must also show context data. We use a geographical database derived from the Digital Chart of the World (DCW) produced by the Defense Mapping Agency and the US Geological Survey. The DCW includes coastlines, primary and secondary political boundaries, waterways, city names and locations, railroads, roads, and urban area boundaries. More context data are drawn as the user zooms in. We currently do not show roads and urban areas because the latter are a large database and the three different cases of roads (light-, medium- and heavy-use) are three very big databases; extracting and drawing these features on the high-zoom maps would take more than a minute.

At low zoom, with little context data, a map of point data takes three seconds to be created. At higher zoom, with much context, a point map takes 11 seconds.

Data Repository
The data repository is currently in a state of flux. The GLOBE student data have until now been stored in a set of ASCII flat files with indexes, in a format devised by the Student Data Archive server. Access is fast and direct, but queries are limited by the available indexes. GLOBE is now implementing a commercial RDBMS (Oracle) on all servers, with rollout scheduled for September 1998.

The flat files are read by another set of Perl scripts which extract the requested data. These extracted files are read by the imager and subsetted to show the desired region or timeframe of interest. Extracted map files are cached to speed later requests; graph files are deemed too volatile to cache. For map data which can be contoured, the Perl extractor calls IDL to perform that interpolation. This contour computation is potentially lengthy (one minute or more), so the resulting files are also cached. Thus, the second request for the same day's contours is rapid. By default, maps do not show contours, but we precompute contours in the background in anticipation of a future request.

There is a second class of data which is handled differently. The reference (non-student) data are a collection of files in Hierarchical Data Format (HDF). The HDF files are compressed and stored in a repository on disk, and upon request the necessary file is uncompressed and moved to a staging area where it is read and from which it is deleted if unused for several days.

Data Ingest and Updating
Data ingest is handled by the GLOBE servers at NOAA (National Oceanic and Atmospheric Administration) and is not part of the visualization function per se. Nevertheless a few words are in order. GLOBE schools typically send data by filling in an HTML form on the Student Data Server. Schools may report measurements made on the current day or on any day(s) in the past. Data are validated and then handed off to the Student Data Archive for permanent storage. With the move to Oracle, each mirror site will be able to function as an ingest point, and updates will be replicated several times per hour among the various DBs. Currently, the primary Data Server in the US in the mirror site in Germany accept data input.
The existing flat-file DB is created by the archive server. Every hour, the visualization server fetches from the archive an update comprising new or changed records, new index files, and checksums to verify integrity. These partial updates are folded into the existing flat files. When new student data arrives, our update procedure determines which days have been rendered obsolete by new submissions; a single new data point invalidates the map for that day. Stale files are culled from the cache.

The update procedure for the reference data is different. New model run files are created essentially once per day by the NOAA Environmental Modeling Center. We archive them as they come in, converting the desired fields to HDF. The files are predictions, so there is no updating of earlier data.

5. Conclusion

The GLOBE Visualization server is a full-featured system for generating maps and graphs of environmental data on-the-fly. Users can modify the visualizations to show any date or location, and can customize the interface itself based on browser capability, native language, and familiarity with the system. Wherever possible, all options are self-generating to avoid the use of separately-maintained content areas.

The system architecture comprises distinct modules for the user interface, the image production, database access, and database updating. The pieces are written in Perl, IDL and C. An Oracle DB is being implemented. The system has been installed by three other groups worldwide and is known to run on SGI, Sun and HP machines. A Linux port is in the works. (Perl and IDL are very platform-independent; only the C-language RPC must be explicitly ported.)

We thank our many colleagues in the GLOBE Visualization group at NASA Goddard, each of whom has played a critical role in developing the system: David Batchelor, Avnish Bhatnagar, Jeff Cieslak, Raul Garza-Robles, Fritz Hasler, Theresa Held, Pete Jackson, Phillip Keegstra, Mike McGunigale, Horace Mitchell, Tony Rosati, Sally Stemwedel, Theo Williams, and past colleagues. Our collaborators at NOAA Forecast Systems Lab, NOAA National Geophysical Data Center and at GLOBE headquarters, the scientific principal investigators, and especially the teachers and students of GLOBE, have all been indispensable in building this program.
Knowledge representation techniques for information extraction on the Web

1 Introduction

The main facilities for a user to search within the enormous amount of information available in the Web are the so called search engines. Their limitations have been addressed in the literature and many proposals for improving their precision have been made. Because of the difficulties arising in precisely identifying the information needed through the query facilities offered by search engines, several other approaches have been investigated to make information in the Web more easily accessible to users (see [1] for a review). One approach to information access is to provide the user with a more semantically-oriented query language, such as data base query languages. The advantages of a more powerful query language come, however, with the cost of a much more difficult access and management of the information in the Web. From a data base perspective the problem can be viewed in a Data Warehouse setting, where the Web provides information sources than one can either access at query answering time or materialize in a view that is maintained locally [2, 3]. In both scenarios the user views the Web as a data base, and is relieved from a direct access to the information sources. The situation is depicted in Fig. 1.

![Figure 1: System Architecture](image)

We have developed a system (see [4, 5]), that automatically extracts from Web sites information on a specific domain and collects such information within a database. In order to fulfill the requirements of usability the system provides a visual interface in the style of [6], where queries are formulated through an semantic data model diagram.

As already pointed out the critical aspect of such an approach is the extraction of information from the sources to make it available to a data base system. In the rest of the paper we concentrate on the Extraction System, investigating the possibility of integrating Knowledge Representation and Data Base techniques. The idea is the use of knowledge representation techniques for representing...
both the domain of interest and the information sources in order to extract from them the relevant data, and a Data Base approach to provide a semantically-based declarative query facility.

The following sections address the problems involved with representation of information, the information extraction process and briefly comment on some preliminary results.

2 Representation

In order to access and classify information contained in Web sites concerning a specific domain of interest, one needs to represent the domain, the structure of the generic site and of the pages, and the terminology about the domain (see IJCAI 97 for a discussion on the role played by content, format and structure). There are many formalisms one can choose: simple formalisms are easy to process automatically but difficult to interpret (e.g. feature vectors), whereas more complex ones are difficult to use but may allow for an automatic interpretation (e.g. knowledge representation systems).

Traditional systems for information modeling present some limitation: Entity-Relationship (ER) model are not suited to represent typical hypertext structures, while Object-Oriented (OO) model are more feasible, but still lack the flexibility needed to handle the variety of structures that one can find in the Web. We adopt Description Logics (DL) as a representation formalism, and the CLASSIC system [7] as a knowledge representation system based on DL. DL can be used as a modeling language, because of the close relationship with semantic data models, and also offer reasoning facilities to automatically classify concepts (i.e. entities).

2.1 Domain of interest

In order to enable the user to interact with the system at a very abstract level, we have chosen to represent the domain using a well-known semantic data model, namely the Entity-Relationship (ER) enriched with additional information about the generic site structure. It is worth noticing also that the attribute types that can be specified in the ER enriched scheme, range among those that the system can recognize automatically in the information extraction process: dates, addresses, phone numbers, names, etc.

2.2 The generic Web site

The notion of relationship in the ER model provide some intuition about the possible structure of web site. However, some additional hints are needed in order to map an ER diagram into a site structure. In particular, one can specify a preferred direction for a relationship in the schema. With this information the system is able to turn the ER schema into a representation of the site structure expressed through the language of CLASSIC. In this step the semantics of the domain is combined with the information about how the domain is instanciated by Web structures.

The intuition behind this is that relationships are given a direction which corresponds to the links in the Web structure. At present this information is provided by the user, but we are investigating techniques to learn it automatically by analysing actual Web sites.

By weakening the representation we accomplish the additional task of turning the domain representation into a simpler one which gives us the ability to reason about hierarchical structures: intuitively, DL concepts correspond to entities, roles correspond to relationships and attributes of entities are mapped into DL attributes (roles with additional constraints).

For example, in a university domain, the concepts Teacher and Course, could be linked by the role teach or by the role given by, but typically in Web sites, information about courses can be found in the teacher's home-page, so the first role is preferred. Such a role gives additional hints to access data about related concept, for example following links, analyzing lists and tables, etc.

Summarizing, we can model at the conceptual level the typical structural organization of Web sites relevant for the domain and the domain itself within the same representation. Moreover, by
using DLs we can face in a more general way the extraction problem by relying on the deductive services that they offer.

2.3 Vocabulary

The system can interpret the terms used in a domain's description, but in Web sites the domain's elements could be denoted with different names. Within the DL representation it is easy to specify synonyms and homonyms, as well as find more general and more specific terms using an approach similar to that of Wordnet [8].

2.4 The Web pages

In this work we are concerned with HTML structures, at present not addressing active components. The syntactic structure of a Web page is automatically built by a parsing process and represented in DL. Specifically a page is represented through a knowledge base individual with an associated set of attributes corresponding to the syntactic structures identified in the page. We consider a set of syntactic structures such as lists, tables, headers, links, etc. and represent them as concept descriptions. Also with respect to the syntactic structure of the pages one can take advantage of the capabilities of DL to organize in a taxonomy the most common constructions. For example, in HTML there are six header types that differ in the way they are shown by the browsers and two link types, one that references an anchor and another one to identify the frames contained in a page. These relationships are represented through hierarchies.

3 Site Analysis

The overall representation described in the previous section is used by the system to analyze a Web site. The goal of this process is to populate a database that may thereafter be queried by the user.

The analysis starts with a page, represented as an individual of the CLASSIC knowledge base, and a concept expression, which is expected to be instantiated in the page. This concept will be referred to as the target concept. In the following subsections we shall briefly describe the vocabulary normalization used to interpret text associated with HTML elements (links, headers, lists etc.), and the information extraction process.

3.1 Vocabulary normalization process

Typically, the terms that the system deals with in the analysis are simple words or noun phrases occasionally in a foreign language. Therefore, we do not apply Natural Language Processing techniques, but simply use a vocabulary and a domain's description to relate terms, specializing or generalizing them through the capabilities of the DL system.

The vocabulary normalization process is accomplished through the following steps. We first check whether the current term is in the vocabulary. If the term is a noun phrase every word belonging to it is searched in the vocabulary. Among all matched terms corresponding to concepts, the most specific concept which subsumes all of them is chosen as the meaning of noun phrase.

3.2 Information extraction

The extraction process aims at identifying the instances of the given concept in the given page and can be decomposed in an extraction and a propagation step. Before analyzing a page, the system performs a preprocessing step in which the concept corresponding to the current page is analyzed in order to identify frame structures. The analysis of a page is split into the analysis of the embodied frames, with respect to the same target concept of the entire page.
3.2.1 Extraction

The extraction phase can roughly be divided in two parts, one in which textual or no structured data are analyzed and another one in which the structure part is analyzed. In the former one can only rely on pattern-matching procedure or NLP techniques to understand the terms involved, whereas within tables and lists one can take advantage of the structure regularities to interpret data. We shortly describe below the two mentioned types of analysis.

**Attribute Analysis.** In the attribute analysis the system gets from domain model the description of the target concept which is expected to be instanciated in the current page. The attributes associated with the target concepts are selected and the system tries to match them with the data contained in the page. If such a match exists new instances in the knowledge base are created for current concept.

**Structure Analysis.** HTML structures like tables and lists are often used within pages to represent homogeneous data related with page content. They can hold attributes of entities instanciated in the page (e.g. in a personal home-page one can collect birthday, address, email in a list structure), or instances of entities related with it (e.g. in a teacher home-page it is possible to find the courses he teaches and their schedule in a table). The system analyzes such structures trying to relate their content with a specialization or generalization of the target concept or concepts directly related with it in domain model, to create new individuals in the knowledge base.

To give an intuition of the approach followed to take into proper consideration the structure (syntax) of the pages while trying to capture its content, we describe in more detail the table analysis. Data stored in tables are typically organized in rows or columns and this is the natural assumption to be made when analyzing them, although the table structure is sometimes used simply to organize the space of the page. We call **heading** the set of terms that specify the data contained in the table (usually the content of the columns of the first row); we call **header** the text that precedes the table and is usually meant to explain its content or highlight specific features.

The first issue to tackle when analysing a table is to find the heading, which is accomplished by looking at the data in the table trying to interpret them as elements of the domain. The vocabulary normalization process is again used here. Identifying a heading is a necessary condition for the subsequent analysis because the heading can be associated with a concept expression for the target concept, while the header provides additional information that can be used to specialize the concept which we are trying to instanciate. Then, the concept expression characterizing the table is matched against the concept to instanciate. This matching is done through subsumption checks with the current concept and the concepts linked to it.

Once the concept that describes the data in the table is determined, it is possible to fully characterize the information stored in it. At this point, the table is scanned and for each row (column) the corresponding individuals are created and the relationships among them and other existing individuals are specified.

It is worth noticing that the semantic of the domain is repeatedly used to extract information from table. Moreover, this is done in a way that depends on the syntactic structures rather then being coded in ad hoc ways for a specific domain.

3.2.2 Analysis propagation

Once the current page has been searched for information to instanciate, the search is propagated by exploiting the information about relationships given in the semantics characterization of the domain. The outgoing links of the page under examination are first normalized with respect to the vocabulary. Then, the pages reached through those links that match the ones modeled in the domain are further analyzed. The input concept becomes the one which the current concept is linked to. In this one the semantics of the domain is used to guide the search within the overall site. Secondly, among the links that do not match those in the schema, the ones whose associated
text matches the name of an existing individual are analyzed to gather information about such individual. This corresponds to verifying, when it is not possible to match a link name with a role in the semantic schema, whether the link name directly matches an already instanciated individual of another concept. The motivation beyond such behaviour is that when the system creates new individuals it has to give them a unique name for their identification. The content of an attribute indicated in the domain model as a key is chosen as a unique name for new individual. So when in the site there is a link which associated text correspond to an instancied individual we make the assumption that following such link we can gather further information for the individual.

The remaining roles of the individuals corresponding to page, relate the current concept with unknown ones. Such roles can be further analyzed looking for clues that allow to find new starting points for the analysis. Many different strategies can be applied and we are currently performing experiment on this aspect. The overall process resembles the rule propagation mechanism used in CLASSIC, and is terminated by checking that individual objects corresponding to pages are not analyzed twice.

3.2.3 Site analysis algorithm

We can summarize the overall extraction process in the following algorithm where domain model (DM) is supposed to be an implicit parameter and where PAGE_IND is the individual corresponding to the current page, CL_CONCEPT the target concept to be instanciated. Moreover, the procedure has a third parameter named CL_IND, which is used only when the propagation through links exploits the information about already instanciated individuals. The output of the procedure is constituted by the generation of instances of the concepts in the domain and are performed by the procedures AttributeAnalysis, TableAnalysis and ListAnalysis as side effect.

\[
\text{SiteAnalysis}(\text{PAGE\_IND}, \text{CL\_CONCEPT}, \text{CL\_IND})
\]

BEGIN
    AttributeAnalysis(\text{PAGE\_IND}, \text{CL\_CONCEPT}, \text{CL\_IND});
    TableAnalysis(\text{TablesContainedIn}(\text{PAGE\_IND}), \text{CL\_CONCEPT}, \text{CL\_IND});
    ListAnalysis(\text{ListsContainedIn}(\text{PAGE\_IND}), \text{CL\_CONCEPT}, \text{CL\_IND});
    FOR each link L contained in the page corresponding to role of \text{CL\_CONCEPT} in DM
        BEGIN
            IF page linked through L is not yet visited
                THEN BEGIN
                    NPI=individual corresponding to the page linked through L;
                    NCC=concept related with CL\_CONCEPT through the role corresponding to L;
                    /* start new analysis with new parameters */
                    SiteAnalysis(NPI,NCC,CL\_IND);
                END
        END
    END
    FOR each link L1 contained in the page that corresponds to an instanciated individual in the knowledge base
        BEGIN
            IF page linked through L1 is not yet visited
                THEN BEGIN
                    NPI=individual corresponding to the page linked through L1;
                    NCI=individual whose name is equal with text associated with L1;
                    NCC=most specific concept NCI is an instance of;
                    /* start new analysis with new parameters */
                    SiteAnalysis(NPI,NCC,NCI);
                END
        END
    END
END
Fixing the mapping between enriched ER scheme and its DB implementation, it is possible to turn the knowledge base content into tuples to populate the DB. Such a process is done automatically by the extraction system.

4 Conclusions

To verify the capabilities of the proposed approach we have tried to retrieve the information automatically extracted by our system using search engines (SEs). We used Lycos, Yahoo! and Metacrawler relying on their particular features to focus the search in a limited Web domain (.it in our case), to exploit taxonomy organization of the Web space and to combine the results of several other SEs, respectively.

We submitted the same queries to SEs and manually analyzed the first 20 top ranked retrieved documents seeking for information automatically found by our system.

Despite the limited scope of the experiment, there are indications that the answers on queries concerning specific information (e.g. the phone number of a professor) are satisfactory, whereas SEs typically fail; moreover, in the domain under consideration (University Departments) the system can acquire automatically a substantial amount of data.

Roger Espinosa, Software Designer
Office of Instructional Technology, ITD, University of Michigan, USA
roger@umich.edu

Abstract: Through the use of comprehensive instructional design and sophisticated information technologies, the University of Michigan School of Education has reinvented the way it educates prospective mathematics teachers. A new web-based instructional environment called SLATE (Space for Learning and Teaching Exploration) combines digital video, searchable transcripts, basic multimedia authoring, and other new media applications to provide a shared experiential frame and a range of investigation previously unavailable to student teachers. This document is also available online: murph.soe.umich.edu/SLATE/SLATE.htm

1. Introduction and Background

As part of their professional training and certification, every preservice teacher spends time in real classrooms under the close mentorship of cooperating practitioners. This apprenticeship period ensures that preservice teachers have had guided, first hand experience in live environments before embarking on careers with their own students. Furthermore, a significant element of preservice teacher preparation is the shared analysis and discussion of these preservice teaching experiences.

Unfortunately, preservice teachers' placement experiences often vary dramatically due to differences in the style and engagement of their mentor teachers and the classroom cultures into which they have been placed. This variance complicates the process of establishing a shared experiential "text" upon which to base methodological discussion. Faculty at the University of Michigan School of Education have recognized the challenges inherent in providing both live classroom placements for preservice teachers and shared classroom experiences for use in socially constructed knowledge building. Dr. Magdalene Lampert's Mathematics and Teaching through Hypermedia (MATH) project, Dr. Anne Gere's Technology Assisted Teacher Education (TATE) project, and now Dr. Deborah Ball's SLATE project are just a few of the initiatives that have sought to address this challenge through the use of emerging technologies. This paper describes the development and functionality of the SLATE project as well as some of the pedagogical underpinnings of the project.

SLATE was conceived in the Summer of 1995 when Dr. Ball began considering the inherent problems with shared context in preservice teacher education placements and how previous attempts to address the issue might be improved. Her discussions with technical staff were informed by close experience with earlier tools including the Student Learning Environment developed by Kara Suzuka under the MATH project (co-directed by Dr. Ball and Dr. Lampert and funded by the National Science Foundation and Michigan State University).

The resulting SLATE design draws heavily upon the Student Learning Environment, but also adds a significant number of features and tools previously unavailable. The Student Learning Environment is a HyperCard-based engine for accessing a variety of multimedia data collected over the course of a year in two elementary school mathematics classrooms. These data, including video and transcripts of the class sessions, digital images of student work, text of teacher journals, seating charts and standardized test scores (among other things), were gathered together and made available for student searching and incorporation into original multimedia compositions. The environment has a number of limitations however, including a lack of random access to all of the video (which is stored on laserdiscs), difficulty searching across the entire data set (for occurrences of a
particular text string, for example), a lack of robust student authoring tools (Microsoft Word and HyperCard have been used with varying degrees of success), and a lack of portability (the environment is difficult to setup and is sensitive to being moved).

After several weeks of analysis and discussion of previous environments, underlying instructional objectives, and technical constraints, a final SLATE design proposal emerged. The design was presented to the SOE/ITD Partnership (a joint venture of the School of Education and U-M's Information Division) which supported the project and sent it to the Office of Instructional Technology for development.

2. Technical Discussion

The completed SLATE environment consists of several commercial software packages, a custom-developed environment manager, and custom server-side tools. Some specific features of the environment include:

- Access to collaborative assignments and notes from previous sessions is provided via an AppleShare server preconfigured for groups of students (arranged into cohorts). All student work is saved on the server, periodically reviewed by instructors, and backed up by project staff.

- Central control of the environment is provided via a custom-developed SuperCard application which communicates with the rest of the applications (Netscape, ClarisWorks, Adobe Acrobat).

![Figure 1: SLATE SuperCard application with pop-up access to media and tools](image.jpg)

- High-quality video and corresponding transcript text is delivered to the desktop using MPEG playback and text-track features built into Apple Computer's QuickTime media technology. The video (and other environment media) is stored on an external 9 GB hard disc attached to each PowerMac 8600.

![Figure 2: MPEG video and corresponding transcript presented in real time](image2.jpg)

- One-click transcript access to any point in the 30 hours of video is provided via a web interface.
A web-based search engine utilizes HTML forms that are tied to a cgi search engine (which runs on a remote UNIX machine). Query results may be saved as HTML documents.

Student authoring is facilitated through the use of predefined ClarisWorks templates. The ClarisWorks productivity suite provides drag-and-drop video editing, graphics manipulation and a full-fledged text editor for
the creation of student multimedia artifacts.

![Student ClarisWorks document with embedded MPEG link](image)

**Figure 5:** Student ClarisWorks document with embedded MPEG link

- A browser interface provides access to a variety of other data, including digital images of student work, seating charts, and teacher journals which are stored in Adobe Acrobat format.

During development, three separate teams were formed to concentrate on different aspects of the project. A technical team concentrated on software development issues and worked with a content team to address instructional objectives and overcome technical constraints. A facilities team directed the construction of the deployment space and ensured compliance with technical specifications.

It should be noted that SLATE was deployed in a new, high-end multimedia classroom designed specifically to support Dr. Ball's pedagogical approach which emphasizes collaborative exploration and discussion. The room, built in conjunction with the SLATE environment, was also supported by funds from the SOE/ITD Partnership.

### 3. Budget and Staffing

The development of SLATE has enlisted the services of numerous instructors, software designers and facilities professionals. An accurate estimate of total time invested is difficult to supply. However during the two years that transpired from the initial discussions in the Summer of 1995 to deployment in the Fall of 1997, the following rough staffing statistics were gathered:

<table>
<thead>
<tr>
<th>Task</th>
<th>Hours</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Item</th>
<th>Cost</th>
</tr>
</thead>
</table>

369
Table 1: Staffing hours used on the SLATE project

<table>
<thead>
<tr>
<th>Service</th>
<th>Hours</th>
</tr>
</thead>
<tbody>
<tr>
<td>Instructional design consulting</td>
<td>200</td>
</tr>
<tr>
<td>Project management</td>
<td>200</td>
</tr>
<tr>
<td>Production work (video capture, transcription, graphics translation)*</td>
<td>150</td>
</tr>
<tr>
<td>Development/coding (OIT)</td>
<td>250</td>
</tr>
<tr>
<td>Testing and deployment</td>
<td>100</td>
</tr>
<tr>
<td>Documentation (student guides)</td>
<td>50</td>
</tr>
<tr>
<td>Total Hours:</td>
<td>950</td>
</tr>
</tbody>
</table>

* Much of the media used in SLATE had been captured, cleaned and edited by previous MATH project efforts. For example, all of the video used in SLATE and the accompanying transcripts existed in edited form on laserdisc and in computer files. Had development of these media been necessary, the production effort for SLATE would have ballooned into thousands of hours.

Although the hourly rate of the staff involved in the project varied, an overall project budget of $35,000 has been spent to date. It should be noted the instructor time does figure into these staffing numbers. The instructional staff (faculty and graduate students) did not track their involvement, which almost certainly matched that of the technical staff and would likely double the total presented above. Obviously the staffing costs do not include the construction or outfitting (machines and software) of the multimedia classroom or any of the servers used by the project. If included, these infrastructure costs would add a half million dollars to the total project cost.

4. Summary of Outcomes

SLATE was deployed to four sections of Elementary Math Methods (Education 411), each containing 30 students, in the Fall semester of 1997. To ease the integration of the technology into the course, a detailed syllabus and course prospectus was delivered to students. Significant effort was made to communicate to the preservice teachers that SLATE is not intended as a replacement for actual classroom teacher experience, but rather that it provides an avenue to some of the shared context that would be the basis of classroom discussion. This sharing of a virtual classroom in parallel with the students' real placement experience, was a resounding success. Dr. Ball and her graduate student staff reported a level of discussion and engagement previously unseen in their courses.

The design philosophy of using off-the-shelf applications (as opposed to custom development) resulted in an uncommonly stable instructional environment. Furthermore, the leveraging of usability innovations such as drag-and-drop video editing, alias-based server access, and predefined document templates facilitated a new level of ease and sophistication of multimedia authoring. The technology also complemented the instructional approach of using collaborative learning teams, group exploration of the environment, and well-structured assignments.

5. Next Steps

Although the initial deployment of the SLATE environment was highly successful, a number of technical and non-technical next-steps have been identified.
A significant non-technical area of effort that will be undertaken is the recruitment of additional faculty to use the environment in different courses. Because the database does not contain explicit content codes (all data is coded based upon intrinsic characteristics such as date captured and type of media, not content abstractions like "multiplication" or "disagreement"), SLATE is generalizable to a variety of course topic areas. A faculty member interested in ethnic and gender issues, might for example, approach the environment with an entirely different set of investigational intents than a mathematics instructor. The development of a non-content specific guide to using the environment would significantly increase the likelihood of additional faculty using SLATE.

On the technical side, further documentation needs to be developed to allow instructors to more fully use the capabilities of the various tools in the environment. Knowledge of the text search and image manipulation tools built into Adobe Acrobat and ClarisWorks for example, may significantly enhance the instructor’s ability to support and evaluate more sophisticated student work. Further testing and bug fixes, code normalization and minor feature enhancements round out the items for continued development.

Acknowledgements

The Space for Learning and Teaching Exploration was developed under the direction of the Mathematics Teaching and Learning to Teach project, led by Dr. Deborah Ball. SLATE was developed at the University of Michigan by the Office of Instructional Technology and funded by the School of Education in partnership with the Information Technology Division. More information about the MATH project, upon which some elements of SLATE are based, may be found online at www-personal.umich.edu/~jmerz/MATHproject/math.html

The SLATE team is composed of U-M School of Education staff, faculty and students, and staff of the Office of Instructional Technology:

School of Education:

Dr. Deborah Ball, Professor; Dr. Merrie Blunk, Lecturer; Sean DeMonner, Director of Technology Services; Jennifer Lewis, Graduate Student; Mark Loeffler, Graduate Student; Ed Wall, Graduate Student; Tony Winkler, Classroom and Lab technical support

Faculty's Perceived Influences for Incorporating Web-Based Technologies in Teaching Practices

Jean Derco
University of Tennessee
Knoxville, Tennessee, USA
jderco@utk.edu

Abstract: Innovative methods to persuade and influence faculty to adopt the new instructional technologies need to be implemented within higher education. Many studies have been performed to document how the obstacles to technology integration in higher education could/should be overcome (Snyder, 1995; Thompson, 1986; Comer, 1986). However, Snyder (1995) notes that although many faculty members throughout the country have overcome obstacles and have successfully integrated instructional technologies into teaching practices, these experiences are largely not well documented.

This study will identify what the primary influences were for faculty who are early adopters of integrating instructional technologies, particularly web-based technologies, into their teaching practices at the University of Tennessee, Knoxville. Findings from this study can help faculty development professionals within higher education work with administrators and others to develop innovative methods of influencing more faculty members to begin incorporating instructional technologies into teaching practices.

During this session, I will report the preliminary findings of this study. By early November, a survey will have been completed by selected faculty members at the University of Tennessee and personal interviews will be in progress with a sample of the survey participants.

Abstract:
This paper gives a short description of a working prototype of an intelligent background knowledge broker as an enhancement module of the Web base training system GENTLE [Maurer and Dietinger 97a, Dietinger and Maurer 98a]. The dynamic and the static library represent a most relevant knowledge repository, which is automatically enlarged and improved by the users themselves according to their needs. The gained relevant information is used to improve the learning process and to support the courseware authoring.

1. Introduction

At the Institute for Information Processing and Computer supported new Media much research has been done in the field of information and document management, computer based training, digital libraries and electronic publishing over the last two decades [Maurer and Schmaranz, 94, Marchionini and Maurer, 95, Maurer and Scherbakov 96, Maurer 97a, Gütl et al. 98a]. Research results and intense co-operation with the industry even led to commercial products like e.g. Hyperwave [Kappe et al. 94a, Maurer 96]. Based on these experiences a group is currently developing GENTLE [Maurer and Dietinger 97a, Dietinger and Maurer 98a], an electronic lecturing system combined with a digital lecture library for teachers and students. GENTLE has already been tested by hundreds of students at the Graz University of Technology. The feedback gained during the lectures is leading to continuous improvements of the system as well as the new research concepts.

One of the experiences we made was that the introduction of new technologies like multimedia or hyperlinked objects alone does not necessarily lead to more effective and more efficient learning. The technology should be used as a cognitive tool to enable entering into the area of creativity, problem-solving, analysis and evaluation [Watson and Tinsley 95, Pivec and Rajković 97a]. Cognitive tools are in fact any technology that enhance our thinking, problem-solving and learning [Reeves 97a]. When computer programs are used as cognitive tools, students use software to analyse problems, tasks, organise unique knowledge representations and share what they have learned with others. For that learners need interpersonal communication, the opportunity to ask questions and discuss problems with the tutors and co-learners. On the other hand technologies are also very useful and necessary for finding proper information, creating courseware and providing a digital background library.

A future oriented collaborative learning system has to provide a smart workspace for teachers and learners. Collections of lessons as well as asynchronous and synchronous discussions related to specific lessons or topics
are represented on the learning platform. Additionally an annotation system allows teachers and students to make remarks to sections of lessons. One lesson we had learned from former projects is that such a collaborative learning system also has to provide a digital background repository. Such a background knowledge system should consist of a static library (e.g. digital books, journals) as well as a dynamic library (e.g. indexing websites, discussion forums and human expert knowledge database). The combination of above mentioned elements to a huge knowledge repository allows teachers and students to get additional and much more detailed information for each lesson. This includes, of course, enlarging the annotation system to make arbitrary references to the background repository as well as annotating the background information itself. On the other hand particularly the dynamic background library gives teachers a smart possibility to update lessons or even extract and combine information to new one.

The background library based on HIKS (hierarchical interactive knowledge system) [Gütl et al. 98a] as a necessary and important part of a future oriented collaborative learning system will be described in more detail in the following sections. Aspects, related to the dynamic component by websites and human expert knowledge are especially highlighted.

2. The Background Library and the Interaction to Learning Process

Learning is a goal oriented process. By methodology we can distinguish between following types of learning methods:

1. Instruction centred (learning by telling)
2. Learner centred (learning by doing)
3. Team centred (learning through discussion & reflection; team – work seminars, case studies, field studies, projects, simulations, discussions)

Combining these methods shown above with available techniques allows to deduce varieties of realisation concepts to reach the postulated goal.

(Figure 1: Interaction of learning methods and knowledge transfer)

Generally the knowledge acquisition is a bottleneck in the construction of proper knowledge base. Therefore reusing and re-modelling the already existing modules and knowledge for educational purposes brings certain advantages for developing courseware. Knowledge Based Courseware (KBC) is per definition a courseware with a separate knowledge representation and is considered as an innovative approach which applies established
techniques from the field of AI in order to overcome some of the limitations of the standard CAL (computer aided learning) or CBT (computer based training) approach [Anderson et al., 90, Valley 95a, Pivec and Rajkovic 97a].

However all those techniques need a proper information structure for preparing knowledge or allow to search and inquiry answering open questions and solving problems. Nowadays our society could be described by the so-called information society. It is characterised by a very huge unstructured information repository as well as the rapid increasing of information. In the last few years the internet has become a very interesting area for publishing and gathering information and must be included in such a future-oriented learning environment. The current number of web pages can be estimated to exceed 150 million [Gütl et al. 98a] but only gathering these information do not satisfy the users' needs. The main problem is to get the right information with proper quality, reliability and actuality and to get only that information that has been requested (knowledge). Rieder [Rieder, 97] addresses this deficit by saying "Not only is the gathering of information demanded; this information must also have meaning ...". So we must change from information society to knowledge society [Gütl et al. 98a].

The introduced background library should be an important step into direction of knowledge society. Teacher and learners are motivated to rise the creativity level by using the knowledge for problem solving and generating new concepts as well as to use it by adding more details to each lesson. Therefore the learners e.g. may inquire on background knowledge base for solving concrete exercises. On the other hand teachers e.g. are allowed to add references on their lessons. The system includes digital books and journals as well as human-based knowledge databases and indexed relevant web sites. Former experiences have shown that the static component (digital books and journals) provide a solid base but e.g. rapid increasing of information claims also for a dynamic component (human-based knowledge database and indexing of relevant web sites).

The human-based knowledge database could be seen as a collection of specific information related to lessons, topics or terms. The sources of such information could be an answer-question process between learners and teachers, former exercises and additional explanations as well as problem solutions, studies, etc. An important point related to the learning process is that a most relevant knowledge repository is provided and will be continuously enlarged and improved by users' needs. On the other hand indexing of relevant web sites provides a huge and always up-to-date repository. Most relevant web sites (first named by teachers) related to lessons or topics are gathered and indexed periodically. Learners and teachers are allowed to name further web sites and assess the quality of information. An important feature related to the learning process is that always a wide range of additional information is available and up-to-date. Teachers e.g. can get latest know-how or can update lessons. Learners are highly motivated inquiring on such repository to solve problems or get their additional information.

The introduced system combines the already common courseware, synchronous and asynchronous discussion and a smart annotation system with a highly-sophisticated static and dynamic background library, explained in much more detail as follows.

3. An System Overview

The collaborative learning system provides a smart working environment for learners, teachers and courseware authors. The learners can use courseware lessons as well as discussion and annotation systems. The synchronous and the asynchronous discussion system allows collaborative working between learners and teachers as private, group-oriented and public communication. Most relevant discussions corresponding to specific topics could be included in the background library assigning keywords and an information level (beginner, advanced, expert). E.g. a student who does not understand some parts of a lesson and discusses with the teacher about the problem. In case of relevant information to others, it can be added to the knowledge repository. Therefore further relevant information is provided and can be used for inquiring by other students. Quite similar is the question and answer process related to courseware lessons. This information is directly embedded or marked concerning to the corresponding subject of the lesson. Of course this information could also be added to the knowledge repository.

The annotation system allows remarks to lessons and other documents as well as remarks to background libraries and even to annotations themselves. The system provides private, group-oriented and public annotations and a proper information level could be assigned. These information could also be added to the background library.
The introduced learning system uses a background library which consists of a static and a dynamic component. The static library provides electronic books, journals, etc. and represents a set of information which has been already reviewed but must be kept up-to-date. The dynamic library provides the human-based knowledge database as well as the indexed web sites. The human-based knowledge repository is composed by most relevant discussion contributions, question-answer processes, former exercises, studies, etc. Usage and work of the learning system guarantees for such information users are needed at their learning process. The information quality will be determined by persons who are allowed to record new information into the system. The gathered web sites represents an additional information repository. Only indexing pre-selected sites could be seen as first steep to higher-level quality of such information. Further quality assessment, annotations and revised indexing will improve the quality too. Like the courseware, all components of the background library are searchable. Also the system allows to annotate specific information at the static library as well as the background library.

The modules function and interaction will be considered on the basis of (Fig. 2). The info gatherer gets information of selected sites and follows embedded links restricted by host and URL filters. Each gathered page is added by a time-to-live attribute to guarantee up-to-date information. Not only the content and embedded meta information are indexed; the content analyser extracts keywords as well as the description automatically and
adds this meta information to each object. Furthermore the extracted keywords are filtered by relevance. Only keywords with low frequency in a specific course may become relevant keywords. To make this point clearer let us have a look at an example: in a Javascript course it does not make sense to include "Javascript as keyword" and therefore have to be filtered; on the other hand a HTML course may include the keyword "Javascript" as a relevant one. A tricky thing is that relevant keywords (corresponding to a specific course) may be used to create new lessons in two ways. First is that the new lesson will also be parsed by the content analyser and the system suggests a set of keywords and a description. The second is that the new-lesson-tool provides references or links to further information related to relevant keywords (see also following paragraph). With that the creation of courseware is supported and on the other hand a smart set of information is built, inquiring background knowledge. Of course full-text search as well as keyword and title search is provided. Besides the content and meta information there is another source of information taken into account: the description of the web server or the whole site itself.

The system has also implemented a special cross reference generator that automatically detects potential hyperlinks and inserts them if the course authors themselves have not already done it. We are speaking of a so-called vocative hyperlink. One of our future work is to combine this vocative hyperlinks with information levels. Therefore learners can define the level settings of their own user preferences. This technique allows the learners to get in touch with the subject by selecting the beginners level. Advanced learners however only get links to higher-level information to prevent getting bothered by uninteresting basics.

The knowledge generator allows to deduce new knowledge by recycling in the background library already existing material as well as including relevant information out of discussion forums, question-answer processes, studies, etc. A group could be defined by user rights to create new or edit old ones. This user group gets an additional interface, the knowledge-adding user interface. This set of collected knowledge represents the human-based knowledge database. Learners' problems and interests as well as teachers' established priorities influence this set of knowledge. Like the gathered web sites also the human-based knowledge database provides full-text and keyword search. This source of knowledge could be perfectly used by learners following the shown learning process (see "The background Library and the Interaction to the Learning Process")

The background library manager handles all necessary activities concerning the dynamic and the static components. An overview of functions concerning the dynamic library (gathered web sites and human-based knowledge repository) was described in former paragraphs. As already mentioned the static background library consist of electronic books and journals. By including a new electronic book also keywords and descriptions to each document (book's paragraph or chapter) are built. Both, additional meta data combining content and other available meta information, are indexed and therefore searchable. Further work will be done on using information levels to provide level depended references at courseware environment. The collection of journals are working quite similar as described above. Both components of the knowledge repository provide a relevant base for learners.

The knowledge broker represents the user interface inquiring and searching in the background library. Of course the courseware and annotations search are also provided but in this paper the background search should be closer examined. Let us consider one learner who is going to solve a problem. The system allows to search on a limited scope, e.g. to search only in human-based knowledge databases. Considering another example: one is preparing a presentation and is looking just for brand-new information about a specific topic. Therefore the search scope could be set to gathered web sites. The combination of the set of different knowledge sources results in a highly-sophisticated inquiring tool for teachers and learners.

5. The Users' View

The introduced future-oriented learning system provides a set of tools supporting courseware authors and teachers as well as learners. Not only a courseware environment is needed; also a smart background library providing many features as shown in former Chapter.

The courseware author can use background libraries inquiring specific information to create new or update existing lessons. The system supports authors by suggesting keywords, description, links and references.
Furthermore relevant information by discussion or question-answer process can be used to deduce "recycled information".

Learners can use courseware itself as well as the annotation system and discussion forum. Also the background library provides a huge source of knowledge. In addition different views and different sets of functionality are controlled by the so-called user preferences. Preferences like information level, multimedia component selection (text, sound, videos), language information and group information are taken into account. For example one learner could be described by a beginner, preferring textual information, wants to get only German-language information. Setting proper attributes the user only gets specified information. Getting only that information prevents frustration to the user.

6. Conclusion and Future Work

As we have seen above simply combining multimedia material and hosting it on the Web does not lead to a good WBT system because it lacks interactivity and moreover is difficult to manage and keep up to date for a longer period of time.

By adding static and dynamic background libraries we do not only provide a profound additional knowledge base for learners to widen their horizons but also a huge data collection for courseware authors to create new courses.

Apart from that the contents of these libraries are automatically organised and updated by providing contributions through the users or through the system by gathering information from other relevant sites and by adding vocative hyperlinks within the information structure.

One of our future works is to combine these features with information levels according to the users preferences (e.g. talent, learning style, language, etc.), to increase the relevancy and quality of the provided knowledge.

The Internet was once a research project. Today it is the largest computer system in the universe. Also known as the net or cyberspace, this super highway to the stars offers a variety of useful information as one navigates down its ocean of URL’s, browsers and hyperlinks. With advanced technology comes new legal issues to battle. The age of information has given rise to greater concerns about copyright law. Although it would appear we are headed to a Star Trek-like world, we need to address fundamental areas so vital to educators, business people, computer professionals and the like before beaming too far into our future.

The age of intellectual information dissemination via cyberspace has clearly arrived. There are those who side with the infamous White Paper, the creation of the Clinton Administration’s Working Group on Intellectual Property/Infrastructure Task Force. On February 26, 1998 HR 2281, the Clinton administration’s alleged solution, made its way to the Judiciary Committee from the House Subcommittee on Courts and Intellectual Property. The bill is among several measures presently before Congress such as HR 3048, The Digital Era Copyright Enhancement Act and HR 2652, The Collections of Information Antipiracy Act (passed by the House on March 24, 1998).

Government intervention and private rights seem to always butt heads in this and many areas of legal society. I am not advocating a circumvention of law. Nor am I in favor of total abandonment of existing standards, regarded as totally obsolete by some. However, with the rapidly developing technology some concessions must be made by all concerned. No law will be able to effectively cover all situations. Nevertheless let us try before finding ourselves too entrenched in this Net of wonder. It is far better than finding ourselves caught in a net and left to merely wonder.
Using Metadata to Improve Organization and Information Retrieval on the WWW

Bich-Liên Doan, Michel Beigbeder, Jean-Jacques Girardot, Philippe Jaillon

e-mail: {doan, mbeig, girardot, jaillon}@emse.fr

Abstract: Until now the growing volume of heterogeneous and distributed information on the WWW makes increasingly difficult for the existing tools to retrieve relevant information.
To improve the performance of these tools, we suggest to handle two aspects of the problem:
One concerns a better representation and description of WWW pages, we introduce here a new concept of "WWW documents", and we describe them thanks to metadata.
We'll use the Dublin Core semantics and the XML syntax to represent these metadata.
We'll suggest how this concept can improve information retrieval on the WWW and reduce the network load generated by robots.
Then, we describe a flexible architecture based on two kinds of robots: "generalists" and "specialists" that collect and organize these metadata, in order to localize the resources on the WWW. They will contribute to the overall auto-organizing information process by exchanging their indices.

1. Introduction

On the WWW, many search tools are now available to help users access information more easily. But these tools are giving often irrelevant responses as they do not focus on the particular context expected by the user.
What do we mean by context?
Suppose that a user wants to know ten very well-known sites dealing with environment. He may ask with:
Q1 = environment
The answer to query Q1 contains many correct matches, but they are lost in a lot of noise. AltaVista gives back some 3 000 000 responses matching the word environment, containing pages dealing with computers, ecology and other topics. These different answers are embedded within different conceptual domains, which are part of their respective contexts. But the contexts are generally not explicit in the inqueries, nor they are recognized during the flat indexing done by usual robots. Moreover, even if the result contains pages dealing with environment, these pages are not organized, i.e. we cannot have a resumé of the sites which contains relevant information, inducing difficulty to exploit the responses.
Suppose that another user looks for information on water treatment. He can try the query:
Q2 = water treatment
Q2 induces noise, because water treatment occurs within both the medicine and the environment domains.
So, he can try to refine his query by adding the contextual word environment, leading to query Q3:
Q3 = water treatment + environment
This time, he or she would get silence because pages containing only water treatment and not environment are not retrieved. In this case, the context environment was implicit and did not appear on the pages, but was explicit in the query.
To help capture the semantics associated with each site, we propose to redefine the concept of a WWW document as an abstraction of a set of page which can be organized into different hierarchies of clusters. We introduce metadata that describes the documents at an apt level of granularity.

Then we propose to define a flexible architecture using the existing and available search tools on the WWW which will enable everybody to participate in the improvement of document descriptions. This architecture is based upon high interactivity between search tools and progressive organization of information on the WWW. With minimal effort we can use cooperation between existing isolated elements of the WWW, resolving the problems of scalability of centralized servers, networked bandwidth overload, while improving the quality of information retrieval on the WWW by reducing noise and silence.

2. Related work

At present, information retrieval on the WWW is made by search tools that have limited capabilities. Two kinds of tools are used currently:

2.1 Universal robots

These robots are "universal" in the sense that they try to index the whole Web, no matter what topics are addressed by the pages, or where the pages are localized. As the WWW grows, universal robots become more numerous, resulting in overload network bandwidths. They become inadequate in finding relevant information all over the WWW. Their main weaknesses are:

* too many irrelevant responses,
* no organization in the responses leads to difficult way to exploit them,
* loss of context around the responses because of the lack of semantic description while indexing and the lack of expressive request (terms with boolean operators),
* no access to the non-textual documents (images, sounds, video) which are not indexed.

2.2 Thematic directory

Other search tools exist, such as Yahoo, which provide users with the means to browse a hierarchy of thematic directories. A provider can register by filling a form to describe its site, indicating in which topic he wishes his server to appear and at which particular level in the tree of subjects. The advantages of this process is to enable exploratory research and better control in indexing (reducing the noise). The problems encountered by this approach are:

* manual indexing,
* only a part of WWW is indexed, so there is lot of silence in the answers,
* manual classification of the universal information requires manual and high cost for maintenance and updating,
* no content-text indexing of pages.

2.3 Metadata

The use of the tag META in HTML page has been solicited. The aim is to give the creator the possibility to insert in his pages the indexing information to be used by the robots. Moreover these metadata should be inserted in every page leading to both a work overload for the creator and some noise in the answers. Currently, meta tags have no standardization. There is no consensus of meaning and the users unintentionally or deliberately can circumvent the use of these form of metadata. Recently, research has showed a great interest on using the metadata to improve the description of electronic documents and to standardize the exchange of this metadata. For example, applications have been developed to access digital libraries through the Internet, combining text and structured fields (author, abstract, title...
3. WWW documents

The WWW pages are linked in a "flat" way, so there is neither hierarchical organization nor overall structured information. HTML structures the display of pages, but provides very little information about the content of pages or collection of pages; it is precisely this structured content we want.

3.1 What are WWW documents?

Consider the following analogy:
A librarian needs a list of words to describe the books he/she has to catalogue and a classification (for example the Decimal Dewey classification or DDC) in order to put the book in its right place on the shelves. What we call a document in this context is in general a paper document, which can be easily identified as a physical unit of information.

Let us consider now a WWW document. This kind of document is electronic and has no clear physical boundaries. For example, is a WWW page considered as a document [White 1996]? In fact, there is a great diversity in the granularity of information found on WWW servers. You can find very short and independant pages, considered as documents by themselves, and pages linked to other pages that form a cluster or another document.

We give a new definition of a WWW document: a document is a collection of pages or documents, created by an authority (e.g. author or organization).

3.2 Describing WWW documents

We introduce now the notion of a context around a page or a document: Each page or document has a context associated with. Let's go back to the library example, and consider a paragraph of a book. This page takes place in a section, within a paragraph, within the book itself. Each level of organization of the book gives a context, from the highest level (root is the book) to the next level in the hierarchy up to the page level. These contexts may inherit from their father context, depending if the attributes are dynamic or static (this will be defined later). The contexts are composed of both pieces of information about the content of the document or external to that content. For instance, at the book level the author name, the publication date and the title are outside its semantical content.

So we suggest to make explicit these contexts and their attributes within documents, The following figure shows how the WWW pages can be organized into clusters called documents, one page can belong to different documents, therefore bounded to different contexts (here represented by the subject attribute).
Figure 1: Several organizations of pages

Contexts are in fact represented by what we called metadata in the precedent section. Introducing metadata within a document rather than within a page has several benefits:

* describing the logical unit of information at a correct level of granularity; enabling the author of the documents or experts to explicit the context associated with the documents;
* offering a better control over the structure of the WWW by making explicit the organization of documents;
* enabling flexibility of clusterization of pages, which corresponds to several organizations of the same collection of pages;
* avoiding to duplicate the same information in all the pages which belong to the same document; therefore lightening the author work load.

The contexts have different attribute types: static and dynamic. Static means that the metadata is local to the context, then it will not be propagated along the tree of documents. Conversely, dynamic attributes means that they can be forwarded along the hierarchy. For example, coming back to the [Fig. 1], we can see that for the subject attribute, the word Pollution specializes Environment, and Water Pollution specializes Pollution. Environment is forwarded along Water pollution and Water by inheritance.

Each author may have a certain view of the organization of the information within his pages and is responsible for the creation of the corresponding documents descriptors, or metadata. Each document contains a collection of pages or documents and is described by a set of attribute-value pairs. These metadata are based on XML for the syntax and on MetaData Dublin Core for the semantics. This is an example of the document metadata:

```
<XML>
<environment-document>
  <identifier>env001</identifier>
  <subject>
    <scheme>
      <thesaurus_GEMET>Environment</thesaurus_GEMET>
      <DDC>333.7</DDC>
    </scheme>
  </subject>
  <title>Environment server</title>
  <author>Bich-Lien Doan and Michel Beigbeder</author>
  <description>enterprise and teaching server about environment.</description>
  <subject>Environment, pollution, water treatment</subject>
</environment-document>
```

383
The basic element for the representation of descriptors of documents is the inclusion relationship with other documents or pages. These relationships are represented with the relation (type = child, type = contains) attribute. With this attribute, it is possible to represent hierarchies of documents.

The subject attribute is another important one. The value of this attribute can be described with the DDC for instance. With such a scheme, any ambiguity of terms is avoided, but the author can describe freely by keywords terms as well with the subject attribute without any scheme. Let us come back to our three first requests:

Q1 = environment
Q2 = water treatment
Q3 = water treatment + environment

In contrast with the classical search tools, we produce the following results: Q1 returns the documents described by the environment subject. Q2 gives the set of pages containing water treatment embedded within medicine or environment documents.

Q3 returns the pages containing water treatment in the environment context.

We can now suggest how the use of metadata associated with documents can be helpful in a cooperative architecture of search tools.

4. Specialist and Generalist robots

4.1 Definitions

* Universal Robots: Universal robots currently exist on the WWW (eg. Alta Vista, HotBot, Lycos), although most of them include complementary topical search, they are keeping on their well-known function of indexing whole pages of the WWW.

We define two further kinds of robots: robots for general purpose tools and robots for specialist tools.

* Generalist Robots: They create an overview of the WWW by achieving two functions:
  o first, they collect the metadata of whole sites on the WWW and they index descriptors of WWW documents,
  o second, they manage an acquaintance database of services (addressed by other generalists and specialists) in order to route the queries towards the right services.

* specialist robots: They have knowledge in a particular domain. They use the metadata to decide if they are interested or not in exploring subtrees and indexing pages.

Our concept is based on high interactions between the entities defined above which form a specific structure. Each of the specialist robots is described by its own metadata (like a document) and can be requested by other specialists or generalists; the hierarchy of documents is then extended to the hierarchy of specialists. The robots are able to cooperate using the metadata specified in the last section. The advantage of this structure is that specialists or generalists may use metadata instead of the documents themselves for building their indices, thus reducing the network load. In this case, it is possible to improve answers to general queries (those that give thousands of answers): if a query generates 10000 URLs located on 100 sites, it is probably better to return the metadata associated with these 100 sites
rather than a (poorly) ordered list of 10000 URLs. Such non-specific queries should be addressed to the
generalists. Reciprocally, well-defined queries should be addressed to specialists.
In this section, we will detail what exactly are the roles handled by the entities in our structure.

4.2 Roles

4.2.1 WWW sites providing metadata

A WWW site stores a set of WWW pages. If metadata is embedded within an existing hierarchy of
documents then a site may provide:
* one or several organizations of pages and documents
* metadata describing pages and documents, that specify:
  o One classification scheme (e.g. DDC), or a thesaurus if used
  o The Meta Dublin Core fields, in addition with the number of pages or volume of the site. These
    metadata may be stored within the site, at the root place or may be a reference to a URL stored
    somewhere else, for example maintained by a specialist.
* a fingerprint of others specialists which have already indexed it.
* a standard robot.txt file

4.2.2 Specialists

A specialist is created when needed to provide an identification, a description of his domain. It may
contact a generalist to "push" information about itself. Its main function consists in gathering and
indexing information about its specific domain, and more precisely:
* collecting metadata according to its subject (for example environment),
* indexing HTML pages associated with the knowledge domain,
* storing and managing metadata and indexing pages (updating, deleting data...),
* routing requests to generalists if it cannot answer the query
* publishing its own metadata, to be later indexed by other robots.
* answering by giving either pages or summaries of documents, so that the user can navigate the
  hierarchy of contexts linked to the retrieved documents.

4.2.3 Generalists

* collecting metadata from one or several specialists while maintaining references to these specialists
* directly collecting the metadata from the WWW sites
* routing the refined queries to the adequate specialists or providing summarized responses to general
  user requests,
* adopting a political decision to collect all the metadata on the internet or not.

4.3 Architecture

Suppose we have two specialists S1 and S2 dealing respectively with environment and pollution.
Consider now the W1 site which fills S1 and S2 in environmental data, with metadata and pages. G
knows S1 and its knowledge domain, whereas S1 knows S2 which is more specific than itself.
* The user asks a generalist Q3. Q3 is translated to subject = environment, keywords = treatment + water.
* The generalist finds one specialist in the environment area. He contacts S1 and transmits the request.
* S1 knows another specialist, S2, whose area is specific to "pollution of water". He transmits Q3 to S2.
* S1 gives the user a collection of documents and pages he retrieves from his local database and shows the context of his responses with the description of S2 included.
* S2 gives the hierarchical tree of concepts to the user.
* The user requests S2 for more detailed information.
* S2 searches his database and gives results to the user.

5. Conclusion

Defining structured metadata embedded within the documents should be used for organizing information and improving the construction of general indices. Here we have defined a scalable architecture which offers the present search tools the ability to index quickly and with better control. Our structure has the following advantages:
* Decreased consumption of the bandwidth. Robots exchange indices and may only index summaries of documents;
* More relevant answers. The contexts attached to the documents are hierarchically organized, involving interpretation and analysis of the structure and the content of the server;
* Distributed indexing. Specialist robots are focusing the information upon one particular domain;
* A self-configuring system. Specialist and generalist robots are discovering metadata from each other.
We are currently implementing a prototype of specialists and generalists for an environmental application project.

Students using interactive media learn the same amount of material in half the time or less with equal or better understanding and equal or longer retention than when using traditional means of instruction. This statement summarizes literally hundreds of well-documented and well-controlled research studies. A few years ago Congress allocated over a million dollars for research into the effectiveness of interactive media. The Institute of Defense Analysis produced a lengthy meta-study that analyzed over 600 research studies on the effectiveness of interactive media. The results of this study are summarized in the first sentence of this article.

For the past six years at the Graduate School of Business of the University of St. Thomas, we have been developing an interactive financial accounting course with the support of a number of corporations in Minneapolis. In addition, New College, the University's outreach to adult learners, has developed a weekend college format in which adults capable of independent learning spend only half the number of classroom contact hours as traditional students during the regular program. For weekend students, class participation is supplemented by independent study.

In the fall of 1996, an introductory financial accounting course was taught in the weekend college format every other Friday night from 5:00 to 9:30. Students used a CD-ROM and an interactive Web site in addition to a textbook. A regular section of the same course was taught by the same professor during the day using the same textbook and class outline. Both classes took the same quizzes and tests. The students in the traditional class knew nothing about the CD-ROM or interactive Web site, although they spent twice as many class contact hours with the instructor.

This was done partly for convenience and was by no means a scientific study. No variables were controlled, and there were obviously demographic variables (what kind of student would choose to take a class on a Friday night?) and other intervening variables. However, the results of this practical experiment were very consistent with results of scientifically controlled studies.

The students in the weekend format section using the Web site and CD-ROM did substantially better on all tests and quizzes than the traditional section. There was also a nearly perfect correlation between frequency of contributing to the Web site and their final grade based on the tests and quizzes. The more the student contributed to the Web discussion (which was available twenty-four hours a day seven days a week), the higher the student's grade.

It became apparent that the responsibility for learning shifted from the teacher to the learner for the students in the weekend format. Students came to the orientation session and first class or two with the traditional attitude, "OK, I'm here; teach me." By the third class (about midterm), they came to class with questions. "How does ... work?" "In the company I work for, thousand such happened ... how does that fit in with this..."
new concept we're learning?" I don't understand ..." The rapid fire lectures grew into discussions with specific learning objectives set in the syllabus and specific objectives each student wanted to achieve. By the end of the course, the lecture format was almost entirely abandoned, although discussions were sometimes interrupted by short didactic explanations of specific complex concepts.

Ever since John Dewey espoused progressive education, many teachers have attempted to encourage students to take responsibility for their own learning. However, the combination of less class time and the structure of the Internet caused this to happen naturally. Students realized that if they were going to learn the subject, they had to do it themselves - a very empowering motivator. The freedom actually seemed to generate responsibility.

In some cases the student's self-concept inhibited learning on the Internet. During the first few weeks it was extremely difficult to get students to post their questions on the Internet for everybody to read. No learner wants to appear stupid. Asking questions on the net is a risk that most students find hard to take. In a typical class many students are unwilling even to verbalize a question in front of their classmates. Asking them to post a question on the Internet for everyone to read is exponentially more difficult. The potential for embarrassment is a significant inhibitor to learning.

On the other hand, the risk of embarrassment can be a motivator. Students reported that before they put a question up on the Internet, they were careful that their grammar and spelling were correct. Frequently they would check in the book or several books and often found the answer to their question. Or, in the process of framing their question, a better question occurred to them, which they posted on the Internet.

The greatest motivator for those who preferred not to participate or post questions or comments on the Internet seemed to be their grade. If a substantial percent of their grade depended on their participation in Internet discussions, the amount of participation (and their understanding of the material) increased substantially.

Many other discoveries were made as these learning technologies have proliferated throughout the university during the past year.

The Internet and World Wide Web is the most recent popular media for interactive learning and communication. Technology will change our educational system dramatically. Our grandchildren are likely to learn accounting by sitting in their rooms, putting on helmets and gloves, and flipping a switch to activate the system. Instantly they will enter a virtual world designed to help them learn accounting. For example, they might be "hired" in an entry level job and given a task, such as recording accounts receivable and sending out invoices. As the student sets about the task, they can ask their "supervisor" or "coworkers" how to do the task(s), why the task needs to be done, and how it fits in with the rest of accounting department and company. Everyone in this 3D virtual community responds as a patient teacher and gives theoretical as well as practical knowledge that helps the student develop skills needed to do the job. The next job (i.e., unit) might be in the accounts receivable department, or in inventory control department, or another accounting department, until the student eventually gets promoted to be manager and is asked to analyze the financial statements. The classroom teacher will act as a mentor, guide, advisor, evaluator, and tutor throughout this learning process. The student/teacher relationship is likely to revert to the Mentor/Telemachus model described by Homer, and is likely to be a closer personal relationship than the current relationship allows.

Sound incredible? Most of the pieces of this model are already available. When IBM assembled its PC, it obtained the CPU from Intel, the operating system (DOS) from what is now Microsoft, the monitor from Perceptronics, the disk drives from Syquest, the keyboard from Keytronics, and parts from many other manufacturers. Henry Ford, like many individuals and companies that "invent" revolutionary complex products, used a similar approach. The CD-ROM and interactive Web site are just two components of the future system. They may well be just a step along the way toward more effective learning based instruction that will replace teaching based instruction.

EMC/Paradigm Publishing has adopted and published the materials used at the University of St. Thomas.
Instructors can visit the Paradigm Accounting Interactive Web site at <http://www.emcp.com> (College Division, Electronic support). Instructors can also obtain a free CD-ROM demonstration disc for Paradigm Interactive Accounting by calling (800) 535-6865.

Some observations about the CD-ROM and Web site
(1) responsibility for learning shifted from the teacher to the learner;
(2) emphasis shifted from teaching to learning;
(3) the level of classroom discussion became much more sophisticated;
(4) the Socratic method of asking worked better than telling or explaining;
(5) the role of the instructor changed from one of lecturer to one of mentor and coach;
(6) instructors' office hours and time in class were optimized; and
(7) ancillary use of the Web site that was not integrated into the core of the class was ineffective.
(8) Internet access was a problem for some students who didn't want to come to the college.

Student access has increased at a stunning rate during the past year.

A good example of an exchange on the Interactive Web Site went like this:

Assets vs. Owners Equity

Laurie - 02:38pm Sep 18, 1996
I'm having difficulty understanding the difference between assets and owners equity in a business.

Amy - 07:28pm Sep 18, 1996 (#1 of 5)
It helps if you change the equation around such as Assets - Liabilities = Owners Equity. I don't know if this is 'legal' but it helps me to understand what Owners Equity is. It is the retained earnings from the previous year and information regarding stocks (how much in stocks, what they are worth and how much was paid in dividends)

Abstract: Lifelong learning and training has become an important issue in industry, because keeping track of innovations and adopting new developments is necessary for maintaining competitiveness in the market. In this paper we want to show how VRML can be generally used for teaching and training in an industrial context. We will discuss some aspects of learning and training in industry and sketch several application scenarios for VRML based training. Moreover we give an overview of tools that are suitable for designing teaching and training applications, and present authoring tools we have developed in this context.

1 Introduction
In industry, lifelong learning and training on an individual, team and organizational basis in all hierarchy levels from top management down to the work force is becoming increasingly important due to ever faster changing market dynamics, the rapidly evolving labor market and the constantly changing employment culture. Internal training of personnel, initial training and preparatory training for new tasks, the continuation of employee education, and also training on the job are the key forms of individual training. Team training often consists in special training courses on group dynamics and psychological aspects, but also includes the use of communication supporting software solutions that provide some assistance for efficient team communication. For instance the use of WWW technology as a basis for sharing information and documents, or the use of visualization techniques, aiming to provide a common understanding, can be classified into this category. Organizational learning and training often comprises the problem of knowledge representation and collection, especially in internationally operating companies and in companies that have historically evolved from mergers and buy-outs of different enterprises. For such organizational learning and training, well defined and globally accessible information systems are often a favored concept, for propagating factually transmissible information. Apart from internal training, external training of suppliers and sales agents on new products are other frequently occurring training situations. For global organizations it is an increasingly complex and difficult task to maintain an overview of the "strategic knowledge" the company and its affiliations and subsidiaries own. In the course of globalization of markets, an increasing number of companies rely on global communication networks such as the WWW for communicating internal information and for building up company wide information systems. Due to recent technological developments in the IT sector, the quest for more compelling visualization and information access is increasing and the demand for 3D graphics is rising. Innovative technologies such as VRML (Virtual Reality Modeling Language) [VRML97] enable the web based use of interactive 3D environments. VRML is applicable in different training scenarios, such as virtual training environments, both real time interactive 3D and immersive VR or hypermedia environments.

In this paper we first describe the state of the art of VRML. After that, we present tools that are suitable for creating teaching and training applications using VRML, and show some application examples.

2 VRML State of the Art
The Virtual Reality Modeling Language (VRML) is a language and file format specification for exchanging 3D data, especially across the Internet. Since its inception in 1994, VRML, as an open and platform independent
format, has gained widespread acceptance and support in both industry and academia. With its ISO standardization, finished in record time in November 1997, it has taken the step from de facto to de jure standard. By now, there exist numerous VRML browsers and plugins on many platforms, typically free of charge. Several dedicated VRML authoring tools are available. Most industry standard modeling and animation tools support VRML format, at least through export filters, and even more are supported through converters. VRML offers among others the following features:

- description of 3D geometry, including material properties and textures
- fog and light effects
- linear key frame animation
- user interaction with the 3D scene (e.g. through mouse clicks or drags)
- 3D sound
- animated (i.e. video) textures
- HTTP hyper links
- programming APIs for the Java and ECMAScript programming languages

The further development of VRML is coordinated by the VRML consortium [Consortium] and is carried out in working groups, such as the Humanoid Animation WG or the MPEG-4 Integration Task Group. VRML is supported by the common WWW browsers Netscape Navigator and Microsoft Internet Explorer by means of "plugins" or "ActiveX controls". This means that VRML data can be integrated into WWW pages much like other multimedia file formats such as MPEG video or Macromedia Shockwave files. Moreover, HTTP hyper links and multimedia files such as sound (WAV, MIDI) or MPEG video can be integrated into the 3D scene, so that VRML is tightly integrated into the WWW hypermedia structure. This can be used to advantage by applications such as product information systems, which can be set up to provide 3D presentations of products, where additional information can be obtained by clicking on different parts of the 3D object.

An even more powerful way of integrating VRML into the WWW browser environment is the VRML External Authoring Interface (EAI) [Marrin 97], which makes it possible to access and modify a VRML scene from within a Java applet running on the WWW page. Many applications such as 2D user interfaces for manipulation of the 3D world, database access, or simulator linkage, are thus feasible. Despite the increasing availability of authoring systems and supporting tools, VRML content creation is still a very labor intensive and time consuming process. The manual tasks such as editing of the VRML scene file and especially Java programming are often unavoidable even with today's tools, and require special knowledge, such as programming skills. They are therefore often not done by the same people creating the 3D models, which makes VRML content creation even more expensive.

3 Applications

3D animation and Virtual Reality can be applied in industry as a medium for vocational training and for continuing education in the context of lifelong learning. For instance, in order to train technicians, engineers, but also users on a newly launched product or on special tasks to be performed with that product, such as installation or maintenance, manuals and courses are usually provided. The use of VRML for such training manuals allows to take advantage of features such as a true 3D representation of the product, the display of animations showing special actions to be performed, the definition of interaction and behavior, the integration of links to additional information, or the addition of sound, such as spoken instructions.

In repair instructions for technicians, 3D animation and annotated, interactive 3D exploded views of the product model can be of great help to intuitive understanding. The same technology can also be used in 3D installation manuals and user manuals. 3D exploded views of product models are of great help to intuition and are already widely used for intra-organizational communication, marketing and management presentations of all kinds. However, the generation of such views is still expensive and thus reserved to a small number of special areas. Efficient methods and tools for generating interactive exploded views will enable their routine use in a larger context, such as 3D interfaces to product information systems.
In the same way VRML, as a web-based technology, is well suited for distributed information access and offers the option to use 3D interfaces. To access technical information on a product or on its parts, a 3D interface that shows an exploded 3D view of the product is a very compact and intuitive interaction metaphor. Because programmed code can be easily integrated into VRML scenes and objects, the VRML representation of the product and its parts can be dynamically related to additional information, such as a part list or bill of materials, where each entry in the list can be dynamically related to the parts in the VRML model.

3D navigation interfaces, representing a product or production plant, are well suited for training applications due to the intuitively and immediately understandable metaphor. They can be equally used for training of new personnel, anticipant training on new products and on new production facilities. VRML applications are also suitable for mobile environments [Raposo 97]. VRML can be used to share one model with other employees via WWW. For instance, in construction, several engineers can work together on the same object. The same technology may also be used to communicate shared mental models [Stout 96]. VRML can be used for surveillance of production processes. Here sensor data can be used to automatically generate a time-variant 3D visualization. Presenting the sensor data in a 3D model makes it easier to locate a malfunction in the real machine. Additionally, the 3D model can also be used in a training scenario.

Providing technology and tools, however, is not sufficient. In industry, cost effectiveness is usually a major concern. The authoring of 3D environments has to be done in an efficient manner. Animation, for example, is not considered as central as in traditional application fields of computer animation such as film and entertainment. This implies for instance that in the industrial application context a dedicated animation or network expert may not be available. Thus, easy to use authoring tools and support for automated generation is of special importance. At the economical level one main argument for using 3D/VR training environments is that they are often less expensive than real life training environments, while providing similar training quality, and offering the option of distributed access—the trainee does not have to be present in one specific place in order to participate in the training. Furthermore, instruction material may be collected and offered at a central point in the company.

In some industrial areas, the timely training of personnel on the distribution, installation and maintenance of new products is mission critical. For these time critical applications, it is essential that the training material be provided in time, i.e. prior to the launch of the product. In order to ensure this, the process of generating a training application must be parallel to product design.

4 VRML Authoring and Application Building Tools

We have developed enhanced VRML authoring and application building tools, suitable for creating interactive, annotated and animated VRML based applications such as training environments and information systems. One example is the CASUS system, which offers a linkage between industrial simulations and VRML. Other examples are authoring tools that support the automated generation of 3D exploded views of complex models and allow to embed the VRML application in different contexts using different interaction metaphors. These tools include a scene composing editor, a VRML structure editor, an animation editor, and an application builder.

The VRML authoring tools described in this section are realized in Java and work in conjunction with any VRML97 compliant browser supporting the VRML External Authoring Interface.

4.1 CASUS System

CASUS System [Luckas 97], an acronym for Computer Animation of Simulation Traces, is an object oriented approach to linking a three-dimensional visualization to an event-oriented simulator. The goal is a realistic visualization, which is, therefore, well suited for learner-oriented presentations. This is achieved by using computer-generated, three-dimensional animation. In realizing this approach, a modular concept is provided which allows—apart from offering easy adaptation to a variety of simulators—a highly automated animation generation.

CASUS System as a whole was designed to remedy the lack of visualization capabilities of many event-oriented industrial simulators. Since nowadays the presentation is primarily done with numeric tables or abstract symbolic visualization learners are very often unable to evaluate the results and develop own strategies or interpretations. Moreover the learner is forced to get involved with abstract simulation models and presentation tech-
CASUS System solves this problem by establishing a link between the abstract simulation and the real world. Based upon event-oriented data, an automatic translation into dynamic animation sequences is established, making use of animation elements [Dörner 97], clipart-like predefined 3D objects with integrated behavior. Both the simulation expert and the trainee receive an adequate and meaningful presentation of the simulated problems and solutions individually adapted to their specific knowledge.

![Figure 1: System Architecture of CASUS System](image1)

The architecture of CASUS System is based upon a pipeline that consists of an arbitrary simulator, the translator (CASUS Trias), the animation system (CASUS Anim) and different visualization systems, such as CASUS Presenter or CASUS Render [Figure 1]. At first the output of any event-oriented simulator is processed by the Translator CASUS Trias. Since there is no standard format for storing simulation traces a normalization tool is used. Referring to the normalized trace, this tool translates the simulation events into unified animation sequence descriptions. All animation sequence descriptions together form the animation script that is then processed by the animation system CASUS Anim. CASUS Anim allows the author to modify presentation parameters such as camera position, lighting, visualization time or frame rate, as well as the output format used, e.g. VRML. Therefore CASUS Anim offers a user interface that only provides the functionality that is essential for the user profile described earlier. The animation generation process is completely hidden from the user. Internal features, such as routing of events inside the VRML scene or reducing scene complexity, are maintained automatically by CASUS System.

![Figure 2: Visualization of Production and Logistics Scenarios](image2)
4.2 VRML Authoring

The VRML scene composing editor provides the functionality of a general scene editor, and allows to build all kinds of VRML scenes regardless of the application context. The standard scene composing functionality is supported, such as to add new objects to the scene, to place objects, to group and ungroup objects and to define new objects. The scene composing editor uses a 3D graphical user interface, where the VRML objects can be directly manipulated. While building the scene, the user is monitored, and information on how objects have been grouped or joined is retained by the system. This information is used for animation computation.

The structure editor allows to modify the structure of the VRML scene, i.e. the hierarchy of VRML objects in the scene graph. The VRML structure editor provides both a 3D and a 2D graphical user interface, where the object hierarchy can be modified by drag and drop mechanism. The objects selected in the 2D view are also marked as selected in the 3D view of the scene. This has the advantage, that the user gets an immediate visual feedback of the selected VRML part.

The semantics of the scene graph hierarchy depends on the application, the user wishes to create. Imagine for example a scene that consists of different rooms or areas inside a building, such as a factory layout with different production areas. The user could thus decide to interpret a hierarchy level as a room or a production area. For another application example imagine for instance a scene that consists of a highly complex 3D model, such as a motor or other machinery. In this case the user can decide to interpret a hierarchy level as a part group of the motor or of the machinery. The part hierarchy is used for the automated computation of explosion and disassembly animation.

The animation editor offers support for the creation of general key frame animation. An explosion editor supports the automated generation of explosion animations. The automated generation of the explosion is based on the information tracked while the user has built the model. This includes information on the connectivity of parts and on surface normals. Based on this information an explosion animation is computed, that can be adjusted to the individual needs of an application.
4.3 Application Builder

The application building tool allows to embed the VRML application in a hypermedia context. The linking of parts of a VRML model to entries in an HTML based list or table is supported as well as the access to additional information. The examples depicted in [Figure 3] have been created with the tools described here and in the previous section. An overview of the technical structure of the applications described here is presented in [Figure 4]. The application builder consists of a relation editor, an annotation relation editor, and a composing editor.

The relation editor supports the definition of a relation between an object of the VRML file and an entry in a HTML page (table). When the default relation mode is applied, the relation editor will automatically create a relation for each object of the VRML file to a corresponding entry in the table on a sequential basis. The relation editor provides a 3D view of the VRML file, where objects can be connected to table entries by a double selection mechanism.

The annotation relation editor allows to define a set of information files to be related to both the VRML objects and the entries in a table or list. In the application depicted in [Figure 3], the additional information related to the parts in the VRML files consist in CAD drawings of the respective parts.

The composition editor composes the application, i.e. joins the relation information and the relation selectors (buttons) and creates an applet, and an embedding HTML page, from which the training application can be started.

The conjunction of both tools provides both automated support for the creation of 3D animation and automated support for integration in a hypermedia context.

5 Conclusion

In this paper we have shown how web-based technology using the Virtual Reality Modeling Language (VRML) can be applied in an industrial education and training context. Using VRML is not only a matter of providing technology but also of adapting technology to the specific application field. In the industrial application field automated VRML generation, cost-efficiency, industrial simulator linkage and integration in the established workflow are stressed. We presented examples of tools that show solutions how these application requirements can be met. As a result VRML in connection with the WWW opens new application fields of web technology in industrial companies.

Authoring and delivering networked multimedia is extremely complex process. The essence of multimedia authoring is that the author wants to communicate a message to the reader. In order to achieve this, the author uses an authoring tool to create the presentation schedule. Depending on the features of the authoring tool, the authors may be able to vary some presentation parameters such as font and size of text objects, spatial layout of graphical objects, and temporal parameters of continuous media objects. However, presentation delivery characteristics are impacted on by delivery environment including network bandwidth, latency and local disk storage, and the amount of multimedia data transmitted and invalidate the schedule. These varying characteristics are not addressed adequately in the authoring process. We propose a new approach to multimedia presentation scheduling that utilizes constraint technology and a flexible set of scheduling heuristics. The Constraint Satisfaction Authoring Framework aims at increasing the expressive power of a multimedia authoring paradigm with regard to resource capacity conflicts and deals with domain uncertainty and incorporates it into the presentation schedule.

1 Introduction

Given the temporal specification of the playout of a collection of objects the correct results depend on multiple components: operating system, visual-audio subsystem, network facilities, and server database retrieval times. The presentation schedules created by any of the existing authoring tools are fixed predictive schedules with no regard to the varying performance of the multimedia delivery systems.

Although different types of reactive playout services have been suggested in several research projects (e.g. [Heiko and Klass 1996] and Papathomas, Blair, Coulson, Robin 1995]) they seem to pay limited attention to the generation of optimized presentation schedules and their seamless integration with media objects. In particular, the model of resources and types of resource constraints is typically simplified or non-existent.

The overall goal of Constraint Satisfaction Authoring Framework (CSAF) is to present a flexible, constraint based, authoring framework which can capture varying characteristics of delivery environments and deliver adjustable (elastic) multimedia presentation schedules. The heart of CSAF is the ILOG Constraint Solver™, which is used to generate presentation schedules.

2 Motivation and background

The objects involved in multimedia orchestrated presentations have typically very strict playout requirements. The violation of these requirements results in subsequent violation of temporal relations (temporal and precedence constraints) between the media objects. The current authoring paradigm does not encourage resource scheduling which would predict and minimize these violations in a way, which is highly independent of the underlying transport and highly transparent to the user. The scheduling services also should prevent the suboptimal utilization of shared resources and should encourage users to review their quality needs with regard to the cost of delivery.

2.1 Brief summary of current work

The examples of recent projects which incorporate synchronization specification and scheduling include: AthenaMuse [Hodges, and Sasnett 1993], Firefly [Buchanan and Zellweger 1993], HyTime/SGML [Buford and
Rutledge 1994], MHEG [Markey 1991], MADE and CMIFed [Hardman, Bulterman, and van Rossum 1994], and AMOS with its δ-sets [Heiko and Klass 1996]. Table 1 summarizes the features relevant to a resource scheduling process for the subset of case studies. The summary is based on the available reports in the literature and may be incomplete.

During the scheduling phase, these systems treat each ‘active’ resource separately (e.g. CPU, network bandwidth, etc.). Typically, only coarse-grained specifications are used to adjust the presentation parameters for each resource. They lack an integrated approach to optimal usage of resources using rich temporal specifications and strategies to stretch or shrink the activity playout duration.

Table 1 Summary of properties of scheduling entities in the selected case studies (? = not reported)

Only three of the surveyed systems [Blakowski, Hubel and Langreher 1992] [Buchanan and Zellweger 1993], [Heiko and Klass 1996] use a hybrid approach to resource management: a compile time scheduler to prepare presentation schedules in advance and then a run-time system which resolves fluctuations in media object behavior according to a fixed algorithm. None of these authoring frameworks provides support for consistent resource allocation specification with regard to user perceived quality and given capabilities of the resources. Optimization and constraint relaxation schemes are either non existent or too simple.

3 Constraint Satisfaction Authoring Framework

The architecture of our Constraint Satisfaction Authoring Framework relies on the following components: Presentation composition editor, Predictive scheduler, and Sensory module. The Predictive Scheduler is further decomposed into two cooperating modules: Scheduling engine, and Synchronisation enforcement. An overview of the architecture is in Figure 1.

The Predictive scheduler uses its Scheduling engine to create one or more consistent schedules which can be used for temporal management of the presentation and for the enforcement of synchronization among media objects. The dynamically varying internal constraints are represented by a set of quality classes (represented by a group of Precision objects) which contain information about system internal constraints and intercept via the sensory module possible changes in the multimedia system. The collection of estimation methods within the Precision objects allows the Predictive Scheduler to gather and statistically process the long term performance data and to apply appropriate statistical estimation methods to predict the behavior of the system.

The Presentation composition editor is the subsystem which interacts with the multimedia presentation author. The output is a coarse grained specification of spatial and temporal presentation layout. The author’s quality and ordering requirements are communicated in the form of external constraints to the Composer. The Composer’s role is to create composite media objects and associate their handles with the temporal layout requirements and communicate this information to the Predictive scheduler.
Figure 1. CSAF architecture

The Sensory module detects system internal constraints and provides feedback information regarding the needs of the presentation at run-time via sensors to the Precision objects. The Precision objects maintain knowledge about the environment, as indicated in the diagram.

3.2 Resource reservation model and schedule flexibility threshold

All the components of the resource reservation time are variables selected from the admissible time domains: \( t_1 \) (start time domain), \( t_2 \) (end time domain), \( t_3 \) (duration domain), and \( t_4 \) (unexpected delays domain). An activity must reserve a resource for an extended duration \( T_{ext} \) as suggested below (Figure 2):

\[
T_{ext} = ST_{ij}(c) + ET_{ij}(c) + d_{ij}(c, \delta_{ij})
\]

Each of the components of the activity duration is a function of the resource available capacity (denoted \( c \)). In addition, the activity duration depends on the size of unexpected delays (\( \delta_{ij} \)). The \( T_{ext} \) is an explicit entity that resides within the presentation schedule as a result of expected and unexpected events which impact on the actual duration for processing the activity. The upper and lower bounds of resource reservation time change dynamically whenever components of the resource reservation time change. This view is different from that taken by the majority of authoring tools in which the activity duration is modelled independently of the resource as a constant. This implies that the resource reservation time is also an indivisible constant.

The quality of a multimedia presentation is a function of the activity duration which in turn depends on the resource presentation parameters and processing constraints (external and system internal constraints). We assume that for each activity \( A_{ij} \) the average expected processing duration (allowance) \( d_{ij} \) is available and the required resource can initially be reserved for this duration. The resource can lack capacity or may have some left-over capacity, both of which will impact the presentation quality. In this context, we define a value - Quality slack time (see Eq 1: \( QST_{ij} \)) which represents the variations in presentation quality of the activity \( A_{ij} \) as
a function of its allowance, earliest start time (EST\(_y\)) and latest completion time (LCT\(_y\)).

\[
QST_y(c) = LCT_y - EST_y - d_y
\]  

The QST\(_y(c)\) is an explicit entity within the scenario presentation schedule. It is composed of two portions: 1) predictable delays impacting the activity allowance which we termed lower slack, and 2) unpredictable delays impacting the activity allowance which we termed upper slack. Note that as the values EST\(_y\) and LCT\(_y\) are modified the value of QST\(_y(c)\) for the activity A\(_y\) and possibly other activities will also change.

Resource capacity is a function of time as well as a function of Quality slack time. For simplicity, we assume that the resource capacity and the Quality slack time are directly proportional, and we compute the remaining capacity of the resource as:

where RRC\(_y\) is the resource’s remaining capacity, RAC\(_y\) is the resource’s available capacity, RC\(_y\) is the resource’s required capacity. The schedule flexibility threshold is approximated as , where \(TI\) is the number of all non-overlapping time intervals in the schedule.

We have designed and implemented a scheduling approach that maintains flexibility in the form of a bounded quality threshold that is an explicit value in units of time maintained for each activity. The sum of over all non-overlapping time units (intervals) represents the schedule flexibility threshold. This means that as long as the temporal dimensions of the activity remain within the expected bounds and the schedule makespan is within the schedule flexibility threshold there is no need to reinforce synchronization constraints and generate a new schedule.

4.3 Scheduling process and elasticity strategies

The multimedia scheduling process is described as a Constraint Satisfaction Problem (CSP):

- a set of \(n\) variables \(X = \{x_1, \ldots, x_n\}\) with values in the discrete finite domains \(D_{x_1}, \ldots, D_{x_n}\).
- a set of \(m\) constraints \(C = \{c_1, \ldots, c_m\}\) where

\[
for \ i = 1, \ldots, m.
\]

The problem is to find an assignment such that

For each activity a variable is introduced. Furthermore, for each activity a domain of possible start times is specified where \(d_i\) is the activity allowance and at this point it is a constant integer value. The assignment corresponds to a schedule where and is the domain of all possible schedules which satisfy the given set of constraints. A solution to the CSP assigns a value to each variable from its respective domain that satisfies all constraints.

Three elasticity strategies have been implemented (Figure 3): The activity elasticity is determined by three properties: the minimum expected allowance - \(T\), the lower slack time and upper slack time. The allowance is specified during a authoring process. The lower and upper slack time represent a measure of the known and unknown quality fluctuation. The quality fluctuation depends on the performance of
the resource used or synchronization policy applied and may be different for different resources or policies. The activity allowance bounds are computed as solver preconditions.

The resource energy contention strategy is based on the amount of resource energy required to perform a given activity in the time interval and to meet the quality threshold. Let cumulative resource energy be , the resource energy required by an activity for the activity duration be .

For each time interval , we can set a constrained condition where are permissible domains for the activity allowance and the resource demand respectively. The size of both domains can be established from the system internal constraints, resource presentation parameters and constraints. The problem then consists of determining a suitable trade-off between the duration of the activity and utilization of the resource calculated as the cumulative resource energy reduced by the sum of all remaining resource energy requirements within this time interval (Equation 1).

$$E_{total} = E_{activity} + E_{remaining}$$

5 Conclusion

CSAF incorporates uncertainty of the environment such as varying quality of resources, detects situations where the quality requested is not possible to maintain due to the environmental changes. We have enhanced the coarse grained synchronization specification supplied by the presentation script with the following constructs:

Activity elasticity strategy incorporates the system internal constraints in the form of a variety of the resource constraints. The activity is a variable which boundaries can be specified with regard to the systems internal constraints and the available resource capacity.

Energy contention strategy is based on finding a suitable trade-off between activity duration and its...
demand for a resource.

Flexible quality threshold strategy is based on the observation that many multimedia applications are scaleable according to the utility function. Using this strategy, we can derive the expected benefit function and relate it to the cost of resource reservation and its presentation parameters.

CSAF framework showed good real-time performance to be used as a predictive scheduling mechanism.

Enterpirse Learning Architecture
Author: Peter Duffey

Purpose

The purpose of the document is to outline a comprehensive architecture for a Learning Delivery System. Based on the architecture outlined, and the requirements to be addressed by the architecture, a number of specific capabilities are described. Each capability is matched with a specific skill set. Finally, the key elements for a successful architecture are described, as well as the danger to avoid for a successful deployment of learning architecture.

Architecture

The architecture of the Adaptive Learning Platform is outlined in the diagram below.

[Diagram of the Adaptive Learning Platform]

BEST COPY AVAILABLE
The architecture comprises a content repository, a virtual classroom or learning server, a database, a number of tools that are used the server, and a variety of delivery mechanisms.

**Architecture Components**

**Content Repository:**
The content repository is a standard Web Server, holding a variety of content relevant to the course topics selected. This content will include:
- On-line, HTML version of the course Text
- Text graphics in .gif or JPEG format
- Teacher lesson plans and outline for course delivery
- Specific content used for async delivery
- Specific content used for synch delivery
- Any supplementary content
- Supplementary learning resources

**Participant or People Database**
The platform includes a relational database that holds are information on participants. Information includes course registrations, attendance, quiz scores, and other activities.

**Virtual Classroom and Delivery Server**
The learning server manages the "state" of the various learning groups and individuals access the server for learning situations. The server knows which people are in which class, which people have the hands up in the synchronous class, and all other associated data related to teaching and collaboration delivery. The server is able to deliver the content in both asynchronous, self-paced learning situations, on for live, virtual class interactions between students and instructors.

**Content Views**
The platform provides access and a variety of views into the content repository.

**Instructional Tools**
The uses a variety of instructional tools to add to the richness of learning experience. Some of these tools are; White Boards. Hand raise, Yes/No indications, audio between participants, threaded discussion, and more.

**Participant management**
The platform provides a variety of participant and course management tools. Some of these tools are; course building, course scheduling, course catalog, student registration, student homepages, and more.

**System Management**
The platform provides a variety of system management tools. Some of the tools are; active pinging to report on participant connectivity, monitoring of server performance, logs of server errors or exceptions, and more.

**Situational Learning Option**
Most importantly, the platform provides support for three learning or content view options. The participants can
- use standards browsers to access and query the content repository. These activities can be for reviewing of the reference material, or for downloading of repository assests to be used at the participant discretion.
-asynchronous review, for self-paced study of the course flow and content.
-synchronous review, in a live, virtual classroom situation, of course flow, content and
instructor facilitation.

Requirements Overview

At the highest level, the key requirements of an adaptive learning architecture are:

- Situational adaptability
- Scalability
- Robustness
- Manageability
- Support for a wide variety of content types
- Content repository for re-use
- Rich variety of learning and instruction tools
- Front-end capabilities for class scheduling, student registration, etc.
- Back-end capabilities for holding data on attendance, quiz scores, activities, etc.
- Reporting on student, instructor and class activity
- Reporting on learning platform use
- Support for Web standards for viewing Multimedia content.

Each requirement area is discussed in more depth.

**Situational adaptability**

The adaptive learning architecture will accommodate requirements for learning that are presented at various learning situations. For example,

- Publish the course outline for Before Class review
- Publish pre-class reading assignments for Before Class review
- Publish home work assignments for Before Class activity
- Provide a repository for home work submission
- Publish instructor review of home work
- Accommodate a full group virtual class experience
- Accommodate a number of sub-group virtual class experiences
- Accommodate the ad-hoc meeting or collaboration
- Maintain a view into the text or reference material for Before, During and After class
- Quizzing and testing for Before, During and After class
- After class ability to review what happened in the class, even if cases where a student missed the class
- After class group collaboration
- After class self study

Situation adaptability requires both the learning platform to be accommodating to the above requirements, and for learning implementers to incorporate a rich range of the above requirements into the learning experience they design and build.

**Scalability:**

The adaptive learning architecture must be accommodating to a range of class sizes and experiences. Of primary concern are;

- The highly collaborative class of 20-50 students, synchronously interacting with each other and the instructor
• The “executive all-hands update” broadcast of information to 250 participants. This group experience relies less on peer-to-peer collaboration and interaction
• The solitary, self-paced study situation, with hundreds of students doing individual study at one time.
• The sub-group or team oriented study experience.

Robustness
The adaptive learning platform must be robust in the face of many factors that combine to compromise the learning experience. Some of these factors are:
• A mix of participants with both fast and slower network connections
• Provide warning when slower connections become inadequate due to public Internet traffic.
• Support a variety of mix usages, including live, virtual classes, students in self-paced study and students accessing the class catalog and registration facilities.

Manageability
The adaptive learning platform should provide system administrators information as to the health and performance of the learning system. Some of the required information would be:
• Software performance monitor
• Network connectivity performance monitor and warning system
• A back-up system, with switch over capabilities
• Ability to move courses from one server to another and student registration groups from one system to another.

Support for a wide variety of content types
The adaptive learning architecture will support the widest possible variety of learning content types, including
• Any HTML content
• Any content viewable via a Plug-in
• Popular native content types, like PowerPoint
• CBT's
• Streaming video and audio
• Java and JavaScript applications
• Text on-line references
• Other reference material

Content repository for re-use
The adaptive learning architecture will support the re-use of content both from within the learning system, and for use outside the learning system. For example, either HTML or PowerPoint slides used for a synchronous class experience should be readily available for use in asynchronous experience, or for viewing in a simple browser. The content cannot be available only the adaptive learning platform. Therefore all content should be “housed” in a separate content repository that is easily assessable to outside users. This content repository is likely a standard Web server.

Rich variety of learning and instruction tools
The adaptive learning architecture will support a rich variety of learning tools and experiences. Some of these tools are;
Front-end capabilities
A number of delivery platform features are required to prepare content and participants for a variety of learning situations. Some of these features are listed below.
- Course builder, preparing a syllabus of materials and activities
- Course or meeting scheduler
- Catalogue for viewing scheduled courses
- Procedure to participants to register for a course from the catalogue
- A list of courses that a participant has registered for
- A way for participants to download any required class material or content

Back-end capabilities
Any activity on the delivery platform creates useful data. All data relating to participant registration, attendance, quiz scores, in class activities, homework submission, and grades assigned should be held in a database. The database should allow;
- easy input form other data sources
- flexible report building
- export of data to other data repositories

Reporting on learning participant activity
The back-end database will provide information for various reports on participant activity. Some of the reports required are;
- Active participant users in the database
- Accesses into the platform, and average time spent on activities
- Number of classes, and hours of synchronous instruction by instructors

Reporting on learning platform use
The database will also provide reports on the overall use of the learning platform. Some of the reports required are:
- Total student hours connected

Consistent and supportive of standards for multimedia viewing
The Adaptive Learning platform will support multimedia viewing and streaming standards, and particularly those standards supported by the World Wide Web. All viewing of content should be from a standard Web Browser. All streaming of content across the network should use standard Web protocols. Emerging Web standards, like Real Networks streaming video, should be supported.

Situational adaptability
Most importantly, the Adaptive Learning Platform should support a rich variety of learning situations. This will include:
- Before class, asynch review of the class outline, the scheduled meetings, the reading assignments, and any homework assignments
- Asynch review of class and associated materials
- Before class testing
- Before and after class threaded discussion
- In class synchronous facilitated class lead by an instructor, attended by up to 30 participants, and also attended by subject matter experts
- After class review of synchronous lecture and activities by students that happened to miss the live class
- After class team or small group meetings.

Features and Skill Sets

The features of the Adaptive Learning Platform require a number of features, and a equal number of skill sets by the individuals deploying the system.

Content Deployment

The range of content should be supported by the Adaptive Learning System. Some of the content types are listed below.

- Textbooks and reference material in HTML format.
- A syllabus of async course specific material, and a way to navigate through that material
- A syllabus of sync course specific material, and a way to navigate through that material
- Audio recording of synch class lecture and Q&A, for play-back by students that missed the class
- Video authoring
- CBT authoring
- Quiz authoring

In addition to content authoring, content deployment requires the skills of Web master. All content and syllabus navigation pages need to be stored in a Web Server repository. This content repository should be separate from the delivery platform, and should be able to provide a view of the content to a variety of collaborative interactions.

Technical Support

Deploying the Content Web Server repository and the Adaptive Learning Platform will require the skills of server and network administrator. This individual will need to be skilled with NT Servers, and have knowledge of network connectivity and TCP/IP. Some of the technical support skills are:

- Set-up and configure an NT Server
- Set-up and configure a TCP/IP network, and have knowledge of firewalls and proxy servers.
- Trouble shoot server and network connectivity problems.

Instructional Design

Course subjects will be selected for delivery on the Adaptive Learning Platform. An instructional designer will need to outline the activities and flow of content that will comprise the course. This outline will include

- Asynch, self-paced study
- Synch class content and lecture outline
- Quizzes
- White board activities
- Breakout activities

Course Building

In addition to designing the flow of the course, and authoring the modules of content, an individual must package the content and flow into a complete course. This new skill typically requires some mix of web content authoring and instructional design.

Student and Course Management

The Adaptive Learning Platform will be used to provide instruction to thousands of participants. This will require significant activity involved with scheduling courses, registering students, and gathering post instruction data. This student/course management supervisor will need to be knowledgeable of databases, and importing and exporting data from one repository to another.

Instructor/Facilitator

New skills are required of the instructor/facilitator. Adaptive Learning Platform instructor must have skills in the following areas;

- Sound knowledge of the Web.
- Good facilitator skills
- Knowledge of a multimedia PC
- Excellent verbal skills approaching that of a radio talk show host.

Project Management

One person is required to lead and direct a team with multiple members and multiple skills. A balance of skills is required to make any deployment of network-based learning successful. Of the above skills already mentioned, none of them are default candidates for this lead position. The project leader should be an individual that can balance the various skills and requirements, and guide the project to success.

Key Elements of Success

There are a number of areas that have proven to be critical for a successful deployment of a learning architecture. The key areas are:

- Web-centered delivery
- A delivery platform that provides for all the Before, During and After class activities
- A delivery platform that is will integrated and easy to use
Areas of Avoidance

Areas of deployment have been noticed to

• Excessive time and expense with content authoring
• Lack of delivery platform scalability
• Too much software installation required on participant machine
Developing Web-based Performance Support Systems to Encourage Lifelong Learning in the Workplace

Joanna C. Dunlap, Ph.D.
School for Professional Studies
Regis University
U.S.A.
jdunlap@regis.edu

Abstract: Conventional training and electronic performance support system strategies which focus on meeting short-term performance requirements fail to prepare people to meet the ever-changing needs of today's complex workplace environment. Generative and intentional learning environments focus on the development of transferable, long-term, and higher-order skills that enable people to engage in lifelong learning activities. Influenced by generative and intentional learning environment strategies, a Web-based tool has been developed to empower people to build their own Web-based Performance Support Systems (WPSS) to support their learning, professional development, and performance in the workplace. Enabling people to develop their own WPSS accomplishes two goals: (1) people learn about the domain while they are locating, evaluating, and organizing resources to support their work activities and/or their lifelong learning activities, and (2) once the WPSS is completed it can be used to support performance and further professional development while working in that domain. In this way, the WPSS not only enables people to build a learning and performance resource that will provide them with immediate support and guidance, but also helps them develop structure, strategies, and skills for subsequent lifelong learning activities.

What do you do if...?

- Your company has just completed a major reorganization in which a number of number of positions — including yours — have been restructured and responsibilities reassigned. Now you are required to work on tasks you've not done before.
- You're a UNIX programmer for a company that has decided to replace its UNIX servers with PCs. Now, all new application development must be done for the PC platform.
- You've been a technical writer in your organization for three years. Now, in a move to reduce costs and build in quality assurance measures, instead of out-sourcing the desktop publishing of the documents and manuals you develop you will be required to "publish" the documents yourself.
- Your company has caught the World Wide Web bug and wants to implement a company-wide intranet. You've been assigned to convert the print-based Employee Handbook to an HTML document — by next Friday!

In a climate of rapid change, increasing innovation, emerging technologies, and proliferating knowledge, lifelong learning is a necessary professional development objective. In order to keep current, people have to be willing and able to continually "retool" their knowledge and skill base. Simply knowing how to use tools and knowledge in a single domain at a specific point in time is not sufficient to remain productive and competitive. People must apply tools and knowledge to new domains and different situations. This is especially true given our current climate of rapid change, increasing innovation, and proliferating knowledge; people are having to face new domains and novel situations with increasing frequency due to the information explosion [Nash 1994]. The need to be a continuous learner is especially apparent in domains influenced by scientific and technological advances; these advances cause knowledge and skills to become obsolete overnight.

To deal with today's complex workplace environment, employers need personnel who possess contemporary skills and knowledge, and are willing and able to proactively update their abilities to meet the ever-changing needs of the organization. Employees who are able to keep up with the information explosion are valuable assets; employees who fail to "grow with the flow" are restructured out of their positions. Therefore, lifelong learning is a necessary professional development objective.
learning is essential to staying current, competitive, productive, and innovative in today's workplace, and therefore employed and in-demand.

Following the prescriptions of the generative and intentional learning methodologies which promote the development of metacognitive and self-directed learning skills to support lifelong learning activities, a Web-based development tool was created. This tool was designed to help people in a workplace environment generate their own, individualized Web-based performance support systems (WPSS) to address the concerns described above by encouraging and providing a supportive structure for lifelong learning activities.

**Lifelong Learning Defined**

Lifelong learning is any purposeful learning that an individual engages in throughout the life span...it is an activity engaged in...to gain greater individual self-fulfillment and to improve the quality of life for the individual and the emerging society. To achieve this requires moving away from a view of learning that is controlled outside the individual to a view of learning that is internally controlled by the individual. (Overly, McQuigg, Silvernail, & Coppedge, 1980)

The knowledge explosion requires professionals to engage in lifelong learning if they intend to stay current — let alone evolve, advance, and remain competitive — in their profession. Therefore, lifelong-learning skill development is imperative if people are expected to learn over the full expanse of their professional lives. Unfortunately, some of the people that most need lifelong learning skills — those with careers in ill-structured, complex professions — are not developing them during their formal education. Regarding the lack of lifelong-learning skill development in schools, Walton and Matthews [Walton & Matthews 1989] state, “Some [professionals] from...schools with the usual type of curriculum behave as if they had been immunized against further learning, and many [professionals] often do not continue to learn sufficiently.” In order to better prepare for lifelong learning activities, learners must be exposed to learning activities that require them to take on and develop many of the responsibilities normally afforded to educators. “We teach most effectively when we help our students learn how to learn...not what to think and make and do in [the current year]; but how to think and how to learn for those years of life and profession than lie ahead” [Nash 1994]. To achieve this requires moving away from a view of learning that is controlled outside the individual — by a teacher, trainer, instructional designer, or subject matter expert — to a view of learning that is internally controlled by the individual [Overly et al. 1980]. Therefore, in order to internally control the learning process, the development, and subsequent successful application, of two skill areas -- metacognition and self-directedness — is required.

**Metacognition**

Von Wright [Von Wright 1992] defines metacognitive skills as “the steps that people take to regulate and modify the progress of their cognitive activity: to learn such skills is to acquire procedures which regulate cognitive processes.” Glaser [Glaser 1984] describes metacognitive or self-regulatory skills as knowing what one knows and does not know, predicting outcomes, planning ahead, efficiently apportioning time and cognitive resources, and monitoring one’s efforts to solve a problem or learn. More specifically, metacognitive skills that are required for lifelong learning include [Ridley, Schutz, Glanz, & Weinstein 1992]:

- the recognition of content and skill limitations;
- the ability to set goals and create action plans based on those defined limitations;
- the ability to activate the appropriate prior knowledge to achieve set goals;
- the ability to accurately assess progress in learning and task performance and effectiveness of learning resources selected;
- the awareness of what still needs to be completed to reach a set goal, and how best to allocate time and resources; and
- the ability to modify strategies, tactics, processes, and resource selection based on the needs of the task at hand.
Because metacognition involves these self-regulatory skills, it can have a positive impact on problem solving ability and the transfer of knowledge across domains and tasks if developed during instruction [Bereiter & Scardamalia 1985] [Bransford et al. 1986]. In fact, if not developed, students have difficulty recognizing when they have failed to adequately meet learning goals or complete tasks [Bransford et al. 1986]. Since these are skills utilized by successful practitioners and experts [Chi, Feltovich, & Glaser 1981] [Bransford et al. 1986], adequately developed metacognitive ability is needed in order to not only engage in effective problem solving and reasoning activities, but also lifelong learning.

**Self-directedness**

Self-directed learning is:

...the process in which individuals take the initiative, with or without the help of others, in diagnosing their learning needs, formulating learning goals, identifying human and material resources for learning, choosing and implementing learning strategies, and evaluating learning outcomes [Knowles 1975].

The domain of medicine provides a perfect example of self-directedness. When dealing with real patients, the doctor has to begin assessing the patient’s condition before having all of the data necessary to evaluate, diagnose, and treat the patient. Characteristically, the patient provides the doctor with fragments of information (“My stomach hurts. I can’t hold any food down. No one else in my family is experiencing any problems.”). The rest of the information needed to solve the patient’s problem comes from the study of a variety of other resources: patient and family history, laboratory results, x-rays, other doctors’ opinions, past experiences, similar cases in the case file, and current research findings on new diagnostic and treatment procedures. These skills are described as “self-directed learning skills” [Barrows 1985] [Barrows 1986].

Barrows [Barrows 1995] defines the process of self-directed learning as utilizing the following skills to solve a problem or fulfill a learning requirement:

- the ability to identify and define a problem/learning need;
- the ability to identify, find, use, and critique resources for solving the problem or meeting the learning requirement;
- the ability to capture and apply information from resources to the problem or learning need; and
- the ability to critique information, skills, and processes used to solve the problem or meet the learning requirement.

Staying abreast of new innovations, research, techniques, and information is a prerequisite for successful decision-making and problem-solving on-the-job. Therefore, professionals need to develop lifelong learning skills, specifically metacognitive and self-directed learning skills, if they intend to stay current in their fields.

**Organizations and Professional Development**

Although employees' ability to engage in lifelong learning has a direct impact on an organization's effectiveness in today's ever-changing marketplace, the development of the skills needed to engage in perpetual learning activities has been neglected by many employers. Unfortunately, many organizations rely on short-term solutions, such as conventional training and performance support tools.

**The Conventional Training Solution**

How are professional development activities typically addressed? We often see trainers imparting knowledge and procedures to trainees using canned, inflexible instructional materials which often do not reflect the true complexity of an ever-changing work environment. [Unfortunately, this is the case whether we are describing an instructor-led environment, computer-based training (CBT), or Web-based training (WBT) (which is often just CBT repurposed for the Web).] After the training activity is over, employees struggle with applying what
they learned from their training experience to the demands of their jobs. Not only did the conventional training solution not accurately represent the on-the-job performance requirements, but it did not prepare the employees to:

- transfer the knowledge and skills to their specific job requirements,
- extend the knowledge and skills presented during training to address increasingly complex job requirements, or
- update the knowledge and skills presented during training when their job requirements change or the knowledge and skills change.

In other words, what is missing from the equation is the development of domain-specific lifelong learning skills so those employees can actively transfer, extend, and update the knowledge and skills acquired during training. So, employers have looked for other professional development solutions that address this problem. One solution that has presented itself is electronic performance support systems (EPSS).

The Electronic Performance Support Systems Solution

Although redefined and revised over the last few years, the term electronic performance support system refers to an integrated database of information, tools, learning experiences, resources, and guidance/advice designed to help people learn how to perform a task just-in-time or on-demand with limited conventional training support [Gery 1991] [Raybould 1995]. Addressing the failings of conventional training, electronic performance support systems have been utilized as alternatives and supplements for conventional training solutions.

However, the problem with conventional training is also, in part, the problem with EPSS. EPSS products are typically developed by instructional designers or performance technologists working with content experts. All of the tools, references, job aids, and tutorials are created to meet the generic needs of all the individuals who will access the EPSS. EPSS limits individualization because it assumes that everyone who needs to access the EPSS has the same performance issues, learning needs, and learning preferences. In addition, like with conventional training solutions, all of the higher-order thinking, problem-solving, and decision-making that goes into creating the “content” of an EPSS — all of the activity that helps people develop domain-specific lifelong learning skills — is done by the development team. So, again, the issues of transfer, extension, and updating are not effectively addressed by EPSS.

So, how do we develop lifelong learning skills?

In order to develop lifelong learning skills, the learners — as opposed to the instructor or development team — need to be directing and driving the learning process and activities based on their learning and performance needs. Two instructional methodologies that specifically address the development of lifelong learning skills are generative learning and intentional learning.

Generative Learning Environments

Generative learning environments require students — individually and collaboratively — to be responsible for creating, elaborating, and representing domain knowledge in an organized manner [Cognition and Technology Group at Vanderbilt 1992] [Hannafin 1992] [Scardamalia et al. 1989] [Scardamalia & Bereiter 1991]. Through this process of “generating” knowledge, instead of passively receiving information, learners develop structure, strategies, and habit for lifelong learning.

Generative learning environments require students to take responsibility for determining what it is about a particular domain they need to know, and then direct their activities accordingly to effectively research, synthesize, and present their findings. Schank and Jona [Shank & Jona 1991] describe a generative learning environment in their discussion on the research method of teaching. Under the research method of teaching, students are asked to research a particular topic and then present their results to others (the class, a collaborative
In this way, students are taking over the responsibility of information gathering and synthesis and dissemination/presentation from the teacher. For this teaching method to lead to successful learning, students need to be allowed to select their own topics to research and report on, so that they have a real interest in proceeding with the assignment and have more control over their learning. Because the learning is student-directed, where each student makes choices and takes responsibility for those choices, the learning is more meaningful; "...in general, material that is organized in terms of a person’s own interests and cognitive structures is material that has the best chance of being accessible in memory" [Bruner 1961]. In addition, because students are responsible for selecting a topic, developing a question to research, making decisions about how to gather information, analyzing and synthesizing information, etc., they are engaging in activities that help to develop high-level thinking and problem solving abilities.

In a generative learning environment, content and skills are learned within a context that is similar to the context in which the knowledge will be applied and performance is scaffolded by a social structure that supports them during learning and problem-solving activities. Contextualization of learning and social support during learning help prepare people to transfer what they have learned to new situations and avoid the pitfalls of inert knowledge. Generative learning environments involve learners in a particular set of instructional strategies and tactics to have the desired cognitive effects on learning:

- **Learner responsibility.** Using self-directed learning activities, learners are encouraged to be responsible for their own learning.
- **Dynamic, active learning.** Learning is essentially an act of active construction on the part of the student [Resnick 1989]. By requiring learners to take on the roles of the profession and engage in self-directed learning, learners experience the knowledge construction process.
- **Authentic learning.** Because learning is embedded in realistic contexts, learners acquire content and skills through the resolution of problems. Because the problems learners work on refer to concrete situations or events in the real world, knowledge gain is situated and, therefore, more easily retrieved when needed [Brown et al. 1989].
- **Collaboration.** Through collaborative group work and the accessing of a variety of resources, learners experience and develop an appreciation for multiple perspectives.
- **Reflection.** One of the key educational outcomes of generative learning environments is knowing how we know: the ability to (1) analyze personal knowledge construction processes and (2) articulate why and how a learning task was completed or a problem was solved [Honebein 1996]. This self-awareness of the knowledge construction process is encouraged during reflection activities embedded in the problem-solving process.

### Intentional Learning Environments

Intentional learning refers to the "cognitive processes that have learning as a goal rather than an incidental outcome" [Bereiter & Scardamalia 1989]. Intentional learning encourages students to take "an intentional stance toward cognition" [Scardamalia & Bereiter 1991], which means that learners must learn how to monitor and be aware of their own learning processes, and take responsibility for pursuing desired and/or required learning outcomes. Intentional learning is learning that is actively pursued by and controlled by the learner [Resnick 1989]. Palincsar and Klenk [Palincsar & Klenk 1992] describe intentional learning as an achievement resulting from the learner’s purposeful, effortful, self-regulated, and active engagement. By encouraging students to take "an intentional stance toward cognition", intentional learning helps students learn how to not only monitor and be aware of their own thinking and learning processes (i.e., metacognitive skills), but also to take responsibility for pursuing individually-determined learning goals (i.e., self-directed learning) — the "cognitive processes that have learning as a goal rather than an incidental outcome" [Bereiter & Scardamalia 1989].

The objective of an intentional learning environment is to create a supportive structure in which students can engage in cooperative knowledge building as they move towards greater autonomy. Addressing students’ need for higher-order abilities in thinking and learning, intentional learning helps students develop the general metacognitive and self-directed learning skills that facilitate autonomous lifelong learning [Palincsar 1990] [Scardamalia et al. 1989]. These skills are developed by engaging students in situations in which they need to
build a body of knowledge based on their learning interests and needs using a variety of information resources. While building the knowledge base, students practice tactics for making claims, collecting evidence in support of their claims, and evaluating and responding to counterarguments from peers and teachers. Through this knowledge-building process, students reflect on specific aspects of their learning and thinking processes, and consider the effects of collaboration on each other's learning, such as the impact of opinion, bias, controversy, debate, and negotiation [Glaser 1991].

An example of a computer-mediated, intentional learning environment is the Computer-Supported Intentional learning Environment (CSILE). The goal of CSILE is to support students in the purposeful, intentional processing of information [Scardamalia et al. 1989] [Scardamalia & Bereiter 1991]. Using CSILE, students are supported in the construction of a shared knowledge base, representing and organized the domain in ways that can be understood and utilized by others interested in the domain. In other words, instead of accessing information from a pre-existing database that was structured, organized, and filled in by someone else, students engaged in CSILE create their own knowledge base based on what they want to learn and on how they want to structure and organize the information to be an effective resource for other learners.

Generative and intentional learning environments encourage students to construct their own meaning, perception, understanding, and knowledge. Through the process of creating, elaborating, and representing their own knowledge, these learning environments utilize instructional strategies such as collaboration, knowledge construction, reflection, and self-directedness to promote the development of lifelong learning skills and strategies, as well as a predisposition to lifelong learning activities.

**Throw them all together and what do you get?: Web-based Performance Support Systems (WPSS)**

Influenced by generative and intentional learning methodologies as well as the EPSS technology, I have developed a Web-based tool empowers learners to build their own Web-based Performance Support Systems (WPSS) to support their learning, professional development, and performance within specific domains. Similar to electronic performance support systems (EPSS), a WPSS uses the Web to provide on-demand access to integrated information, guidance, advice, assistance, training, and tools to enable high-level job performance. In fact, using the Web to create performance support systems is a perfect fit because the Web is actively used by professionals as a forum for the distribution of current and up-to-date references, instruction, and guidance.

By creating a structure that supports individualized and collaborative knowledge building by the people who will actually be using the knowledge, the higher-order thinking, problem-solving, and decision-making regarding the selection and utilization of appropriate learning materials and performance support is done by those who can get the most out of the process. In addition, because these activities occur in the workplace and are driven by the needs of the job at hand, the learning activities are contextualized, authentic, and meaningful. Enabling people to utilize an easy-to-use tool to develop their own WPSS accomplishes two goals:

1. they learn about the domain while they are locating, evaluating (which requires utilization of resources), and organizing resources to support their job performance activities and/or their generative and intentional learning activities; and
2. once the WPSS is completed it can be used to support performance and further professional development while working in that domain.

In this way, the WPSS not only enables learners to build a learning and performance resource that will provide them with immediate support and guidance, but also helps them develop structure, strategies, and skills for subsequent lifelong learning activities.
Overview of WPSS Development Tool Components

The WPSS development tool helps employees — collaboratively and as individuals — organize, assess, and utilize Web-based resources. In order to build an effective WPSS, the development tool enables people to organize Web resources into a variety of self-determined categories. Categories may include:

- cue cards: brief definitions, reminders, directives, job aids, best practices
- computer-based instruction: tutorials, case studies, practice activities
- wizards: intelligent demonstration/application functions; assistance
- coaches: response sensitive correction and feedback
- mentors: individualized responses to questions from experts in the field
- practitioner forum: access to other practitioners in the field
- examples
- tools

In order to build a WPSS that meet individualize, specific learning and job performance needs, people engage in a number of generative and intentional learning activities including:

- determining their learning needs and goals
- developing a plan for action for finding resources to help fulfill those goals
- researching Web resources that meet the appropriate needs
- utilizing Web resources in order to evaluate usefulness, difficulty level, strengths and weaknesses
- updating links to Web resources when appropriate
- responding to other learners' comments regarding WPSS contributions
- developing Web resources via HTML pages and threaded discussion forums

In other words, employees practice and develop the very skills and strategies needed to engage in lifelong learning activities while they are learning domain-specific content and skills needed for their jobs.
**Animation Shareware**

**Level:** Intermediate  
**Description:** This site provides shareware that you can use to display animations.  
**Strengths:** There are several players including the AA:WIN which I demonstrated on Monday. I also found an advanced program (PowerFLic) which has many more features than AA:WIN. If you have any interest in multimedia animations for your WBI, this is a must-see site.  
**Weaknesses:** It has very little supporting information, but it works and you can get the shareware.  
*Anthony Mostek, created 10/1/1997*

**Microsoft's NetMeeting**

**Level:** Beginner  
**Description:** Microsoft NetMeeting is a web-based communication tool for people who are deaf or hard-of-hearing. You can use NetMeeting 2.0 to communicate more effectively in real-time with others in the workplace, the classroom, and the home—gaining substantial benefits over using traditional TTY devices. Read all about our benefits for users who are deaf or hard-of-hearing.  
**Strengths:** It's free, and it is a great communication tool that can be used for web conferencing, online seminars, real-time classroom instruction. Has chat-like and whiteboard-like features. Allows people to show each other documents and work on them together.  
**Weaknesses:** I'm still thinking about it.  
*Joni Dunlap, created 10/8/1997*

**Figure 1:** Sample categories, corresponding reflective entries, and “add a resource” screen
Figure 2: Example of advice and guidance features, collaborative knowledge construction

Examples of the WPSS in Use

Although still in a formative stage with enhancements being added all the time, there are a number of examples of the WPSS tool in action. These WPSS examples can be viewed for examination purposes only via the following URL:

http://www.cudenver.edu/~jdunlap

[Note: In order for the WPSS to function properly, your browser must accept cookies and have JavaScript enabled.]
Conclusion

Because of the failure of conventional training and performance support environments to meet the perpetually changing needs of today's working professionals, the application of generative learning and intentional learning strategies are vital to promote the development of the lifelong learning skills and strategies needed to stay current and remain competitive and innovative. A Web-based development tool was designed to enable people to develop their own Web-based performance support systems. The activity of building a WPSS helps people learn about a domain, construct a knowledge base to support their future performance and professional development in that domain, and develop the skills, strategies, and structure needed to engage in the type of lifelong learning activities that will help them stay current in their professions.

The 3Ls of Introductory Web-based Instructional Design: Linking, Layout, and Learner Support

Abstract: If you are just starting to develop Web-based instruction, you may be wondering how to make decisions regarding the overall look-and-feel of your Web site. If this is the case, then understanding how the 3Ls — linking, layout, and learner support — of Web-based instructional design can help you develop an effective structure for your instructional products. Consistent with the hypermedia learning environment design guidelines provided by Kommers, Grabinger, and Dunlap [Kommers et al. 1996], the following WBI design guidelines will provide some guidance for laying the foundation for your WBI environments.

If you are just starting to develop Web-based instruction (WBI), you may be wondering how to make decisions regarding the overall look-and-feel of your Web site. If this is the case, then understanding how the 3Ls -- linking, layout, and learner support -- of Web-based instructional design can help you develop an effective structure for your instructional products. The guidelines -- or heuristics -- presented in the paper will give you a foundation for doing basic Web page design; in fact, I provide these guidelines to my students in introductory HTML courses to give them a starting point. The basis for these guidelines are four chapters cover topics related to the design of hypermedia learning environments [Kommers et al. 1996]; I revisited and adjusted the hypermedia design guidelines to better reflect design requirements of Web environment. Although not empirically based, the following WBI design guidelines (presented more as a job aid or performance support tool) will provide you will a practical way to begin thinking about WBI design as you begin developing your own WBI environments.

Nodes and Links: Macro Level Design

Nodes and links are the basic building blocks of Web and other hypermedia systems -- they are what allows learners to maneuver through a Web site or move from one Web site to another with the click of a mouse button; the node/link mechanism is what makes the Web a hypermedia technology. Nodes are information units within a Web site. Links are the way these information units are physically and conceptually connected and interrelated. Web designers use the depth and breadth of content coverage to determine the links and nodes needed to meet the learning and information dissemination objectives of the Web site.

More About Nodes

How Nodes Work

Web nodes may be accessed, if supported with the appropriate links, in any sequence that meets the learning and/or information needs and interests of the learners. Rather than coming across as a continuous linear flow of information, such as that found in books or videotapes, Web sites chunk information into nodes and establish connections between the different nodes. This is referred to as modularizing the information on a Web site. Modularization enables users of Web-based instruction (WBI) to determine for themselves which node to access next. It may be that a node consists of an elaboration, an opposing point of view, an example, or an illustration. In a typical Web-based application, learners navigate through the program via links because they want to get from one segment of information to another—one node leads to another. For example, one learner engaged in a Web site covering English history may go to a node on the reign of King James I and see a reference to the works of William Shakespeare. This reference may encourage the student to proceed to a node that provides information on the works of William Shakespeare. Another learner viewing the same node on King James I may be intrigued by a reference to Mary, Queen of Scots and choose to access that node instead. Therefore, by modularizing the information in a Web site, learners are able to access information more efficiently. This kind of flexibility provides learners with opportunities to explore a wider variety of information on the topics that they are studying.
Determining Nodes

Determining the nodes needed for your Web-based instructional site begins with defining and focusing on your content area. To determine what will be included in the WBI, you must:

- determine the purpose of your WBI (based on learning objectives, audience, outcomes, etc.);
- decide how much information will be covered and how it needs to be covered to meet the learning objectives; and
- in the case of a problem-based application, you may need to determine the information necessary for the learners to solve a problem or to participate in a simulation.

After you determine what should be included in the Web site for it to meet the objectives, then comes the tricky part of determining how to organize that information into coherent, modularized, easy-to-digest pieces. This is no easy task, considering that most Web sites rely on an abundance of information in order to fulfill the information and/or learning needs or interests of the target audience. But how do you decide how the information should be chunked?

Node Size

The easiest way to think about nodes when trying to determine size is to think of them as separate pages or screens, each containing one idea or concept. Nevertheless, the size of a node raises interesting problems in a Web environment. A book gives learners direct physical reference cues to its size and to the location of information relative to the rest of the information in the book—visual and touch comparisons are easily made. On the Web, however, the next node always replaces the previous node. The “next” node may be from an earlier or later part of the WBI. It may or may not be in direct sequence. The physical anchors so important in the print medium (i.e., thickness of the book, position within a chapter, number of pages) disappear and so does our ability to make comparisons and keep track of where we are at any given point. It is also important to remember that people do not care to read a great deal of text from computer screens, so information must appear manageable and brief.

Presentation Format

Within each node type, the format of the information can vary significantly, depending on the best way to represent that information. In fact, many different forms may make up one node: text, graphics, animation, video, or audio.

More About Links

Characteristics of Links

Web-based applications connect nodes of information through links—one node is connected to other nodes via links. Links are the essence of Web-based applications. A well-designed set of links reveals information and helps learners attain their objectives. A poorly designed set of links misinforms learners or inadvertently hides things from them.

On the Web, links are typically represented in two ways: different colored text or an imagemap (i.e., a hypergraphic or photograph that engages a link). Learners know that a link is available when they pass their mouse cursor over the colored text or imagemap and the cursor changes from an I-beam to a pointer or from a pointer to a finger-pointing hand. In addition, Web links usually use a visual cue to indicate the activation of a link, such as
changing color. For example, the current color convention for text-based links is to use blue to indicate which text is an active/available link, red to indicate that you have successfully clicked on an active link, and purple to indicate a previously visited link.

**Kinds of Links: Contextual Links**

Contextual links join various parts of a Web-based instructional system to enable learners to find the information they need. There are two types of contextual links: sequential and relational.

**Sequential Links.** Sequential links create a linear path among a set of related nodes. A set of sequential links is a predetermined path through a Web site that directs learners to either go to the next node or the previous node. They are most easily represented by the ever-present left and right arrows. The caveat associated with sequential links is that you may direct learners to go linearly through a series of nodes, but they don’t have to due to the hyper nature of the Web.

Some Web sites provide default routes through the site represented by clickable arrows or table of contents. Learners who do not wish to make their own way through a Web site may elect to use a path defined by the site’s designer. A linear path is especially useful when a learner should view each node in a particular sequence in order to better understand the content.

**Relational Links.** Relational links enable learners to pursue information tied together by common elements, although not in a sequential manner. There are three main kinds of relational links: associative, elaborative, and hierarchical.

**Associative Links.** An associative link searches for information related to (or associated with) a specific node, word, or phrase. A set of associations creates a web or network of different kinds of related information that can be accessed from multiple points within the Web site. Associative relationships are often defined more by the needs of the learners than by the content. They permit learners to jump across different nodes and Web pages to find information pertinent to their needs and interests. Associative links are significant parts of most WBI systems because they provide access to information in ways that were not planned by the designer. The goal behind the creation of associative links is to emulate the way people think. We do not think or process information in a linear manner; instead, we take in information simultaneously from a variety of inputs. The concept of hypermedia environments was developed to allow users to follow their own associations. It is these kinds of links, that if well-designed, provide learners access to all the information in a Web-based learning environment. Associations can be created by using keyword searches or by setting up links based on a variable setting which represents a learner’s actions. The primary advantage of associative links is flexibility: the more flexible the links, the more powerful the system. Associative links provide a means of individualization—a way of making information more personally meaningful.

**Elaborative Links.** Although the relationship between two associated nodes may be defined either by context or by learner goal, the relationship between two elaborative nodes is context dependent. An elaborative link is a special kind of sequential link that provides more complex and more detailed information on a specific topic. An elaborative series of links differs from a sequential series of links because learners are free to decide whether or not to enter the elaborative series and, once the series is entered, how deep to go.

**Hierarchical Links.** A hierarchical structure links information in a progressive manner, illustrating rank or level of importance. Hierarchical links provide a good overall organizing structure for Web-based environments that deal with several levels of classifications, such as diagnosis within a class of diseases, explanation of genus in biology, or description of an organizational structure. They differ from elaborative links in that the path down through the
hierarchy is not usually optional: For learners to understand the hierarchy, they must continue along the complete path. Therefore, hierarchical links are highly structured, leading learners through a logical path with a predetermined end.

<table>
<thead>
<tr>
<th>Nodes</th>
<th>1</th>
<th>Where possible, modularize information on each Web page in the site so that each node fits easily on one screen or window.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>2</td>
<td>Label sections of the Web page to describe the kinds of information they contain.</td>
</tr>
<tr>
<td></td>
<td>3</td>
<td>If possible, avoid forcing learners to scroll through screen after screen of text. Exception: lists (like a glossary) and indexes.</td>
</tr>
<tr>
<td></td>
<td>4</td>
<td>Use different backgrounds to distinguish among different node media formats.</td>
</tr>
<tr>
<td></td>
<td>5</td>
<td>If resources are available, use the node form that most appropriately represents the information contained in the node.</td>
</tr>
</tbody>
</table>

**General Links**

1. Avoid the "click here" syndrome. For example, when you want people to know that your name is a link for sending you email, make your name the actual link.
2. Avoid too many text-based links in a paragraph of text. Too many links can distract from the overall message trying to be conveyed.

**Sequential Links**

1. Use arrows when the option of proceeding through a hyperertext in a sequential path is necessary. When it is appropriate to design a sequential path through a hyperertext (e.g., presenting chronologies or logical step-by-step processes), provide users with left and right arrow keys informs them that they are proceeding through the information in a sequential fashion. (Note: The use of left/right arrows may be culturally bound. Societies that read from top to bottom may be more comfortable with up/down arrows.)
2. When using left/right arrows to proceed through several pages of information related to one idea, remove the left arrow from the first page/screen and the right arrow from the last page/screen.
3. In a multiple section or page sequence, use the section or page x of y strategy to tell learners how many pages are in the sequence and where they are in the sequence.

**Associative Links**

1. To remind learners of where they are within a Web site, provide extensive verbal/textual support. Web pages should always include headings to indicate what the topic of the page is and to which section it belongs. Extensive use of menu and content lists are also helpful.
2. Where there is a sequence representing critical information, build the sequence into the associations so the user does not miss part of the sequence. In other words, use sequential strategies.

**Elaborative Links**

1. Use elaborative links to present information in a progressively deeper manner (or in a progressively less detailed manner).
2. Make learners aware of the depth to which a sequence of elaborations goes (e.g., "level 1 of 5").

**Hierarchical Links**

1. Hierarchies are highly structured. Keep users aware of that structure with verbal and graphic support.
2. Use up/down arrows to indicate the path through a hierarchy. Indicate which level of the hierarchy a learner has entered (e.g., "level 1 of 5").

**Figure 1. Design Guidelines for Nodes and Links**

**Page/Screen Design Issues for Web Sites: Micro Level Design**

The objective of effective WBI is to communicate information and ideas to a specific audience. Thus, a Web site requires more design consideration regarding the display of text and graphics on a page than a work of fiction such as a novel or short story. Novels maintain reader involvement with literary devices such as plot, story, characterization, theme, and dialogue. In WBI, learner involvement through literary devices is not always possible or desirable. While fiction gets by quite well with page after page of one word beside another, WBI uses more than words. Web-based instructional programs are for learning, and require different techniques to maintain learner involvement and encourage cognitive processing of content.

As you probably have already noticed, Web-based instructional applications tend to rely heavily on the written word to present information. Even Web sites using a large number of sophisticated graphics and animation combine those graphic forms with written words. All of this information is presented by combining text elements, images, and graphic devices (e.g., lines, shading, boxes) in an empty space to present information. The combination and arrangement of text and graphical elements in meaningful ways are problems of message design and layout.

Some of the Web page design elements which require consideration include:

<table>
<thead>
<tr>
<th>type size, style, weight</th>
<th>contrast</th>
<th>header, body, footer</th>
<th>animation</th>
</tr>
</thead>
<tbody>
<tr>
<td>word spacing</td>
<td>foreground color</td>
<td>tables, frames</td>
<td>special effects</td>
</tr>
<tr>
<td>leading, kerning</td>
<td>background color</td>
<td>fields, forms</td>
<td>graphic resolution</td>
</tr>
<tr>
<td>rules</td>
<td>background texture</td>
<td>buttons, icons, imagemap</td>
<td>text-to-graphic balance</td>
</tr>
<tr>
<td>headings</td>
<td>letter color</td>
<td>pop-up windows, alerts</td>
<td>shading</td>
</tr>
</tbody>
</table>
However, none of these elements matter unless they are organized and displayed to promote legibility.

Legibility

Techniques used to facilitate learner involvement with WBI fall within the domain of legibility. Legibility is the influence of the total format of the display on the ability of the learner to understand the text. The words “total format” are emphasized because we often tend to think of legible text as that which can be seen. However, visibility is only one part of legibility. Legible text possesses two primary design qualities which designers must work to enhance: visibility and recognizability. You have to work, to some extent, with these three qualities to facilitate retention of information by encouraging deeper learner involvement.

Visibility

Visibility refers to the perceptual detectability and discriminability of the printed character. Visibility includes characteristics related to the clarity of the image, crispness of type, and contrast between foreground and background. A visible display presents symbols clearly and accurately. Visibility variables interact with the eyesight of the reader, as well as with conditions external to the reader such as lighting. For example, a Web page with poor contrast between letters and background fails the visibility test of legibility, because without adequate contrast the shapes of the letters would stand out from the background. Another important factor in visibility is the size of the text. Letters that are too small may not be perceived for what they are. Visibility is a prerequisite for recognizability, for without adequate visibility the learner fails to recognize the meaning of individual symbols on the Web page.

Recognizability

Recognizability refers to the ability of a Web page to convey the meaning of letters, words, and objects. A recognizable Web page presents meaningful symbols so the meaning of each symbol can be identified and understood. Recognizability interacts with both text elements and reader characteristics—the background or prior knowledge of the reader. For example, a first grader may be able to recognize each of the letters on this page, but would have difficulty recognizing the meanings of all of the word symbols on this page, even though they are quite visible. Additionally, a screen display in Russian may be quite visible, but it would not be recognizable to most North Americans because most North Americans would not be able to perceive the meaning of each symbol or the words made up by the symbols. Format variables that effect recognizability include type style, word spacing, leading (amount of space between lines), and kerning (amount of space between letters).

Basic Typography

After Gutenberg invented the printing press, the primary focus on the science of typography was the creation of visible and perceptible documents. The principle typography factors related to the visibility and perceptibility of a document include type size, type style, line length, leading, case, and justification. A great deal of research has been performed with these type variables in the printed page world leading to accepted standards. Generally, research into the application of these standards to computer monitors has supported the findings of print researchers, as well as have generated research findings regarding characteristics unique to the use of screens (for example, see Grabinger, 1993) [Grabinger 1993]: contrast, resolution, brightness levels, color, font style, and visual fatigue. These findings include:

- Use only a few simple, familiar, and portable type styles. Use both lower and upper case text.
- Use type sizes appropriate for the audience and the amount of reading to be done. Be consistent in their use.
- Keep line lengths reasonable. Generally, use single spacing between lines of text.
- Left justification is adequate. Use full justification only when proportional spacing is available.
Macro Level Design: Site/Page Layout

The macro level organization of a Web page refers to the general layout. The constructs of organization and visual interest provide some heuristics for arranging text elements to create Web pages learners want to read and study from. Instead of wondering about each individual text element, you can focus on arranging whatever elements you want to use to create organized, structured, and visually interesting Web sites. Storyboarding is a great way to begin making Web site and page layout decisions. Use accepted aesthetic publication guidelines. Strive for balance, harmony, and simplicity. A good reference for these guidelines is Yale C/AIM Web Style Guide (http://info.med.yale.edu/caim/manual/).

<table>
<thead>
<tr>
<th>Site/Page Layout: Macro Level</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Begin macro level organization of the Web page by dividing the page into functional areas appropriate to desired tasks and consistent with the knowledge level of the learners. Use a header, body, and footer structure. Maintain this level of organization with only minor changes throughout the Web site.</td>
</tr>
<tr>
<td>2</td>
<td>Maintain consistent internal margins and distribute the bulk of the white space around the exterior margins of the Web page to help create a sense of balance. Distribute light and dark areas and objects evenly around the Web page.</td>
</tr>
<tr>
<td>3</td>
<td>Create a separate area to indicate important status and orientation information: location, page, topic, subtopic, objective, and so on.</td>
</tr>
<tr>
<td>4</td>
<td>Keep any navigation controls in a separate area. Consistently use the same area of the Web page for the controls.</td>
</tr>
<tr>
<td>5</td>
<td>Use graphic devices including boxes, shading, color, white space, and textures to organize the functional areas and set them apart from each other on the Web page.</td>
</tr>
<tr>
<td>6</td>
<td>Avoid Web pages that are solely text without any graphic devices or illustrations. However, keep Web pages simple and avoid too many graphical devices. They can be distracting and take the learner's attention away from what is really important.</td>
</tr>
<tr>
<td>7</td>
<td>Use tables or preformatted text (although using tables is more flexible) to create a unified, clean, structured layout for your Web site.</td>
</tr>
<tr>
<td>8</td>
<td>Use frames with caution. Unless implemented well, frames can cause some navigational confusion. In addition, frames can eat up a lot of a screen’s real estate, making the text in each frame more difficult to read. If you are using frames to create a divided layout, consider using tables to accomplish the same requirements.</td>
</tr>
<tr>
<td>9</td>
<td>When using frames, enable learners to also access the site in a non-frame format.</td>
</tr>
</tbody>
</table>

**Figure 2.** Macro Level Design Guidelines for Web Site and Page Layout

Micro Level Design: Site/Page Layout

Micro level organization of the Web page refers to structural techniques to reflect the organization of the content. The constructs of structure and organization provide some heuristics for arranging text elements to create Web pages that help learners organize the content. Micro level organization refers to how the content is presented within the overall macro level design.

<table>
<thead>
<tr>
<th>Site/Page Layout: Micro Level</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Remember that the audience is looking at your Web site on a computer screen. Select font sizes that are large enough to easily read for better visibility. Use a sans serif font for better legibility.</td>
</tr>
<tr>
<td>2</td>
<td>Keep one idea per Web page.</td>
</tr>
<tr>
<td>3</td>
<td>Use margins to improve readability of pages.</td>
</tr>
<tr>
<td>4</td>
<td>Use indent to indicate hierarchically related subject material.</td>
</tr>
<tr>
<td>5</td>
<td>Use closely related items within a box, table, or a common background color or shading. Use the same graphic devices, as well as white space, to separate unrelated or contrasting ideas.</td>
</tr>
<tr>
<td>6</td>
<td>Use headings as organizers.</td>
</tr>
<tr>
<td>7</td>
<td>Use directive cues (i.e., bold, italic, underlining, inverse) to emphasize important terms or ideas.</td>
</tr>
<tr>
<td>8</td>
<td>If using background textures, keep in mind the “mood” you are trying to create. Also, if the background is too elaborate, text can be difficult to read.</td>
</tr>
<tr>
<td>9</td>
<td>If using imagemap for navigational purposes, consider employing an image that reflects the metaphor and/or content of the site.</td>
</tr>
<tr>
<td>10</td>
<td>If you use columns to organize text and graphics, don’t let the columns be longer than the screen length to avoid excessive scrolling.</td>
</tr>
<tr>
<td>11</td>
<td>Set up comparison/contrast situations in a side-by-side columnar arrangement.</td>
</tr>
<tr>
<td>12</td>
<td>Don’t incorporate JavaScript, applets, animated gifs, or sound files unless there is a clear purpose. These elements can be time-consuming to download. If you want to include them without causing trouble for users, give users the power to decide if they want to see or hear them.</td>
</tr>
</tbody>
</table>

**Figure 3.** Micro Level Design Guidelines for Web Site and Page Layout
Learner Support Strategies for Web Sites

Hypermedia applications, such as Web-based instructional sites, are often highly complex owing to the flexibility of environments in which they can be used and the depth and breadth of information they make available to learners. This level of complexity can leave users feeling confused and frustrated. Unfortunately, designers of hypermedia consistently make a serious error. They forget or ignore what it is like to be a novice user of a hypermedia environment. If initial support is lacking, learners may be unable to access the Web site's contents. This problem can be quite a disappointment for both the learner and the designer. Regardless of how wonderful the Web-based instructional site is, it is useless to learners who have neither the tools nor the information to access it. Therefore, providing this support based on the learners' characteristics and determined needs helps to ensure that they are able not only to access and use the Web site appropriately, but also to have the positive learning experience that results from using the WBI.

| Macro Level Guidelines | 1 | Use site maps to provide learners with valuable graphic representations of where they are within a Web-based environment. The hyperness of a Web environment can be very powerful because they enable users to direct their own movement through the information. However, in power there is confusion. The more flexible the Web site, the easier it is for learners to get lost or lose track of their original goals.
| | 2 | Provide learners with a glossary of terms that they can access at any time if the Web site includes new or unknown terms.
| | 3 | If the site includes any real-time or timed features, provide learners with the ability to take a time out by including a pause feature.
| | 4 | All Web sites should include detailed help information specific to the site.
| | 5 | If your Web site requires plug-ins, allow learners to test if they have the necessary plug-ins before they become too involved in the site. There is nothing more frustrating for learners than to be interrupted because you need to go and download a plug-in.
| | 6 | Use site maps, check lists, etc. to help learners keep track of their positions in the program.
| | 7 | If learning is a prime objective of the hypertext, provide a chance for learners to enter a purpose or provide a menu of suggested goals to help them stay focused in the WBI environment.
| | 8 | Design help systems with an elaborative approach. Keep initial explanations brief and provide options for more in-depth information.
| | 9 | Always include a way to easily get back to the main page of a Web site (e.g., table of contents, site map, etc.).
| | 10 | When using images, you can provide a low resolution version of the image, which takes relatively less time to download to a Web page, as a place holder for a high resolution version that will take longer to download. You can also allow learners to choose whether they want to view your Web site with low resolution or high resolution images.
| | 11 | If your Web site is viewed better under specific conditions (e.g., with a particular browser), inform learners on the title page.
| | 12 | If components of your Web site are "under construction", indicate this status to users before they click on a link and discover the page cannot be found. Allowing users to click on a link only to find the page with an "Under Construction" notification is frustrating to users and a waste of their time. One way of indicating that you are planning a particular link but have not completed it is to "gray out" the link; this way users know you are planning it but that it is not available yet.

Figure 4. Macro Level Learner Support Guidelines

Launching

1 | To provide learners with a good first impression of your Web-based instructional site, introduce users to the site by providing a title screen.

Web Site Functions

1 | If you anticipate learners who are unfamiliar with a certain aspect of your Web site (e.g., using the pull-down fields, using the Back button of the browser, etc.), build prerequisite instructions into the site.

Navigating the Web Site

1 | Make Web site menus accessible to learners regardless of their position in the site. Strive to make it so that learners only have to click on no more than two buttons to get to a menu.

Keep Learners Informed

1 | Use interactivity indicators to keep users informed about their actions within the site.

2 | If you are using images that take time to load, let learners know that there will be a delay. Incorporate text and images on the same page so learners have something to do while the images are loading.

3 | If the application includes test items, use immediate and individualized feedback to inform learners about the status of their answers. Provide learners with a glossary of terms that they can access at any time if the Web site includes new or unknown terms.

4 | If the Web site has several sections/pages (two or more), use a table of contents as a reference point for the site.

5 | To avoid early boredom, get learners involved in the site as quickly as possible.

6 | Use interactivity indicators to keep users informed about their actions within the site.

7 | If the Web site includes any real-time or timed features, provide learners with the ability to take a time out by including a pause feature.

8 | Use site maps, check lists, etc. to help learners keep track of their positions in the program.

9 | If learning is a prime objective of the hypertext, provide a chance for learners to enter a purpose or provide a menu of suggested goals to help them stay focused in the WBI environment.

10 | Design help systems with an elaborative approach. Keep initial explanations brief and provide options for more in-depth information.

11 | Always include a way to easily get back to the main page of a Web site (e.g., table of contents, site map, etc.).

12 | If components of your Web site are "under construction", indicate this status to users before they click on a link and discover the page cannot be found. Allowing users to click on a link only to find the page with an "Under Construction" notification is frustrating to users and a waste of their time. One way of indicating that you are planning a particular link but have not completed it is to "gray out" the link; this way users know you are planning it but that it is not available yet.
When learners make easily reversible mistakes, provide a forgiveness feature that allows them to undo their last action.

Abstract: The Java Music Toolkit is a set of Java classes that can display and play musical scores. The classes are used in music courseware in which students hear problem sets and notate their solutions to the examples that they hear. Students are able to compare their solutions with correct answers to enhance their understanding of the musical thought processes involved. Courseware using applets based on these classes will run on multiple platforms and can be served over the internet. This provides students with a larger variety of interactive instructional programs and facilitates the offering of courses delivered by distance learning.

1. Introduction

When microcomputers became available for computer based instruction in the early 1980s, courseware authors were able to develop instructional materials for students in their college or university. With the current interest in distance learning, these same instructors need tools that enable them to provide the same interactive instruction remotely. This paper describes a set of Java classes that support applets for music computer based instruction. These classes enable students at any location to complete drills served from remote hosts, with the same interactivity that is possible if they were at a microcomputer at the host institution.

Serving instructional materials developed in Java over the internet has several indisputable advantages:
1. It enables students with different platforms to use the same materials, since the student's web browser will interpret the Java code and control presentation of the materials.
2. It enables students in many locations to take advantage of pedagogical methods developed and used at other colleges and universities.

2. Java for Music Instruction

2.1 Advantages of the Java Music Toolkit

The Java Music Toolkit is a set of classes that reads compressed score files and converts them both to a graphical image and to a MIDI file that can be played. These files are very small—a set of five harmonic dictation exercises, each four measures long, fits in less than 4 KB. Consequently, an entire drill with all its component exercises can be served in one step. The client will decode each score in the drill as the student needs it. If score images were served as gif files, they each could be 50KB to 500KB in size. MIDI files used to play scores typically range in size from 20KB to 150KB. The toolkit thus provides significant size and speed advantages over traditional means of transporting musical images and sound files.

The toolkit also enables the student to create scores that are solutions to dictation exercises. The classes that display scores are the same ones that enable the student to create a new score. The student could not interact in the same way with drills using images prepared with a music notation editor.

2.2 Classes in the Java Music Toolkit

The Java Music Toolkit is divided into five groups of classes:
1. Score definitions: constants that represent types of staves, ties, notes, etc.
2. Score types: data structures for notes, chords, voices, etc.
3. Score drawing: the classes that draw images, staves, clefs, notes, etc.
4. Score canvas: the graphical object onto which items are drawn
5. Score data file: the file that stores the binary representation of scores in a drill

431
The total size of all these classes, uncompressed, is less than 200 KB. Ideally, users of the Java Music Toolkit would download and install the classes before accessing any applet that used them.

2.3 Structure of the Score Data File

Scores are arrays of data structures, organized hierarchically. Each score is an array of systems. Each system is an array of staves. The array of data associated with each staff—its clef, key, meter, etc.—describe the score’s "background" elements, which are those that change little or not at all. Also associated with each system is an array of voices. The voice data—notes, rests, chord symbols, etc.—define the score’s "foreground" elements. These are mapped to staves of the score, and they define the melodies and harmonies that characterize the score. Each item in this data structure has a class associated with it. The class knows how to read the data it needs from the score file and to convert the information into drawing and MIDI commands.

2.4 Displaying a Score

Each element of the score’s foreground and background has a timepoint in the score. This timepoint is associated with its physical location, or placepoint, on the screen. The placepoint of any timepoint will vary, depending on the contents of the score. A note preceded by an accidental requires more space on the screen than does a note without an accidental. When chords are drawn, notes forming the interval of a second must be offset from one another, and accidentals also must be offset if they occur within the interval of the sixth. Consequently, the ScoreCanvas class must calculate the placepoint of each element of a score with respect to the context in which it occurs.

To prepare for drawing the score, ScoreCanvas creates a list of ScoreEvents, which associates the timepoints and placepoints of each element of a score. Each score event also has a type, which ScoreCanvas uses to draw the element. To draw background elements, ScoreCanvas sends a draw message to a Staff object, identifying the type of element (clef, key signature, or meter) that this object should draw on the staff. To draw foreground elements, ScoreCanvas sends a draw message to a Voice object, requesting that it draw beats on the staff at the appropriate locations.

Drawing the score background entails iterating the list of systems and staves that constitute the background and determining the physical location of each on the screen. DrawStaffData then invokes the appropriate drawing routine. ScoreCanvas has the ability to transpose the key signature of a score, so that one model score can be used to create several different examples, each in a different key.

To draw the score foreground, ScoreCanvas initializes voice data based on the timepoint of the current score event. After calculating note offsets and accidental offsets for chords, and aligning notes vertically, it then invokes DrawVoiceData. This method draws the score foreground by iterating the list of systems and voices that constitute the foreground. If a voice contains a beat at the timepoint specified by the score event, ScoreCanvas asks the voice to draw its beat. If not, the voice determines if its last sounding note needs a beam or tie, and if so, it draws the appropriate shape. By segmenting the score into a series of score events, ScoreCanvas is able to draw the score one beat at a time.

The following example shows a harmonic dictation example drawn by the Java Music Toolkit classes.

Computers: More Effective at Feedback than Your Average Presenter?

Scott Dynes, Executive Perspectives, Boston, MA, USA (sdynes@execp.com)

Renee Cooper, Executive Perspectives, Boston, MA, USA (rc@execp.com)

Nicole Trudel, Executive Perspectives, Boston, MA, USA (nt@execp.com)

Chris Guglietti, Executive Perspectives, Boston, MA, USA (cg@execp.com)

Abstract: While in important ways the on-line environment for educational experiences is very different than that found in the classroom, Executive Perspectives believes that the underlying foundations of why and how individuals learn is the same. We seek to replicate important interactive elements of the classroom in single-user on-line educational experiences. While in general this is difficult, we have found the use of behavioral models allows us to accomplish this goal for certain focused, important management issues.

Introduction

Computer-based and intranet-based learning have recently been the center of much hope and hype in the executive training and education industry. The hope (and hype) is based on the perceived ability to decrease training expenses via reducing travel costs, create electronic support systems for just-in-time problem-based training, and moving from a punctate classroom-based paradigm to a more continuous training effort driven by the needs of the individual. The company can also leverage its human resources via sharing the best experiences online, integrating those lesson with both internal and external content to form a "knowledge base" that can be tapped at any time for authoritative information.

Executive Perspectives (EP) is an international firm that seeks to promote organizational change via experiential education methods. While we are charmed by the vision presented above, the on-line educational environments we have developed have made us very aware of the details that accompany such a migration to the online world. For the past 14 years, EP has developed stand-up classroom education based around in-class facilitators giving coaching and debrief based on the participant's in-class experiences with a custom computer-based simulation of their business and industry. The in-class techniques we use are based on principles derived from academic research about adult learning; we and our clients have found these principles to be very effective. For us the question has not been, "Can we develop continuous on-line learning systems and web-based tutorials?" but rather "Can we develop on-line training that is as effective as our in-class training?"

We believe for many important executive training issues we can.

EP's In-Class Experience

Executive Perspectives utilizes five underlying principles from adult learning theories to design and deliver classroom experiences:

1) Adults learn best when they know what they need to learn, and how it is relevant to their personal interests.

2) Adults learn best when they learn in groups.

3) Adults learn best when they take an action, and then reflect on what they have done (Action/Reflection).
4) Adults learn best via experiential learning.

5) Adults learn best when the learning is reinforced over time.

EP is typically contacted about specific business issues. EP develops course materials around those issues that emphasize how the course will impact the participant's capabilities in these areas, targeting item (1) above. After extensive analysis of the client's business, a computer-based simulation of the business is created that allows the participants to have input into the company's business as they would on a daily basis. This provides the basis for the experiential learning.

Someone who is an expert on the business and its issues facilitates the in-class experience. This person leads the class through the prepared materials, soliciting experiences and providing coaching on those experiences. This is an example of the action/reflection strategy in item (3) above. The class is broken into small teams for breakout sessions on particular issues and for the simulation experience, where each team "runs" a company that competes against companies "run" by other teams. During the simulation, participants must deal with the same issues they are faced with on a daily basis. The team's choices are used by the simulation model to determine their company's success; the model's output is used as a basis for coaching on how their choices impacted their business (action/reflection). After the teams have run several "quarters", the facilitator debriefs the entire class on what their experiences were, reinforcing the earlier coaching (point 5).

Our clients regard these methods as very effective, and the interactive coaching and debrief provided by the in-class facilitators is a key component of this effectiveness.

The move to online

Our clients are aware of the advances in intranet/web/computer-based training, and have repeatedly asked us to develop online versions of our in-class experiences. As described above, the reasons have mainly to do with cost and accessibility. Our in-class experiences typically take a week of top-level executive time; by moving the experience on-line the hope is that the same experience will be able to take place on the desktop in a less-demanding time frame, allowing the participant to be productive while participating in this experience.

The availability is also an important factor. The class experience described above is typically about strategic and operational issues; EP also develops soft-skills experiences using the same principles described above. Whereas there might be a few hundred executives who would benefit from attending such a course, there might be many thousands who would benefit from a soft-skills experience. Putting such a single-user experience on their desktop is a top priority of our clients.

We have looked at many CD-ROM and on-line soft-skills courses and find them to be much less compelling than our classroom-based offerings. Since we view the coaching and debrief around the simulation experience as a key component of our offerings, we were very interested in determining how to move the human coaching and debrief so important in the classroom to the on-line experience.

Online: Issues and Opportunities

The online educational experience is very different than the classroom educational experience. There are areas in which the online environment is decidedly inferior, and others in which it is superior.

Opportunities

There are two key advantages to computer-based on-line learning. First is the ready availability of adjunct materials. This is expected of on-line training applications; being able to drill down into, or find a more
appropriate representation of a particular concept is the promise of hypermedia, and to fail here is to fail your audience.

The second advantage is the undivided attention of your computer. We believe that the computer must become a much more proactive partner in your quest for knowledge and development. Computers are born passive, and will not do anything unless told to. This passivity is so pervasive that a good interface is thought of as one that lets the user explicitly tell the computer what to do as easily as possible. While we believe that excellent UI design is fundamental to any application, we feel that just as much effort should be spent getting the computer to determine the needs and capabilities of the user, and then acting on that information to provide a customized experience that more effectively supports that particular user.

Issues

The overarching disadvantage of on-line training is the lack of interactions between the participant and the facilitator and his peers. These interactions result in being exposed to other viewpoints, which is essential for reflection and cognitive reframing. The facilitator, through coaching and the debrief, provides authoritative feedback on in-class learning situations. Fellow participants share their perspectives on both in-class learning situations as well as common workplace issues. The lack of these diverse viewpoints denies on-line simulations crucial elements needed for effective assimilation of key concepts.

There are internet-based applications that work to provide a semblance of these interactions via IP telephony, shared whiteboards, and other features. While some of these technologies are promising, their usefulness is limited by scheduling constraints and the lack of the subtle cues (facial expressions, body language) that are an important part of any dialog.

EP views replicating these interactions as a requirement for effective computer-based training.

To give a quick summary, going from the classroom to an on-line environment involves a drastic reduction in the quality of interactions you can have with others, but a drastic increase in the availability of ancillary materials and of the instructor (the computer).

Constants

While there are significant differences in the classroom and on-line environments, we believe that the fundamentals of an effective educational experience, as embodied in the five points made above, remain invariant, and it follows that at a high level the design process should be similar as well. When an EP design team starts work on a project, they first define a set of simple, focused learning objectives. Throughout the design and development phase of any project, our design team continually asks the question: "What are the basic learning objectives of this training experience?" This focus results in the production of a framework in which the business issues are exposed and dealt with logically; the framework is reflected in both the classroom as well as the simulation.

Frameworks

In any training session, participants are usually asked to modify behaviors they use daily. We are telling them that this change is needed for them to become more effective contributors. What people generally need at this point is a new norm, a new paradigm, a new framework in which to view old issues. This framework is that which is described above, and typically reflects the perspective of the top executives in the company.

This framework also serves to a large extent as the basis for the coaching and debriefs by the in-class facilitator.

Focus
The frameworks that inform the coaching and debrief for classroom-based experiences are, to a large extent, ad-hoc. While EP has much experience developing successful training experiences, the framework developed for a particular company is very specialized, and has little application to other situations. They also tend to be fairly broad, which leads to the coaching and debriefs being quite open in terms of the issues that may be addressed.

It is this breadth of possible issues that is at the root of the problem for developing effective computer-generated coaching and debriefs. If it were possible to greatly restrict the possible issues, then computer-generated coaching and debrief might be useful.

Executive Perspectives has realized that this is possible, using very focused behavioral models that address many important managerial issues. These behavioral models allow EP to develop training experiences that maintain the essential features of in-class experiences while using the ability of the computer to focus on the participant to produce coaching and debriefs that are likely more informative than those of an average presenter.

Behavioral Models

Behavioral models are frameworks in which to think about issues dealing with human behaviors. Individual models have been developed over many years, with the developers gaining insight from multiple studies of test populations. They then develop reasoned frameworks in which to describe the issues and their consequences.

These models typically describe the interactions between groups of individuals; these groups are divided into functional subcategories using some metric. The behavioral aspect arises from predicting how the various subcategories will interact. Knowing the issues that might arise, the developers then describe the types of interactions that would minimize the impact of these issues.

Practically, these behavioral models result in frameworks which:
1) Describe distinct categories of individuals,
2) Describe issues that might arise from interactions among the different categories in the situation being modeled,
3) Suggest types of interactions that would serve to minimize those issues.

From the viewpoint of creating effective training experiences online, these behavioral models require that
1) The category that the participant occupies is determined
2) The participant can place individuals into their correct category
3) The participant knows how best to interact with those individuals.

Coaching and Debriefs

The focus and reasoned framework of these behavioral models solves the most pressing issues of providing effective on-line training. Coaching and Debrief are now restricted to a very focused domain; the actual coaching and debrief relies on qualities of the participant that are obtained by the computer proactively examining the participant's actions.

Through coaching, the participant actively receives positive and constructive feedback. If the feedback is positive, it acts as a reinforcement of action. If the participant is given some coaching or constructive feedback, they may be asked to think of the situation from an other view point, or perspective, which in turn, facilitates a process of cognitive reframing. Because the scenario dialogs are presented in small amounts, it is easy for the coach to respond to the actions of the participant "just-in-time". This "just-in-time" coaching allows the participant to observe his or her own instinctual behavior, while also considering, a more appropriate approach to the problem at hand. A scenario-based simulation coupled with a coach and behavioral model provides the perfect environment for experiential, action-reflection-based learning.
One exciting aspect of tailored, intranet-based training of this kind is that it really focuses on the person as an individual. The debriefing, is the point in the exercise where the learning is tied back to specifics that are relevant to the participant's improvement going forward. This is done by the coach giving a summary of feedback to the participant based on the behavioral model.

The participant is given an assessment of their individual strengths and opportunities for improvement in relation to the behavioral model. The main goal of the debrief is to bring out the strongest parts of the learning for the participant, and give them something to walk away with in terms of what they need to improve on.

A Sample Experience: Situational Leadership

We would now like to give you a sample experience based on situational leadership [see Blanchard 1985], a commonly needed soft-skill. This example incorporates the ideas presented earlier in this paper, yielding an experience where the participant will likely receive better coaching and debrief than from a human facilitator.

Definition

Suppose you are required to build a widget. You have one helper. How you and your helper can most effectively interact to produce the widget depends on your interest in building a widget, your perceived ownership of this project, and your partner's interest and skill in building widgets. This is an example of situational leadership, and has been studied extensively by many groups over a long period of time. Situational leadership models are implemented in various ways; for this application we use a model where you (the manager) have your management style assessed, and where your subordinates are classified along two dimensions. The model presents reasoned methods of interactions for various combinations of your management style and your subordinate's interest and skill.

The key components of a successful experience are for you to become familiar with your management style, for you to be able to determine where your subordinates fall on the two dimensions of the model, and to know the appropriate interaction styles between you and your subordinates.

Scenario-based simulation

Executive Perspectives felt that a scenario-based simulation was the most appropriate means to simulate this experience. In our scenario-based simulations, instead of interacting with pro formas, spreadsheets and numbers, the participant interacts via scenarios where he interacts with characters. The participant has access to the background of the character, and what the character says to the participant. The participant can then choose a response action from a selection. The next interaction is dependent upon the choice; associated models are also influenced by the chosen action.

Experience

The experience opens with an introductory segment where the participant is given an overview of the behavioral model. He is made aware of the issue that the model addresses, the general framework the model creates, and the classifications that create the framework. The types of issues that may arise from interactions between these classifications are detailed, as are the suggested methods of interaction. This introduction contains links to textual summaries of the points made so the participant can refer to them during the scenario-based simulation.

The first part of the simulation serves two purposes: it acts to train the participant on placing individuals in the correct skill/desire classification, and at the same time the computer is inferring the participant’s management style based on the reactions the participant has to the presented individuals.
The participant is presented with several scenarios. In each scenario, the participant views a character in a situation. The participant has sufficient background to correctly classify the character. The situation that is presented is written to be revealing about the classification of the participant. The participant then classifies the character, and what action he would have taken in the situation. The coaching around this situation is based on whether the participant correctly classified the character, and is drawn directly from the behavioral model.

The situations continue until the participant has demonstrated that he can correctly classify individuals. At the same time the computer has generated great insight into the management style of the participant.

The debrief is generated based on this characterization, and centers on making the participant aware of the issues he might face in interacting with different classes of individuals, and how the issues can be avoided via the use of alternative types of interactions.

In this short experience, the participant has been exposed to a reasoned framework that effectively deals with the issues he wishes to solve. He has been tutored in the framework, and on how to classify individuals. He has been made aware of his particular management style, and the issues that might arise when dealing with different individuals. He has learned alternative methods of interactions that avoid these issues. And while doing this, he has been coached effectively in a one-on-one manner, and was given a debrief that was customized to his particular needs.

This participant would be fortunate to have a classroom-based experience so complete.

Conclusion

Executive Perspectives is developing techniques for maintaining key elements of the classroom experience in an on-line setting. For many important management issues, the use of very focused behavioral models allows for the development of on-line experiences that do maintain these elements, and may well give the participant a better experience than that provided by an average in-class presenter. Executive Perspectives is looking for methods to extend these capabilities to situations that are not as focused as those detailed here.

Abstract: The first issue we are going to present is education in relation to multimedia and psychoanalysis. In this part of our speech we want to express our personal conviction that multimedia and psychoanalysis constitute the problem as such in education. To the present days in our country psychoanalysis has existed almost only on the clinical level and for bulk of psychoanalysts it is impossible to break the walls of the consulting room and enter the classroom. Educators do not know what they can take from psychoanalysis to improve their professional work. From the multimedia point of view there is a similar difficulty. Teachers are not familiar with richness offered by multimedia technology. We are going to discuss the ways multimedia and psychoanalysis can enter into the process of education.

The second problem we would like to describe is devoted to a rather bizarre, we mean, suspicious presence of psychoanalysis in the world of multimedia. We are ready to defend the thesis that the multimedia constitutes the new horizon for psychoanalysis.

The third task of ours is to connect the psychoanalysis with the question of understanding. We perfectly know that analysts are doing their best to understand patients. They are also doing their best to understand themselves. We are discussing the role of insight in the process of education. Looking back at the history of psychoanalysis we can notice one of the fundamental controversies. It is a question what is the most important factor of successful treatment. Is it an analyst's personality or maybe there are only appropriately applied techniques?

It is not a coincidence that three people co-sign this paper. Each of us is engaged in a different discipline. Czesław Dziekanowski is a psychoanalyst, Jacek Górnikiewicz is fascinated by educational transformation, Arnold Toczyski by multimedia. We hope that our speech will expose particular significance of the meeting of these three different disciplines.

Without a doubt the appearance of multimedia has changed the status of educational activities. One can, of course, ignore the presence of multimedia in education, which is what most teachers still do in Poland. When we think about the cause of that situation different possible answers come to mind. Ones say, that the Polish laziness can be blamed. Some fiercely accuse technology of destroying spiritual values safeguarded by God and Nature. Others point out an economical aspect that limits us. And the others repeat: do not hurry, wait, we still have time, so they temporize the process. The frequently used argument is that multimedia serve an entertaining – not educational purpose. But we are convinced that the crucial problem here is rather unconscious anxiety. This fear distorts our perception, multiplying and magnifying obstacles. It is this fear that makes an average Pole feel permanently threatened. That menace is double bound – one in the presence, the second in the past. Just now the average Polish person feels the jaws of the monster called multimedia. We call it the jaws of the monster because nowadays multimedia seem to be another embodiment of a traumatic archetype of invasion. Those who know even superficially the history of Poland know what we mean: the partitions of Poland, the wars, etc. We suggest that now multimedia play that inglorious part of symbolizing another form of invasion. The described situation allows easily to foresee the future task for our education: to free our society from the demon of multimedia. How are we supposed to achieve that? We think that the most efficient way, especially from psychoanalytical point of view, would be to make the society aware of the nature of the demon. But what should that process of making conscious mean specifically? We should create a certain attitude among the educators, based on the function of
understanding. That is analogous to the role the psychoanalyst assumes towards their patients. The educators and their understanding should enable the society to see into the true nature of the above-mentioned obstacles, which are more defense mechanisms (mostly rationalization, projection and denial) than actual problems.

But for the educators just like me (Jacek Górnikiewicz) fascinated by the transformation of the education it is difficult to think of multimedia in such an extreme manner – as a nightmare or as a sacrum. I approach multimedia pragmatically, free from utmost emotions.

For me (Arnold Toczyski) – a multimedia specialist at the University with the ambition to be the leader in promoting the latest educational techniques, the visits of different people interested in using multimedia is real anguish. It is not easy for me to know those people’s real needs because of their usual excitement caused either by exaggerated fascination of potential possibilities of multimedia or just the opposite - by the demonized difficulties and dangers in utilizing them. Over and over again I ask myself why after so many years of experience it is still so hard for us to communicate. I think that the main problem is the lack of the common language. In that situation common sense demands to blame individual persons. But I known that our unfortunate relation is based on more general context. What I mean is the dual nature of our culture in which two paradigms: humanistic and technological hardly intermingle. Simplistically speaking, humanists misunderstand technocrats and vice versa. To face the challenge of our times we have to overcome this unfavorable situation the one-sided progress has entangled us in.

Perhaps this is the right time to consider seriously the role of multimedia in psychoanalysis. So far in our paper we have treated the science created by Freud as useful in the educational development of the society especially in relation to assimilation of multimedia as effective tools of work and development. Surprisingly and paradoxically, the psychoanalysis itself seems to underestimate multimedia as a desired tool in the psychoanalytical process. Intimacy is one of the crucial values constituted in the consulting room. The question is whether the modern media are able to work within the limits of intimacy. Freud writes that the psychoanalysis is not possible without the presence of an analyst. The introduction of multimedia into our world makes us think again what the presence of the analyst really means. Many analysts have already given some thought to the idea of their absence and presence in psychoanalytical relation. Their thinking was limited by the conclusion that although psychoanalysts and patients are physically together they are nevertheless alone. The most general and at the same time the most basic goal of the psychoanalytical process is to lead the patient from the dependent relation to freeing them from that. But the still valid principle is the one of anonymity in the relation psychoanalyst – patient. In order to be consistent one has to admit that it is much easier to follow this postulate for the analyst who works on the computer terminal. We cannot imagine that this attractive potential in multimedia should escape psychoanalysts’ notice. Thus, we suspect that the psychoanalytical world will split into two parts. Those who are afraid of destructive influence of multimedia on psychoanalytical process will definitely reject them. But those who are intrigued by the new possibilities will try to experiment to learn the new things about the nature of psychoanalysis and will want to know whether psychoanalysis will manage in the world inevitably changing under the multimedia revolution.
The Efficacy of Distance Learning in Affecting Attitudinal Change

Karen Eastwood and Marina Onken
Department of Management, College of Business, Florida Gulf Coast University, USA
Eastwood@fgcu.edu
Monken@fgcu.edu

Abstract
This paper looks at the importance of distance education in reaching a larger and more geographically dispersed group of students. The authors focus on technology-mediated distance courses that are concerned with affecting attitudinal and behavioral change. Because these courses place a greater emphasis on process, as opposed to content, pedagogical approaches that utilize role-play, debates, experiential exercises and other face-to-face strategies have been effective means of changing attitudes and behaviors. The source, message, medium and audience are important factors that have an impact on attitudinal change. This paper looks at each of these factors as they relate to technology-mediated distance education. If higher education is going to successfully implement entire programs at a distance, it must find ways to enrich the distance learning of process-oriented courses. The objective of this paper is to compare the effectiveness of traditionally taught versus distance courses in affecting attitudinal changes.

The first stage of this research is to determine if attitudes are indeed changed in traditionally taught classes. The first class that we use is an undergraduate course in conflict management. This course was taught on campus using various methodologies such as case studies, lectures, guest speakers, debates, etc. Students were given a questionnaire at the beginning of the semester and at the completion of the course. In addition, a survey was administered at the end of the semester to determine students’ impressions of their learning, and of any changes they experienced in their conflict resolution styles.

A thirty item “behavioral description questionnaire” provided the students’ scores at the beginning and completion of the course on these conflict resolution styles: competition, collaboration, sharing, avoiding, and accommodation. We computed a t-test that showed statistical significance in competition, collaboration, and accommodation. The fifteen-question survey of students’ perceptions of their attitudinal changes used a five point strongly agree (1) to strongly disagree (5) scale. The means for all of the questions ranged from 1.79 to 2.73.

This first stage demonstrated changes in attitudes in a traditionally taught conflict management class. It provides a baseline for studying the efficacy of technology-mediated distance education, and in helping us to determine the most effective technology to utilize in process-oriented courses.
Virtual URLs for Browsing and Searching Large Information Spaces

Sara Elo, Louis Weitzman, Christopher Fry, Jeff Milton
IBM Advanced Internet Technology Group, USA
{saraelo, louisw, cfry, jwmilton}@us.ibm.com

Abstract: As an information space grows, it becomes more difficult to find the information you seek. Nowhere is this more evident than on the Web. This paper presents the use of Virtual Resource Locators (VRLs) to facilitate browsing conceptual information hierarchies, or taxonomies. In this project, URLs on distributed web servers are classified under one taxonomy. Using a standard browser, a web visitor can reach any page in the collection using its VRL. A VRL is a logical name corresponding to the position of the page in the taxonomy. VRLs mask inconsistent URLs on distributed servers organizing heterogeneous information spaces into a consistent logical structure. The process that resolves VRLs into URLs, the VRL Mapper, also supports user input of partial or incorrect VRLs. Rather than give you an error message, it automatically performs a heuristic search and presents the user with valid alternatives.

Introduction

The IBM Intranet is a complex information space containing over a million web pages hosted on more than three thousand servers across the world. Semantically similar pages, or ones relating to the same subject, are often stored on different servers and not linked to one another. For example, even if an employee finds a good starting point to download software, the employee probably misses many other sites that host downloadable software of interest. The problem of locating content is familiar to any corporate site of moderate complexity.

One solution is to rename hosts, directories and pages so that the corresponding URLs reflect the content. However, this breaks existing links to the pages, creates load-balancing problems, and forces authors to relearn the web space when updating their pages. Another solution is to modify the search tools. Users are often forced to choose between browsing and searching. Browsing is appropriate when a collection is well organized, relatively small, and the user does not know how to form valid queries. Searching is more effective when the information space is large and disorganized, but the user knows a few discriminating search terms. In most cases, neither is sufficient. Toggling back and forth between searching and browsing is often the most effective strategy. Unfortunately current tools make this cumbersome.

Our approach is to create a virtual service. In a virtual service, a heterogeneous collection is structured into a single, logical information space. The service presents an integrated interface that minimizes the physical and cognitive load of switching between browsing and searching. Various search algorithms can take advantage of this organization and limit result sets to categories and/or subtrees of the taxonomy. This is similar to other structured information stores such as on the Yahoo website. A virtual service begins with webmasters at different sites classifying pages within a single hierarchical organization, or taxonomy. While the physical location of pages is unchanged, pages on the same subject get grouped together under the taxonomy. The new organization masks the existing inconsistent names of hosts and directories. Each page now has a logical address, or VRL, that reflects its position within the taxonomy. A more stable information space is created because a taxonomy does not change as rapidly as individual pages classified within it.

As users of the virtual service navigate the new information space, the VRL Mapper handles their requests. The VRL Mapper never lets a user-entered VRL fail. Instead of giving the user an error message for an invalid URL, the Mapper tries to find nodes or pages based on the VRL requested. The inference rules and explanations of the VRL Mapper improve upon standard web server error handling.

The IBM Intranet virtual service is based on a relatively small taxonomy consisting of less than 300 nodes with a depth of about 4 levels. The taxonomy reflects the contents of the IBM internal web and contains information from corporate communications and personnel information to software downloads.

This paper starts by defining VRLs and the VRL Mapper process. Then, it describes taxonomy creation, management and classification. Finally, the paper covers related work and a conclusion.
Virtual Resource Locators

A Virtual Resource Locator is the logical address of a piece of information. A VRL has the same syntax as a URL. While a URL describes a physical location on a server on the net, a VRL describes a logical location within an information taxonomy. The goal is to make a VRL address more meaningful and easier to understand. Because items can be classified under more than one taxonomy category, a page may have several VRLs. This allows users to access the same information from a number of different perspectives.

The process of classifying a page into a category in a taxonomy creates metadata, or information about the subject matter of the page. Usually, metadata is stored either in a metadata server or as special tags in the page, like the markup in an XML document. Because the VRL Mapper needs fast access to the taxonomy and the metadata associated with all the pages, the classification metadata is stored in a centralized relational DB2 database.

VRLs behave like URLs. Each category in the taxonomy and each classified page can be addressed using a VRL. A user simply types the VRL into the URL field of a standard web browser or embeds them in html pages. No additional software or configuration of the user's machine is required.

A VRL can be implemented on the server in two ways, an explicit form or an implicit form. The explicit VRL shows the name of the virtual service, while the implicit VRL does not. An explicit VRL has the following format:

- **protocol**: VRL Mapper uses the http protocol
- **host**: the name of a web server that recognizes a virtual URL
- **v**: the virtual tag indicating an explicit VRL
- **service**: the virtual service name (this paper describes the web service, others include news and personnel directory)
- **category**: a node in the taxonomy
- **page**: the name of the page within the taxonomy

An example of an explicit VRL is http://w3.ibm.com/v/web/What_We_Sell/Software. In the explicit model, the web server's forwards any URL with the top directory "v/" to the VRL Mapper. The string "web" indicates that the VRL belongs to the IBM Intranet virtual service. "What_We_Sell" is a top level category in the IBM Intranet taxonomy, and "Software" is a subcategory under it. The implicit VRL for the same category is http://w3.ibm.com/What_We_Sell/Software.

VRL Mapper Process

VRLs are processed in three steps: a forwarding phase, a resolution phase and a page generation phase.

Forwarding Phase

In the forwarding phase, the web server running a virtual service sends VRLs to the VRL Mapper. The first step is to differentiate a VRL from a normal URL. In the explicit VRL model, the server forwards any virtual URL with a "v/" after the host name to the VRL Mapper.

In the implicit VRL model, the host web server is configured to forward all top level category names to the VRL Mapper. In addition, the server forwards erroneous URL requests. When the server fails to locate and serve a URL, it does not generate an error message. Instead, the request is passed to the VRL Mapper which offers valid options. The advantage of the implicit VRL is that it cannot be distinguished from a regular URL while still supporting the user in finding information. Any server on the net can be configured to do these mappings.

Resolution Phase

During the resolution phase, the VRL Mapper uses a browse & search algorithm resolving in one of three information types, a category in the taxonomy, a classified page, or a collection of categories or pages. By
comparing the entered VRL to the categories in the taxonomy, the VRL Mapper handles incomplete or erroneous input as best as possible. If the Mapper cannot find a taxonomy category or page that matches the VRL, it launches a series of searches, enlarging the scope for increasingly “fuzzy” matches.

The VRL Mapper is implemented as a Web Browser Intelligence (WBI) agent WBI. Developed at IBM Almaden’s USER research group, WBI is a system that organizes agents to observe user actions, proactively offer assistance, and modify web documents (http://www.almaden.ibm.com/cs/user/wbi/wbipaper.html). A WBI proxy can monitor the stream of data coming from the client browser, modify the stream going back to the client, and record the activity between the client and the web. In our application, WBI runs on a server and at startup time loads the complete taxonomy into memory. This one time cost allows for relatively quick processing of VRLs during runtime. During runtime, the VRL Mapper applies its knowledge of the entire information space to support a user browsing and searching through the taxonomy. It uses features of WBI to redirect to an actual URL or modify the HTML returned to the client.

When faced with an invalid VRL, the Virtual Mapper keeps the valid part and searches on the remainder. For example, the VRL http://w3.ibm.com/v/web/what_we_sell/soft is partially valid: it exactly matches the top level category "What We Sell" but "soft" is not a sub-category under What_We_Sell. The Virtual Mapper uses "soft" to begin the browse & search algorithm. In this case, the matching is simple since "soft" completes only to the "Software" category under What_We_Sell. The user is presented with the unique match of the typed in VRL.

**Browse & search algorithm**

The VRL Mapper transitions smoothly between the various stages of the browse & search algorithm. This search can be characterized by three attributes. The first is the scope within the taxonomy: the immediate children of a category, all of the descendants of a category, or the complete taxonomy. The second browse & search attribute is the content which the Mapper compares to the VRL. The content can either be the name, alias, keywords or description of a category, or the text in the body of a classified page. Finally, the method used in the matching process can either be an "exact" match, a "starts-with" match, or a "contains" match. The three attributes become less constrained as the browse & search algorithm advances. The attributes are summarized in Table 1.

<table>
<thead>
<tr>
<th>Scope</th>
<th>Content</th>
<th>Matching Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>children</td>
<td>category name</td>
<td>exact</td>
</tr>
<tr>
<td>descendants</td>
<td>category alias</td>
<td>starts with</td>
</tr>
<tr>
<td>entire taxonomy</td>
<td>category keywords, description, page bodies</td>
<td>contains</td>
</tr>
</tbody>
</table>

Table 1: Browse & Search Attributes

In theory, the browse & search algorithm ought to exercise every combination of scope, content and matching method in its full complexity. In reality, the IBM Intranet taxonomy is relatively small and the resulting algorithm would be rather tedious. Instead, the browse & search algorithm is collapsed into a sequence of seven steps presented in Table 2.

<table>
<thead>
<tr>
<th>Step</th>
<th>Scope</th>
<th>Content</th>
<th>Matching Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>children</td>
<td>category name</td>
<td>exact</td>

</tr>
</tbody>
</table>

Table 2: Browse & Search Algorithm

Users learn how resolution gradually turns into a search across the entire taxonomy and classified pages. As a result, users can force the VRL Mapper to bypass early stages of resolution and imbue a search request directly in the VRL string. If the VRL includes a question mark, "?", the VRL Mapper treats the remainder of the VRL as input to the search process. This search goes directly to step 5 in the browse & search algorithm. If the VRL contains a double question mark, "??", all subsequent characters are treated as input to step 7 in the algorithm. The VRL mechanism allows the user to go directly to searches of differently scopes. For example, a VRL to find a category in the taxonomy related to Java might be http://w3.ibm.com/v/web?java. When processing this VRL, the VRL Mapper
searches the entire taxonomy for categories that contain the substring java in the category name, alias, or keyword field. To simplify the search process, all generated pages include a type-in area and a button to initiate a search over the entire web taxonomy, as well as over all services.

The VRL resolution is unlike the URL completion in the Netscape 4.0 browser. The browser maintains a history of sites the user has recently visited and completes any partial URL with the latest visited matching URL. The VRL resolution resembles more the Emacs editor command completion. Both present all valid completions to a valid partial string. However, Emacs completion always matches from the beginning of the string, while VRL resolution falls back to a "contains" search method, where a VRL is matched with substrings of category names, keywords, and aliases.

Page Generation Phase

The final phase of VRL processing is the generation of a results page for the user. The VRL Mapper generates three types of pages, one describes a category in the taxonomy, a second lists a set of choices from an ambiguous VRL and a third presents the web page classified within a category.

When a VRL matches a category in the taxonomy, the VRL Mapper displays the VRL with each segment as a hyperlink, allowing a user to easily move up the taxonomy to higher categories. The description of a category is a free text explanation. Keywords provide additional ways to search across the taxonomy. The children of a category are hyperlinks. A home page is a good starting point for browsing pages in a specific category.

If more than one category fits the VRL typed in, the VRL Mapper generates a page with all valid matches. For example, if the user types in the ambiguous request http://w3.ibm.com/v/web/what_we_sell/s, the system lists "Software", "Services" and "Solutions" because they are valid subcategories of "What We Sell".

If the VRL points to a web page classified within the taxonomy, the VRL Mapper returns the page with a header with the one or more VRLs that correspond to the page. This implementation is simple for the user but has the drawback of changing the HTML. This may cause unwanted problems in the presentation of that page. Another alternative is to provide a separate, smaller window that pops up to indicate the multiple VRL paths to the specified web page. We are continuing to investigate these design tradeoffs.

Taxonomy Creation and Management

The VRL project builds on two components: a hierarchical information taxonomy, and a collection of web pages classified under the taxonomy. An on-going IBM Intranet Classification project provides these two components. Creating a taxonomy for a large web collection like the IBM Intranet is no simple task. Users come to the Intranet with different needs and questions in mind. One organization hardly fits everyone's mental models [Lakoff 87]. But as we know, any organization is better than no organization [Sano 96]. If presented with a stable taxonomy, users will learn to use it.

The Intranet taxonomy was entered into a database using an IBM internal toolkit that supports the management of database driven taxonomies. The toolkit also allows webmasters to classify web pages into one or more categories in the taxonomy. The webmaster can also flag a page as a "home page" if it serves as a starting point to a lot of relevant content.

The process of classifying over million pages is daunting. Our strategy is to manually classify prototypical pages into the taxonomy. Then, for each unclassified page, an automatic classification algorithm uses these manual samples as the seed documents in classifying the page. Currently, these automatic classifications are reviewed by a human. Their task is narrowed down to "accept or reclassify" rather than the more time-consuming "where does this page belong?"

The IBM Intranet taxonomy has been carefully designed by a group of experts familiar with the content on the Intranet. (http://cs-tr.cs.cornell.edu:80/Diens/II/2.0/Describe/nstrlj.cornel1%2fITR86-765?abstract=text+clustering)

An alternative to manual taxonomy creation is the automatic category creation based on the pages themselves via a technique known as hierarchic clustering. Clustering groups documents by similarity and dynamically creates labels.
for the groups. While a carefully edited taxonomy holds more meaningful labels, assuring that it reflects content changing over time requires manual changes. On the other hand, a discovered taxonomy always reflects the content, but holds labels of concatenated words, instead of more meaningful concepts.

Related Work

A URL (http://www.w3.org/Addressing/URL/url-spec.txt) is the address of a retrievable object, an address bound to a physical location. Combining the address and the location of an object prevents any abstraction of how to access the object. Some work has been done to overcome this limitation. “Persistent URLs” (http://purl.oclc.org/) maintain a many-to-one mapping from potentially several URLs as addresses to another URL as a location, so that the persistent URL can be used in a stable fashion. This is very similar to the way Post Office Box addressing works in the physical world -- mail addressed to a POBox may be delivered to that box, or to some other actual address, with the redirection being done invisibly to the sender. As an example, if http://www.kaput.com/index.html is a persistent URL, then a connection to it may be redirected to any of a number of different actual URLs.

URL addresses and locations are mapped many-to-one, addresses being aliases of a URL location. This mapping limits the information space of the WWW to one dimension. Metadata, such as defined by Uniform Resource Characteristics, or URCS, add dimensionality to this space. URC metadata allows for a flat file to have many attributes, such as abstract, access, author, date and time, location, review, signature, subject, title and version. But missing from URCS is the ability to position a document within a structured information space.

Work in virtual names has a precedent at IBM. The Web Object Management (WOM) server, the web server that hosted the Official 1996 Olympic Web Site, used virtual naming. Pages were composed of text and multimedia items stored in the server as unique objects with metadata. The virtual URL path that appeared in the client browser was a string stored as metadata with the object. The underlying architecture of WOM was designed to serve objects based on their virtual names. A virtual URL was mapped to the internal name of an object without the use of a proxy server. The VRL Mapper is an extension to a web server that does not support virtual naming, such as Domino, IBM's Go, or Apache. While WOM supported only one virtual path per page, the VRL Mapper supports several. Furthermore, WOM did not construct virtual paths from a centralized taxonomy.

As web-based systems are becoming more "intelligent", tagging pages with metadata is becoming more common. XML is emerging as a standard for embedding metadata within the markup of traditional documents. The VRL approach separates the metadata into an external store. Any processing refers to that store to retrieve the metadata for a document. An advantage is the easy execution of relational queries on metadata for all documents. In the future, the VRL Mapper could dynamically modify the documents it servers by embedding XML tags with metadata from the central store.

Yahoo (http://www.yahoo.com) is probably the best known web-based taxonomy. It supports search within a predefined hierarchy much like the VRL Mapper. In fact, the VRL Mapper could import the Yahoo taxonomy and make the hierarchy available directly in the syntax of the URL. Furthermore, a VRL Yahoo service would provide helpful hints to erroneously entered URLs.

The Pan-Browser (http://www5conf.inria.fr/fich_html/papers/P15/Overview.html) supports the creation, presentation, viewing, and control of user created metadata. [Schickler 96] The metadata is stored separately from the documents. The prototype is focused on attaching annotations to HTML documents and using it in multiple ways, such as trails, voting, and seals-of-approval.

WebCutter (http://www6.nttlabs.com/HyperNews/get/PAPER40.html) is a dynamic mapping system that tightly integrates browsing and searching. [Maarek 97] WebCutter tailors the map it creates based on concepts relevant to the user. As defined by WebCutter, searching involves engines that use text analysis tools over a set of documents, while browsing uses site mapping and visualization techniques. Unlike Webcutter, the VRL Mapper lets users browse and search over a predesigned, logical taxonomy that reflects the space of all documents. This "meta-search" allows users to focus on the type of information they are seeking before searching the information itself.

Conclusion
A virtual service supports users in exploring a heterogeneous distributed information space. Documents in the collection are structured into a single, logical information space. Each document has one or more virtual addresses, or VRLs, reflecting its positions within the taxonomy. While the physical location of documents is unchanged, the virtual names mask the existing inconsistent names of hosts and directories.

As users of the virtual service navigate the new information space, the VRL Mapper handles their requests. The VRL Mapper never lets a user-entered VRL fail, instead it tries to provide relevant options. The system also explains how it comes up with the options. The inference rules and explanations of the VRL Mapper improve upon standard web server error handling.

The Intranet information space is the first in a series of virtual services planned for the IBM Intranet. Other services include information spaces for the internal news stories and the employee directory. For rapidly changing content, such as a news feed, categories change from week to week as new topics emerge in the news. Unlike the intranet, a news application must support a continually increasing set of categories.

The Intranet virtual service is currently running as an early prototype. The next phases of the project will tell how well the current VRL implementation scales to support the increasingly high hit rates on the IBM Intranet. IBM's Network Dispatcher technology is a possible solution to balance user requests across multiple VRL Mapper servers running in parallel.

A Laboratory Course for Undergraduate Students of Phonetics.

Anders Eriksson
Department of Phonetics, Umeå University, S-901 87 Umeå, Sweden
E-mail: anderse@ling.umu.se

Abstract: A laboratory course for undergraduate students of phonetics has been developed and tested at the Department of Phonetics at Umeå University. The course consists of exercises designed to acquaint the students with basic acoustic analysis methods and a section on speech perception. All instructions were in the form of web pages. Questionnaires, assignments and student tracking were administered using Internet-based tools. Acoustic analyses were made using the ESPS/Waves+ analysis package; the perception experiments were run either entirely within a web browser or called from a web page but run in a separate X-window. Data collection and analyses were made in the UNIX environment and the results sent back to the students in the form of Java applets readable in web browsers.

1. Background

Laboratory work in phonetics or speech science is particularly well suited for telematic teaching. Students often work alone or in small groups, analysing their own voices or stored data, using computer-based analysis tools. Traditionally taught laboratory courses could therefore quite easily be transformed into telematic courses as far as content and methods are concerned. However, present limitations in bandwidth make the transfer of speech data too slow to be practical. This problem can be circumvented by storing the sound files on the local computer and running the analysis programs locally for example as Java applications. However, today there are no analysis tools available in versions that run inside a web browser, locally or over the Internet, and the sound handling capability in Java is still too poor to be used for things other than demonstrations. It is highly likely that these problems will be overcome in the not too distant future. But until that happens, a laboratory course like the one described here, will have to combine Internet based components with components which run outside the Internet environment. Instructions, examples and demonstrations, course administration and student tracking may all be run in an Internet environment while audio files and acoustic analyses are better handled outside the Internet environment, typically locally on the users’ own machines.

2. Course Objectives

A laboratory course for undergraduate students of phonetics, recognising the present limitations, has been developed and tested at the Department of Phonetics at Umeå University. The laboratory course was time-tabled towards the end of the first semester of a full-time course on phonetics.

The goals of the course were for the students to become familiar with
1) basic concepts of the acoustic analysis of speech
2) basic tools used in the acoustic analysis of speech and learn how to use them for simple analyses
3) fundamental concepts and problems in speech perception
4) experimental techniques used in speech perception research

3. Course Structure and Content

The course consisted of 17 laboratory exercises, each centred on a given topic and included suggested background readings as well as demonstrations and experiments. The total number of contact hours was thirty, but students had access to the laboratory outside these hours and were free to work through the course at their own pace, but within given deadlines.
All instructions for the laboratory exercises were in the form of web pages, but the course recommended textbook was used for the background readings. Questionnaires, assignments and student tracking were administered using Internet-based tools. This part of the course was developed with the help of the WebCT course development tool.

All acoustic analyses were made outside the Internet environment, using the ESPS/Waves+™ analysis package. Since the instructions for the exercises were made with a particular analysis package and computer environment in mind it was possible to tailor all accompanying illustrations so that they corresponded exactly to what the students encountered on their screens as they performed the experiments. Experiments and measurements were performed on pre-recorded material accessible as digitized sound files. Although the equipment would have allowed on-line recording this option was not used because earlier tests had shown the sound quality of such recordings to be too poor for the analyses to be undertaken. The sound files contained simple and complex non-speech signals as well as recorded speech illustrating various linguistic phenomena such as VOT, vowel quantity, fundamental frequency contours. The non-speech signals were used to familiarize the students with analysis techniques and units used in describing acoustic properties like decibel and Hertz. In the speech files students measured selected acoustic parameters and were asked to reflect upon their significance for speech production and perception.

The perception experiments were accessed from a web page. All programs were written in Java and could in principle run as Java applications inside the browser but due to the rather poor sound quality in Java, only one of the experiments was delivered this way. The rest ran in windows outside the browser and used audio tools from the UNIX environment. Data collection and analyses were also run in a UNIX environment. The results were sent back to the students in the form of Java applets readable in their web browsers. The student's own result was presented, in the form of a diagram, immediately upon the completion of the experiment, and the combined result of the whole group of students was presented in another diagram. The diagram showing the results for the whole group could be updated at any time to include the most recent results until all students had completed the task. The perception tests were chosen to illustrate some basic properties of the auditory system such as temporal integration and the threshold of hearing. In addition a re-creation of a classical test on Categorical Perception was included.

4. Environment in Which the Course was Taught

The laboratory in which the course was given was equipped with nine Sun Ultra 1 SparcStations connected to the university network. Each computer was equipped with three headphones so that students could listen to the sound files they were working with without disturbing other students or groups. The number of students taking the course has ranged from 15 to 20. During contact hours students thus had to work in groups of 2 or 3. Although students were, thus, allowed to work in groups, all assignments had to be handed in (i.e. submitted over the net) individually. Outside contact hours they often worked alone.

5. Results

The course has been given twice to first semester phonetics students and also once to a group of speech therapy students. Most students had no, or very little, experience with computers. Needless to say, this caused some initial problems, but this disadvantage was outweighed by the students' feeling that the exposure to computers and the Internet was something generally beneficial and a kind of knowledge that would become useful to them in other contexts. Comparing the students' results on theoretical parts of their written tests and assignments, they performed on par with students in previous years when the course was taught in the form of lectures supplemented by a few laboratory exercises. Their command of analysis procedures was, however, markedly better as was their understanding of these procedures and the relevance of acoustic analysis in the study of speech. Their understanding of experimental techniques and results in the field of speech perception was also improved. The immediate feedback of the results of their own perception tests and the possibility to view the accumulated results develop, as more subjects completed the task, gave them deeper insights both into experimental techniques as such and the particular aspects illustrated by a given test.

Abstract: This paper describes the development of an introductory course in Information Systems that is taught in a learner independent mode using the Internet. The paper focuses on the conversion process from the face-to-face format into the Internet-based independent learning and highlights some of the issues found during the conversion efforts.

Introduction

There is a tendency to view education on the Internet as a universal innovation applicable to all types of instructional situations. It is true that Internet-based independent learning (IIL) has the potential for a fundamental and beneficial transformation of higher education. By combining the best aspects of our present university systems with the opportunities offered by the Internet, distance independent learning could lead to the creation of high quality, highly individualized instruction and the creation of student communities which transcend the limitations of time and space [Besser and Boon, 1996 and Jorn, Hill, and Walstrom, 1996]. However, there are also some negative effects of the widespread adoption of these new instructional delivery vehicles. A number of important questions need to be answered before Internet-based independent learning can fulfill its potential and become a tool that augments and supports traditional education rather than just cheaply replacing it. In this article, the authors describe the process being used to move the End-User Computing course (IS 215) from a face-to-face lecture delivery to a student-centered delivery structure using the Internet.

Background

The three-credit End-User Computing course is a service course that is offered to every student in the College of Business. Students must take this course during their sophomore year. The course provides an overview of the concepts, tools, and methodologies related to the use and design of information systems. The course description in the 1996-1997 catalog is:

Managers and professionals are using computers more extensively. This revolution is known by the name “End-User Computing”. Students learn traditional information systems topics such as software life cycles, transaction processing systems, and business problem solving. In addition, a wide range of applications including Decision Support Systems, Executive Information Systems, Non-clerical Office Automation, Data Communications, and Local Area Networks are covered. These applications cover all the functional areas of business. Coursework includes conceptual as well as laboratory material.

This course was chosen for Internet delivery because: (1) the focus of this course is primarily conceptual, (2) it presents students with a fixed wide but shallow set of skills, knowledge, and goals, thus a more suitable prospect for Internet medium, (3) it is a multisection course, providing a choice for a larger number of students.

Students enrolled in this course are required to learn the basic concepts and functionality of information systems including decision support systems, expert systems, network systems, database systems, and support systems. In addition, the course must also provide hands-on experience in using spreadsheet, wordprocessor, database, and decision support systems applications. The current course structure consists of a three-hour lecture per week to the entire class followed by individual student work in the open computer laboratory. In
addition, students were requested to attend a number of workshops to learn specific applications such as Microsoft Excel, Microsoft Access and Microsoft Word and to learn about email, web page development, and FTP. The three classroom hours per week were dedicated to the presentation of the course's topics, answering questions concerning problems encountered in executing exercises, and describing project requirements. Student tutors were available in the open laboratory to answer application specific questions. The text used for the course was Introduction to Information Systems 8th edition by James O'Brien.

The primary problem in the current structure is the wide variation in the student's entry level computer skills (15 percent of the students have all skills for 85 percent of the course's hands-on competencies, 25 percent have never used a computer, and 67 percent do not have keyboarding skills).

New Delivery Structure

Two major changes in the structure of the class were implemented:

1) provide access to instructional material critical for independent work on the applications through a course home page on the web;
2) divide the students' learning experience into two components, namely an independent component where students learn concepts and applications on an independent basis and through a weekly one-hour traditional class meeting.

The web was chosen for the delivery mode over an implementation using authoring software because it is platform independent and students could access the course from home using local web service providers. In addition, the new structure must support: unit testing on demand, independent access to tutorials on major application software concepts, and opportunity for experienced students to explore and learn advanced functions in the software applications.

New Course Elements

The new course has the following elements online:

Course syllabus and general course information: The standard information normally distributed through a course syllabus is included.

Late-breaking news and course information: A “Latest News” section on the main web page of the course provides communication from the instructor to the class for weekly course information. This is the primary communication link to students working independently on the course.

Workshops and lecture schedule: The schedule for demonstrations and application lectures in the traditional classroom and a schedule for the hands-on workshops are included in this element. Students use the schedule to determine the class lectures and/or workshops they need to complete the unit exercises. Skilled students may attend few lectures; however, a student new to computers might attend every lecture and workshop.

Application exercises files: Required exercises in each of the software applications are included. The exercises include basic work from the text or web files to learn the specific software applications.

Test schedule: A test schedule is provided on-line. Tests are conducted on-line making it possible for the student to know the results of the test immediately.

Team building exercise files: Two exercises in team building are included to prepare students for work in teams in this course and in future courses.
Issues

During our developmental efforts we encountered a number of issues that need to be taken into consideration before an effective system can be developed. Following Hartly [Hartly, 1996], we classified these issues as administrative/academic, technical, and societal.

Administrative/Academic

Administrative support: Without support from the administration to facilitate the introduction, maintenance and effective operation of WWW based educational systems, development of such systems will be hampered.

Development time: Internet-based educational systems take substantially more time to develop, set up and maintain than traditional courses. Thus, it is important to be conservative in the introduction of new systems to avoid overreaching the lecturer's capacity and ability.

Administrative acceptance of WWW educational tool construction: Again, without the support and recognition from the administration by making the development of such systems a viable part of faculty load and including it in tenure and promotion consideration, very few instructors will start developing such systems.

Student type: Systems must be designed with regard to the type of instruction delivery intended (distance vs. on-campus learners) and the types of students using them (mature vs. immature learners)

Changing role of teaching in this environment: While preparing this course, we realized that the role of the instructor in such a course needs to change. For instance, instructors using lectures to anchor the course (as opposed to providing the primary means of instruction) will find themselves playing the roles of:

- Gatherer of knowledge, by the fact that we searched the Internet looking for tutorials in different areas of the course.
- Facilitator, by the fact that we created a resource web page to direct students to the corresponding sites where they were able to collect information and acquire knowledge.
- Mentor, since students asked questions and requested direction regarding the material covered in the course.

Technical

Bandwidth availability: Depending on the material being delivered varying network capacities are required. Some of the students participating in this course were accessing the materials from home using low-end data communication equipment. This sometimes caused their phone connections to drop or slow transmissions.

Site management: The status of links to material contained on other sites must be tracked due to the fact that they are dynamic and can be changed or removed.

Development tools: At the time of this write-up, many of the tools available for the development of Internet-based educational systems lag behind the Web standards. For instance, some products do not yet support frames.

Societal

Copyright protection and other legal issues: There is a temptation to use copyrighted material to supplement the lecturer's own efforts. Use of an electronic means of delivering course material means that implementers can be held liable for any copyright infringement in material placed on their system.
**Haves vs. have-nots:** At the moment high-speed access to the Internet is facilitated through expensive computational resources. This limits the suitability of systems intended for student’s home use.

**Phenomenon of isolation:** We found that some students had a feeling of isolation when working exclusively from home. Thus, care must be taken to ensure that students are not isolated by the new systems but are encouraged to participate at every possible opportunity in interaction and cooperation.

**Student Outcomes**

In our initial evaluation, we have experienced that students taking the Internet course have achieved a mastery of course material equal or superior to that in the traditional classroom. Moreover, students have reported higher subjective satisfaction with the Internet course than the traditional courses (TC) on a number of dimensions, including improved overall quality, whereby the student assesses the experience as being "better" than the TC in some way, involving learning more on the whole. Finally, those students who experienced "group learning" in the virtual classroom are most likely to judge the outcomes of on-line courses to be superior to the outcomes of traditional courses.

Signaling Theory and Internet Epistemology

Don Fallis
School of Information Resources & Library Science, University of Arizona, USA
E-mail: fallis@u.arizona.edu

Abstract: Since almost anyone can put almost anything on the Internet, there is a lot of inaccurate information out there. The standard line is that the only solution to this problem (that does not involve censorship) is for Internet users to improve their critical thinking skills. In this paper, I point out that we can also deal with this problem by making information easier to verify. I then suggest that signaling theory can help us to figure out exactly how to make information more verifiable.

1. Inaccurate Information on the Internet

As access to the Web has widened, legitimate information has been subsumed by a deluge of vanity “home pages,” corporate marketing gimmicks and trashy infomercials. ... It is impossible to know where information comes from, who has paid for it, whether it is reliable and whether you will ever be able to find it again. A student looking for information on the Internet about, say, World War II, cannot know whether a given “page” has been posted by a legitimate historian or by a Holocaust revisionist. ([Hecht 1997], p. 15)

There are two factors that make it very difficult for people to acquire knowledge (or at least true belief) using the Internet. First, since there is a vast amount of information on the Internet, it is often difficult for an individual to find the information in which she is interested. Second, once she finds the information, it is often difficult for an individual to determine whether or not the information is accurate. (And since almost anyone can put almost anything on the Internet, there is a lot of inaccurate information out there.)

A lot of effort has recently been put into solving the first problem (e.g., research has been done on improving search engines, classifying information on the Internet, developing automated retrieval systems, etc.). However, the second problem has received much less attention. How can we make it more likely that the users of the Internet will be able to distinguish accurate from inaccurate information?

The standard suggestion is that we have to improve the critical thinking skills of Internet users. Following this suggestion, several recent articles (see, e.g., [Tate & Alexander 1996] and [Fitzgerald 1997]) have tried to identify a number of features that Internet users should look for on a web page. For instance, Internet users are advised to look for a statement of the name and affiliation of the author of the page, the absence of spelling and grammatical errors, the absence of common logical fallacies, etc. Such features are supposed to be fairly reliable indicators of whether or not the information contained on the page is accurate.

Unfortunately, there are two main drawbacks to the aforementioned research. First, these articles have very little to say about exactly why those features that Internet users are supposed look for on a web page are reliable indicators of accuracy. Second, these articles leave the mistaken impression that improving the critical thinking skills of Internet users is the only way to solve our problem. In fact, we can make it more likely that Internet users will be able to distinguish accurate from inaccurate information not just by changing the users (e.g., by improving their critical thinking skills), but also by changing the information (e.g., by making it easier to verify).

2. Signaling Theory

There are a number of “signals” that might allow Internet users to distinguish web pages that contain accurate from web pages that contain inaccurate information. However, some of these signals will not be under the control of the authors of web pages. If we want to make information more verifiable, we need to focus on those signals that are under the control of the authors. Signaling theory (see, e.g., [Spence 1974]) can help with this endeavor. Signaling theory lays out the criteria that such signals must meet in order for them to be reliable.
indicators of accuracy. We can then use these criteria to determine if particular signals (such as those identified in [Tate & Alexander 1996] and [Fitzgerald 1997]) do the job.

Signaling theory deals with situations that have a structure similar to the following situation. There are a number of salesmen. Some of these salesmen only sell high-quality products; the other salesmen only sell low-quality products. There is one buyer. The buyer has to decide which salesmen to buy from. He would prefer to purchase only high-quality products. However, he cannot tell the high-quality products from the low-quality products just by looking. (Such situations are games of asymmetric information. The buyer is the uninformed player and the salesmen are the informed players.)

There are a number of different situations that have this structure. The Internet user, for instance, is in a situation that has this structure. There are a vast number of web pages on the Internet. Some of these pages contain accurate information; the rest of them contain inaccurate information. The Internet user would like to believe only accurate information. However, she cannot tell just by looking whether or not the information contained on a web page is accurate.

The buyer needs some way to distinguish the high-quality salesmen from the low-quality salesmen (and the Internet user needs some way to distinguish accurate web pages from inaccurate web pages). Signaling can help the buyer to make this distinction. In particular, he can make this distinction if the high-quality salesmen send a signal that (unlike the quality of the products) the buyer can easily observe and if the low-quality salesmen do not send the signal.

In order to apply signaling theory to this situation, we make the assumption that the salesmen are more or less rational. In particular, we assume that a salesman will send a signal if and only if the benefit of sending the signal outweighs the cost. Given this assumption, two things have to happen in order for a signal to do the job. First, for the high-quality salesmen, the benefit of sending the signal must outweigh the cost. (In this case, the benefit to a salesman of sending the signal is having the buyer purchase his product.) Second, for the low-quality salesmen, the cost of sending the signal must outweigh the benefit.

Given this analysis, there are some further conclusions that we can draw about the criteria that a signal must meet in order to do the job. First, it must cost something for a low-quality salesman to send the signal. (And it may cost something for a high-quality salesman to send the signal as well.) If signaling were free, then all of the salesmen would send the signal in order to have the buyer purchase their products. Second, if the benefit to a low-quality salesman of selling his product is at least as high as the benefit to a high-quality salesman of selling his product, then it must cost a low-quality salesman more to send the signal than it costs a high-quality salesman. If it costs the same amount for all salesmen to send the signal, then all salesmen would make the same decision about whether or not it is worth sending the signal. In order for a signal to be a reliable indicator of accuracy on the Internet, it must meet these same criteria. For instance, it must cost something for the authors of inaccurate web pages to send the signal and it must cost the authors of inaccurate web pages more than it costs the authors of accurate web pages.

Of course, in order to apply these (and other) lessons from signaling theory to the Internet, we again assume that the authors of web pages are more or less rational. However, we also have to assume that (all other things being equal) the authors of web pages prefer to be believed by Internet users. (In this case, the benefit to an author of sending the signal is having the Internet user believe that his information is accurate.) If it does not matter to an author whether or not he is believed, then he has no reason to send a signal that his information is accurate. (It went without saying that salesmen prefer to sell their products.)

Finally, I should note that some signals that are under the control of the authors of web pages do fall outside the scope of signaling theory. In order to do the job, a signal must be something that the author of an inaccurate web page is unlikely to send. In most cases, the author of such a web page is unlikely to send the signal because it is not cost effective. However, in some cases, the author of such a web page is unlikely to send the signal because he is simply unable to do so.

Even so, as I have tried to suggest in this paper, signaling theory can be a very powerful tool if our goal is to make information more verifiable. It provides an analysis of a large and important class of signals that are under the control of the authors of web pages and that are reliable indicators of accuracy.

Navigational Patterns in Interactive Multimedia and Their Effect on Learning

Sue Fenley
Institute of Educational Technology, Open University, Walton Hall, Milton Keynes, MK7 6AA E-mail: S.I.Fenley@open.ac.uk

Abstract
Research on navigational patterns in interactive multimedia outlines previous research and then proposes a new set of navigational patterns from the empirical work, and comparing these to the earlier patterns. Empirical work tested these and assessed differences between novices and experts, and children and adults. Differences in navigation can be explained by factors such as: how the users have been taught to use software, their usual learning or teaching methods, their exposure to computers and multimedia, their age range and the specific task. Methods of defining and encouraging learning strategies in multimedia are investigated and a usable classification developed. The benefits of multimedia for individuals are outlined e.g. personalised work patterns. The conclusions, state that most users have preferred methods of navigating and learning strategies and these methods, the benefits for the individual learner and the link between navigational patterns, experience and learning strategies are important.

Introduction
The construction of multimedia packages to date has usually been developed along conventional software design. However the unique learning environment which can be created when using multimedia means that innovative methods of constructing packages must be encouraged in order that the facilities and qualities of multimedia can be exploited to give the best learning environments. My research investigates the ways people learn from multimedia, and how we can incorporate these into the design structure. This paper commences with present navigational research, it then investigates the results from the initial empirical work. A new classification for navigational patterns is then outlined and these patterns are then tested by further empirical studies, where the users actual navigational patterns will be analysed in terms of my classifications and these are then compared to those of other researchers. Finally work on learning in multimedia is detailed and some methods of defining and encouraging learning within multimedia are developed, by proposing a series of learning strategies.

Research on navigational patterns
Horney's work (1993) is important here as he investigates users using hypertext and discovers five navigational patterns, namely Linear Traversal, Side Trip, Extended Star and Chaotic. His patterns can be described as: - Linear Traversal where the user visits each node in order, moving in a linear pattern; Side Trip which is mainly linear but with visits to other nodes not on their main path and is a more than the first; Star pattern, which uses a central or root and returns to this; Extended star which includes nodes the user wants to revisit, such as out and back cycles and Chaotic where the user has different traversal methods and randomly moves through the document. Horney does not fully explain his star pattern but this appears to differ from his linear one if the user moves to a different level in the package, this is the criteria I have used to determine the difference between linear and star and it seems that Horney had a similar distinction. Horney's view of the chaotic pattern was that these users were not lost, but that their navigational routes were too complex for a more regular pattern to be discerned and therefore the Chaotic pattern could be a mixture of other patterns.

Parunak (1989), also looks at various strategies people use and produces a series of topologies to relate to them. He identifies five common strategies: - Identifier, Path, Direction, Distance, and Address, where the Identifier allows the user to distinguish the target; path follows a definite linear route (and could be a basic component of other more complicated strategies); and direction, such as north. However direction is more of a working method, rather than a distinct pattern. The next strategy, distance limits the search to a distinct circle around the current location and address gives it a specific location. Parunak then briefly develops six topological structures to support these strategies which are - Linear, Hierarchy, Hypercube/Hypertorus, Directed Acyclic Graph and Arbitrary, which I find much closer to my navigational strategies than are his navigational strategies, which look at methods of navigating rather than at patterns and so I have used his typologies to relate to my navigational patterns. His first linear topology, is straightforward and presents a one-way linear route but it can also form a ring, (as in my circular definition), but if it uses different levels this would be classified as my star pattern, not linear. Parunak's second topology is Hierarchy. The next topology Hypercube/Hypertorus is difficult to relate to multimedia as there are few software packages that would conform to this structure. The next topology is one called DAG - Directed Acyclic Graph. My view of this strategy is that it is too similar to the hierarchical one to be categorised separately. The final topology is arbitrary, which consists of any connected graph, this could be a huge category and probably needs subdividing. In Parunak's categories the linear, ring, hierarchical and arbitrary topologies can be broadly compared to my classifications. Having looked at the two main contenders for
navigational patterns I now want to investigate the work of others whose research has influenced my work. Trumbull, Gay and Mazur (1992) experimented with a system which had three different built in navigational and guidance tools :- index, guide and browse. The Index allows the user to search through a textual description of the topics, Browse enables users to use screen commands to move through the package and the Guide provides an online advisor. The three navigation tools were designed to allow users to decide on their own strategies for obtaining information. The results from the survey identified four distinct groups of users, all of whom were classified by using the individual navigational tools for varying amounts of time - Browsers (89% of time), Indexers (65%), Guiders (26%) and Mixers who used all the tools. Hammond and Allinson (1989) also support Trumbull et al's conclusions that as the students were using different strategies, designers should develop a variety of interfaces that allow for different search strategies. Trumbull et al's work is particularly relevant to my research as it looks at the use of particular tools to navigate through multimedia and these tools can be compared to the different ways of approaching an encyclopaedia. Beasley and Vila's (1992) work looked at two main areas, namely the relationship between navigational patterns in multimedia and academic ability, and secondly whether these patterns related to gender. They identified patterns of access in terms of linearity or non-linearity and examined the relationship between these patterns of access and learner aptitude. They stated that females took a less exploratory approach than males, however this appears to be only true for the lower ability female group, while males of higher ability use non linear methods. Mischanuk and Schwier's (1992) work which discusses the use of audit trails in interactive hypermedia is potentially very useful. Their audit trails involve recording each screen that the user visits and factors such as :- the number of repeat visits, how long they spent on certain sections and the exact paths they took, are useful. They suggest four distinct types of audit trails, but state that in reality these are often combined within programs. Their four types are linear, classic feedback loop branching, learner controlled parallel path branching and multimedia/ hypermedia. The first linear is the basic path recognised by several researchers. The second branching structure allows some paths to reconverge, this path resembles my star pattern. Their third structure - branching paths run parallel to one another and converge and the learner then continues on the instructional sequence, rather like my hierarchical one. This final path has the most complex structure and is much more variable than the others. They then give ways of utilising these audit trails:-- formative evaluation in instructional design, basic research in instructional design, usage audits and counselling and advising. Hence Mischanuk and Schwier's results are broadly comparable to mine, except for the fact that they have only found four main types of trails and I believe it is possible to differentiate these patterns into more finite types.

Canter, Rivers and Storrs (1985) looked at user navigation through interactive databases and discovered a set of indices to characterise users search sequences which could give more precise definition of strategies such as browsing, looking at crucial factors such as the task the user is performing and their preferred strategies. They developed six indices to characterise users navigational behaviour:- pathiness, ringiness, loopiness, spikiness, NV/NT and NV/NS. Pathiness describes a route through the data which does not cross any node twice, a typical linear path in my classification. Ringiness, a route through the data which returns to the starting point, is simple and closed, and is like my circular route. Loopiness, is a route in a ring shape which contains no other rings, the main difference from the ring being that the latter usually emanates from a specific base node and is usually the only route from that node. Spikiness is a route which retraces the path taken on the outward journey in exactly the same way and is most like my Star extra pattern. NV/NT is the ratio of number of nodes visited, to the total number of nodes available in the system and gives the proportion used by each individual. Finally Zhao (1992) found that the same type of navigational strategy was adopted by nearly all of his subjects. Zhao describes how he found three types of browsing - hierarchical, depth first search-like and chaotic. He finds that there are a variety of factors which affect the navigational strategy applied by a user such as the hypertext topology, interface design, navigation tools, learning objectives and learner individual differences.

Empirical Work
The empirical work for this study has involved a pilot study of primary and secondary children using multimedia and a main study which looks at the ways adults use multimedia, how they commence using a package, how they navigate through particular routes and how they approach projects. The pilot study used a range of commercially available software, such as The Way Things Work, Grolier's Encyclopaedia and Medieval Realms, among others. The first task involved a short browsing or orientation session, where the pairs of children were allowed relatively free access to the software, followed by a more restrictive set subject that they researched and where their exact routes were recorded and a final task asking them to assess how the material they had been using was structured and if possible to describe or draw the layout. My initial empirical research showed that younger students have very distinct preferences for certain types of multimedia packages, but also that older students were much more task orientated and that they found browsing more difficult and time consuming than the younger ones. These results are also comparable to some of those from Misanchuk and Schwier. Information from the pilot study which is useful to the main study includes the navigational patterns used, the type and nature
of the tasks given to the users, the amount of work possible within the allowed time and problems with recording. This has allowed an analysis of the navigational patterns used, ranging from a simple linear structure through to complex patterns. Furthermore for most users there seems to be either one preferred pattern or a limited range of patterns that they habitually use. However most of these users were new to multimedia and their selection of particular patterns may alter with longer use of such packages, although even more experienced users of multimedia did have preferred patterns of use. In the main study adult students were asked to perform various tasks with a selected multimedia package to assess their navigational patterns and their learning. Both pre and post questionnaires were performed. The pretest questionnaire covers aspects of the students previous computer and multimedia use and their interests. The post test questionnaire asks for some factual responses to specific questions relating to the knowledge they have learnt in the test, and then continues in the form of an interview, where their opinions on the software and their method of navigation are investigated. The following hypotheses will be investigated: - that each individual has preferred methods of using multimedia; that certain navigational patterns are more beneficial to the learning process than others; that navigation patterns can encourage deep learning; that beneficial navigation patterns can be learnt and reused; that experience can improve learning from multimedia; and that controlled use of multimedia can improve learning. Encarta was chosen as the encyclopaedia which allowed the most flexibility and greatest range of navigational patterns, as well having a resource pack which detailed ways of using the package for research and gave templates and instructions to teachers on how to use the package and examples of its use. These are: - an exploratory Task 1, an investigative approach which forms the main sequence of set tasks (Task 2), and a final open task (Task 3). The first task is a browsing task (15 mins) which should allow the individuals personal preferences on navigational patterns and their interests to be determined. The second task is to search for information on a topic in four different conditions. These four navigational routes are linear, circular, hierarchical and complex. The amount of user choice will increase through each of the four patterns. This second task is used to assess navigational patterns, whether or not users keep to the prescribed or flexible routes, how often and in what manner they diverge from these paths, and the learning that is achieved during this time. The third task involves users selecting a topic and researching it within the package for 25 mins.

Results of the main study
From the empirical work in this research it appears that most users have a preferred set of navigation methods. The most popular combination is linear and hierarchical patterns, which appears to be the case across the expert to novice groups, with some users being very linear. These users seem to be very methodical, but as the students who strongly prefer the linear approach are mostly novices this may represent the way they have been taught or the way they usually approach learning, i.e. in a sequential manner, although this may not be the most successful approach with multimedia. Intermediate users proved to be very variable in their preferences, although there were only a few of these, so this may represent the range within the sample rather than the way this group of users would normally perform while the expert users tended to be very complex and this suggests they may have been using certain strategies for certain tasks. The expert users use many other types of routes, some in part, but generally in a more mixed way, showing abilities in switching to different methods or changing their strategy. Most of simpler routes are favoured by novices, the intermediates are slightly more adventurous but it is the experts who on the whole are much more likely to branch out, try different strategies and to follow different navigational patterns for each task. There seems to be a fundamental difference in how inexperienced people choose to navigate, or how they commence using the package and how the experts do this, as their navigation is much less purposefully followed, it appears to be much more intuitive, especially if they reach a dead end, when they are much quicker at re-assessing where to go next than the other two groups.

Fig. 1 Main navigation Routes Used (20 Students in all)
Very linear/ little hierarchical - 2 Users (Novices)
Linear and Circular - 1 User (Intermediate)
Linear and Star, some hierarchical - 1 User (Novices); 1 User (Inter)
Linear and Hierarchical - 4 Users (Novices); 1 User (Inter); 4 Users (Experts)
Complex and Hierarchical - 1 User (Inter)
Complex users - 5 Users (Experts)

The linear route is the most common, although not the most frequently used route. Most users need to have some sequential movement through the resource, although this is more noticeable in the novices. There are fewer example of the use of the linear extra route and perhaps this is a variant of the main type rather than a specific route on its own. There are relatively few examples of the circular route in this group of users, although there may be some examples of users using it for small amounts of time. It was much more prevalent in the pilot study as younger users seem to use this, as well as the star pattern, to check that they have covered everything and as an orienteering device, have a quick look around, and come back to the beginning before going on. The star and
star extra are also relatively little used in the adult groups. Most users seem to use the hierarchical or hierarchical extra pattern at some stage during their search, with the possible exception of some of the very linear preference novices. Also some of the children in the pilot study rarely, if ever, used a hierarchical pattern. For most users the use of the hierarchical pattern comes after the initial use of the linear or star pattern, i.e. in the middle of the search. The complex chaotic users are all confined to the expert group and only occur quite rarely. The complex planned type of navigational pattern is the more common of the two types of navigational patterns in this category and is again only used by the experts. The experts were much more competent users and were much faster, covering a lot of ground and making quick decisions. There are several links between the pilot and the main study. Firstly the younger students in the pilot study also had distinct preferences in their choice of navigation routes. Most of the younger students preferred either a linear or a hierarchical route while some of the students also used the star and circular routes. In the main study the linear and hierarchical routes were again most common, although most users used some linear followed by a hierarchical pattern for different stages of the research, rather than the younger students habit of selecting either a linear or a hierarchical route. Few of the pilot study students used several patterns and none were complex users. In the main study there were some users of multiple patterns which became the complex users. The star and circular pattern also seem to be more common with the pilot study students than the main study students.

**Development of my own series of navigational patterns**

I have developed a series of navigational patterns from the information gained in the initial pilot study. For this research a broad genre of types is sufficient to adequately describe the patterns and to distinguish them from one another, future research may enable further more finite classification. The detailed descriptions of each type follow and are then compared to the types found by other researchers (Fig 2). My list has been created by comparing individual or groups use of multimedia. All the users patterns observed could be put into these categories, although obviously there are more in some categories and the latter two categories of complex, chaotic and planned may need further refining as it is possible that these may provide a final classification for all the complex or unusual patterns as well as the very complicated ones.

**Description of Navigational Patterns**

The following types of navigational pattern have been discerned, with a short description of each :-

1. **Linear** - Following path on same level, using index, time line, or word search features, usually one way.
2. **Linear extra** - Mostly as linear pattern but some paths/routes leave this, then return to path.
3. **Circular** - Initially and in some incomplete forms recognised as linear, when complete can be one way or two way becomes arc or circle when nearer completion, or is dependent on the design of the software.
4. **Star** - Moving along in linear fashion but changing level, going into all or some second level areas from first level and returning, can be one way or two way, breadth first qualities, going into complete star pattern, selection all through package especially in those with a circular or thematic structure e.g. looked at all themes and moved into second level.
5. **Star extra** - User goes into 2nd/3rd level of package, i.e. additional level, beyond usual star boundaries.
6. **Hierarchical** - User moves down hierarchy and then may return to go down one or more other branches of tree structure, usually one way down structure and across or return to next branch of tree structure, depth first qualities, can be two-way, although not usually totally returning to original starting point.
7. **Hierarchical extra** - Can go along multiple hierarchies, different subject/types but all in the same way, can return to same tree structure or may continue onto linked tree structure, i.e. several branches of same tree.
8. **Complex** - Chaotic, Random use of navigation, may be mixture of some of the above types.
9. **Complex planned** - Sequence of moves following established paths, can usually see which patterns are being used, a mixture of different types but forms ordered route through resource. The types can be mixed within the route, i.e. some recognition of each type but too confused or short to classify as each individual pattern.

**Fig. 2 Comparative Navigation patterns**

Comparison of my patterns with other researchers

There are some links between my work and that of the researchers above, especially Horney. There are links with most of his search patterns, although he probably does not extend his classifications far enough. Comparing Parunak's work I can find relatively few links with his strategies, although his topologies are very relevant and can be linked into my classifications quite neatly. In Trumbull et al's work their Index strategy is like my Star pattern, the Browser suggests the Linear pattern or Horney's Linear Traversal and their guide perhaps - Side Trips or my Linear extra. In Beasley and Vila's work their linear strategy links perhaps to Horney's Linear Traversals or a generalised linear pattern and is similar to my basic linear route, however their non linear pattern is perhaps most similar to Horney's Side Trips, which in Horney's classification system is not really hierarchical, and perhaps slightly to my hierarchical pattern. Hence most of the research has some links to my patterns, but on the whole is less comprehensive and suggests that there are more routes or ways of looking at navigation and most of the researchers have concentrated on quite a narrow range, when compared to my more global approach.

Learning strategy research

The next area of research to be discussed is that of learning cycles which I also investigated, looking at those proposed by Kolb, Driver and Laurillard. The stages in Kolb's (1984) experiential cycle include Experience, Description, Analysis, Generalisation, and Action Plans. Driver's model (1988) covers more of the necessary stages with orientation, elicitation of ideas, restructuring of ideas, clarification and exchange, exposure to conflict situations, construction of new ideas, evaluation, application of ideas, review change in ideas, comparison with previous ideas; but it is a rather linear sequence, whereas Laurillard's has the cyclic process but also includes more reiteration as well as input from the teacher, which she considers to be crucial. Laurillard's cycle (1993), which is perhaps the most applicable to multimedia design, includes stages for both the teacher and the student:- the teachers conception, then the student conception, discussion then the teachers redescription and the students redescription, then reflection and adaption, before more discussion or interaction, then the third part task goal, action, feedback, modified action more interaction follows and the fourth part of the cycle which involves another period of adaption and reflection. Research on the way people learn from multimedia has involved looking at the work of people such as Yildiz and Atkins, Barker and King, and Self.

Yildiz and Atkins (1993) criteria for evaluating multimedia has also been useful to my research as they suggested a whole list of reasonable factors in evaluation which I would support, notably that evaluation should concentrate on courseware characteristics, the user and the learning task rather than the platform; that the software should be exploited to the maximum; that implicit beliefs on student learning methods should inform the design; that the learning context is important and that the evaluation of outcomes, conceptual learning and higher order conceptual skills are essential. Barker and King (1993) suggest the use of self-anchoring where their points of view are anchored graphically or numerically. Their research also highlighted engagement as being highly rated in good multimedia as is tailorability and interactivity, all features which I would agree with. John Self (1995) has been using student modelling with multimedia and in particular stated that 'developers of multimedia learning systems are realising that presentation needs to be adapted for individual learners'. Finally my learning strategies are compared with those of Trumbull, Gay and Mazur; Midoro and Pedemonte; Canter et al; and Conklin. Conklin (1987) states that the browsing of a database can be done in three distinctive ways; by following links, and opening windows successively; by searching all or part of the network and thirdly by navigating around the hyperdocument, using a browser that displays the network graphically. Trumbull, Gay, Mazur (1992) grouped their users according to which of three main navigational tools they use predominantly the Browser, Index, Guide, or a Mixed group. Canter, Rivers and Storrs (1985) work used the type of paths found, e.g. pathiness, but as they also discovered five search strategies to do with ways of learning, their work is also included here. These five strategies are defined as Scanning (mixture of deep spikes and short loops as users seek to cover a large area but without great depth), Browsing (many long loops and a few large rings, users go where data leads until interest is caught), Searching (ever increasing spikes with a few loops for users motivated to find a particular target), Exploring (many different paths, suggesting users are seeking the extent and nature of the field), and Wandering (many rings as the user ambles along).
Description of the learning strategies

From an investigation of this work from other researchers and observations a series of learning strategies have been developed, which can be used singly or in conjunction with the navigational patterns above, these are compared to the other researchers in Fig 3. The use of terms such as browsing is open to abuse as different researchers have applied the term for a whole range of diverse activities and it is more helpful to be more specific as to what each of the activities refers to. Many of these could be attributed to more generalised browsing, and so I have been much more specific in both the naming of the terms and in allocating their use to certain observations. The following list outlines the learning strategies found:

- Orientation, Ordered/Structured - Linear/Circular, Systematic/Hierarchical, Complex - Random and Complex - Planned. The table below links these with the strategies from other researchers:

There is an element of experience in the use of all search strategies, i.e. does repeated use refine the methods of use and the effectiveness of a particular strategy, or are experienced users likely to develop complex ways of investigating multimedia resources. Frau, Midoro and Pedemonte's (1992) work is very relevant here and can be compared to this study as they concentrate on the modes of interaction and the strategies students use to investigate the software, the problems they encounter using the system and its learning effectiveness. They suggest supervisor functions should be:- the selection of topics to match educational objectives and learner status, choosing the next best topic and the best strategy for that topic, and selecting the best unit of learning (ULM) to both implement the strategy and perform the given educational function. Questions that Frau et al are asked of the students, such as how long do they spend on each activity, what order they proceed in, problems etc, are similar to the questions asked by Laurillard in her student assessment work (1993). Their second aim is to analyse how effective the learning is, an aim which is very close to my own study. They decided on a qualitative approach and assessed different strategies of browsing and the learning that resulted. Interestingly they impose two conditions; a self service mode with no explicit task (similar to my initial browsing task) and task guided navigation, which can be compared to my task based exercises. Frau et al also find that 20% of the time is spent working out how the system worked, understanding and accessing functions, by deductive (looking at system, seeing if appropriate) and inductive methods (using material and then looking for system information). Their results are based on users interviews and the changes in their concept maps and suggest that some students have acquired new knowledge, many others acquiring a lexicon of terms and fewer students understanding the underlying concepts. Looking at the learning strategies, although both groups tended to use some form of linear strategy at some stage in the session the younger students more frequently used the rapid orientation style and less of the ordered strategy, while only some of the pilot group used a hierarchical pattern this was much more common in usage by the main study users. There are also links between the navigational patterns that students use and the learning strategies they use. The experts again have the majority of the links as they tend to use more patterns and strategies generally and are usually able to determine which of these are most suitable for a specific task and use it. The novices are more restricted and will often remain with the one they know rather than try something new. The students that predominately use linear patterns in the navigation are also the most prone to use these, especially the order structure in the way they learn, although there is a small overlap with the hierarchical methods. The experts tend to be more willing to use hierarchical rather than linear learning strategies and link more of the information to outside sources via hot text. There again seems to be some individual preference for particular learning strategies, although this is not as strong a preferences (or set of preferences) as in the navigational patterns. However there is less of a link between the navigational patterns and the learning strategies used in the pilot study than in the main study.
Conclusions
The main element of this research has been exploring the navigational patterns that users employ. External factors may have an effect, such as: how the users have been taught software, their usual learning or teaching methods, their exposure to computer and multimedia, their age range and the task they have been given. The findings of the research suggest that each student has their own individual preferences in how they navigate through software and how they approach learning from it. If we are to encourage students to construct their own learning environments in the constructivist sense then we must encourage them to develop their skills on directing their own learning and in becoming aware of methods of increasing or improving learning, in other words allow them to develop themselves but give them the skills and abilities to be able to do this. If motivation is increased and students can select their own options this deep approach should allow the potential of each individual to be reached. Multimedia can enhance this process by allowing students to develop themselves and providing individual help angled for that particular student and given to them, both in terms of instruction and content as well as help, in the way they prefer and in the manner in which they are likely to gain the most from it. The main empirical work has shown the benefits of multimedia for individuals such as allowing a personalised pattern of work and being able to progress at their own pace. The results of the main empirical work help to support some of these factors and the hypotheses and create some more definable links between navigational patterns and learning in multimedia.

Abstract: There has been increasing interest over the past few years in systems that help users exchange recommendations about web documents. Programs have ranged from those that rely totally on user pre-selection, to others that are based on artificial intelligence. We propose a system that falls between these two extremes, which has distinct advantages over other existing systems since it utilises the structure and attributes associated with Hyperwave documents. This recommender system, which also ensures integrity of external links through its underlying server environment, can enhance the knowledge base of learning associations and other intranet groups.

1 Introduction

Online recommender systems are a relatively new idea, although several innovative projects were described in detail within a special issue of Communications of the ACM [Communications, 1997]. They offer a shared knowledge base of empowerment for online collaboration; to which our intended development adds several unique features. In addition to generating personalised pages of new recommendations, the system will provide users with a historical record of their past and present recommendations to search, review, or rearrange. Each user will be able to review the results of their own archive, but since the recommendation links are to be stored in Hyperwave’s structured database, users can also browse and query an anonymous display of an entire group’s online history of selective media collaboration. This shared resource can be ‘seeded’ with a carefully selected set of links at the time a group of some kind is formed, giving new users a basis upon which to begin interacting.

Since this system relies heavily on certain characteristics of the Hyperwave server (developed by Professor Hermann Maurer and his colleagues in Graz, Austria) we will describe these capabilities briefly in Section 2.

1.1 The Context of the Project

The recommender system we describe here evolved from the more general concept of a system that would produce a personalised electronic ‘newspaper’ for members of the web community at large [Fenn & Shearer, 1996]. In this study we focus on tighter-knit communities such as those in intranet contexts, e.g., those in banking consortiums, medical groups, and education systems.

1.2 User Participation

Our initial approach assumes that all members of the participating group(s) have the same basic aims and objectives, with strong personal incentives toward collaborative cooperation. This ensures that users are sufficiently motivated to quite regularly pass on recommendations for the good of the group as a whole.
2 Hyperwave

It is appropriate to include a brief summary of some of Hyperwave's main features, as these relate to the capabilities of the recommender system that we describe here. More detailed information can be obtained in both book form [Maurer, 1996] and online [http://www.iicm.edu/hw_mm].

Hyperwave was designed and developed as a document management system for very large quantities of multimedia data that can be spread over multiple remote servers. Since efficient maintenance of such massive collections of data is a critical issue, a structured approach was pursued right from the beginning (of what was originally called Hyper-G) [Andrews et al., 1994, Andrews et al., 1995, Flohr, 1995].

The Hyperwave server consists of a set of object-oriented databases. Hence, it supports a range of useful features such as assigning attributes to objects, full-text indexing, and searching (which, in this case, can be confined to a limited scope). The server also maintains a hierarchy of user and group identities.

A variety of attributes can be assigned to each document:

- Multiple, searchable keywords
- Language (with support for multilingual clusters)
- Display properties; such as sequence within a hierarchy
- Read and write permissions for both groups and individuals
- Direct debit, from the user's account, of the cost of viewing a document
- Setting of a time period during which the document is visible to other users
- Any other custom or system-specific attributes

Since attributes are not stored within the documents themselves (as is the case with most web servers), but in a separate database, they can be very efficiently managed, searched, and redefined. Even hyperlinks have attributes.

Each object is labeled with a globally unique object identifier that allows unambiguous referencing from every Hyperwave server. Since these identifiers will not be re-used when the document is replaced or deleted, remote Hyperwave objects can be cached without requiring a sophisticated cache update protocol.

Another aspect of Hyperwave allows multiple servers to be organised into a 'server pool' that shares a common user-hierarchy and keeps the distributed data consistent within the pool (e.g., within a corporate intranet). The Hyperwave protocol is session oriented and stores status details ('session information') about every user currently connected to the system, which can help facilitate various real-time user-to-user communication possibilities.

3 A Simple Recommender System (SRS)

At the University of Auckland's HyperMedia Unit we are prototyping what we term a Simple Recommender System (SRS), based on the fact that we as humans are inclined to express opinions about things. As mentioned in Section 1, the system that we are developing also rests on the assumption that people in a closely collaborating group will actively make recommendations to each other - provided it is reasonably easy to do so. SRS requires that group members use a Shockwave- or Java-enhanced web browser, and that they are logged on to the Unit's local Hyperwave system.

The enhanced browser window will enable users to easily make evaluated and recipient-list-directed recommendations about the currently active page (see Section 3.2). The system will then incorporate all of these recommendation into an interlinked database of URLs, in such a way that each individual user's view is
completely customised on the basis of their own past interaction with both online resources and the rest of the collaborating group.

An absolutely critical aspect of this overall scheme is an intuitive means for users to provide feedback about the accuracy of any recommendations coming through the system, essentially to 'vote' on the relevance of each media resource encountered. This gives the local assessment database a means to adapt its 'rating' of each referee in terms of their success at tagging appropriate resources, from the point of view of the recipient.

3.1 Client-Server Arrangements

3.1.1 Server-side Considerations

On a Hyperwave server the group administrator initialises the SRS by setting up an appropriate collection structure that reflects primary categories of interest to the group. The administrator may also 'seed' the initial collection with URLs of introductory material needed by new users. We'll use Hyperwave's attributes to first prioritise those documents which we consider to be 'core' content; e.g., any documents about using the system itself that new group members should read before beginning to look at other users' recommendations.

In the background will be the software machinery that manages the user-database and meta-collection of recommended links. This can be configured to recognise identical links, having been input by different users, and accept only one numerical evaluation of any particular link from each individual user. Each user can later return at any time, however, to revise their 'value judgment' about a specific online resource. On a regular basis the system will perform a simple statistical analysis of the cumulative assessment of each link and holds the result as a 'group' evaluation attribute. This 'democratically' averaged evaluation can then be viewed within a user's browser interface, whenever they access that resource.

The most critical aspect of the system will be the database analysis functionality that keeps track of the complex pattern of evaluation and interaction between users. It is beyond the scope of this paper to describe the technical details of this process - other than to mention that any resource assumes a relatively higher value within an individual user's own index if it has been specifically recommended, rather than just personally evaluated at the same numerical level. Thus any interpersonal action is rated higher than the same isolated system event.

3.1.2 Client-side Considerations

All of this depends, of course, on users having an effective means of interacting with the background system. To the greatest extent possible, the design of the interface and patterns of interaction must be determined by the needs of end users, rather than by the constraints of any particular suite of software. We have therefore chosen to approaching the production of the client components of the system along two parallel avenues of development: Shockwave and Java.

Shockwave documents are the runtime versions produced from Macromedia's 'Director' application, which require a plug-in to function within a browser. Director is one of the most versatile high-level authoring tools for interactive media, while its underlying language 'Lingo' allows for a reasonable amount of customised programming. As such, initial development with Director/Lingo provides a rapid prototyping environment for implementing various possible forms of SRS client appearance and functionality.

Java, on the other hand, offers the attraction of being able to interlink much more closely with the operation of a web browser and thus more easily access the full capabilities of Hyperwave. This carries the cost however of a longer development cycle and (at present) considerably less assurance of reliable operation on varied systems, compared to an implementation based on a proprietary plug-in.

These two lines of development are not really so separate, since Macromedia is working to position Director as a higher-level programming tool for Java, as well as for its own proprietary formats. Unfortunately, however, the Java output from the current 6.5 version of Director is not yet capable of handling the tasks that are normally delegated to 'helper' components, termed 'Xtras', in the native Director environment. While the functionality provided by these Xtras is not absolutely essential to our initial recommender system, it does
constrain the design to rely only on those network activities that can be delegated to a normal web browser. This seems an acceptable trade-off at this alpha stage of development, though, as a means to readily implement a variety of different approaches to determine the most effective design for the system's basic interface and user interaction.
3.2 Making Recommendations

One of the most important considerations in the design of the SRS is that it should be as easy as possible to make recommendations. Whenever a group member logs onto the group's site, using a Shockwave or Java-enhanced browser, they will see a new-recommendation page (described in Section 3.3.1) along with a specialised interactive options bar as shown in the 'screenshot' below:

![Screenshot of options bar]

The browser-based options bar has the following features (viewed left to right):

- A 'Settings' button which lets each user customise their interface as well as their personal relationship to the overall system.
- A 'Home' button. Clicking on this takes the user to their Home collection archive which serves to index all previously followed recommendations, on a prioritised basis, as well as holding links to that user's own files on the server.
- A 'New Links' button, showing an exclamation point if any fairly highly-valued fresh links are available, which will then bring up an automatically-structured display of all recommendations that have been received since the last (cf. Section 3.3.1), or appears greyed-out if there are no fresh links.
- A central 'Value' slider for entering a personal value judgement about the resource currently displayed. In the case of any document that is new to the user, this slider is preset to a middle value for an 'average' recommendation. (Note that the number scale could be set by each user, to suit their preference for 'granularity' of assessment, and then cross-calibrated at the server.)
- The 'Group' summary field. This is initially a closed window that the user can click to open, revealing the mean value of all evaluations of the current document by other users. This policy of initial concealment was chosen as a way to encourage users to make their own independent evaluations, before effectively polling the average judgment of the whole group.
- A 'General' notation button that sends the URL of the current document to the user's own archive – as well as the group collection - with a value, but without choosing a category for it or designating any specifically defined subset of recipients.
- A 'Specific' recommendation button. On clicking this button the user is provided with a separate interface window wherein they can define the category, user group, and even individual user name(s) for this particular recommendation.
- A 'Help' button, offering context-dependent information about the system.

3.3 Receiving Recommendations

Although the core functionality of the SRS will rely primarily on graded recommendations made directly by users of the system, there are other interesting possibilities. For example, the system can be extended to match up user profiles (based upon their detailed history as evaluators) and then make its 'own' prioritised
recommendations. This effectively serves to create identified but 'virtual' referees (based on an automated analysis of users with similar profiles, who have not otherwise specifically exchanged links that appear to be relevant to each other). This is the general sort of recommendation strategy employed by the Firefly system [http://www.firefly.net]

As described in the next three sections, group members will have several different ways of viewing the recommendations that they've received:

3.3.1 The New Links Display
The New Links 'page' will display the recommended URLs as a list sorted on the basis of an analysis of the referral scores for each individual link. The system enables this page to be personalised on the basis of several interrelated factors. For a start, some users may choose to receive only recommendations that fall into their own selected categories. The display graphics themselves can be selected to suit their own representational choices. Then they can adjust the bias of the system's calculations, giving more or less weight to recommendations that come from any other identified user. Finally, they can specify the degree to which they want the system to adaptively readjust the weighting of each referee's new submissions, based on their own history of evaluated reactions to all of that person's previous recommendations.

Just how the New Links page is presented can also vary widely. Although our initial SRS design only displays a sorted list of URLs, a later version of the system will dynamically create a customised newspaper-like HTML document. This can include banner headlines, re-sized graphics, and selected sections of text - all automatically laid out on the basis of the same underlying sorted-list functionality [Fenn & Shearer, 1996].

3.3.2 The User's Home Collection of Recommendations
In a Hyperwave environment, each identified user has a Home collection that is their personal document space, to which they have both read and write access. Within our recommendation system, the server itself can automatically write to this collection, creating and updating a prioritised index of all the recommendations previously followed or freshly introduced by that user.

In the SRS, these collections and links are to be displayed simply as hierarchies within a browser window. However, we believe that ultimately the system could benefit greatly from having an alternate mode of access to this Home data, including a suite of specialised interaction tools, for the manipulation of data where time, rather than space, is the essential coordinate. The Lifestreams concept, originally conceived at Yale University, makes very compelling arguments for the further development of such a temporal interface metaphor [http://www.lifestreams.com].

3.3.3 Browsing and Querying the Group Collection
The link to this shared view of all recommended links is to be found at the top of each individual user's Home collection. In essence, it is managed by the system in much the same way as each individual's Home archive of SRS links, except that in this case the evaluation criteria is the averaged judgment of the group as a whole and the structure is maintained by the system administrator. New users in particular may find it useful to be able to browse the structured collections containing past years' recommendations. In addition, all users can query this group database using the Verity search engine that is built into Hyperwave.

4 Maintaining Referential Integrity within a Library of Recommendations

The archive of recommendations can form a most valuable resource library and will become an important part of the group's knowledge base, but one of the most difficult aspects of electronic library maintenance is that of ensuring the referential integrity of the links themselves. Within any really useful system these links can number in the hundreds of thousands and it is not humanly possible for any webmaster to maintain them all. Fortunately Hyperwave, as mentioned in Section 2, maintains the link integrity of all documents stored on a 'pool' of Hyperwave servers [Kappe, 1995]. For links to URLs on conventional web servers, the HyperMedia Unit has developed a program to regularly check these external documents, notify interested parties of any
changes, and supply at least the text of any missing documents from a local cache [Anderson and Lennon, 1998].

5 Conclusion

The system we have described will help to establish a shared knowledge base by way of recommendations provided by participants in online group collaboration. The process relies on identified users who intentionally classify URLs, but then employs a database of past activity and an automated evaluation meta-structure to manage the weighted distribution of recommendations. It can thus effectively track and ‘learn’ each user’s preferences for online media by giving individual documents particular priority with respect to the judgment of other referees - without having to rely on any high-powered AI capabilities. We believe that the further development of this approach to collaborative filtering will yield systems (and related service offerings) of very widespread usefulness - particularly within dedicated intranet settings.

Abstract: When researching a topic, users often need different kinds of information which are provided by different information sources. In developing the SINGLESOURCE application, we are building a framework for accessing multiple sources, both for querying several sources simultaneously and viewing the results in a hierarchy of related documents. We first discuss our approach to querying multiple sources, including query translation and result parsing. We then describe our strategy for classifying documents and displaying documents within a taxonomy.

1. The Problem

One of the Web's great strengths is its diversity: one can find information on almost any topic, from many different sources. However, people often want to combine data from multiple sources in a sensible way. For example, someone studying Asian cooking might want information on specialty stores that stock exotic ingredients, recipes and a discussion of regional differences in Asian cuisine. Finding different kinds of information often requires combining results from many different information sources. A user must identify promising sources, and then submit queries to each source. Next, each search request must be recast in the query language of each source. Having gathered results from many sources, the user must often organize the results in a meaningful way, grouping related results by category rather than by information source. At Northwestern University's Intelligent Information Laboratory (the InfoLab), we are currently developing the SINGLESOURCE system to research these and related issues.

2. Accessing Multiple Information Sources

As mentioned above, certain web searches are difficult because they require reformulating queries for different search engines, and the results are difficult to categorize. SINGLESOURCE is designed to address these problems in two ways: a unified query interface and a document classifier. Through the SINGLESOURCE query interface, users enter a single query, and then choose which information sources will be queried. (See [Fig. 1] for a view of the Boolean menu query interface.) There are three styles for entering search queries: complex Boolean, Boolean menu (shown in [Fig. 1]) and free text. (The free text query style allows users to enter plain text to be used in a query-by-example search.) The user only needs to enter the query once, and choose the desired information sources. The sources are chosen using the Search Where? Section, shown on the right-hand side of [Fig. 1].

After the user clicks the Search! button, SINGLESOURCE will send the query string to each of the checked sources. Within the program, each source is represented by an information adapter. The adapters are objects (in the object-oriented programming sense) that encapsulate the information needed to submit a query, and parse the returned results. Each adapter must translate between the SINGLESOURCE query language (a garden-variety Boolean query language) and the specific language of the represented source. Although the syntax of many
Boolean-style languages is quite similar, different features are available for different sources. For example, some sources allow proximity searches that enable searches like: find "relevance" within six words of the phrase "information retrieval". The SINGLESOURCE query interface supports proximity searches, but not all information sources do. Thus, the information adapters must "translate" a proximity query into a reasonable approximation. For example, a proximity search might be treated as a simple conjunction:

\[
\text{relevance WN 6 "information retrieval"}
\]

could be translated to:

\[
\text{relevance AND "information retrieval"}
\]

One research issue we are currently addressing is the design of an information source description language. Each information adapter would then include meta-information on the facilities of the underlying search engine, for example whether or not an engine supports proximity searches and the syntax of such searches would be represented in the source description. Then, the SINGLESOURCE could use more general transformation rules, coupled with a source description, to create source-specific queries dynamically. The W3C is actively developing standardized approaches to representing meta-information, including the new Resource Description Format (RDF) [Lassila and Swick (1998)]. RDF (which is based on the eXtensible Markup Language, XML) is a convenient representation language designed specifically for describing metadata and a likely format for our description language. Information adapters must do more than just transform queries though — they must also parse the query results.

Figure 1: The SINGLESOURCE Search interface, using the Boolean menu query mode
2.2. “A chicken in every pot, and a format for every search engine”

Once a user’s query has been sent to each of the information adapters, and they in turn have queried the underlying search engines, the returned results must be transformed into a common format. (The common format is needed because the results will be classified before being displayed for the user, and the classified results will be displayed with a consistent view. The classification and display of results are discussed in [Classification and Display of Results].) Each information adapter encodes a description of the underlying result format, and methods to extract needed data from the result display format. A comparison of search results between AltaVista and Infoseek is shown in [Tab. 1].¹ Although the two formats look very similar to the human eye, they are quite different to the untrained computer.

Despite the difference in formats, the information included in the results from the two sources is quite similar. Both results sets include: a title, date, size and location (here, a URL). SINGLESOURCE needs to read the different result formats, and represent the information for each result in a common format. The sequence of results from a query to particular information source is given as a result list. Individual results can be accessed either by asking for the nth result, or through successive calls to a getNextResult() procedure. Accessing a result returns a result object, which can in turn be asked for more detailed information. For example, the method getDocumentDate() returns date information for a result.

[¹] Both Web search engines support different display formats — the two shown here are the default formats.
3. Classification and Display of Results

Although searching multiple sources can yield better search results, the user must collate the results from all the accessed sources. For example, when searching for Asian cooking information, you might use your favorite Web search engine, but you might also try more specific search engines on the Web, such as: Asian American Cooking Exchange, OrientalFood.com and Kosher Asian Recipes. Once you’ve located the search interface to each of these sites (or indexed the pages locally) and entered a search, you would still have a list of results for each site without any overall organization. In the SINGLESOURCE application we are building tools that categorize documents given a taxonomy. (A taxonomy is a classification of objects and their relations. A well-known taxonomy is the division of living things into kingdom, phylum, class, order and so on. In this case, the relation represented is inheritance, or “is-a”. See [Fig. 2] for a portion of a business-related taxonomy).

![Figure 2: Classifying a document given a taxonomy](image)

The system begins with a taxonomy and a set of pre-classified documents. SINGLESOURCE is then trained with the exemplar documents; at compile-time, a discrimination network [Feigenbaum 1963] is built using these documents. (Currently, the system only supports a single taxonomy, but the design makes it easy to add alternative taxonomies, and perhaps to allow end-users to choose the taxonomy to be used for classification.) At retrieval time, the system collates the results by retrieving results from each of the requested sources, which are given in the common result format. Next, the result documents are classified using the previously constructed discrimination network. The classified results are then embedded in a tree structure based on the underlying taxonomy. The user can then browse through the result using the tree structure, as shown in [Fig. 3]. As a user clicks on a class or document while browsing the tree, information on the class (or document) is displayed on the right-hand side of the window. When a document is selected, the user can view the document in a separate browser window by clicking the View Document button.

4. Conclusion

The SINGLESOURCE application is a research framework, but one addressing a very practical problem. As online information sources proliferate, users can benefit from better targeted, and perhaps more accurate, sources. However, retrieving results from many different sources can be difficult both when entering queries and when making sense of results. Our initial results suggest that the approach outlined here is promising, and that users see it as a substantial improvement over current usage. In the future we plan on refining the classification procedure and building a description language for information sources that captures both their syntax and content.

Reading Classroom Explorer: Video streaming models of excellence

Abstract

Emerging video streaming technologies, although still considered bleeding-edge, present many new opportunities for more than just businesses on the web. They provide a new medium for teaching and learning among educators and their students. When considering the role of streaming video and audio in education, one commonly thinks of distance learning and telecommunications which provide greater access to available educational resources. We believe that the full potential of streaming technologies goes beyond the simple, although quite important, characteristic of increased access. The purpose of this paper is twofold: (1) to highlight the benefit of web-based video, as we see it: it provides models of excellence—an approach in which network-based learning environments and video streaming can be combined to broaden students’ educative experiences; and (2) to document and analyze the Reading Classroom Explorer as a case study of such an approach to education and uses of these new technologies.

Teacher Education

Many new opportunities have been created in education with the introduction of video and audio streaming technologies. One of these opportunities has been called distance learning/telecommunications. Educators who teach “on the web” embed pictures, graphs, and sounds to support and extend their content-area information, often in hopes that their points become clearer. Like these educators, we also view student access to video as a power of the web medium. In the domain of teacher education, this is especially valuable. Instructors have the flexibility to offer preservice teachers video images of teaching. Current research (Authors, 1998) indicated that some preservice teachers evidenced frustrations and disappointment with their collaborating teacher's classrooms, stating that their collaborating teachers did not use the innovative instructional techniques that they were learning about in their course. With video images in The Reading Classroom Explorer, they received a chance to see what great teaching could be like, in action. The access to many models of teaching was encouraging to them, and was vital to preservice teachers who were especially frustrated by what they considered to be non-progressive teaching methods espoused by their collaborating teacher.

In the past, using video on the web required viewers to download the video (i.e., wait until the computer received it in its entirety) before the user could watch the video excerpt. These download times, often up to a half-hour, reduce its applicability to time-sensitive educational courses. Video streaming offers users a few seconds of download time after which the video begins to play on their screen, buffering the rest as the video proceeds. Only now, with the development of video streaming capabilities, has video and web-based learning environments become feasible for implementation in educational settings.

We now offer the Reading Classroom Explorer as an example of a project which uses video-streaming in an educational context.

Reading Classroom Explorer

477
In an attempt to engage preservice teachers as actively as possible in classrooms in which they can see teachers exercising their craft with a wide array of culturally and intellectually diverse students, we developed The Reading Classroom Explorer, a hypermedia tool for teacher education. The Explorer is a hypermedia learning environment containing about 200 video clip excerpts of the Center for the Study of Reading “Teaching Reading: Strategies from Successful Classrooms” series of video tapes (documenting six diverse classrooms), as well as video transcripts, questions for further thinking, reference citations for further research, and an interactive notebook. We not only wanted to transport students to these classrooms, which we could already do via videotape, to see the diversity in action, but we wanted to allow them to visit, revisit, analyze, critique, compare, and contrast a set of diverse classrooms in the rich, flexible, and idiosyncratic manner that hypermedia might provide. The many different types of media from many classrooms combined in an environment in which the user has a significant amount of control over the delivery of the media may broaden teachers’ knowledge of teaching reading and expand their repertoire of experiences from which they form a teaching philosophy. Further, using RCE could also serve as a stepping stone to help teachers learn to use hypermedia environments and increase their comfort level using other technologies.

Reading Classroom Explorer focuses on preservice teachers as the intended audience. However, our research (Authors, 1998) also indicates that RCE may be very attractive to and have benefits for practicing teachers as well. Student interns report that access to these six teachers’ practice after beginning their first teaching position would be invaluable. In addition, interns desired the opportunity to “visit” the six classrooms with their collaborating teachers. Such an experience would provide common ground for more discussions about multiple models of the teaching and learning of reading.

Implications

There are benefits of using video streaming as a means to distance educate. In the case of Reading Classroom Explorer, the most important feature is the control the student is given over the medium regardless of where they are located. The student has the opportunity to not only critically analyze video of classroom situations, she also may consider these images of excellent teaching when developing her own philosophy of pedagogy.

As a part of a network-based learning environment, video streaming can indeed become a powerful tool. Our database tracks the students’ progress through the videos and allows her to see what topics she has discovered and re-access her notes while watching the segments. RCE poses questions for users. Users not only can thoughtfully consider the questions on their own (which then becomes part of the database) but they can also access other users’ opinions through the RCE chatroom or the database of others’ answers (which grows as use increases).

In sum, students of network-based learning environments which incorporate video streaming are able to categorize and recognize exemplar models of instruction, and are able to further develop their own philosophies of pedagogy with consultation of these models. It is also possible that experienced teachers who use the Reading Classroom Explorer may find new ways of teaching or reflect on their own practice. This case study of the Reading Classroom Explorer, an interactive learning environment which uses video-streaming in a distance learning context, provides effective models of excellence for students at any distance. These users can critically analyze models that, without access to RCE, they may never have had the opportunity to view. This offers one way to harness the power of streaming technologies on the web for the benefit of education.

References
In 1997, a large association in education took a giant step towards integrating technology into its organization with the induction of Tiger--a web-based electronic proposal-processing system. The system allowed users to submit proposals via email or the web, reviewers the ability to review on-line, and program chairs the opportunity to reject, accept, and organize the submitted proposals--all within the click of a button. Because all of the divisions using Tiger accessed the same database, researchers had the unique opportunity to look at some of the behind-the-scene activities surrounding the acceptance and rejection of proposals for that. This availability of data provided a lens to examine some of the underlying assumptions about the organization and its processes. The purpose of this paper is to provide evidence through actuarial analysis that those underlying assumptions are not only false, but may in fact be dangerous in blinding members to the needs and trends that have arisen as part of the evolution of the institution.
Using NetShow for Development of Information Technology Modules

Rhonda Ficek
Instructional Technology
Moorhead State University
Moorhead, MN USA
e-mail: ficek@mhd1.moorhead.msus.edu

Abstract: A series of information technology skills modules is under development to address the needs of students, faculty, and staff for information literacy skills. The modules will be delivered via the Internet and CD-ROM. They involve the use of audio synchronized with corresponding screen captures, and web pages. Online quizzes are provided via a JavaScript application and a Perl program. The products were developed to work on both Macintosh and IBM computers, and will work with Netscape or IE browsers. Microsoft's FrontPage software and RealPublisher were used in the development process.

Overview

The Information Technology Skills modules will be utilized to train faculty, staff, and students in essential skills related to search, retrieval, evaluation, and presentation of information. Students of every major must be competent in handling electronic information. This proposal lays the foundation for development of a 1-credit, self-paced course for freshmen and new students which gives them skills vital to every graduate. The self-paced components of the module will also be used in faculty/staff training. To date, three modules are complete. The modules utilize audio synchronized with screen captures and web pages. Two products were utilized to develop the modules – NetShow and RealPublisher. In addition, scripting for online quizzes was developed in JavaScript and Perl.

Information Literacy Skills

The list of information literacy skills to be delivered in the modules includes Searching Library Databases, Using Online Library Catalogs (WebPals), Internet Search Techniques (Parts I and II), Computer Viruses, Internet Privacy Issues, Citation and Assessment of Electronic Materials, Data Entry, Retrieval, Evaluation and Presentation using Microsoft Excel, Copyright and Fair Use Issues for Electronic Media, Organization of Electronic Materials, Electronic Discussion Groups -- Listservs, WebBoard, and Presentation Tools -- PowerPoint and Web-Based Presentations.

Module Development Process

The process of developing the modules started with organization of the content, which was of utmost importance. A script for the audio was developed, outlines for the material were designed, and appropriate screen images were captured to correspond with the audio. For the first module (“Searching Library Databases”), six lessons were developed, each approximately 15 minutes in length. Quizzes were also developed which provide immediate feedback on the number of correct responses as well as the correct answers. JavaScript was used to design the tool for interactive quizzes on the CD-ROM. A Perl script was used for the Internet version.

While the content was being organized and developed by the content, members of the Student Technology Team worked on the design of the interface for the web materials. A frame-based introductory page was
utilized in all modules. The left side of the screen lists available lessons while the upper part of the screen contains audio controls.

Next, the audio recording was done, using the scripts provided by the content specialists. Students worked with the various codecs (compression / decompression) to decide on an appropriate choice. Factors involved in the decision included the need to deliver the content in two ways (via the Internet, where most users would have access to a 28.8 modem or better, and via CD-ROM) as well as an acceptable quality.

Finally, NetShow and RealPublisher software was utilized to create the final layout for the module. Timing information was entered so that the screen images and web pages corresponded to the audio appropriately.

Development Software Decisions: NetShow vs RealPublisher

Microsoft’s NetShow [Microsoft 1998] was used for the initial development of two of the modules. However, several issues forced us to consider RealPublisher [RealNetworks, 1998] software for development. First, at the time of module development, NetShow had a Macintosh player for browsers, but no plug-in. Terms of the grant included providing software which is compatible on both IBM and Macintosh. RealPublisher provides a plug-in for the Macintosh browsers.

The final version of our CD-ROM product for the NetShow version of the “Searching Library Databases” occupied in excess of 100MB. The RealPublisher version was 17MB. Most, if not all, of the Information Literacy modules will fit on one CD-ROM if development continues with RealPublisher.

NetShow’s environment is currently easier to use in terms of the interface. Start and stop times are easily specified within a dialog, as well as the corresponding HTML or image files. The RealPublisher environment currently requires the use of Notepad, where starting and stopping times are manually typed in a specified format. This is error-prone, and needs to be improved.

NetShow v2.0 had several problems when the development was for the Netscape browser. Certain paths had to be encoded as absolute (development for IE browser supports relative paths), and thus, when the module is published to an Internet provider, changes must be made. The beta version of NetShow v3.0 would not play the show correctly, so that the v2.0 player had to be included on the CD-ROM, since product delivery occurred before the final v3.0 was released. RealPublisher’s environment did not differentiate between browsers -- the issue of different paths for different browsers didn’t exist.

Acknowledgements

The “Searching Library Databases” module was funded by a grant from MnSCU. Sincere thanks to Matt Weum and Jeremy Jensen, members of my Student Technology Team, for their excellent work on the modules. Also, the content specialists, librarians Stacy Voeller and Brittney Chenault, deserve credit for their exemplary organization of the materials for the modules. Finally, Daryl Paulson (AV services) spent many long hours to provide CD-ROM materials which were compatible with both Macintosh and IBM hardware.
Libraries, the Internet, and Social Issues

Barbara J. Ford, Executive Director, University Library Services, Virginia Commonwealth University, U.S.A., bjford@vcu.edu

Mary W. Ghikas, Senior Associate Executive Director, American Library Association, U.S.A., mghikas@ala.org

Abstract

Libraries are a place where a number of societal issues related to the Internet come together. As governments around the world address societal issues relating to the Internet, some of the experiences of the American Library Association can be helpful in developing strategies to take full advantage of this important learning tool. For more about this educational campaign, see the ALA home page - http://www.ala.org.

Introduction

Many societal issues related to the Internet come together and can be addressed at the library. Libraries provide Internet access and often training to the general public, addressing the vital question of equity of access to Internet resources and the need to “re-skill” out-of-school generations. Librarians, in their traditional roles, handle challenges and mediate inter-group conflict, set standards and criteria, and seek out and identify resources that should be available on the Internet.

The American Library Association (ALA) – the voice of America’s libraries, and the world’s oldest and largest library association – is both using the Internet to provide services to its 57,000 members and beyond and is acting vigorously to protect free and uncontrolled access to information resources, including the Internet. Opportunities are also provided for Association members to enhance skills and maintain competencies in response to changing work practices, rapid development in technology, and expanding needs of library users.

Protecting Access to Internet Resources

ALA was at the forefront of the legal battle in the U.S.A. to protect citizens’ First Amendment rights on the Internet. The U.S. Supreme Court ruled the Communications Decency Act unconstitutional. This act had been proposed as a way to keep obscene materials out of the hands of children, but the Court ruled that the act, as passed by the U.S. Congress, abridged the rights of adults to access legally-protected materials or speech on the Internet.

Following this ruling, in July 1997, U.S. President Bill Clinton and Vice President Al Gore convened a small closed meeting with politicians, Internet industry leaders, and educators including a representative of ALA to discuss children and the Internet. The ALA representative discussed librarians’ critical role in reviewing and recommending web sites, just as they select books and other materials. ALA also noted that while technology is an important tool, education – particularly development of information literacy skills – is still key. A toolkit – “The Librarian’s Guide to Cyberspace for Parents and Kids” – was introduced at this meeting.

Librarians as Internet Organizers and Evaluators

Following on the White House meeting, the Internet Online Summit: Focus on Children was held in Washington, D.C. in December 1997. The Summit brought together public interest groups, computer and communications
industry representatives, government leaders, and citizens to address ways to ensure that the Internet experience is safe, educational, and entertaining for children. As one of the summit sponsors, ALA was involved in both planning and implementation.

As part of the concluding panel at the Summit, ALA affirmed the role of libraries as key points of access for children and families who cannot afford computers, as well as ALA’s commitment to protecting First Amendment rights. In the library setting, this raises complex issues for librarians seeking to follow legal guidelines regarding access to legally-protected speech as well as laws regarding illegal speech.

ALA’s “700 Great Web Sites for Kids and the Adults Who Care About Them” – reviewed and recommended by children’s librarians across the country – was presented at the Summit. Over 50,000 web sites were reviewed to select 700. KidsConnect — a question-and-answer service where children can get online help with their homework — was also highlighted. These and other ALA efforts to educate and support parents and children in using the Internet have been featured on the “Today Show,” in Parade Magazine and The Washington Post, and in other media throughout the U.S.A.

Libraries as Providers of Internet Access and Continuous Learning

Historically, the role of libraries is to bring people together with information – not to block information. ALA believes currently-available filtering tools can be useful in the home, but it does not endorse their use in libraries, because studies have shown that legally-protected and useful material about sexuality, health, and other sensitive subjects may also be blocked by currently-available tools. Libraries are in an extraordinarily difficult position. The courts have established that minors have the same constitutional rights as adults to free speech, except for a class of information identified as “harmful to minors,” which is defined at the state, not federal, level.

ALA has focused on educating parents about the issues and how they can work with their children to make good use of this revolutionary learning tool — the Internet. Parents not wanting children to access certain sites must teach kids which sites to avoid — as parents have historically designated safe and unsafe streets or neighborhoods for children.

With less than 20 percent of homes in the U.S.A. connected to the Internet, libraries provide important Internet access for many. ALA is continuing to build its web site into a dynamic Internet collection for children and parents, as well as providing links to libraries around the world that have online children’s sites. “Teen Hoopla” — developed by young adult specialists within ALA — was unveiled in January 1998. Librarians provide continuous learning and guidance for adults and children in using the Internet. If the Internet is our vehicle into the next century, librarians are the navigators.

Conclusion

As governments around the world address societal issues relating to the Internet, some of the experiences of the American Library Association can be helpful in developing strategies to take full advantage of this important learning tool. For more about ALA’s educational campaign, see the ALA home page — http://www.ala.org

Technology has provided opportunities to expand the global reach and local touch of libraries by providing expanded lifelong learning opportunities for library users and staff. As the Internet grows and becomes more complex, libraries will continue to be key in organizing the resources and educating the public about what is available. Libraries are places where many societal issues related to the Internet come together and can be reasonably debated and addressed by communities. By working together, librarians can ensure the availability and use of this important learning tool.
Developing an Online Help System for a Complex Search Engine

Sebastian Foti, College of Education, University of Florida, USA, sfoti@coe.ufl.edu
Gail Ring, College of Education, University of Florida, USA, gailring@coe.ufl.edu

Abstract. Culture and Technology is a CD-based software containing over 15,000 text pages, video clips, and audio tracks. A complex search engine allows users to find appropriate resources in a variety of ways. Targeted documents include information sheets (abstracts of the documents as well as categorization parameters), multi-paged documents, links to related material and several system-level options.

This article discusses strategies used to develop a suite of web pages designed to tutor present and potential users, serve as an online help system, and respond to user needs. The web suite contains over 130 web pages of information and a comprehensive index.

Goals

As the designers of the online help system for Culture & Technology we hoped to augment the abbreviated help system contained in the software, and improve on the paper based tutorial supplied as part of the program's documentation. We also hoped to provide existing users a comprehensive index of terms and processes associated with the product, and to develop a dynamically growing collection of frequently asked questions (FAQs) which could be used to help refine future versions of the product. Finally, we believed that by illustrating the program's features, we could generate additional consumer interest in the product.

Decisions

A tutorial system should be comprehensive yet easy for the user to navigate. We decided that the tutorial should present a realistic, task oriented activity illustrating an actual search using the Culture & Technology search interface. After guiding the user through a typical search, we would engage in a more free-form exploration of the program's features. Since web materials can be designed using a linear or random access format, tutorial design problems centered around whether too many choices interfere with a novice's learning experiences. Specifically, we feel that the successful instructional design of such a tutorial depends on isolating the pitfalls associated with the activity, providing a rich enough context for meaningful exploration, and devising a system sophisticated enough to attend to the user in an intelligent way. We decided to create a presentation which initially offers little choice and gradually evolves to include more links. Further, we chunked the tutorial into functional pieces and allowed users to randomly access specific parts of the tutorial (the section on printing, for example).

Culture & Technology is a complex program, and that complexity is compounded by the software's dovetail with the computer's operating system. Since our online help system had to address sophisticated processes as well as program features, we decided to use a color-coded convention throughout the system. If an object under discussion is related to a process supported by either the computer or the Culture & Technology program, the object appears as bold red print. If the object is an item in a list or a document, its name will be in bold black print. We are currently setting up an informal research study to determine the effectiveness of this strategy. Our instinct is it will take multiple iterations through the material before a user will internalize the color-coding scheme.

Any sophisticated software system contains too many features to discuss effectively in a tutorial format, and Culture & Technology is no exception. In addition, users sometimes want straightforward definitions, descriptions, or examples of terms without verbose tutelage. We decided to include a comprehensive index, essentially a linked list, as part of the help system. Further, we decided that there were many cases where the index should provide information distinct from that presented in the tutorial. In other words, although terms in
the index could easily be linked to the tutorial, there were often very good reasons to construct new documents containing alternate explanations. These included simple definitions, meanings of iconic representations (buttons, for example), identification of a level's function (show me what each screen element means or does), and information not related to the program's function. Indexing seems a perfect use of the web, since indexed documents can be linked to each other to provide additional information, and see also references.

Marketing

We found the nearly obligatory Frequently Asked Questions component of our online help system to be surprisingly useful. In addition to obtaining user requests for features, we are able to disseminate some important information. We offer general information about the program's content, which doesn't seem to have a place in the index or tutorial. In the software section, we can discuss installation procedures, and offer updates to the search engine software free of charge (our software requires CDs to operate). The access section (where can I buy the product?) provides a direct link to marketing. Although research shows that selling goods electronically may be 40 to 50% cheaper than by conventional means [Maglitta & Booker, 1994], we feel that it is perhaps more important that marketing efforts link to help systems. A potential buyer may read information about the product and also take a tutorial tour. We feel that this may help overcome the customer's anxiety about using a new product. In addition, seeing a comprehensive help-system online may encourage the purchase of the product. According to Bernadette Tracy, president of NetSmart, the internet can generate virtually pre-sold customers for a variety of products like cars, computers, cruises and financial services. It can provide leads and prospects who are predisposed to buy as a result of their interactive online relationship [Tracy, 1996]. Executives seeking web-based solutions for their businesses seem to agree. A survey released by Computer Research Corporation [Meyer, 1998] found that more than 60% of survey respondents confirmed that both their existing and planned web-based business initiatives focus on marketing and sales solutions that promote profitability through expanded sales channel options and strengthened customer relationships. Finally, the online tutorial provides a simple way for sales people to demonstrate the capability of the system in vendor booths or in a customer's office.

Future Directions

Based on the information gleaned from working with Culture & Technology, we are developing a new online help system for our latest software release Enhanced Science Helper. Although we will use a similar approach to the system, including a comprehensive index and tutorial, we intend to incorporate some new features into the help system. We feel strongly that animation can be an effective way to present process information about software functioning. We will offer sample documents, including digital video samples as free downloads. We will offer a demo version of our search engine as a free download. Downloaded software may contain promotional material and/or discount coupons for fully functional versions.

The development of the Japanese learning system which used PDA (Win. CE)

Makio Fukuda
Faculty of Human Science, Osaka International University for Women,
JAPAN, fukuda@oiuw.oiu.ac.jp

It is extremely difficult to learn Kanji Character of Japanese for the learner who learn Japanese as a second language. Because, the Kanji character is complicated compared with the alphabet and there is much number stroke. The Kanji character is the ideogram character of the origin of which is China.

We already have developed the Japanese learning system using personal computer (MAC) and handwriting input system. But, This system was not the one which it is possible to use anywhere for the learner. Therefore, we decided to use the PDA as a platform. That PDA is "CASIOPEIA". It is operated by "Windows CE". And, it is simple in the development of the program and the data maintenance by the personal computer.

In this conference, we will explain the outline of this learning system and demonstrate the performance of this system.
Greek Indexer - A New Web Subject Catalog:
Statistics, Comparisons and Study of Net-Surfer Web Preferences

Garofalakis John, Kappos Panagiotis
[garofala, kappos]@cti.gr
Department of Computer Engineering and Informatics,
University of Patras, 26500 Patras, Greece

Abstract: A lot of surveys have covered many aspects of user habits, ranging from age to social status of web users and from political preferences to security issues. However, only little work, based on log file analysis data of a web subject catalog, has been conducted to unveil the most favored kind of resources the users access. The development, maintenance and analysis of web server's log-files enlighten many useful aspects of the way users traverse the web and click through links. Based on access log-file data from three famous subject catalogs, this paper measures and compares the most favorite user subject categories and draws some guidelines on the potential content that creates a successful and highly accessed site.

1. Introduction

The potential of the World Wide Web [Berners 1994] has been widely accepted as the most useful means of transmitting information throughout the world in a platform-independent way. A lot of surveys have covered many aspects of user habits, ranging from age to social status of web users and from political preferences to security issues. However, only little work, based on log-file analysis data [URL 7] of a web subject catalog, has been conducted to unveil the favored kind of resources the users access. Based on access log file data from three subject catalogs (Greek Indexer [URL 4], Starting Point [URL 5] and Yahoo [URL 6]) this paper measures and compares the most favorite user categories and subjects and draws some guidelines for a marketing company, a webmaster or an institution on the content that will create a successful and highly accessed site.

Web demographics can help web site creators to improve the site contents or site appearance and simultaneously reveal common user attitude while traversing whole web document structures [Vassiliadis et al. 1997], [Garofalakis et al. 1997].

A lot of surveys have been produced to investigate a wide range of web demographics. The 6th WWW User survey [URL 2] answers questions on the web and Internet usage, the percentage of male and female users, data privacy, politics, security of transactions and web-mastering. Many media researchers and marketing campaigns are increasingly using the WWW. It is about one-forth less costly to perform direct marketing through the web than through conventional channels [Verity 1994]. Recent research [Hoffman 1996a], [Hoffman 1996b] also suggests the demographics of Internet use are shifting over time, with the result that the Internet appears to be going more "mainstream" in its demographic makeup and that this trend is likely to continue as the Internet moves toward critical mass as a commercial medium. Also, other studies that address the issue of who is on the Internet and what they are doing there can be found at CyberAtlas [URL 3]. Also information about a proposed ubiquitous advertising on the WWW can be found in [Kohda and Endo 1996].

This paper is divided into 2 parts. The first part describes the process of developing and operating the biggest Greek-oriented web subject catalog, named “Greek Indexer”, at first. By measuring the total number of accesses on every category of the catalog, the most user favorite themes can be defined by counting the absolute number of accesses to each category. The second part of the paper compares the above results with the ones that come from a similar measurement of two other famous international subject catalogs (Yahoo Inc., and Starting Point Inc.)

The GI's access log files being used in this survey start from December '95 until April '97. Starting Point's logs are from January '97 to March '97. As far as Yahoo is concerned, a three months' "What's New" web pages are considered.

This paper is organized as follows. Section 2.1 addresses the technical issues faced to develop the Greek Indexer on-line service, while section 2.2 describes its operational and maintenance issues. Then,
in section 3, a detailed statistical analysis shows the most favored web-user categories. Section 4.1 shows the most frequently accessed categories from Starting Point's subject catalog. Section 4.2 shows Yahoo's "What's new" service and category specific results are being conducted. Section 5 makes some comparisons between the three subject catalogs, while section 6 concludes on the ways of exploitation of web preferences results, ranging from marketing to multimedia page design.

2. Greek Indexer

"Greek Indexer" (GI) is a Greek-oriented hierarchical web directory that is being used by both Greek users and foreigners who want to locate up-to-date Greek oriented information. GI has been on-line since December 1995 at http://www.gr-indexer.gr/. It currently serves more than 8500 accesses per day from all over the world (measuring unique hostnames). The number of hits, (including html documents, images, sounds), exceeds 1,900,000 per month and is linked by more than 4,000 web pages. It is updated twice daily and contains an up-to-date image of the web resources existing in the Greek Cyberspace.

2.1 Technical Issues

Each GI's link has the following structure:

- A 2-3 word description of the resource
- A small English Description defining the main purpose of the site
- A small Greek Description defining the main purpose of the site

GI consists of a set of CGI scripts and a lot of dynamic HTML pages. The scripts are written in PERL and C programming language and being deployed to collect, analyze and sort input data. People, who want to have their site or even other's owned web resource listed in GI, should click on the "Add link" button. Then they enter useful data such as a 3-word description of the new web resource, an English and a Greek description of the site and their e-mail address for notification of the date the link is included in GI.

When all the required data are submitted, an error checking routine is automatically run against them. The error checking routine verifies the existence of the user e-mail address, the URL and of valid, no-blank strings for the description of the resource. If the submitted data do not contain errors then a new entry containing the link for the submitted category, is automatically built as HTML code. This code is being inserted into a temporary file and a final acceptance or rejection is carried out by GI's administrators. Administrators supervise the addition of the new links by checking if the sentences representing description of the new web resource are semantically and syntactically valid for both Greek and English language. They also check if they contain unacceptable words (i.e. insults). Upon approval, the link becomes part of the Dynamic HTML page that represents the links for a particular category of the catalog. At the same time, two e-mails are being sent. The first one is destined to the administrator of the catalog to inform him about the new addition and enable him to have the maximum possible logging parameters (e.g. IP address, time etc.) and is stored in an SQL Database. The second e-mail is sent to the user who submitted the entry and informs him about the link addition as well as with much other useful information about the GI (e.g. advertisement of new services, new banners etc.).

Server-Side Includes (SSI) was exploited to create Dynamic Pages and banner advertisements. They do not consume too much CPU time and help the webmaster make additions or modifications to the whole setting of the site easily and effectively. The APACHE web server provides many additional capabilities such us advanced debugging, script management and configuration, flexible scripting interface (ISAPI) etc. The further exploitation of those features is currently our concern.

The banner advertisement appearance is defined in GI's configuration file. There are two options. The first option is category-specific advertisements where the banner is appeared only in that particular category. When GI is displaying a category and does not have any category-specific advertisement, a random banner is being picked from the rotating advertisement repository. This pool contains banners images that are meant to be displayed randomly throughout the GI's pages without any category-specific advertisement.

Each user can have more than the default appearance of GI's categories. The user is free to choose from a variety of colors for text and the inclusion of graphics. From user's perspective the configuration is simple by entering the desired values in a simple web form. From server's side the definitions of different user preferences are easily handled using CGI and cookies.

2.2 Operational Issues

Despite explicit note on what kind of data should be inserted to each GI's field, many users tried to insert arbitrary or incorrect data. A lot of users tried to insert all of the description's words in capital letters and others
with symbols like "!" or "*" or even ":-)" (smiley) to emphasize the sentences. Some others did not provide their e-
mail address for notification if the link is accepted for inclusion or not to the directory.

Many users were sending multiple copies of the same link to the same category, which was a serious matter of
concern. Blank additions were not common but existent, despite the fact that in most cases there was no network
overload or line drop during the link addition process.

At present, the scripts used in GI can diagnose many kinds of common user mistakes and can handle many
problematic situations.

3. Greek Indexer Metrics

The development, maintenance and log file analysis enlightens many useful aspects of the way users traverse
the web and click through links. In this paper the GI's access log files being used are from January 1st, 1996 until
April 30th, 1997.

The Greek Indexer consists of 37 top-level categories, overlooking its first highly accessed page. At this point
we define the following equation:

\[ P_i = \frac{A_i}{A_{total}} \]

where \( i \) is one of the 37 categories, \( P_i \) is the percentage of the accesses the category \( i \) has against to all the
other categories, \( A_i \) is the total number of absolute accesses to Greek Indexer's category \( i \) and \( A_{total} \) is the sum of all
accesses to all GI categories. The greater the percentage (\( P_i \)), the more favorite for users the category (\( i \)) is.

[Tab. 1] has been compiled to show the accesses of each category. The 1st column gives the name of the
category, the 2nd column shows the percentage of accesses of each category (\( P_i \)) out of the total access that this
category has currently served and the last column introduces the Anticipated Annual Growth (AAG) of each
category. The AAG is calculated as follows: Let \( i \) is one of the categories. The number of accesses of category \( i \) (for
all categories) in 1996 (\( A_i \)) is being calculated. Then the accesses of each category of the first quarter of 1997 (\( B_i \))
are being counted, which multiplied by 4 can approximately show the number of accesses in the year 1997 for that
particular category. The percentage of the absolute difference from the accesses of year 1996 to 1997 is named as
"Anticipated Annual Growth". So the AAG for category \( i \) (\( AAG_i \)) is defined by the following equation:

\[ AAG_i = \frac{\text{ABS}(A_i - 4* B_i)}{A_{total}} \]
Combining the above top-level categories in a wider sense, merging the categories with semantic similarities to create fewer categories of wider meaning, [Tab. 2] is produced. Its 1st column shows the concatenation of top-level categories (whose 1st level categories are contained in each wider one), the 2nd column shows the name of the wide category, the 3rd column shows the number of accesses as a percentage of the total accesses of GI categories and the last column shows the "Anticipated Annual Growth".

Table 2: Wide GI's categories

4.2 Yahoo

Yahoo is a semi-automatically constructed and hierarchically organized web directory whose links come from user submissions only. We used Yahoo’s "What’s New" section to reveal the trends on the increase of new sites included to it. For statistically correct results, three-month new additions were examined and the results are being presented in [Fig. 3].
All of the new additions are categorized under one of the following main categories: Business & Economy, Entertainment, News & Media, Society & Culture, Arts, Computers & Internet, Science, Health, Government, Social Science, Education, Reference.

Despite the fact that Business & Economy category has much more percentage than the others, this is due to the way Yahoo categorizes its links. The percentage is virtually shared among entertainment, recreation and media. In Yahoo, there is an implicit emphasis in the categorization of links in specific business oriented parts and less to top-level generic categories. For example, most of Yahoo's links are being categorized under Regional/Countries due to the fact the Yahoo wants to have its links country specific sorted, which is a vital and highly acceptable criterion.

5. Comparisons

The above data reveal which are the subjects that web users more frequently access. [Tab. 1] shows the GI's categories that are mostly accessed. [Fig. 1] and [Fig. 2] shows the most interesting links to the users based on data coming from Starting Point Inc. and Yahoo.

Comparing the above, a lot of common similarities can be extracted. People mostly like to visit Entertaining material (e.g. Fun, Music, leisure time etc.). News & Media follow (e.g. TV, Magazines, Newspapers etc.). Educational issues are at the third place (e.g. Universities, Institutes etc.). At the fourth place Sports, Travel and Recreation, while the fifth position is populated with Cities and geographical information and Economy.

The three catalogs have many differences on the number of registered links, the number of visits per day, the country that they operate on and the audience they would like to attract. Greek Indexer is oriented to Greek resources and accepts links with Greek content. Most of its users are Greek people or people who would like to visit Greece. Starting Point and Yahoo are more general catalogs and have registered sites from all over the world.
Despite the fact that all three catalogs can not be classified in a common place, this paper reveals that there are many similarities between the type of information web users access, regardless the country they come from or the type of Internet connection.

6. Conclusions

Commenting on the results of the previous sections, conclusions on many aspects of the process of web site and web content development can be made. The most common of them is the type of the information provided by a particular web site. A web user clicks on a site and browses its pages only if this material is of interest to him. The statistical analysis of this study have shown that only if the site belongs to at least one wide subject category do the user visit the site frequently. If the user likes to access such a category, then it is more likely to choose one of the top ranked sites mentioned in Tab. 2. Web users most favor sites with entertaining subject such as music, humor, movies, home pages etc. Sites with informational material such as broadcasting channels, TV, Radio and Newspapers as their second concern. Educational material is in the middle of their preference. Business and Economy comes next.

Bearing in mind that searching using a robot produces indiscriminate quantity of potential data, subject directories are the means of producing a list of quality information resources that quickly guide the user to the desired subject area. Handling the expiration of the catalog's links is a great concert and must be handled in an efficient and user transparent way.

The provision of user customizable information should be considered when building a subject catalog. The next generation subject catalogs might provide such option to the average user. The first step to that direction is the provision of country specific options in web subject catalogs.

Our research team is currently involved in the improvement of the link classification, expiration and reorganization. In addition, research on building sophisticated analytical and statistical results from web server log files is also in progress. The successful definition of user sessions and a link re-organization procedure for the contents of a web site is under beta testing [URL 8].

Acknowledgments

All of the above work wouldn't be feasible without the help of HIWAY Network and Starting Point Inc. We would like to thank HIWAY Network for their generosity to give us the log files of the Greek Indexer as well as Mr. Frank Addante for the provision of the 3-month log files of Starting Point to be used in this survey.

How to Use HTML Page Popularity to Improve a Web Site's Structure

Garofalakis John, Kappos Panagiotis, Mourlukos Dimitris
garofala@cti.gr, kappos@cti.gr, mourlouk@ceid.upatras.gr

Department of Computer Engineering and Informatics,
University of Patras, 26500 Patras, Greece

Abstract: The structure of a World Wide Web Site (i.e. how its HTML pages are linked together) is a serious concern to all web administrators. Nevertheless, an inapt page arrangement can discourage a potential Internet user as it fails to present properly the site's contents. In this paper, it is discussed how a link-editing algorithm, based on Relative Page Popularity (RPP), can be used to automatically revise the initial page structure and build a new one, that exhibits a significantly higher number of accesses. It is also examined how one can define the notion of popularity among HTML pages, and how the re-arrangement of a Web site, based exclusively on page popularity, can lead to a substantially more effective scheme.

1. Introduction

The notion of a log file is to record every request that a server accepts accompanied by some extra information such as date/time of the request, the client who submitted the request, which file was requested etc [URL 2], [Vasiliadis 1997]. Based on this neat source of information we can make many significant observations that can contribute to a higher overall performance of a given WWW [Berners et al. 1994] site. One of them, called page popularity henceforward, is the subject of this paper. It is examined how one can define the notion of popularity among HTML pages, and how the re-arrangement of a Web site, based exclusively on page popularity can lead to a substantially more effective scheme. An author-oriented link management system can be found in [Creech 1996].

This paper is organized as follows: Section 2.1 and 2.2 define the basic knowledge behind Page Popularity; section 2.3 contains a case study of link re-arrangement and a is fruitful of information of the proposed algorithm. Section 3 shows the commercial use that bring out of this paper, while section 4 and 5 conclude and define our future work, respectively.

2. Defining Page Popularity

One easy but rather unjust way to estimate which page is the most popular, is to calculate the accesses to this page based exclusively on a given Log File [URL 1]. Indisputably, this approach has many weak points. The so-called absolute accesses might mislead the evaluator since the closer the page is to the home page (the initial page of the server) the more accesses it will probably have, as it stands on the path(s) from the home page to a target page located deeper in the HTML tree. As a child-page might have links towards one of its ancestors, the term "tree" is not absolutely felicitous. Nevertheless, the factors that must also be taken into consideration when popularity is examined are:

- the depth of the page (how far it is from the home page)
- how many pages are at the same depth as the page that is being examined
- how many references (hyperlinks) this particular page has from other pages of the server

Let's assume that there is a factor $a$ that embraces all the above parameters. Then, we can coin a new term called relative accesses, which is derived from the following equation:

$$relative \ accesses = a \cdot (absolute \ accesses) \quad (I)$$

---

1HTML tree: Home page is the root of this tree, and every hyperlink to another page constitutes a parent-child relationship.
2.1 Defining the coefficient $a$

As the depth of the page $d$ can detract from the popularity of the page, it is reasonable to assume that coefficient $a$ must be proportional to $d$. Likewise, the number of pages at the same depth $n$ should be proportional to $a$ since the number of different choices is bigger and the selection of a specific page carries more weight. Of course, we must take into account the number of references $r$ from other pages, as they generally bolster up page popularity, and so $r$ must be in inverse proportion to coefficient $a$. Since we usually don’t track down the references to our pages from all around the world, $r$ normally is an estimation based on the references of our own pages.

Putting them all together, the relation between $a$, $d$, $n$ and $r$ should have the following form:

$$a = F(d, n, l/r)$$

(2)

In the subsequent paragraphs it is presented how the selection of a specific formula can affect user’s profile, as this is recorded in the Log File.

2.2 Link Editing

We have developed a pilot software (SOALA v2.0) [URL 3] that has the ability to reorganize the links between pages based on some criteria that were previously set by the Web Server’s Administrator. In the following measurements, if the relative popularity of a given page exceeds the popularity of at least one page with shorter distance from the home page, then a link re-arrangement occurs. The calculation of RPP (Relative Page Popularity) can be done periodically (e.g. every week) and the metrics, which are usually calculated, as the most instructive, are:

- PT: the mean page time (i.e. how much time a user spends on a specific page)
- UT: Mean elapsed time (i.e. how much time a user spends on the server every session)
- NA: number of absolute access per page
- RA: number of relative accesses per page
- NP: mean number of pages (i.e. how many different pages a user visits every session)

A simple version of the link-editing algorithm has as follows: "If any page has RA higher than its parent, then interchange it with its parent page. Repeat the previous step until every page has ancestors with higher RAs".

In the following paragraph the above algorithm is applied for a specific definition of factor $a$. It is really instructive to observe how an awkward organization of a WWW Server can discourage Internet users and how link editing (based on relative accesses) can be used as a first-class remedy.

2.3 Case Study

It is important to mention that in order to have results as accurate and untainted as possible, only authorized permission was permitted. Therefore, the authorization field of the Log File is not empty ".". Furthermore, there were no references to our site (outside our Server) so that the value of parameter $r$ will be accurate. The group of users, as well as the pages, was selected carefully to facilitate the interpretation of the results.

According to the above discussion one possible way of specifying the coefficient $a$ can be the following equation:

$$a = d + n/r$$

(3)

Any abnormal value for time variables (too small or too long) was discarded. The site comprised 32 pages (namely Page1, Page2, ..., Page31) organized into the binary tree structure depicted in figure 1. Page1 is the initial home page having two children (Page1, Page2). For every $n=1$ to $15$, Page(n) has two children: Page(2n) and Page(2n+1). There is only one reference to each page (one from its parent,

---

2 User's profile: User's behavior towards a Web Site (i.e. what pages he visits, in what order, for how long etc.).

3 Session: each time a user accesses the WWW Site, a new session is initiated. All the successive accesses belong to the same session provided that the interval between them does not exceed a given time-threshold.
with the exception of home page) and therefore parameter $r$ has a value equal to 1 in any case. It is important to underline that the binary structure remains until the end. What changes is the position of the pages in this structure. For instance, at the end of link-editings Page3 occupies a position in a deeper level (in the HTML tree) than the initial one.

![Figure 1: Initial Binary Tree Structure](image)

[Tab. 1] summarizes the accesses to our system prior to any link editing. For example Page2 has 181 mean page time, 340 absolute accesses and 1020 relative accesses ($RA=a*NA$, where $a=d+n/r=1+2/1=3$)

Table 1: Measurement of accesses prior to link editing

As it can be inferred from [Tab. 1] the initial arrangement of HTML tree was rather inapt. Pages such as Page22 were undervalued as they exhibit significantly higher RA than other pages located closer to home page. Applying our link-editing algorithm to [Tab. 1] results in a new binary tree that is depicted in [Fig. 2].

</tbody>
</table>

As it can be easily derived from [Tab. 2], as a result of the new tree-organization, there are pages with a substantially different NA, while the new sum of NAs

\[ \text{SUM(NA)} = \text{NA}_{\text{Page1}} + \text{NA}_{\text{Page2}} + \ldots + \text{NA}_{\text{Page31}} \]  

(4)

exhibits a significant increase (SUM(NA)$_{\text{new}}$ = 2896, SUM(NA)$_{\text{old}}$ = 2386). UT has been increased too (UT$_{\text{new}}$ = 352 sec, UT$_{\text{old}}$ = 259 sec), whereas PT fluctuates. Furthermore, the new page arrangement boosts NP with an increase similar to UT (NP$_{\text{new}}$ = 5.36, NP$_{\text{old}}$ = 3.92).

Even though the statistical nature of the above measurements cannot be neglected, there are significant inferences that can be drawn. First of all, even a neat approach to link editing, based on page relevant accesses, can have a significant impact on user's behavior towards a particular Web Site. Comparing [Tab. 1] to [Tab. 2], it can be inferred that there was a 21% increase in the number of accesses to our site without changing the content of the pages, while the 36% higher NP and UT indicates that the new organization seems to be more convenient and more attractive for a potential user. Another important aspect is that the reorganization can be done automatically: using a simple link-editing algorithm, the system ends up in a more balanced state (from a relative-access point of view).

3. Commercial aspects

The preceding paragraphs substantiate the fact that the organization of a WEB Server can have a sizeable impact. Up to now, it has been implied that the easier a user can find the requested data the better the organization of the WWW Server is. But what happens if a WWW Site contains commercial material (advertisements, etc.)? In this case, the objective is different: probably the best organization is the one that achieves the highest NA to all those pages with a commercial interest. Therefore, a weight factor w should be associated with each page and the link-editing algorithm should be modified correspondingly so that the pages with a higher w will be promoted more vigorously. The modified version of our link-editing algorithm is beyond the scope of this paper (A beta version is under evaluation with encouraging results).

4. Conclusions

As it was elucidated in the preceding paragraphs, an inapt arrangement of the HTML tree can discourage a potential Internet user. A link-editing algorithm can automatically fix this organization by calculating each page's relative popularity. Even a simple approach to RPP (the combination or relations (1) and (2)) led to a substantially enhanced scheme. After the link editing, we found out that our site had much more accesses than before. Furthermore, users tended to stay longer and visit more pages, showing that the Site was made more attractive even though the content of each page remained the same. Finally, the idea to associate a weight factor with each page was briefly mentioned, so that the
administrator can single out HTML pages with a particular interest and enable the link-editing algorithm to promote them more vigorously.

5. Future Work

Surely, there is a large number of different approaches of how one can re-arrange the links between pages as well as how to perceive the notion of popularity. For example, one can give coefficient $a$ a more complicated definition than the one given in equation (2), or re-arrange the initial page structure using a more sophisticated method than our link-editing algorithm. Nevertheless, the simple approach that was followed in this paper should not be underrated, as apart from being easily analyzed, it has also been proved to be adequate in most cases.

Probably a link-editing algorithm with the capability of adding new links and discarding others (apart from interchanging pages) would demonstrate a better enhancement.

Our team is still in the process of identifying several new variables that affect the HTML Page Popularity and the new results will be available as soon as they will be extracted.

An Example of Project Based Learning in a Distance Environment:
Financial Statement Analysis Case

Sharon Garrison
Finance Department, Florida Gulf Coast University
sharon@tmag.com

Dee Burgess
Accounting Department, Florida Gulf Coast University
dburgess@fgcu.edu

Abstract: Florida Gulf Coast University has a mission of delivering distance courses to 25% of its enrolled students. In finance, the challenge is how to deliver effective learning a distance environment. One method that has been employed is project-based learning.

Florida Gulf Coast University, the tenth university in the State University System of Florida, taught its first courses starting in August 1997. The University was mandated by the state Legislature to have a heavy emphasis on technology, partly to conserve costs of delivering instruction. Part of the mission of the university was to deliver a significant portion of courses via some distance learning modality. Some of the methods being employed are Web-based courses, interactive compressed video courses, videotaped courses, and classes at distance sites.

The College of Business at FGCU embraced this mission and predicted that within a short period of time it would deliver 25% of courses using some distance learning modality. This was in response to not only the mission of the university, but also to student needs and requests. For some classes, the design of distance delivery can be particularly challenging. For instance, in finance and accounting classes the challenges of teaching courses which rely heavily on techniques, but also on conceptual learning, sometimes create difficulty in maintaining the proper balances in courses. One class which faced these challenges is Financial Statement Analysis.

Financial Statement Analysis

Financial Statement Analysis is a junior-level course in the College of Business. Most of the enrollees are either finance or accounting majors. To enroll in the course, students must have completed two semesters of basic accounting and also an introductory finance course. The objectives of the course are to:

- Learn the basics of financial reporting
- Become familiar with basic financial statements
- Learn how to perform a ratio analysis
- Learn how to forecast financial statements
- Learn the role of financial statement forecasting in business planning
- Understand the implications of debt on the firm’s financial statements
- Understand growth and how it is reflected in financial statements
- Understand the uses of financial statements in special cases
- Understand how financial statements and special categories of issuers
- Understand the uses of financial statements and “getting behind the numbers”

The course then is one where students learn and refine techniques, but they also work toward a conceptual understanding of various finance and accounting topics. It is a daunting challenge in any environment, but in a distance environment it is even more of a challenge to effectively teach such a course.
One way to make the course more effective has been to base the learning on a semester project. In other words, students learn financial statement analysis by actually analyzing financial statements.

Project Based Learning

In the past, the efficacy of project based learning has been examined in some detail. [1991, Hunt], [1989, Muller], [1996, Verderber, and Serey]. Some authors find that project based learning helps students to “engage actively in self-exploration, self-discovery and self-evaluation.” Other authors find that project based learning can be quite successful, but require that faculty must assume extensive additional responsibilities for effective student learning to occur. Among the activities that contribute to the success of project based learning are:

- Effective Goal Setting
- Teaching Student Project Management Skills
- Effective Project Consultation and Monitoring
- Effective Feedback

Financial Statement Analysis Course at FGCU

Keeping in mind these suggestions, the financial statement analysis course for the College of Business at Florida Gulf Coast University was designed. The Web page for the FGCU Financial Statement Analysis course may be viewed at http://www.tmag.com/sgarrison

The Financial Statement Analysis Course is FIN 3461. While walking through the page, it is evident that the project is an important component of the total course. The instructions are shown at http://www.tmag.com/sgarrison/courses/fin3461/assign.htm

The project is an in-depth financial statement analysis of a company of the student’s choice. The course includes an 8-hour “boot camp” before students enter the Web-based portion of the course. During this portion of the course, students are given detailed instructions on how to prepare the paper. They are also shown samples of previous papers from students who have given permission for other students to use their papers. Students are also given an in-depth session the use of library and electronic resources in preparation of their semester projects.

The paper is turned in by sections, so that if students are “on the wrong track” they have time to correct their work before the final grade is received. Work is carefully monitored and quick feedback is provided students. They are also encouraged to meet in small groups and share their insights.

Conclusions

The course has been quite well received by students. They feel that the project compliments the material they study for the course. By having a practical application of the knowledge base for the course, they report that they retain the principles they learn in the course. A few students have also reported that they have used the projects as a sort of “portfolio” to show prospective employers the kind of work that they have performed in their coursework. All in all, the project-model for distance learning is an experiment that appears to have worked. The instructors will attempt to use such a model in building other distance learning courses.

Responding to Stakeholders:
An Example of Distance Learning Modality in Teaching Finance Skills

Sharon Garrison
Finance Department, Florida Gulf Coast University
sharon@tmag.com

Dan Borgia
Finance Department, Florida Gulf Coast University
dborgia@fgcu.edu

Abstract: Florida Gulf Coast University, the newest in the state university system, opened its doors in August, 1997. As part of the university’s mission, departments were mandated to deliver distance courses to 25% of enrolled students. The challenges to the finance department were great, so faculty decided to seek input from stakeholders.

Review of the Literature

Stakeholder analysis focuses on defining quality for education. [Fenwick, 1992] This entails forging a consensus between stakeholders such as learners, faculty, industry, and the community, [Fenwick, 1992], [Kinyanjui and Morton, 1992], [Bruce, 1992], [Maki and Nightingale, 1992]. By including such stakeholders in defining quality, more useful benchmarks may be created. These benchmarks may include dropout rates, assignment response rates, student evaluations, the teaching package, the degree of freedom in pace and content, and the level of independence of students. [Nunan, 1992]. Other inputs may impact on the quality of course offerings [Fenwick, 1992], [Schuler, 1993].

Finance Department Course Design

Keeping these notions in mind, the finance department paid particular attention to building a curriculum by consensus. The department talked to over 80 community business people on what type of graduate they would like to see. In addition, student focus groups to help design the curriculum and courses. The finance faculty also had as a primary goal to build a sense of identity among finance majors. Some of the facts we learned were:

- Businesses wanted to hire students with good communications skills.
- Businesses wanted graduates to have “hands-on” financial skills.
- Students wanted classes at convenient schedules and were quite interested in distance learning modalities.
- Students wanted comprehensive courses, yet carefully designed to optimize their time.

Distance Learning Courses

One example of a distance learning course designed in response to these findings is FIN 3240, the introductory finance course. The Web page for a sample course is located at http://www.tmag.com/sgarrison

FIN 3240 is taught in-class and at a distance. This distance class has been taught three times to good reviews from the students who completed the course. The attrition rate is high in the course (27%), but this compares favorably to the attrition for distance courses at the university (32%) and to comparisons at other institutions.
While “walking through” the page there are a number of items to note. First of all, there are a number of “topic overviews” which give a thumbnail overview of the topic at hand. These are designed to explain some of the theoretical concepts in simpler terms, and to lend the practical bent to Finance learning that employers said they wanted.

There are also a number of tutorials to give students “hands-on” financial training. Some of the tutorials cover the basics of using financial spreadsheets, the basics of working with time value of money, and how to use spreadsheets in valuing corporate securities.

The course page contains the syllabus for the course, as well as some general materials that we developed such as sample exams and various tutorials. We also have a page devoted to each chapter in the course textbook.

The materials that we have for each chapter are objective-driven. We have learning objectives listed for each chapter and all the following materials derive from those objectives. We also include a chapter outline, solved problems and a Web site of the day. In addition we allow students to review the PowerPoint slides that we use in our classes. These are viewed using a PowerPoint animation player. We purposely do not put the actual PowerPoint slides on the page to minimize download time. Also, we have observed students in university classes printing out PowerPoint slides in the lab. We thought that this was not a good use of university resources, particularly when in our class we have the chapter outlines available for student note-taking.

Perhaps the most important feature of the page is the Feedback Form. We decided that in a TQM environment we could not wait until the end of the semester to make course improvements. Rather our goal was to make continuous improvement. To that end, we give students the opportunity to provide us with feedback every lesson. Most of the time, the comments have been fairly gratifying. Occasionally, we get a good suggestion which we can use to immediately improve the course. By responding to suggestions quickly, we feel that we are treating students as stakeholders in the course. We frequently peruse other courses in Finance. Few distance courses are currently being offered, but we try to remain in contact with other Finance professors who work in a distance environment to keep abreast of new developments. (See http://www.cob.ohio-state.edu/~fin/resources_education/edcourse.htm.)

Conclusion

Teaching Finance in a distance environment is a challenging process, but input from stakeholders in the process optimized efforts. The class that developed has been running smoothly and we continually seek to improve it.

Abstract: The widespread and rapid growth of the World Wide Web is a clear indicator of its success as an instrument for information delivery. At the same time, significant limitations in many current Web-based applications demonstrate the need for new research. This paper describes a design in which the limitation of static, overloaded and "one size fits all" Web sites is addressed through customized Web views. The application domain is a Web-accessible reference guide for the Mississippi Center for Supercomputing Research (MCSR) user community referred to as "SmartGuide." The design makes use of object-oriented methods, full text analysis tools, and user modeling.

Reaching a Diverse User Base

This design presented here and the SmartGuide reference guide grew from a specific need. Mississippi Center for Supercomputing Research (MCSR) consultants faced the challenge of providing technical support to an expanding and increasingly diverse user base. Originally, the MCSR user base consisted mostly of scientific and engineering researchers who had technical backgrounds, and the services offered by MCSR were limited to one or two high performance computing systems. In this environment, MCSR consultants developed and distributed paper-based reference guides that explained how to use the available systems. As time went by, MCSR consultants took on more and more general academic computing support with little change in staffing. MCSR consultants now provide support to statewide users on high performance computing, UNIX and Internet/World Wide Web (WWW) applications.

This shift has increased the user base from several hundred to over ten thousand faculty, staff and students; moreover, the user base now consists of people with widely varying information needs. For example, UM students need to know things like how to get an account, where labs are located, how to use e-mail and how to register for classes through the Web. Instructors need to know things like how to set up a course Web page or mailing list. Researchers need to know about the available computing platforms, software applications, and how to compile a program and run a job on the MCSR computers. As the role of the MCSR expanded, the WWW emerged, offering almost universal accessibility and platform independence with easy-to-use client interfaces. As a result, MCSR consultants began moving from paper-based to Web-based reference materials and now rely almost solely on the WWW for reaching users.

The Challenges

While the WWW offers advantages in distributing information, it also entails new challenges. Keeping MCSR Web pages up-to-date as machines are installed and de-installed, as applications are added and as procedures change is a tedious and error-prone process. With the MCSR, reference material is spread across heterogeneous sources, including
databases, text files and HTTP documents. Separating content from presentation is a good design approach, but integrating the content into a single, unified interface can be a major undertaking. Another challenge is finding a way to organize and present the reference material so that users can easily get to the information they need. This may require some level of information hiding so that users are not bombarded with information that they will never use.

WWW developers most commonly present information to users by manually creating and arranging hyperlinks and storing these with document content in static Hypertext Markup Language (HTML) files. When the user selects the marked text or object, she is taken to the destination document identified by a hyperlink. A domain expert studies the items in a collection to determine where hyperlinks should be placed and how they should be connected to other documents. While the developer may arrange information so that items of interest to a particular type of user are grouped together, there is no real customization. Furthermore, the ongoing maintenance of the Web site, updating document content that is embedded with formatting specifications and validating the links between documents requires significant effort on the part of the developer.

**Hypermedia and Adaptive Hypermedia Systems**

Over a decade of research on hypermedia offers promising possibilities for enhancing the WWW, the most well known hypermedia system to date. While conventional print technology is rigid in the way that information is presented, hypermedia methods can potentially provide a more flexible way of organizing and presenting information. Ideally, a hypermedia application is structured to avoid information overload; the characteristics, motivations, and needs of different individuals can be taken into account. Bieber and Vitali [Bieber & Vitali 97] offer the following advice: "Web Environments should not overwhelm users by providing too many options. Web environments should include filtering mechanisms to present only the most relevant links, based on the users current goals."

Eklund and Zeiliger [Eklund & Zeiliger 97] note the history of hypermedia usability research predating the WWW and suggest that the next logical step is to apply these research findings to the WWW. They describe the relatively new area of research in Adaptive Hypermedia Systems (AHS), where AHS are defined as "externally structured systems which are explicitly based on hypertext (or hypermedia), and use a model of the users knowledge or goals to modify link or content to present individualised instruction or guidance." According to Brusilovsky [Brusilovsky 96], adaptive hypermedia systems are useful in domains where the system will be used by people with different goals and knowledge and where the hyperspace is reasonably large.

**The Problem**

The resulting problem is to design an adaptive hypermedia system which (1) allows one to integrate information from heterogeneous sources into a unified interface, (2) provides a filtering mechanism so that users see and interact with a view that is customized to their needs, (3) delivers this information through a Web interface, and (4) supports the automatic creation and validation of links between related items to help with ongoing maintenance of the application.

**The Design**

We address this problem with a design that makes use of object-oriented methods, full text analysis tools, and user modeling. The major system components are the object server, the Web server, the index server, and the user server. The user, index, and object servers are implemented using the Inter-Language Unification (ILU) system [Janssen & Spreitzer 97] from Xerox Parc. ILU is a software tool for building multiple program modules which are interconnected through language-neutral, object-oriented interfaces. The Web interface is implemented with an Apache HTTP server and Java servlets. ILU clients are built into the Java servlets to support interactions with the other servers.

**The Object Server**

An object model is needed in this application for several reasons. The data that makes up the reference guide comes from different sources and machines. Requiring a special interface for each data type is clumsy and inefficient. A better
approach is to define a universal and consistent interface for operating on all data types. That is, regardless of how the data is formatted and stored, certain operations, operations which can be expressed concisely and elegantly, are guaranteed to be supported. Also, the application must be designed to easily incorporate new kinds of reference guide content such as audio files or bibliographic references. An object model facilitates the inclusion of new data types into the application.

The function of the object server is to interface with the reference guide content. The reference guide content is modeled as information objects—in this case, tasks, examples, knowledge base items, URLs, consultants and terms. The object server sits between the data stores and client modules and responds to client requests. Methods such as GetObject() and ShowHTML() allow clients to interact with the reference guide objects. The object server consults object meta-data to find out how to display objects in a given class. The details of how data types are formatted and stored are embedded in the object server and, as a result, are hidden from other modules in the application. Interaction with the data stores resides in the object server, thereby freeing the client modules from knowing the details of how information is stored and accessed.

The Index Server

In this design, the index server and the user server (described next) provide the filtering capability. The index server responds to a client request by constructing an appropriate query, comparing this query to a set of object surrogates, and returning a ranked list of object ids. Prior to the reference guide coming on-line, a software robot performs a full text analysis of all reference guide objects and generates object surrogates which represent the actual objects. Object meta-data dictates how heavily to weight the various attributes making up the object. The robot first interacts with the object server to get the universe of objects in each class and then to get each object one-by-one. The index server uses the object surrogates that were generated by the indexing robot to decide which objects best satisfy a particular request.

The indexing robot is implemented using Salton's "blueprint for automatic indexing" [Salton 89]. The Vector Space Model [Salton & McGill 83] is chosen as the full text analysis tool for this design because (1) previous studies have shown that retrieval results based on this method are very good, especially when documents are relatively short, (2) the implementation of the algorithm is straightforward, and (3) the similarity function between a query and items in the document set can be computed with a reasonable amount of system resources (CPU, memory, and disk). The limitations of this approach are (1) terms are not always orthogonal, (2) the same term may have different meanings in different contexts, and (3) the algorithm does not take into account the subjective quality of the documents. Also, the fact that two documents, or in this case information objects, share certain terms may not necessarily mean that they cover related concepts.

The User Server

Stated simply, the user server handles user information. For example, the user server keeps track of who is logged in and adds/updates user profile information. A central component of any adaptive hypermedia system is its user model. The user server facilitates the construction of user models by collecting user profiles and then generating stereotypes based on these profiles. Before using the reference guide, the user must first answer a short set of questions related to her background, affiliations, and computer usage. The user server stores the profile information for future visits.

The notion of using stereotypes as a means for modeling users was first introduced by Rich [Rich 79] two decades ago. In order to use stereotypes, the system must have two kinds of information. First, the system must know about the stereotypes themselves—for example, what characteristics are associated with a particular stereotype. Second, the system must know what events "trigger" the various stereotypes. The triggers can be one or more user attribute values that imply a particular stereotype. For example, in this setting, the stereotype "UM Student" is assumed if the user indicates that one of her primary roles is the student role and that the institution with which she is associated is UM. It is automatically inferred that people in the "UM Student" stereotype will want to know things like how to register for classes through the Web, how to set up a student organization Web page, what labs are available and so on. Similarly, the stereotype "Supercomputer User" is assumed if the user indicates that one of her roles is the researcher role, that she compiles and runs programs, and that she optimizes resource-intensive programs. In this case, it is inferred that she will want to know things like how to submit a job to a queuing system such as NQS, how to get a research account, and how to evaluate a program performance.
Some user models incorporate stereotype hierarchies where one stereotype forms a subset of another stereotype. In the hotel application, HAM-ANS [Morik 89], facts about the user imply different, independent stereotypes, and a single user can belong to several stereotypes. These stereotypes are mixed together to form a user profile. This design does not use hierarchical stereotypes; instead, it uses multiple, independent stereotypes to describe users as with HAM-ANS. This way, many facets of an individual can be represented, resulting in a rich and expressive user profile. For example, an individual might play the role of both teacher and researcher and would thereby be assigned both stereotypes. A danger with this approach is that an individual may assigned too many stereotypes and, as a result, see widely varying topics listed together in the application.

Rich [Rich 79] identifies three dimensions along which user models can be classified: (1) who is being modeled a canonical user or an individual user, (2) how is the model constructed by the user directly or by the system based on the user's behavior, and (3) what type of information is contained in the model—short-term, highly specific information or longer-term, more general information. This user model can be classified according to Rich's dimensions as follows. It uses individualized models for each user. It creates each user model explicitly rather than implicitly by asking the user to respond to a brief set of questions about his or her background and typical use of computers. Finally, this user model keeps both long-term and short-term information about each user.

A collaborative model in which the user is involved in the creation of the model may be the best choice for adaptive hypermedia systems [Brusilovsky 96]. This design uses a collaborative model; specifically, users directly provide information about themselves and, if they choose, can indicate the tasks that best fit their needs through the use of relevance feedback. When the user connects to the Contents page, she can indicate the tasks that best match her current needs, and her responses are then used to create a new Contents page.

The Web Server

The Web server evaluates user requests and interacts with the other servers in order to respond to those requests. Each user request for a reference guide Web page includes a template name. The template name corresponds to an enhanced HTML file that contains object placeholders along with information on how to match and display (e.g., as references or in full) objects. The Web server consults the index server to determine which objects to include and then interacts with the object server to retrieve and display those objects.

Interactions between System Components

Figure 1 shows the system components and how they interact with one another. Listed next are a few examples showing how the various components interact in response to different user requests.

Registering

When the user connects for the first time, she registers by choosing a user name and password. Upon receiving a register request, the Web server gets and validates the request parameters that were provided by the user. The Web server polls the user server if this user name is taken. If the name is free, then the Web server asks the user server to create a new user with this user name. The Web server responds to the user by taking her to the update profile page.

Stating Current Goals

At the start of each session, the user states her current goal and connects to the reference guide. The Web server interacts with the user server to find out if this user is logged in and whether this user has a profile. The Web server requests the index server to initialize this user's session information. The index server gets the stereotypes for this user from user server and updates the session information. If the user has entered her current goals, then the Web server requests the index server to set the goals for this session. The index server evaluates the goals statement and updates the session information for this user. If these actions are successful, then the Web server responds to the user with a Contents page.
Connecting to the Contents Page

When the user connects to the Contents page of the reference guide, the following interactions occur. As with the other requests, the Web server interacts with the user server to find out if this user is logged in and whether this user has a profile. The Web server gets the remaining request parameters including a template name in this case "contents." The Web server reads in and parses the text file corresponding to the contents template. The Web server simply displays the lines in template file that do not correspond to object placeholders. For each object placeholder that it encounters, the Web server builds an index server request. The Web server asks the index server to supply a list of object IDs which best satisfy the request. The index server builds a query based on the request from the Web server. The query may incorporate user profile and goals information, object surrogates as context information, previous queries and also feedback from the user on how well previous queries performed. The index server compares its query with all of the
object surrogates in the target class and builds a ranked list of object IDs to return to the Web server. For each ID in the returned list, the Web server gets the object from the object server and then asks the objects server to format the object for display according to the parameters given in the HTML template.

Results

One of the tests conducted measures whether the filtered system performs better than an unfiltered system. In this test, we calculated "time to complete a task" for both filtered and unfiltered systems, where the "task" was to find the answer to a question related to general Internet usage among the information sources that are included in the reference guide. The test subjects were students enrolled in computer literacy classes. In the first part of the test, the students interacted with an unfiltered system. Complete lists of tasks, examples, knowledge base items, related Web sites, and consultants were displayed, and the students looked through these to respond to the set of questions. In the second part, students interacted with SmartGuide using a predefined user profile set to the "UM Student/Internet User" stereotypes. In each part, the students were asked to answer five questions related to general Internet usage and to identify where the information was found (e.g., task or example id) in the reference guide. After the students answered the questions, they completed a brief attitudinal survey to measure subjective satisfaction with the system.

We found that students were able to find correct answers 22% faster in the filtered system. The average time to correctly answer a question was 198.84 seconds with SmartGuide and 255.77 seconds with the unfiltered system. Also students were less likely to skip or miss a question in the filtered system. The average number of skipped questions was 1.03 using the unfiltered system and .48 using SmartGuide. The average number of questions answered incorrectly was .63 using the unfiltered system and .23 using SmartGuide. The attitudinal survey responses were more positive for SmartGuide than for the unfiltered system.

While additional tests are planned to further evaluate this design, the outlook is good. The use of an object server supports the integration of information from heterogeneous sources into a unified interface. The index and user servers provide a filtering mechanism based on the user's background and current goals. The use of Java servlets with Apache enables the delivery of information through a Web interface. Finally, this design supports the automatic and dynamic generation of hyperlinks between related information objects, thereby freeing the developer of this task. The system components work together to achieve filtered Web views.

A Method for User Verification

K. M. George
Computer Science Department
Oklahoma State University
Stillwater, OK 74078, USA
kmg@ac.cs.okstate.edu

Abstract: This paper addresses the issue of user verification in a multi-transaction session using HTTP and proposes a server side solution that does not require the cooperation of the client. A user initiates a request (a session) to a server from a browser and obtains a result through a sequence of transactions. The sequences of transactions have a linear order. Since HTTP is stateless, two problems arise. The first problem is to preserve the order of the transactions. The second problem is to determine that two consecutive transactions are associated to the same user. The first problem can be solved by imposing an order among the associated CGI programs. This paper presents a formal transaction model and proposes a solution to the second problem using hidden variables and time stamps. A user initiates the session by logging on to a virtual system. User verification is enforced as the session progresses for one transaction to the next.

Introduction

There are several applications that require multiple stages of input from the user where each stage depends on the previous stage. A simple generic example is a program that collects user input using menus. Usually menus may be organized as a tree. The response to a menu determines the new child menu to be presented. In such a situation, it is presumed that the user who executes the program is the one who is responding to the menus and retrieving the results. It is a safe assumption because the executing program is in control of all actions and its state remembers all relevant actions. This simple scenario becomes complicated in a WWW application because the http communication protocol is stateless.

In order to present the problem in a clear and concise manner, an example is considered. Consider the case of an automatic bank response system which allows a user to obtain account balances and balance transfers over the telephone. In such a system, a user enters his account number and a PIN to get access to the system. Once the user gets access, he/she is presented with a menu of choices. For the sake of simplicity, let us assume that the top level menu presents two choices - obtain balance information and make transfers. The menu for balance information allows two choices - checking and savings. The menu for balance transfers also allows two choices - from checking and from savings. The third level gives two choices - exit or go back to the top level.

Assume that the above mentioned scenario is implemented using the WWW. Each menu will be presented as a form. The problem is to determine if the person who logs on is the one conducting the subsequent interactions. Such applications require a method to verify that the same user submits all forms. We formalize this problem by defining a formal transaction model. An illustration of the transaction model is shown in figure 1. In the next section we formally describe the transaction model. Based on the transaction model, a partial solution is presented.

Transaction Model

The transaction model is formally defined a 9-tuple \((S, V, A, E, R, 1, 21, s0, F)\) where

- \(S\): a set of requesting states
- \(V\): a set of verification states
- \(E\): a set of error states
- \(A\): a set of authentication conditions
- \(R\): a set of requests
- \(I : S R V\)
- \(2 : A V S E\)

One state, \(s0\), in \(S\) is distinguished as a start state (or login state). A subset \(F\) of \(S\) is distinguished as final state. The \(s\) are called transition functions. A transaction is valid if it begins at \(s0\) and ends in a final state by applying a series of transition functions. A transaction is illegal if it enters a state belonging to \(E\).
Implementation

We use the above model to implement a user verification system in a WWW application. A state \( s \) in \( S \) is realized as a form. The authentication set \( A \) consists of a set of verification vectors (VV). A VV is a 4-tuple \((u, p, h, t)\) where \( u \) represents a user id, \( p \) represents a process id, \( h \) represents history, \( t \) represents time. VVs are added and deleted as a transaction continues. A history \( h \) is a logical sequence of states traversed by the user. In other words a history represents a sequence of states beginning at start state and ending at the current state. The states \( s_i \) and \( s_{i+1} \) are in the sequence only if there is valid transition from \( s_i \) to \( s_{i+1} \) through an intermediate verification state \( v \). The components \( u \) and \( p \) of a VV is used to identify a specific user. The components \( h \) and \( t \) are used to reasonably verify the user \((u, p)\). The history represents the sequence of states visited by the user and \( t \) represents time at which \((u, p)\) was in the previous state. The VV is recorded in the documents by means of hidden variables. A set of active VVs are also stored in the server side for verification purposes. If \( h_1 \) represents the history at state \( s_i \), then \( h_{i+1} \) represents the history at state \( s_{i+1} \). If \( VV_1 = (u_1, p_1, h_1, t_1) \) and \( VV_2 = (u_2, p_2, h_2, t_2) \) are two verification vectors, \( VV_1 < VV_2 \) (or \( VV_2 > VV_1 \)) if and only if \( u_1 = u_2, p_1 = p_2, t_1 = t_2, \) and \( h_1 \) is proper prefix of \( h_2 \). VV1 and VV2 are related if \( VV_1 > VV_2 \) or \( VV_1 < VV_2 \). All related verification vectors have an associated life time. (This relation captures the states that are reachable by using the "BACK" button in the browser.)

As mentioned earlier, a state is identified with a form (or document containing the form). The CGI program that gets the data from the form produces the next form. The verification conditions are checked by the CGI program. Let \( VV = (u, p, h, t) \) be the verification condition associated to the state and let \( T \) be the life time of verification vectors related to VV. If \( T+t \) is less than the current time, then the transaction enters an error state. VV and all related verification vectors are removed from \( A \). In this case the user will have to start from the login state (start state). If \( T+t \) is greater than current time, it updates all related verification vectors by setting the \( t \) component to the current time. It also updates the set \( A \) by including a new verification vector \((u, p, h, t)\) where \( t \) is the current time and \( s \) is the current state. This new verification vector is encoded in the new form produced by the CGI program using hidden variables.

Conclusion

In this paper we address the problem of user verification in WWW applications with multiple transactions. A formal model is described as an abstraction of the problem. Based on the model an implementation scheme is provided. Even though this scheme does not provide a foolproof solution, it provides an acceptable approximate solution. It does not use cookies [http://developer.netscape.com/find/index.html] and thus avoid client-side cooperation. It is a server-side solution using only CGI [Felton 1997] that can be implemented using hidden variables.

Abstract: German universities are overcrowded. Staff has been cut back, often resulting in poor quality teaching. Public infrastructure developers, on the other hand, try to instigate a market for contents transported via their networks. Among the inferentially sponsored projects is DIALECT - Digital Interactive Lectures, based at the Freie Universität Berlin and founded in 1994. DIALECT's interdisciplinary production team and authoring university teachers develop teachware-applications for students in regular base courses. The first part of this paper introduces basic concepts and requirements of the DIALECT approach. Part two outlines DIALECT's framework and distribution approach for the world wide web. Part three discusses methods for presenting abstract and complex scientific content applied in a recently finished DIALECT lecture.

1. Introduction: DIALECT – A Modern Approach to Multimedia Lectures

1.1. The Project DIALECT - Digital Interactive Lectures

DIALECT lectures are designed as integral part of the courses. They do, however, not require human coaching. DIALECT lectures enable students to prepare and repeat courses on their own. Lecturers can also issue coursework drafts containing problems to be solved with the lecture. DIALECT lectures require Windows® PC clients. The contained dynamic media may be stored locally or remote or streamed over the Internet via HTTP or other transfer protocols. Each client requires a sustained net bandwidth of 2 MBit/s. DIALECT lectures are employed by hundreds of students and professionals. Further information concerning DIALECT's general conditions, infrastructure, interdisciplinary team design and didactic concepts can be obtained from [JENC7 96] and [ED-TELECOM 96] or visit DIALECT at http://www.wiwiss.fu-berlin.de/dialect

1.2. The DIALECT Approach

An interactive video storyline encourages problem-based learning and serves as guided tour through the contents. There is no AI involved. Animations support the user in constructing his own mental models of the contents. Mere drilling of facts is not intended. DIALECT lectures ultimately require the learner to actively practice his knowledge in exercising components.

By adjusting the video storyline to the clichés and symbols of a specific genre, the user's experience with this genre can be invoked, thus tapping individual socialisation as information resource ([Barret 95], p. 68). Thus advantage is taken of his or her existing knowledge. See also Apostolopoulos et al. in [JENC7 96], p. 272-1 to 272-9 and Bielenberg/Carpenter-Smith in [ED-MEDIA 96], p. 57 - 62. This approach is also in line with constructivist learning theory, stating that a learning individual is no empty container to be filled with knowledge by the teacher (condensed in [Schulmeister 96], p. 67 - 71). Learning is rather a continuous process, in which the learner - building on his individual experience - constructs his own worlds of knowledge. A mere collection of explicit facts cannot sufficiently explain reality.
1.2.1. Authors' Interface

University teachers' endorsement of DIALECT teachware is crucial for their acceptance with students. Therefore authors are tightly integrated into the development process and the DIALECT team has developed a screenplay-oriented scripting language helping to express their thoughts.

1.2.2. Developers' Framework

In order to share newly developed features among all DIALECT lectures, a generic set of objects has been developed. Every DIALECT lecture is derived from this framework. Visual basic® has proven to be a reliable and flexible development tool for DIALECT's requirements. Numerous third party components have been integrated into the DIALECT framework. Leveraging the full extent of their features has become developers' major challenge. Media are maintained in a reference database. External media management and storage provide for easy localization.

2. DIALECT Framework and DIALECT-Distribution schemes

2.1. Modules of a DIALECT Lecture

![Conceptually different framework components](image)

To keep the system adaptable to various kinds of contents the framework contains a lecture-independent central services component and a lecture-dependent frame descriptions component. As long as the above mentioned requirements to navigation and didactical approach etc. are kept constant, the central services components remain unchanged.

**Navigation Engine / Lecture Database:**

The navigation engine of the DIALECT framework fulfills two major tasks:

1. Providing an abstract description of each frame and its structural relation to other frames with respect to the construction of a knowledge space (sequence, hierarchy, mesh; authors may choose one or several structuring types). The selected structures are exclusively stored and managed in the lecture database.
2. During each user session the navigation engine sustains the correct user inference (jumps, branching, guided tours) through the knowledge space. This data is also stored externally in the lecture database, alleviating maintenance.
3. The lecture database contains the complete management for all session-relevant media data.
The Frames:
The screens where the information is actually located are called frames. They represent the visible interface between author and learner. Starting from a coarse concept in a process of stepwise refinement the authors assemble the storyboards containing a complete description of the final frame. Those storyboards are then implemented by developers and layout professionals (concerning the production process, please refer to [JENC796], p. 272-5). Under perfect circumstances only frames have to be produced while the framework with its central services remains unchanged.

2.2. Distribution: DIALeCT Goes WWW

The world wide web evolves fast. Software manufacturers, scrambling for market share, now favour proprietary solutions in the field of HTML-layout and authoring systems, database interfaces or component software (ActiveX vs. JavaBeans). New system architectures are established, often deliberately incompatible to those of other manufacturers. This undecided market situation prompts many developers to hesitate. Uncertainty over future runtime environments and over network access quality aggravates the problem.

Nevertheless due to the expanded scope of web authoring and website management DIALeCT will also have to make its decision on development platform and runtime environment for future DIALeCT lectures. The first step was to evaluate to which extent the current DIALeCT framework could take advantage of a world wide web based distribution concept. Please note that the current implementation is IP based but not does not support HTML. This results from the framework's current requirement to access all media objects as DOS files. Such access via internet protocol could only be realised with NFS and the shortcomings of NFS in connection with continuous media are commonly known. This level of abstraction was sufficient as long as the framework operated on the basis of local file access (CD-ROM, hard disk) or as long as a high performing intranet provider was available.

Problems with ‘Quality of Service’ had to be addressed only conditionally in the past. Media access via WWW required the expansion of the logical concept of an object towards the media stream. On the one hand this had technical reasons as, for example, the HTTP protocol per definition transfers data as a record oriented stream of bytes. On the other hand the usage mimic of DIALeCT lectures expects an instant playback reaction from continuous media. Users do not accept longer waiting periods. A complete distribution of DIALeCT lectures via internet inferentially fails due to lacking guaranteed bandwidths and due to the widely differing quality of the multiple internet connections.

The framework would have to fulfill three major demands:
1. The media manager must be capable to retrieve data from URLs.
2. Data transfer must be possible via HTTP.
3. The presentation components of the user interface manager must be able to render media streams with some kind of instant playback.

Apart from the modified framework other problems arose:
1. New media formats
   Are the media formats currently used by the DIALeCT framework capable of streaming? Do better suited formats exist with respect to performance and playback quality?
2. Mediacaching
   Once an internet stream has downloaded completely, should it be permanently stored locally, in order to avoid repeated streaming? Or are established WWW caching procedures (proxy) sufficient?
3. Active media serving
   As distribution of continuous media challenges every network, an active server support of the distribution process should be considered. Certain features stringently require active media servers.
Table 1: The synopsis gives a summary of the media types and formats used in DIALECT lectures. Among these formats there are some proprietary ones. This is due to the character of our development environment, based on Visual Basic®.

Of course AVI, MPEG and WAV can, like other formats, be distributed using HTTP. But the key question is, whether the user can start playback after the first few blocks have been transmitted. This depends on the media and file format. AVI marks an architecture that can incorporate any codec as long as certain interfaces are implemented. The separate codecs may apply very different approaches. Some codecs write certain index information to the end of their files. Such files definitely cannot implement instant playback. Unfortunately all previously used codecs belong to this category. An alternative had to be found.

New media formats:
We evaluated various file formats, e.g.:
1. RealMedia (Progressive Networks)
   This format serves for presentation of audio and/or video, optimised for low and middle bandwidth data transfer (14.4 Kbit/s – 300 Kbit/s).
2. Flash (Macromedia)
   The flash format serves to present 2D animation with synchronised audio. Flash animation is mainly vector based therefore requiring only low bandwidths.
3. Indeo 5 Progressive Download (Intel)
   Indeo5 has a MPEG style encoding algorithm, but is also appropriate for the display of animation. It trades relatively low scalable bandwidths for high demands to hardware performance.
4. NetShow (Microsoft)
   NetShow serves for the display of audio and/or video data, optimised for low transfer rates. A range of different codecs is supported.

Of course, each format has its own advantages and restrictions. But as long as the background drivers are integrated into the operating system properly the lectures should utilise the best fitting file format.

Mediacaching: Once a stream has downloaded completely there should be an option to store it permanently in local storage. This would secure further use and prominently the future availability for high performance playback. However this feature depends particularly on support by format specific client software.
In principal the evolution of leading operation systems converges to this requirement. Microsoft for instance has increasingly incorporated multimedia components into recent releases of its operating systems. One of them (ActiveMovie) allows for the HTTP transfer of formats like MPEG and AVI and their motion presentation. MPEGs can instantly be played back. Simultaneously a range of user interfaces (ActiveMovie player) and programming interfaces (ActiveMovie OCX) have been provided, assuring full programmatic control. But the function saving to local hard disk is not programmatical accessible.

Moreover employment of HTTP proxy servers can be considered. Proxy servers certainly offer advantages with respect to the exploitation of local resources to the maximum extent possible.

3. The DIALECT Approach Demonstrated on the Lecture IRS - Investment Calculus Subject to Taxation
3.1. Major Contents
IRS is a DIALECT lecture covering the impact of taxes on the classic investment calculus, consisting mainly of high-resolution animation. First an extensive survey to the German tax system is given. The survey is divided
into the personal taxes and the corporate ones. The following model for investment (The Standard Model for Investment) taught to students of business administration at the beginning of pre-graduate studies. The lecture aims to prepare the user for the examinations in Finance and Investment.

3.2. The Storyline

One basic concept of DIALECT lectures is to compensate for the lack of human communication by using an interactive video storyline. Our storylines contain an authentic problem, that can be solved with the provided knowledge. The storyline itself contains a lot of knowledge in its situated form. Furthermore, the story serves as navigational wrapper for the entire content, a feature heavily utilized by student-users.

In the IRS storyline a group of young friends start their career as employees of a blue-chip company. At first they encounter personal taxes. Then they get frustrated with the huge company's red tape and decide to found their own company. Having accomplished this, they tackle corporate taxes. Finally their flourishing enterprise comes under threat from their old employer and they have to consider a critical expansion investment. They have got to figure out, whether it is worth it or whether it is not while having to pay taxes ...

3.3. Animation

Animations make complex interactions visible and illustrate sample workflows. According to learning theory, animation can equally alleviate the construction of mental models by the users ([Weidenmann 94], p. 29 - 30). Learning theory also points out that animation requires "prior knowledge" of its elements. Therefore the constituting elements must carefully be introduced one by one.

Mental model animations may be displayed in three modes: indexed numbers, formulae or metaphors. The modes imply an increasing level of abstraction. So one might be blended over into another. Metaphors can display qualitative as well as quantitative interaction. Best fitted for the latter are obviously charts.

Learning theory also suggests, that appropriate pictorial metaphors significantly improve memorization ([Weidenmann 94], p. 37 - 39).

3.4. Active User Components

Numerous pedagogical and psychological papers explain that learning is an active process. Even if the user has understood a solution, he will soon forget, if he has not actively applied it. This implies the following requirements:

1. The user has to act; continuously and independently.
2. The user must have support available at every stage and in gradual levels.
3. The user must have checks on his learning. He must be able to determine, whether he is right or not.

The third item is easy to implement as IRS provides a host of control questions. To fulfill items one and two IRS contains a component called Exercise. Each task therein consists of a commented problem to be solved in a spreadsheet workplace. The user can act freely, but has commented sample solutions available at every stage. In between and final results can be tested for correctness. If he has made a systematic error the system can comment on his errors.

The Notebook feature of IRS supplies the entire content of the particular screen-frame as illustrated text in the right window pane. The left window pane contains a small wordprocessor. The user may now drag'n drop contents from the right pane into the left one, where he may edit them, annotate them, print them or export them to Rich Text Format. This feature enables the compilation of individual user records, encouraging active content reception. A complete set of frame scripts is also available.

3.5. Navigation

IRS contains various content-oriented means to navigate its knowledge space.

1. For beginners there is the storyline and the Guided Tour, a sequential order of screen-frames provided by the
authors.

2. Experienced users eagerly use the hierarchical content browsers and the glossary. The glossary lists every concept, gives a short definition of it and links the screen-frames containing the full scale explanation of it, thereby allowing encyclopedia-style browsing of concept references.

3. The History records the individual path of the user through the knowledge space and includes a function Back. The browsers also indicate frames already visited.

4. The principle of content-based structuring is continued during media playback. Apart from the standard functionality (play, stop, jump) the user may direct the player to designated scenes and even sentences.

5. Media and screen-frames contain commented hyperlinks that alleviate association and repetition of related topics.

4. Conclusions and Results

Production

1. Productivity could be increased by about 50% compared to the previous DIALECT lecture, resulting in 0.5 to 1 man months per ‘hour of learning material’. Expenses for video production tend to be overstated while those for animation tend to be underestimated.

2. Even with DIALECT’s tailored framework university personnel still requires specialists’ support in transforming their contents into multimedia teachware.

3. Though improving, sufficient OS-support for multimedia will take another two years.

Evaluation

1. There are no objective and sufficient evaluation designs available yet for multimedia teachware. Past enquiries have to be put into the perspective of an ever changing technology environment.

2. We do not yet have enough information for a long term evaluation of video utilization. There is some evidence that video proves exhausting if used too lavishly.

Animating Mental Models

1. Descriptive, text-based explanations have to be restructured into animated visual models.

2. Knowledge elements and their interactions must be symbolized with application-wide metaphors.

3. Deliberate use of redundancy and repetition.

5. References and additional bibliography

Acknowledgments

Special acknowledgments to professors W. Dewitz, M. Kleinaltenkamp and L. Kruschwitz for their support and encouragement. We would also like to thank N. Apostolopoulos, C. Bizer, D. Brickwell, J. Caumanns, C. Fungk, A. Jeromin, M. Schwake and G. Seiβ for their active participation.

The DIALECT project is being supported by the German Department for Education, Science, Research and Technology (BMBF) and the German DFN Verein.

517
Databases store information while the Web is the place for the gathering and distribution of information. However, there are inherent difficulties in linking them together. Nevertheless, real-life Web applications need an underlying database to be stable, flexible and scalable. Moreover, legacy database systems need to be connected to the Web. Consequently this poster introduces a new design methodology for the integration of databases and the Web, based on the finite state machine model well known from static hypertext documents. A Web based toolset helps to generate applications from an object based design language. On the client-side Java is compared with pure HTML. For searching, interfaces for both Software Agents and robots are provided. Using this techniques, complete multi-lingual, stable and robust real-life information systems have been built. The techniques presented on this poster will help to make the design of database backed Web applications faster, easier and less error prone.
Establishment of a Virtual Consultancy

Gerald Groh, Dr. Ulrich Jehle
GSM GmbH, Azenbergstr. 35, D-70174 Stuttgart,
Phone: +49 (711) 22563-0, Fax: +49 (711) 299-1978, Email: groh@gsm.de

Abstract: Recently there has been an increasing interest in the concept of virtual corporations. The virtual corporation is envisioned by many experts as the solution for a quick introduction of a variety of high quality products at a low cost. But there are still some open questions and problems to be solved.

In this paper the SERVICE project (SMEs pilot for business process design in order to establish a virtual international consultancy using electronic commerce) is presented. The project is partially funded by the ESPRIT programme Technologies for Business Processes (TBP) from the European Commission and aims to build up a virtual consultancy (VC). The VC consists of partners from Germany, England, Greece, Sweden and Finland.

This paper presents work carried out by SIEM, Greece, in the context of the SERVICE project, towards the specification of the Virtual Consultancy Framework.

Project Objectives

The overall objective is to facilitate the participation of small and medium-sized companies (SMEs) in the global market by pooling their resources and exploiting the opportunities offered by the development of electronic commerce.

As SMEs cannot afford to build up their own corporate networks, they depend on the availability of public networks. Public networks can be used by SMEs to establish a virtual private network. Effective sharing of data and collaboration between manufacturing organisations requires technologies that are cost effective, flexible and portable. During the implementation of the pilot, support training, coaching and qualification measures are taken to verify the VC's efficiency and effectiveness.

The project itself provides for various, interesting items to be discussed. Following the baseline of the conference we will describe the overall framework intended to drive the Virtual Consultancy concept in SERVICE. This paper presents work carried out by SIEM, Greece, in the context of the SERVICE project, towards the specification of the Virtual Consultancy Framework.

The Basic Concept

The basic concept behind the Virtual Consultancy is the appropriation of the complementary skills of the user organisations toward a common objective (e.g. added value products and services) and the commitment to pooling such complementary resources together to facilitate the production of added-value services that would not have been possible by the individual organisations.

It follows therefore that in establishing the Virtual Consultancy there is a broad range of issues that need to be agreed starting from the resources that are to be pooled to defining the added-value products and services to be offered, the way in which they will be practically facilitated (e.g. pilots), the business models and workflows driving the operation of the Virtual Consultancy and the required software and ICT infrastructure needed to facilitate collaboration, co-operation and interaction with the parties involved.

To this effect, the proposed framework comprises several layers which provide the basic support for inter- and intra-communication and collaboration within the Virtual Consultancy.
Technical Overview

The basic technological ground of the Virtual Consultancy will comprise a suitable communications infrastructure (e.g. intranet, servers), software tools to empower the operation of the Virtual Consultancy (e.g. video conference, document editing, etc) and application software which will drive the inter- and intra-faces of the Virtual Consultancy. The following diagram serves as a guideline for discussing the concept.

The internal (or private) information Repository

As indicated in the diagram, there are at least two logical information repositories that constitute the basic software components driving the Virtual Consultancy. The upper information repository is private, and may in fact be realised as a meta-knowledge pool linking the user organisation's individual server sites. This Virtual Consultancy information repository contains data stores internal to the virtual organisation which can only be accessed via the Intranet. Within such a repository, a wide range of data are to be captured, including:

- **Resources** pooled together by the individual organisations. These are the “assets” of the Virtual Consultancy that have been deposited by each individual user organisation to facilitate the agreed aims and objectives. Such assets may vary in type, nature and scope.
- **Client data.** These are data primarily of a private and confidential nature, which will probably be of internal use to the Virtual Consultancy. Such data may reflect a range of client-specific details from financial and legal information to physical location, transaction histories, etc.
- **Business models.** These include representations of workflows and corresponding artefacts, such as processes, forms, etc., that need to be processed to accomplish an intended objective. Such models will also form part of the overall assessment of the Virtual Consultancy, as they constitute an important part of the re-engineered environment that will be created.
- **Registry which will collect and structure the requests for Virtual Consultancy products and services.** This capability can be conceived as a “living” document which summarises past events and provides a
memory-aid for the Virtual Consultancy. Such a memory aid can serve a variety of purposes including access to past data, effective decision making, reuse of past experience, etc. Depending on its organisation and structure, it could provide an important knowledge management tool for the Virtual Consultancy.

The above categories of data stores are only indicative of the types that are considered essential for the operation of the Virtual Consultancy.

The public information repository

In addition to the private repository, the Virtual Consultancy should also possess a public counterpart which will be built around the repository, at the lower part of the diagram.

This component will facilitate a virtual presence of the consultancy and will comprise, amongst other things:

- **Public domains** for data and information exchange between the Virtual Consultancy and the external world (e.g. clients). These are designated stores which can be used by both the Virtual Consultancy and potential clients to exchange project-specific data. For example, a client may deposit a collection of user interface dialogues to be reviewed and evaluated by members of the Virtual Consultancy. On the other hand, such public domains may also be used by clients to review project status or download the results of a particular service contract.

- **Service and product** description to convey what the Virtual Consultancy can offer. This will be a conventional marketing tool for the Virtual Consultancy’s offerings. It is expected that the client will be able to review specific assets of the Virtual Consultancy, outlines of products and services, as well as examples of good practice.

- **Marketing and sales** materials which may be in the form of design case studies, white papers, electronic catalogues and other communications. This facility, as indeed the previous one will provide the primary means of the Virtual Consultancy for attracting attention.

The transformation layer

The intermediate layer between the two repositories, referred to as *transformation layer*, entails all the “middle-ware” components required for knowledge management and inter-operability within the Virtual Consultancy. This entails the articulation of source data (captured into the private repository) into added-value products and services (deposited in the public repository) through inter-operable software components, as well as other tools for tracing past experiences, depositing new content, carrying out contract work, workflow management, etc.

Inter-operability is likely to be an important component of the electronic commerce side of the Virtual Consultancy. There are two issues related to inter-operability. The first is supporting tool inter-operability, which means that a particular tool used by a user organisation (such as Visual Basic) can process data produced by another tool.

The second type of inter-operability refers to complying with the specifications of different standards, such as EDI. Though both types of inter-operability are likely to become critical components of the Virtual Consultancy, in the short term inter-operability across different national, or prevailing European and international standards needs to be explicitly addressed as an important component of the transformation layer, so as to enable financial transactions between clients and the Virtual Consultancy. However, this constitutes a serious challenge, given the current trend of developing incompatible standards. Without such type of inter-operability, several disadvantages may be encountered, such as individuals or user organisations may become locked in specific solutions; it may be difficult to carry transactions between mutually incompatible systems; critical mass may be difficult to achieve, etc. It follows therefore that inter-operability should be an important concern when setting up the electronic commerce side of the Virtual Consultancy.

In conclusion, it should be mentioned that the transformation layer is explicitly separated from the tools repository on the right hand side of the diagram to denote the knowledge-intensive human activities that are still needed in order to produce the added value products and services from source data.
Interaction with the Client

Communication between the Virtual Consultancy and prospective clients may take place either through e-mail, home page communication by visiting its site, and making use of the Web-based application or forum communication. E-mail communication is the conventional means for sending messages from one place to another electronically. It is expected that it will be widely used to facilitate a broad range of communications amongst the members of the Virtual Consultancy as well as the Virtual Consultancy and the external world.

E-mail however cannot be used for more demanding electronic commerce functions. Instead, such activities are currently being undertaken by home page communication. In particular, at present most contracts are formed by a customer accessing a seller's home page and selecting goods. In the case of the Virtual Consultancy, clients may access the Virtual Consultancy through the Internet by visiting the site, which a Web-based application residing within the public repository of the Virtual Consultancy. Clients may visit this site either to retrieve information or deposit requests for services or contract / project-specific data to be further processed by the Virtual Consultancy.

It is important that the virtual presence of the consultancy should provide clients with service descriptions by content rather than name (e.g. what can be done), example case studies, marketing and other sales materials, as well as tools for raising requests for contract work. In order for such seamless communication between the Virtual Consultancy and its client base to be realised, several security mechanisms will need to be in place.

Finally, forum communication refers to the case where one person or organisation posts a message on a special interest bulletin board which is read by others. It should be mentioned that this form of communication is suitable for casual and informal communication as opposed to formal business transactions. The Virtual Consultancy should possess this capability, as it is likely to meet the need to communicate or make announcements to special interest client groups in addition to home page announcements.

Electronic Commerce in the Virtual Consultancy

One important aspect of the Virtual Consultancy which has implications on the ICT infrastructure and the business models to be developed, relates to the type of electronic commerce that is envisaged and the type of interactions that need to be facilitated (e.g. inter- and intra-communications).

In this context, and in contrast with traditional electronic commerce involving business-to-business transaction, the Virtual Consultancy will appropriate Internet-based electronic commerce. The main differences between traditional electronic commerce and the Internet-based commerce envisaged for the Virtual Consultancy can be summarised as in the following table:

<table>
<thead>
<tr>
<th>Traditional electronic commerce</th>
<th>Internet-based Commerce</th>
</tr>
</thead>
<tbody>
<tr>
<td>Business-to-business only</td>
<td>Business-to-consumers</td>
</tr>
<tr>
<td></td>
<td>business-to-business</td>
</tr>
<tr>
<td></td>
<td>business-to-public administration</td>
</tr>
<tr>
<td></td>
<td>user-to-user</td>
</tr>
<tr>
<td>Valued-added networks (VAN)</td>
<td>Internet</td>
</tr>
<tr>
<td>Security part of the VAN</td>
<td>Security and authentication needed</td>
</tr>
<tr>
<td>Known and trusted partners</td>
<td>Known and unknown partners</td>
</tr>
<tr>
<td>Local to the involved industries</td>
<td>Global scale</td>
</tr>
</tbody>
</table>

Table 1: Electronic Commerce

From the table, it follows that the Virtual Consultancy will increasingly need the means to support a wide range of transactions (e.g. traditional business-to-business, as well as business-to-consumers, business-to-public administrations and perhaps user-to-user transactions) in a global market. The main conclusion from the above is that whereas in the traditional electronic commerce the market was basically a closed club, in
Internet-based commerce it is the entire network that constitutes the market. This of course has implications on the business models to be developed and the ICT infrastructure that should be in place in order to drive the operation of the Virtual Consultancy. In addition, it raises a range of considerations regarding liaisons with intermediaries that offer specialised added-value services, such as for example, information brokers, courier, delivery and distribution services, catalogue aggregators, banks, etc..

Summary

We describe the overall framework intended to drive the Virtual Consultancy concept in SERVICE. At the core of this effort is to highlight the process re-engineering which will allow individual companies to streamline operations, so that the Virtual Consultancy reaches the required levels of effectiveness and efficiency. In addition, the proposed framework as described, offers a logical overview of the concept and ICT infrastructure that is needed to realise the operation of the Virtual Consultancy.
Jamming.Net: a Server to Balance WWW Load

Antonio Gulli gulli@di.unipi.it
Computer Science Dept. Univ. Pisa, Studio Associato I-Tech

Abstract: A common problem with hypertext information servers is that they suffer high load of requests. Jamming.Net is a multithread server, written in Java, which performs a switching on the incoming HTTP connections by using the user-preferred policy of balance. Consequently, Jamming.Net is able to share load among a set of conventional web servers, both commercial and public domain, improving performance and reducing latency. Jamming.Net runs without problems on every machine with JDK version 1.1. Tests are performed on Solaris, NT, Linux.

1 The Need of Distributed Servers

A need for advanced solution to manage high load traffic is necessary, as the WWW increases in size and complexity. Today, the most common solution is to have got a unique web server running on a very powerful machine with great capacity of memory, fast processors, low access disk array. This way to face the problem is somewhat limited because the solution is not much scalable. In fact, as soon as the volume of traffic increases, it appears the need to modify the hardware configuration of the machine running web server. There are some cases in which we are even forced to change hardware at all. Beside, this solution is not fault tolerant. If there is some hardware problem in the machine, or software failure in HTTP server, the WWW service stops to work and published information are no more available on line. Here we are identifying three needs that modern system should meet in order to publish information:

- **Network Scalability**: We want to preserve the used hardware architecture and add only a new HTTP server running on a different machine, if the incoming traffic to an existing HTTP server increases.

- **Load Balancing**: Keeping in mind the previously described scenario, we want to share traffic among this set of HTTP servers according to some policies which depend on local load or some pseudo random heuristic.

- **Fault Tolerance**: In case of fault of one of these servers we want to be able to recover, stopping to use it
and, at the same time, replacing it with one of alive servers automatically.

2 Jamming.Net: a Server to Load Balance Existing WWW Servers

Keeping in mind these three needs, we developed a software server architecture that tries to satisfy them. One more need we want to satisfy is not to build another web server; in fact commercial and public domain servers exist with many features in term of programmability (server side script, module extensions and so on..) and with many tools dedicated to manage them. So, we develop a program acting in front of pre-existing set of HTTP servers, each one eventually running on different computers. In fig. 1 we have the position in network architecture in which Jamming.Net is placed. Like a traditional www proxy [1], Jamming.Net is situated between a www client (the browser) and the information content provider. Compared to a www proxy the marked difference is that Jamming.Net is able to decide what HTTP server has to provide the answer for every incoming request, on the bases of local information. Moreover Jamming.Net is transparent to the www client, in fact there is no need to configure the browser in order to use it.

![Diagram of Jamming.Net architecture](image)

**Figure 1:** The position in network architecture in which Jamming.Net is placed.

2.1 Java Multithread Architecture

To build this kind of architecture we decide to use Java [2] as developing language; it grants us desirable features such as portability, object oriented programming, general network API and multithreading. While portability allows us to run Jamming.Net on the most common platform (both Unix and NT), O-O Programming allows us a clear prototyping, finally network API programming and multithread allows us to gain benefits from lightweight process and BSD-like network features [3].

Inner server architecture is described in fig. 2. It consists of many threads. A subset of them lives forever and provides general functions such as management, periodic fault discovery, handling of incoming connections. Another subset is created dynamically for every incoming connection and only lives for the duration of same connection. We can explain it in detail:

- **One Listening Thread** that listens to the incoming connections from www clients, creates a new thread to handle each of them, choosing a www server to serve them, among the configured set. Since now, we call worker a HTTP server in the configured set. The method of choosing a worker is a matter of balance, and we are going to talk about it later.

- **A set of Switching Threads**, each one created dynamically by the listening thread when a new HTTP connection arrives. They take the job to both store & forward both all HTTP packets moving from the
assigned www client to the chosen worker, and all answer from the worker to the client. In this way, they die as soon as there is no more data to handle.

- One **Control Thread** listening to commands given via an ad hoc developed applet. In fact these commands are used to modify the server's state in real time (balance policy, workers' type, fault-tolerance). We are going to talk about Jamming.Net management later.

- One **Sampling Thread** which exploits periodic network's sampling in order to discover a worker's fault and runs with low priority.

![Jamming.Net server architecture](image)

**Figure 2: Jamming.Net server architecture**

### 2.2 Balancing Policy and Network Scalability.

Inside Jamming.Net, load balancing consists in choosing which worker serves incoming requests, **dynamically and for every single HTTP connection**. This technique is more useful than HTTP Redirect or DNS Balancing methods [4] because it gives the administrator an high control level of the load generated by each WWW requests. In fact, HTTP Redirect performs a redirect to another web server only for the first incoming connection. All subsequent requests go directly to that server. DNS Balancing has a lot of problem well described in [4]: above all, it shows poor fault tolerance and poor balancing in case of spot traffic.

Jamming.Net implements three balancing policies in order to let the listener thread choose which worker serves the incoming request:

- **Round Robin**: for every incoming connection, next worker in modulo is chosen.

- **Uniform Random**: a worker is chosen basing on a generated uniform random number.

- **Origin IP Hashing**: given the IP address of WWW client (the browser), a worker is chosen by applying a hash function on it. Consequently incoming connections from the same machine are always served by the same worker, by using this technique.

Network Scalability is simply reached enlarging the set of HTTP servers acting as workers. This could be exploited via the management applet, without performing any Jamming.Net reset. So, when traffic goes over a threshold, a network administrator could preserve the existing hardware and software installation.
2.3 Fault Tolerance

Fault tolerance is the set of techniques used by the server to discover the failure of a worker. Implemented techniques are grouped in two classes:

- **Synchronous Sampling**: as seen before, a worker is selected when a www connection is arriving, basing on the chosen balancing policy. If it happens that a worker does not answer before a time-out threshold, a fault condition is raised. This kind of testing is synchronous; in fact it depends on both www client request and chosen balancing policy.

- **Asynchronous Sampling**: as seen in architecture schema, a sampler thread stays alive with minimum priority. When a threshold time arrives it choices a worker, produces a request and waits for an answer. If it does not come, then a fault condition is raised. This kind of testing is asynchronous since it does not depend on www requests originating from clients.

If a fault is raised, some strategies of recovery could be exploited:

- **Worker Remove**: the worker is removed from the list of those available, and another available worker is selected.

- **Administrator Notify**: the event of worker's fault is notified to the administrator. He / She could decide what to do to recover from fault.

2.4 Security

Some security controls are performed by server:

- **Time-out on Listener side**: a system of time-out is exploited on listener thread in order to avoid that incoming connections with no HTTP request could cause a waste of resources.

- **Network address verifying**: when a new worker is inserted in the set of those available, Jamming.Net performs a control that it has a valid network address, and that there is a www server on the given port. This is to prevent an erroneous configuration.

2.5 System Cache

In order to reduce communication latency for small TCP-IP connection, a simple LRU cache mechanism was introduced in Jamming.Net. Each store & forward thread accesses cache concurrently by using a mutex mechanism. The cached data are stored in local file system and mapped in memory by means of a hash table. It is possible to configure data TTL, maximum dimension of cached data and maximum cache dimension. By adopting a very small cache substantially improves the achieved performance.
2.6 Workers Architecture: Replication or Shared File System

As we know workers are machines running a WWW server. There is the possibility to adopt two strategies in order to maintain the content of these servers. The information published could be:

- *Replicated*: for example on a Unix System using the "rdist" [5] features
- *Shared*: for example on an Unix System using NFS or AFS [6], on NT System via SMB [7]

Workers could be placed on the same LAN of Jamming.Net server or, improving performances, on a dedicated LAN. In such cases, the machine running Jamming.Net must act as a router for this auxiliary LAN. We can note that in these architectures Jamming.Net could act as a simple firewall.

3 Management Applet

The whole server configuration is performed by using an applet written by using JDK1.0 and consequently running on most common browsers. It is possible to modify the inner configuration of Jamming.Net without stopping and restarting the server, by using the applet. We can see a subset of the applet's tabbed panels in fig. 3, they are used to group together server functionality:

- *Workers' Control*: this panel gives to the administrator the possibility to modify the workers' set known by Jamming.Net.
- *Balance Technique*: this panel allows the administrator to select the balancing policy used by Jamming.Net
- *Fault Panel*: this panel permits the administrator to select what to do if a worker fault is raised, what kind of sampling to perform (synchronous and/or asynchronous) and to choose sampling intervals.
- *Cache Panel*: this panel permits the administrator to configure and to manage system cache, to choose maximum occupation allowed in file system, maximum file dimension and data TTL.
Interactions with server are performed by using three buttons. The Submit button submits to the server the choices selected in the applet. The Resync button loads from server the actual configuration. The Status button loads the server's status (number of faults and statistics).

4 Current State of Work and Future Work

Currently, we have a working system that meets the requirements described above. Jamming.Net is used to share traffic on a test bed architecture composed of three workers running Linux on a bi-processor Pentium with Apache[8] used as HTTP server. We are testing what is the maximum throughput reached by the distributed architecture under different load conditions, different dimension of data requested and different balancing policy. Jamming.Net's code is available on request and the executable was accepted by Java Application Catalyst Italia (maintained by Sun Italy), Gamelan (maintained by Developer.com), JavaToys and JARS. We believe that this work could point out the general need to move from an unique information server to a scenario of distributed servers' set.

5 Acknowledgments

I want to thank Dr. R. Perego and Dr. S. Orlando because they have suggested me some ideas behind Jamming.Net. I also thank Prof. G. Attardi, all Agent Group in CS Multimedia Lab, all the cool people belonging to Studio I-tech, Dr. Dario Lupi, Nico Tranquilli and Dr. Paola Padella. They all gave me critic review about this work.

Abstract: Apprenticeship is an appealing alternative to traditional lecture-based classrooms, but is difficult to implement within traditional undergraduate classes. We propose the use of Web-based technology to support an apprenticeship, particularly, support for collaboration and modeling of process. We present two tools that serve these roles: CaMILE which provides for anchored collaboration, and STABLE which provides models of successful project process. Evaluation results are positive, showing improvements in discussion length, student performance on projects, and student learning.

Apprenticeship, and its developing variant cognitive apprenticeship [Collins, Brown, & Newman, 1989], is an appealing alternative to traditional lecture-based classrooms. In an apprenticeship, the master (teacher) supports students by demonstrating techniques, coaching students while they use the techniques, and provides the students with the opportunity to explain what they do to others [Guzdial, 1995]. Cognitive apprenticeship is about applying the apprenticeship structure to help students learn modern cognitive skills such as mathematics and reading—or even design, but avoiding some of the negative connotations of apprenticeship. Demonstrations and coaching works well with small classes (e.g., perhaps 25 students) in K-12 where students have more than 50 minutes per class period. To make cognitive apprenticeship work for large undergraduate classes where time is short, we are using technology to extend the reach of the teacher and support the student designing and learning outside of the lecture hall. Apprenticeship, in a sense, is all about creating connections between teachers and students and students with one another. The technology discussed here helps to create these connections.

At Georgia Tech's College of Computing, we teach a sophomore-level class that introduces students to object-oriented design and programming, CS2390 Modeling and Design. Over the last four years, we have developed a successful curriculum and software supports which enable us to provide students with an apprenticeship-like experience within the constraints of a traditional classroom (e.g., 40-75 students per quarter, three lectures a week, one lab a week, one instructor and three TA’s). This paper presents highlights of the technological supports provided to students. The next section is a brief overview of what educators and cognitive scientists have learned about the critical aspects of apprenticeship learning. I then present two of our tools, STABLE and CaMILE, and the evaluation of each of these in CS2390.

Critical Aspects of Apprenticeship Learning

Cognitive apprenticeship was developed to focus traditional classrooms on tasks rather than abstract concepts [Collins et al., 1989]. By supporting students in learning in the context in which it might be used, the odds are increased of avoiding “brittle knowledge” [Brown, Bransford, Ferrara, & Campione, 1983], where students can pass tests but never use the knowledge in real-world situations.

There are several pieces to a successful cognitive apprenticeship. Three key pieces that we try to create in our class are:

- **Focus on Tasks over Concepts**: Rarely do apprentices learn something because they *might* use it one day. They learn to complete tasks. Learning is not abstract, and its results can be seen in the current design.
- **Scaffolding**: Scaffolding describes the kind of supports that a master provides when students are learning: Demonstrating and explaining the process, coaching the students as they work, and encouraging them to talk
about what they’re doing [Guzdial, 1995]. An important aspect of scaffolding is that it fades – it’s not at the same level for all students, since different students have different needs.

- **Community:** Apprentices learn in a community at all different levels — younger apprentices to be helped, older apprentices to model yet-to-be-learned skills and knowledge, and one or more masters to demonstrate and coach. A community provides the opportunity to demonstrate and articulate knowledge, which is key for students’ learning in an apprenticeship [Blumenfeld et al., 1991; Redmond, 1992].

**Technology to Support Apprenticeships**

We created two pieces of technology to facilitate the creation of apprenticeships in learning object-oriented design and programming:

- **Case Libraries for Scaffolding.** STABLE (SmallTalk Apprenticeship Based Learning Environment) is a case library [Kolodner, 1993] of prior students’ projects. STABLE is a task-focused form of scaffolding (e.g., demonstrations of how to design) with some adaptability. STABLE makes connections between more-expert students and their more novice peers.

- **Integrated, Anchored Collaboration for Community:** CaMILE (Collaborative and Multimedia Interactive Learning Environment) is a Web-based collaboration tool which features the ability to embed a discussion in another artifact, an anchor. CaMILE is effective for supporting, and even encouraging, extended connections and teaming. In our studies, we have found that anchored discussions in CaMILE tend to be longer (while still on-topic) than unanchored, newsgroup discussions, which suggests that discussions are more sustained and potentially more valuable in the anchored setting.

**Case Libraries for Scaffolding**

STABLE provides students with step-by-step description of several projects, most of which are projects completed successfully by prior students. STABLE is a form of demonstration, and also serves as a form of community—a communications mechanism between senior students who have taken the class before and leave behind records of what they did and how.

- **Hyperlinked to a variety of resources:** Each project is organized into a hierarchy of steps, which includes analysis steps, design steps, and programming steps (Figure 1, left). All steps are linked to multiple representations of the project, e.g., a tree representation of the entire current project, or a Coad-Yourdon diagram of the project’s class structure.

- **Linked to relevant concepts and generic steps:** Abstract lessons are presented in STABLE in the context of a task [Fig. 1] (left). When a step addresses an abstract concept (such as “What is a part-whole relationship?”), a link is made to a separate page that presents the concept. Sometimes a step is demonstrating an action which occurs very often, for example, building a graphical user interface. The step might then also link to a *generic step* page that presents the generalized form of how to build a graphical user interface.

- **A form of fading scaffolding:** A step is actually presented at three or four levels of detail [Fig. 1] (right). Students are initially presented with the least detail, but they can request more information if they need it. Additional information about the step is often available, such as *strategy* information (why is this step being done now and in this way, a common piece of information requested by apprentices [Redmond, 1992]), *outcome* information (a test for whether the step was completed correctly), or *repair* information (what are the common mistakes in this step). [Fig. 2] presents a step at its lowest level of detail, simply the statement “Build the DivisorCount Class” (which was analyzed and designed in earlier steps). By asking for More Detail, the student can increase the scaffolding and receive more-and-more support for how to build the DivisorCount class: first a paragraph description, then an outline of the code, and finally the code itself.
STABLE currently contains over a dozen projects which total to almost a thousand Web pages. (STABLE is generated from a database containing pieces of the case library information.) Several of the projects are from the same class addressing the same problem assignment, to show students trade-offs and alternative ways of solving the same problem. We do not yet have negative examples, but are considering adding them. Our focus is not on providing examples of artifacts, but examples of process — how a project develops from analysis through design to implementation.

The CS2390 curriculum has changed to take advantage of STABLE. For example, there are three cases that address the problem of creating a simple spreadsheet constraint mechanism, which was the second assignment during the Case-Gathering quarter (Winter '96). In STABLE-using quarters, I asked students to extend the original projects. One quarter (Spring '96), I asked students to extend the spreadsheet constraint mechanism, and another quarter, I asked students to wrap a more sophisticated graphical user interface around the simple spreadsheet. In both cases, the spreadsheet problem was now the first assignments of the quarter—we have been able to move the class more quickly through reliance on the case library. Students are always offered the opportunity to reuse any of the code from any of the STABLE case, but the reuse was not required.

One of my evaluations was to compare the performance between the Case-Gathering quarter (Winter '96) and a Case-Using quarter (Spring '96). If students were using STABLE to good purpose, one would expect that the Spring students would be more successful at their problem (using the same grading criteria and same graders), building on the
previous students’ work (even though they were getting a problem of greater complexity earlier in the quarter). However, if they were not using STABLE, one would expect lower performance. The results in [ Tab. 2] show that students using STABLE performed with a reliably better overall grade than did the original Case-Gathering class.

</tr>
</tbody>
</table>

Table 2: Performance Comparison between Case-Gathering class (Winter'96) and Case-Using class (Spring'96) on a similar problem

The important question is whether students learned more about design from STABLE than they did previously: Does it help to have students read and reuse a set of object-oriented design problems? To test this question, I created isomorphic problems (similar but not identical) from the Case-Gathering quarter’s final exam. I created an isomorphic design problem and graded using the same scheme with the same graders. Both problems were graded the same. [ Tab. 3] summarizes the learning results. STABLE-using students did significantly better on the design problem.

Table 3: Learning Comparison between Case-Gathering class and Case-Using class on the Isomorphic Design Final Exam Problems

We believe that STABLE is being successful at helping to create an apprenticeship-like environment, leading to improved object-oriented design learning. In addition, students are improving their performance. Students are learning and improving performance through use of STABLE (as advice from former students) in the same way that junior apprentices might learn from and be more successful at a project with help from a more senior apprentice.

Integrated, Anchored Collaboration for Community

CaMILE is a tool for encouraging students to work with one another, to explain to one another what they’re doing and why, and to help one another be successful and learn in the same manner as a communities of apprentices. In our work with CaMILE in a variety of contexts, we’ve found that that’s not an easy goal [Turns, Guzdial, Mistree, Allen, & Rosen, 1995].

- Simply forming teams of students can lead to disaster. While some small groupwork is effective, team projects can go awry leading to poor performance, little learning, or both [Turns, 1996].

- Providing newsgroups may be the right kind of tool, but there may be little or no incentive to use it.

CaMILE is a Web-based threaded collaboration tool that offers features that prompt students to collaborate effectively and structures collaboration to encourage learning [Guzdial et al., 1996; Guzdial, Turns, Rappin, & Carlson, 1995]. A particularly important feature of CaMILE is that each individual note has its own URL, which allows us to create links from any document on the Web to a particular thread in a CaMILE discussion. (A thread is a series of related notes. If note A comments on note B, and note B comments on note C, we say that notes C, B, and A are all in the same thread, and that C has a thread length of 3.) For example, I can post a Final Exam review with problems from prior final exams [ Fig. 4] and provide a link from each problem to a CaMILE thread for student answers to that problem [Fig. 4]. CaMILE facilitates anchored collaboration, and by properly choosing anchors (to be interesting, motivating, and encouraging discussion), we have found that anchored collaboration can help to generate in-depth discussions. Other anchors we have used include design assignments and student projects (for peer review).

To measure our hypothesis, we compared the newsgroup usage (unanchored, since few newsgroup readers allow individual note addressing) in the Fall '95 CS2390 class and the CaMILE usage (some anchors, though many threads were not linked to an external Web page anchor) in the Winter'96 CS2390 class. The two classes were taught by different instructors, but had the same textbooks and nearly identical curricula (e.g., even some of the same slides were used in each class). [ Tab. 3] summarizes the results of the comparison.
A broader distribution of students utilized CaMILE versus the newsgroup, suggesting that the anchors helped to broaden the appeal of the collaboration support.

The CaMILE-using class wrote many more notes with nearly as many top-level threads as in the newsgroup, so it is not surprising that the average thread length is longer (7.2 versus 1.9).

Anchored threads (those pointed to be external Web pages) in CaMILE are much longer (average 56 notes long) compared to unanchored threads in CaMILE (average 2.5).

We have done a qualitative analysis which suggests that in neither the newsgroup class nor the CaMILE class were notes off-topic. Most notes were about class issues (e.g., “What’s a class?”) or on homework assignments.

Table 3: Comparison of a Newsgroup-using CS2390 class and a CaMILE-using CS2390 class

The results for CaMILE suggest that an anchored approach – giving students something to talk about – can be effective for generating deeper discussions. CaMILE can be a useful tool in creating the kind of community seen in successful apprenticeships. We have not measured learning with and without CaMILE, but our sense is that the community-building aspect improves both motivation and learning.

Summary and Future Directions

STABLE and CaMILE are two tools which are helping to create the advantages of a cognitive apprenticeship for Sophomore computer science students at Georgia Tech. STABLE provides a form of scaffolding that fades, particularly scaffolding that demonstrates effective design process. CaMILE creates a forum for community-building, where students can explain what they’re doing and help one another.

Our believe is that apprenticeship is a useful pedagogical model for object-oriented design instruction. It informs us about the kinds of supports that we need to provide to students. That we are getting good design learning and creating an apprenticeship structure with such young students speaks well of the structure and of the kinds of supports that we are providing.
Acknowledgements

STABLE’s analysis has been conducted with Colleen Kehoe. CaMILE was designed and built with David Carlson and evaluation was conducted with Jennifer Turns. Thanks to my fellow CS2390 instructors Rich LeBlanc, Gregory Abowd, and Noel Rappin. Funding for this work has come from the National Science Foundation grants RED-9550458 and CDA-9414227.

Home Network Management Using Internet Management Protocol

Young-Guk Ha  Dr. Chae-Kyu Kim  Dr. Dan-Hyung Lee
Network Computing Department, Computer Software Technology Laboratory, ETRI, Korea.
ygha@seri.re.kr  ckkim@seri.re.kr  dhlee@seri.re.kr

Abstract: The advent of the digital multimedia revolution has created the need for high-speed digital network connecting consumer electronic devices in home environment. In large-scale home network environment the management and operation of many digital consumer devices become very difficult and complex task. Clearly an efficient and consistent framework for home network management is required. SNIvIP, the most famous Internet management protocol, provides an appropriate management model for home networks. This paper discusses our proposed design of IEEE1394-based home network management architecture using SNMP.

1. Introduction

IEEE1394-1995 is IEEE standard for a high performance serial bus supporting both isochronous and asynchronous transfer modes. For example, digital VCRs or DV camcoders can communicate with a digital TV using MPEG2 transport streams and the control packets over the IEEE1394 high-speed serial bus.

This paper describes IEEE1394-based home network management architecture using SNMP (Simple Network Management Protocol), with which we can implement configuration, security, fault and performance management. In the architecture, a set-top box or a PC on home networks does not only act as a manager of digital consumer devices but also acts as a gateway between the Internet and home networks.

2. Home Network Management Architecture

2.1 Manager

The manager system sends SNMP requests (e.g., GET, GETNEXT, SET) for accessing managed objects to managed devices and receives results (see [Case et al. 1990] and [Stallings 1993]). Then received results are calculated to appropriate values and displayed in various formats. The manager system also acts as a gateway between TCP/IP-based Internet and IEEE1394-based home network. Thus users can manage digital devices connected to home network from outside of their home environment via the Internet (see [Fig. 1]).

![Figure 1: Home Network Management Architecture](image-url)

2.2 Managed Devices

The managed devices are IEEE1394-compliant [IEEE 1995] consumer electronic products in which a real-time
operating system, a SNMP agent and their own MIB (Management Information Base) are embedded. The following shortly explains important components of managed devices (see Fig. 2).

2.2.1 Embedded Real-time Operating System

The Real-Time Operating System (RTOS) embedded in managed devices provides execution environment for SNMP agent process and provides APIs to control hardware such as IEEE1394 port and CSR (Control and Status Resisters) [IEEE 1994] on managed devices.

2.2.2 SNMP Agent over IEEE1394

Implementation of SNMP agent over IEEE1394 needs IP layer to be implemented over IEEE1394 [Johansson 1998] using embedded RTOS API. The API must include following functions:
- READ_FROM_PORT, which reads IEEE1394 port and stores incoming bytes into buffer
- WRITE_TO_PORT, which writes contents of buffer to IEEE1394 port
- LOCK_PORT, which locks IEEE1394 port

2.2.3 Home Network Device MIB

MIB is a database of managed objects accessed by network management protocols, and uses tree architecture to organize all available managed objects (see [Rose and McCloghrie 1991]). Each managed object of home network device is mapped to corresponding CSR using RTOS API. The API must include following functions:
- GET_CSR, which gets value of specified CSR
- SET_CSR, which sets value to specified CSR

For example, SNMP GET or GETNEXT request for any managed object on MIB tree invokes GET_CSR function for corresponding CSR and SNMP SET request invokes SET_CSR function.

3. Conclusions

Proposed architecture provides consistent and efficient methods for home network management by embedding most popular and common network management protocol SNMP in managed devices.

Guided Surfing: A Multimethod Assessment of a Layered Hypermap WWW Interface

Dr. Richard Hall
Dept. of Psychology, University of Missouri – Rolla, U.S.A., rhall@umr.edu
Eric L. Stocks
Dept. of Psychology, University of Missouri – Rolla, U.S.A., els@umr.edu

Abstract: A multi-level hypermap interface was created for the display of world wide web pages relevant to an undergraduate class in Sensation and Perception. Assessment of the interface consisted of two experiments. Results indicated that the guides encourage students to broaden the focus of their search. Further, the guides do not appear to be particularly effective for enhancing the acquisition of detailed-factual knowledge. Over all, students subjective reactions to the guides were positive. In particular, they perceived the guides as making the search project more efficient, and providing the learner with "big picture", conceptual knowledge.

1. Background

There is no question that the World Wide Web offers great potential as an educational tool [Anderson & Joerg 1996]. This resource is so new that educational researchers have had little time to examine it, however, research which has been conducted indicates that it can serve to enhance learning. The web seems to be particularly effective when used as an adjunct to, as opposed to a substitute for, more traditional instruction [Goldberg 1997]. A second important finding is that hypermedia environments in general [Jacobson et al. 1995] and the web in particular [Anderson & Joerg, 1996] are most effective when the learner is given some degree of structure or guidance.

With this in mind we set out to develop an organizational tool for displaying relevant web sites within a given subject domain. In our case, we selected Sensation and Perception, since the principal investigator regularly teaches a class in this area, and since there are an extensive number of web sites available [Krantz 1998]. However, we believe that this methodology and our findings are potentially applicable to other domains beyond Sensation and Perception in particular, and Psychology in general. The method that we used was an extension of previous research on two-dimensional knowledge displays called knowledge maps. Knowledge maps are a method of displaying text in a two-dimensional node-link network. (Maps used in the present experiment can be viewed within the Guided Surfing Program). This technique, which was developed by Dansereau and colleagues [Lambiotte et al. 1989], has been found to be more effective than traditional-linear text displays [Hall & O’Donnell 1996]. In particular, the method is effective for imparting higher-level conceptual knowledge [Hall et al. 1991].

We assessed the interface on two different methodological levels. First, we conducted a controlled experiment in which students were randomly assigned to groups, and the hypermap display method was compared directly with a traditional-linear display of web pages. Second, the hypermap guide was examined within the context of a Sensation and Perception class, in which students were required to carry out two class projects using the hypermap guide and corresponding web pages.

2. Experiment 1

2.1 Method

2.1.1 Participants

Twenty Students, enrolled in either General Psychology, Theories of Learning, or Theories of Motivation at a medium sized, midwestern, science and technology oriented University, participated in experiment 1. Those in the General Psychology Class participated as a regular part of their class, and those in the other classes participated outside of the regular class time, for extra credit in the class.

2.1.2 Materials

Site selection. The first step in development was the selection of appropriate web sites for a Sensation and Perception class. An outline for the class was developed and then a number of search engines were used, and many web pages examined, and eventually a set of seventy-five web sites were selected, within four broad categories: vision, audition, smell/taste, and somatosensation. These
sites were selected based on five criteria: 1) The site was relevant to the framework of the course as specified by the instructor; 2) The site tied the basic information to be learned in the course to "real life", "meaningful" information; 3) The information contained in the site appeared to be accurate, as determined by the class instructor/domain expert; 4) The information was presented in an interesting way, making effective use of the hypermedia tools available to the site developer; 5) In the case of sites that were relevant to what the instructor considered "core" concepts, a number of sites, which presented different perspectives/representations of the information, were often selected.

**Guide Development.** The guides consisted of a series of knowledge maps. The domain expert/first author constructed these maps by forming categories of the web pages, based on the class outline, and on the nature of the sites selected, and then noted interrelationship among groups. From this, ten different guide maps were constructed. The vision and smell/taste groups of sites were each represented by two levels of maps - a map, and more specific "sub-maps". When a students clicked on a node on the main maps a second, more specific map would appear on the screen. All of the other nodes on the maps served either as place keepers to aid in the accurate representation of the information displayed within a given map, or were a direct link to one of the seventy-five World Wide Web Sites selected. Audition and somatosensation sites were represented by a single map. The program can be viewed at: http://www.umr.edu/~rhall/class/sap/sapsurffprogram/surffprogramindex.html

2.1.3 Procedure

Students first read a set of directions displayed on the screen. Students were randomly assigned to two conditions. Ten of the students then studied the selected sites for thirty minutes using the guide maps, ten studied the sites using 4 different guides which listed the links for each of the four highest level categories (i.e., vision, audition, smell/taste, and somatosensation), in an outline format.

After studying, students completed an essay from memory covering the information they studied. They then completed a questionnaire, presented on the computer, including specific questions, with Likert scales, and one open ended question.

2.2 Results

2.2.1 Essay Scoring

In order to determine the amount of information that was included in students' essays, each essay was broken down into a set of factually accurate propositions, each consisting of a simple declarative sentence. This scoring technique is based on a technique developed by Meyer [Meyer 1975]. The number of propositions included in each student's essay served to represent the accurate amount of information contained. Reliability was established by having a second experimenter score a random subset of 10 (50%) of the essays. The reliability between the this scorer and the original scorer was \( r = .90 \). Neither scorer was knowledgeable as to the group assignment of the student essays as they were scoring.

2.2.2 Propositional Analysis

A t-test for independent samples was carried out with experimental group (map vs list) as the independent variable and propositions recalled as the dependent variable. The mean difference between the groups on number of propositions recalled was not statistically significant.

2.2.3 Questionnaire Responses

The analysis of questionnaire responses consisted of a series of two-way repeated measures analyses with experimental group serving as a between subjects independent variable, questionnaire items as within subject independent variables, and students responses to the questionnaires, serving as the dependent variables.

2.2.4 Site Category Visited

The questionnaire analysis began with a two-way repeated measures analysis of variance. Group (map versus list) served as a between subjects independent variable, and the first four questionnaire items (time spent on: vision vs audition vs smell/taste vs somatosensation), served as a within subjects independent variables. Students' ratings served as the dependent variable.

No significant effects were found.

2.2.5 Focus of Search
In order to examine how focused vs broad the students' rated their searches a two way repeated measures analysis of variance was computed with group (map versus list) as a between-subjects independent variable, and questionnaire items #5 & #6 ("My search was very focused..." vs "My search was very broad...") serving as a within-subject independent variable, and ratings as the dependent variable.

A significant main effect was found for focus, $F(1, 18) = 17.03, p < .01$. The descriptive statistics for the within-subject variable were $M = 6.45$, $SD = 2.67$, and $M = 2.60$, and $SD = 2.19$, for focused and broad search respectively. A significant group X focus interaction was also found, $F(1,18) = 5.82$, $p < .05$. The means associated with this interaction are displayed in [Fig. 1].

2.2.6 Effectiveness of Guide Pages

Questionnaire items #7, & #8 ("I found the guide pages, helpful ..." "for learning" vs "...for helping me to get an overview) served as a within subjects independent variable in the third, two-way, analysis of variance. Group (map vs list) again served as a between-subject independent variable.

No significant effects were found.

2.2.7 Affect

Lastly, a two-way repeated measures analysis of variance was conducted to examine students mood while studying. Questions #9 & #10 ("I found the ... studying to be a positive experience" versus "I was anxious and nervous as I studied the web pages." ) served as a within subjects independent variable, group was the between subjects independent variable, and ratings were the dependent variable.

A significant main effect was found for affect, $F(1, 18) = 20.354, p < .001$. The means and standard deviations for the "positive experience" versus "anxious and nervous" items were $M = 7.2$, $SD = 1.74$ and $M = 3.4$, $SD = 2.18$ respectively. No other effects were significant.

2.2.8 Students' Open Ended Responses

In general, with respect to the guides, those who were in the map group had more positive comments. Some representative comments are displayed below.

**Hyper Map Group**

- The guide pages helped to make the huge amount of information more manageable. It was helpful to have fewer choices and to narrow down the subject.
- I found them to be very effective in helping me to find information I wanted. The nodal guides were effective in localizing my searches.
- I liked the guide pages because you could see how everything was connected. It let you see everything that was associated with one major topic.

**List group**
I found the guide pages to be fairly helpful, although I mainly just stumbled upon the topics that I thought to be the most interesting.

Some of the guide pages were not helpful simply because I did not know what some of the things listed were.

Personally, I found the guide pages to be only somewhat helpful. I used the guide page to find a basic topic and only went back to it if I ran out of links, or at least interesting links.

3. Experiment 2

3.1 Method

3.1.1 Participants

Fifty-eight students from two sections of an undergraduate sensation and perception class at the same University participated in experiment 2 as a class requirement.

3.1.2 Procedure

During the semester students were required to carry out four web projects spaced out equidistant across the semester. Each project was worth approximately 3.5 percent of their total grade (14% all together). Each web project corresponded to one of the four sections of the class. For the first two web projects students were required to go to certain web pages, read and carry activities and answer specific questions about the pages.

The last two web projects were the focus of this experiment. In both projects students used the guided surfing interface. On the first guided surfing project they were asked to focus on the vision and audition sites, since these were more relevant to the information they were covering in class at the time, and, on the second project they were asked to focus on the smell/taste and somatosensation sites for the same reason. After studying the sites students were required to email an overview to the instructor, on which their grade was determined. They were also required to complete a Likert-style questionnaire, and were asked to supply open-ended comments about the guided surfing interface.

3.2 Results

3.2.1 Questionnaire Item Factor Analyses

The analysis began with two factor analyses, one performed on items for each questionnaire. These were principal components analyses with a varimax rotation. In both questionnaires, the same items neatly into a four factor solution. The factors were: a) Guide effectiveness; b) Category concentration (in the first questionnaire, high scores represent concentration on vision, as compared to audition, and in the second questionnaire, high scores represent concentration on smell/taste vs somatosensation); c) Breadth of search; and d) Experience with computers and the world wide web.

3.2.2 Factor Score and Test Correlations

Factors scores were created by averaging the items included in each factor (after reversing the scoring of items with a negative loading). A series of Pearson correlations was then computed between each questionnaire item for the first guided surfing assignment, and scores on test 3, which was the test that corresponded to the section of the course (section 3) that was most related to those web pages, and that was given after the first guided surfing assignment had been completed. None of these correlations were statistically significant.

The same set of correlations was then computed between questionnaire items on the second questionnaire and students' test 4 scores. The correlation between category concentration and test 4 was significant $r(46) = .378, p < .01$. (The greater the concentration on smell/taste, as opposed to somatosensation sites, the higher the test score.) No other correlations were statistically significant.

3.2.3 Comparison of the Two Web Projects

In order to compare students' responses to the third (vision and audition) versus the fourth (smell/taste & somatosensation) web projects, a multivariate analysis of variance was computed with Web Project (3 versus 4) serving as a within-subject independent variable. Each questionnaire factor, and class test scores served as the dependent variables. A significant overall multivariate effect was found, $A = (4,38) = .0078, p < .001$. 

541
This was followed by a series of within-subject t-tests with section serving as the independent variable and each questionnaire factor, and test serving as the independent variable. Statistically significant mean differences were found in the "guide effectiveness", \(t(41) = 3.12, p < .01\); "category concentration", \(t(41) = 2.69, p = .01\); "breadth", \(t(41) = 3.18, p < .01\); and class tests, \(t(57) = 5.04, p < .001\) analyses, and no significant difference was found with respect to www/computer experience. The means and standard deviations for the statistically significant t-tests are displayed in [Tab. 1].

</tbody>
</table>

*high scores represent vision sites concentration on project 3 and small/taste sites on project 4

Table 1: Questionnaire factor scores and class test scores as a function of Web Project

The last analysis was a within subject t-test comparing students' response to questions 11 and 12, which were only included on the second questionnaire. High scores on question 11 indicated that students found the fourth web project sites (smell/taste and somatosensation) more interesting than section three (vision and audition), and high scores on question 12 indicated that they found the organization of the fourth project's guide more effective than the third project. The mean difference was statistically significant, \(t(47), = 3.14, p < .01\). The means and standard deviations for interest and organization respectively were \(M = 6.23, SD = 2.19\) and \(M = 5.17, SD = 1.69\). Students found the section 4 sites more interesting, as opposed to finding the guide more organized.

3.2.4 Open Ended Responses

An examination of student's responses to the open ended question yielded three general themes:

1. The majority of students felt positive about the guides in both projects. They felt the guides enhanced the efficiency of the searching, and aided the students in getting an effective overview of the information. 2. Those students who did feel negative about the guides felt that they were confusing, and that it was too easy to get lost. 3. Students preferred the second guided searching project to the first, as evidenced by references they made to the first project on their second project comments. This was also evidenced by the fact that virtually all negative comments were associated with the first section, and virtually none were made with regard to the second. Representative comments follow:

Experiment 2 Representative Responses to Open Ended Questions

**Positive Responses to Guide:**

- I have had some experience in trying to find information on certain topics, and this way of presenting the information is a great deal better than could be done by listing links vertically. By presenting the information in a hierarchy, and showing how the links are interrelated seemed to facilitate incorporating the information from the different sources.
- I don't think I could have easily or as effectively found as much information without the guide.

**Negative Responses to Guide (all from fourth web project):**

- I found them to be confusing and hard to keep track of the links. A simple outline or table of contents at the beginning would serve the exact same purpose and probably be more effective.

**Comparison of the two projects:**

- I thought this one was more interesting than the visual one, that is probably because of my own personal interests...
- I was so interested in the smell and taste that I didn't even think about looking into the somatosensation pages.

4. Conclusions

The first conclusion that emerged from these two experiments was that the guides appear to broaden the students' search focus, and, this in turn leads to the student forming a better conception of the big picture. This conclusion is based on student's subjective responses to questions about focus in the first experiment, in which the map guide was compared to a traditional list, and in questionnaire responses and open ended responses in experiment two. As one student put it, "I found your guided
surfing outline to be effective in organizing the information ... for conceptualizing it I think your approach is better."

A second conclusion that can be drawn is that the guided surfing interface doesn't appear to aid students in recalling factual information. In experiment one, the interface was no more effective than a traditional, linear method of listing web pages, in effecting propositional recall. In the second experiment there was no relationship between the degree to which students found the interface effective, and their scores on related class tests. This may be partly explained by the first conclusion, in that the guided surfing interface may be most useful for imparting the general conceptual information, as opposed to factual details.

A third conclusion which was consistent across both experiments, and across both projects included in the second experiment, was that students perceived the guided interface to be effective. This was most obvious in their open-ended comments about the guides. They found the guides to make searching efficient, and, as mentioned, they perceived them as being particularly effective in providing broad domain knowledge. This finding adds further support to the contention that the maps may best serve instructional purposes when the aim of the instructor is to provide the students with broad knowledge about a domain. With respect to the World Wide Web, this would be particularly important to an instructor whose goal is to give the learner an overview of the web sites available within a given area, in order to facilitate a more efficient search.

Abstract: One important objective of cooperative structures, workgroup computing and intranet/internet technology is to intensify the interaction between the source and drain of information. Workgroup computing, e-mail and all forms of collaborative learning are technologies to intensify the coordination and communication of an organization. The following paper will show our special experiences, the social and organizational effects on introducing the new hypermedia and workgroup technology into the field technical mechanics at the University of Paderborn, Germany.

History of GroupWare and hypermedia in the laboratory for technical mechanics

The age of computer supported collaborative group activities started in our labs about three years ago when the use of electronic mail and of a network connecting all personal computers was considered. Early activities such as the simulation software “KARL” which was written in FORTRAN express the need for the development of software to archive, document and to discuss our experiences of physical and mathematical experiments.

Many smaller simulation tools, database applications and mathematical engineering methods (e.g., finite elements) were developed as FORTRAN routines in order to solve daily problems in the field of traditional mechanics. The next step was to use these smaller simulation and animation software systems for the teaching of mechanics to our students. The huge number of students did not allow to perform the necessary amount of real experiments as it would be necessary to give students a thorough understanding of complex mechanical effects (e.g., the technique of caustics or holographic methods which are used to determine stress intensity factors in experimental fracture mechanics).

Therefore, one objective of an animation software, which was originally developed in FORTRAN, was to enable students to understand and master the complexity of modern mechanics by considering the interaction between the various different physical parameters involved. At that time nobody used the terminology multimedia, but these animation software systems fulfilled nearly all definitions of today’s multimedia animations ([Rad70]).

The next step was to integrate animation systems of this kind into hypertext as part of a learning system, or an interactive mechanics lecture. However, it took some effort to reach this goal since many attempts failed when various hypertext formats were used, ranging from Windows Help format to HTML 1.0, and which did not fulfil the need to handle the extensive amount of mathematical formulae and complex graphics used in engineering.
Nobody was able to convert expressions developed in TeX, or with the Microsoft Word Formula Editor, into Bitmap Format to include them into hypertext systems with acceptable effort. Therefore, no concrete system for everyday use in the teaching of mechanics could be established. The people who teach mechanics at our institute did not perceive the new media as being too complex to use and to develop, and accepted them fairly easily. Parallel to this effort, the local intranet of our university was more and more used to exchange scientific data between the various scientist at the different laboratories, but the aforementioned co-operation resulted from shared file systems without any underlying structure, and the security levels and structures of access rights were provided by the UNIX operating system.

Approximately one year later first experiences with the Hyper-G hypermedia environment developed by Maurer [AKM95] were made. This was the first system that allowed us to use postscript as hypermedia text format. By setting up this system it became possible for the first time to use standard tools for the development of hypermedia text versions of papers and tutorials. Scientists at the laboratory for technical mechanics could use their favorite office systems, such as Microsoft Word and TeX, to create electronic versions of their documents.

Now, students, tutors and lecturers were able to exchange documents with the help of the Hyper-G system by using special clients called Amadeus and Harmony. We integrated our animation systems into the Hyper-G system, used a Hyper-G supported “generic” data type, included small video clips and presentations, and soon the first cooperative version of the mechANIma system was born ([FeHa95], [FeHeHa95], [FeHe95].

Experiences how to visualize technical mechanics

One important observation we made was the fact that the development and daily use of hypermedia materials has to be easy and intuitive enough, so that tutors and lecturers are able to concentrate on their real work; the development of new media should not become the main focus of their attention. The same effect we found in the development of visualizations. The use of highly interactive and visual programming languages, such as the Microsoft Visual Basic system or the Borland Delphi Programming Environment opened up opportunities for non-professional programmers, such as students of technical mechanics, to visualize their concrete science-work,
e.g., experiments in the field of holographic or caustic stress-determination (Figure 1). Our goal to work mostly with easy-to-use tools in order to develop hypermedia resulted from the fact that we tried to influence and to include as many members of our lab as possible in the development process by acknowledging their individually different understanding in the use of multimedia and workgroup techniques. Many different internal Hyper-G courses and multimedia-workshops which were held on a regular basis helped to establish the new technologies in many parts of the mechanics courses. One interesting observation was that many tutors and lecturers did accept new media, and even expressed the willingness to use them, but were not able to bring them into a state of daily use due to the pressure of time and resources.

Experience shows that in non-computer science environments, such as our laboratory, a potential user will only accept easy and intuitive to use applications with a graphical user interface. Scientist and students only produce hypermedia documents if they are able to use their normal office or graphic applications in order to compose them. Consequently, we looked for other possibilities to generate electronic versions of the various mathematical mechanics papers. Eventually we found that the Adobe Portable Data Format (PDF) was the best to use for our needs. The PDF format was easy to generate being implemented as an low level printer driver for the Windows system. Now lecturers could use their favorite word processor to generate a PDF version of the document which was easily published on the Hyperwave server. Students who have access to this intranet server can download and even print entire documents. The main part of our students still prints the hypertext papers and tutorials found on our hypermedia server in hardcopy version, as no continuous access to the new media can be guaranteed ([BrKeil+97]). As it was mentioned by Keil-Slawik students should have a continuous access to hypermedia data during lectures, at home and in tutorials to accept electronic versions of documents as an alternative to classical paper. Hyperwave enables students to have continuous access to the latest release of electronic documents. Errors and typos which are found in lecture or tutorial manuscripts can easily be corrected and published on the information server. Printed versions require much longer turn-around times. It is even possible to let students put their homework on the server and discuss it in later tutorials. This concept called “learning-supporting infrastructure,” introduced in [BrSchSe97] and [BreKei97] of collaborative learning with the help of integrated teaching and learning environments, satisfies many requirements to achieve more flexible forms of combining individual and social learning processes.

For the same reason we produced a CD-ROM for our students which consists of a complete collection of helpful and illustrated course material, such as all necessary mechanics papers, complete dissertations, many exercises and a lot of small Visual Basic and Delphi animation and simulation software. The interesting fact is that for many students and members of our institution an updated version of this CD-ROM often forms the starting point to participate in our collaborative work and intranet activities. It seems that people who are no daily users of cooperative environments first have to explore a clearly defined and limited part of the hyperspace, such as the one provided by the CD-ROM, in order to find out about their individual needs. The next step is an active participation in collaborative learning environment, such as our Hyperwave based mechANIma server.

Current hypermedia activities in the field of technical mechanics

Our present activities in the use of new media for education lead in two directions. First, we currently evaluate and test tools and methods for an easy-to-use development of hypermedia documents and animation applications. Second, we try to integrate all media into a collaborative hypermedia environment, such as the Hyperwave system. The Hyperwave information server meets our immediate needs since it offers several features which do not belong to the usual web and intranet servers. As an object oriented data base Hyperwave stores various hypermedia documents, links and document attributes to provide automatic link consistency. It dynamically indexes text and custom-made document attributes and, consequently, provides easy access to information. But the most important point is the capability of a user and group management system which results in the possibility to limit control access to the server, the documents, links and structural elements based on user authorization and sophisticated access rights. These multi-user features of the Hyperwave system allow students to work together simultaneously and to collaborate in the further development of hypermedia documents. On the mechANIma server.
A hypermedia system every member of our institution gets his own personal collection. An normal front end such as a common Web browser is easy to use, even by non-computer experts. Hyperwave offers the advantage to let people develop their personal hypermedia and offers an interactive way to load documents up to the server.

Our basic concept to use highly interactive visual programming environments in order to create small visualizations and simulation programs is the only solution to the idea to let students develop multimedia applications individually and independently.

We claim that it is impossible within the restrictions of human and financial resources to develop high quality hypermedia applications without cooperation at work. Our main goal is the development of design principles for coordination, distribution and, thus, sharing of work. As mentioned before we used Visual Basic as the first easy-to-use programming environment. Experiences show that students who have no programming skills at the beginning of their work are satisfied by the swift progress they make with Visual Basic and by their productivity. Mechanics students who get a short, two day introductory course to the programming techniques need about three weeks to produce their first small visualization systems. Consequently, the hypermedia development is achieved directly by the user. Naturally we are not able to produce such high quality products as commercial developing systems where the help of professional computer scientists becomes imperative. However, in the field of non-commercial use we do not need such professional systems. How do we define a "professional" system? The crucial point is that a system which supports cooperative learning has to be current and up-to-date. Our research activities in the field of technical mechanics change very rapidly. Therefore, students have to adapt to new requirements more or less immediately. Hence, the user has to be an ongoing participant in the design of lectures, tutorials and hypermedia materials. We are not alone in our decision to apply collaborative structures for the development of hypermedia materials.

Recent work on the field of statics (course A on technical mechanics) by two of our students indicate that they were able to produce interesting illustrated course material in due time. Other students and lecturers were surprised how easy and illustrative this first mechanics course could be presented. We are very encouraged by these early experiences. Students who design hypermedia have proven to be very efficient to grasp the necessary tools and expressed their individual views on the underlying mechanical background. One of our students (fifth semester) even developed small Java applets for the illustration of beam deflection curves. She integrated digital video, hypertext and data-base functionality to form a hyperspace drawing and to present a more or less complete overview on this subject. One goal of this particular project was the integration of different tools, e.g., common office word processors like Microsoft Word to generate HTML hypertexts. Students were able to use their favorite systems and formula editors to write the basic text material. They used a digital camera to produce small video sequences of the lecturer explaining key aspects of the topic. Common WYSIWYG Hypertext-HTML editors were used to implement the hyperlink structure. In the next step these materials were integrated into our Hyperwave information system with open access to all students. Hyperwave like version management and annotations are the necessary prerequisites for a lively discussion of the hypermedia materials.

As discussed previously we have produced a CD-ROM which includes all hypermedia documents. Despite the fact that many course materials already include small animations, programmed with the help of Visual Basic, we developed our own Nentescape plugin which allows to execute Visual Basic applications. In other words, any hyperlink of the hypertext documents can point to an animation. However, a potential disadvantage of this procedure, namely its limitation to Microsoft Windows platforms which use Windows Programming environments, such as Delphi or Visual Basic, is not crucial for our application. More than 90% of our students own Microsoft based Windows PCs.

A second benefit is the popularity of such systems. Students get an extreme amount of information, code fragments and example programs through the internet and literature.
Java applets as animation systems for the teaching of mechanics

Recent work on Java development environments focuses on the design of applets to illustrate complex mathematical relations. Our main criterion when choosing one of the available design environments is their degree of usability.

Tools, such as VisualAge from IBM, which offer a programming-from-parts option point into the right direction (Figure 2). However, there is room for improvement. As an example: One of our mechanics students who was not extremely familiar with programming needed about one month and extensive help of a computer scientist to produce a prototype of a small simulation system for the computation of the forces acting within an arbitrarily arranged system of beams (Figure 2). One of our tasks ahead will be the development of extensive class libraries for the visualization of mechanical concepts and problems that arise in technical mechanics.

Our experience shows that the gain involved with such visual Java development environments results mostly in a swift construction of the user interface of an application. The design of application semantics is not supported in the same degree. On the other hand, students still have problems to understand the various elaborate Java concepts, e.g., the rather complex Java Foundation Classes.

Learning in a learner-friendly environment

The problem of conventional learning, as with the help of black boards, flip charts and overhead slides, is the non-integrated use of these media. A student who attends a lecture together with many other students, e.g., twice a week, is unable to transfer the presented materials to tutorials or even to access literature referenced in the courses at home. Consequently, no continuous access to necessary educational material is guaranteed. A student who does his / her homework must get the same materials as in group working in the university or at the lectures. In the classic form of learning, this continuity was realized in a primitive form by the use of pen and paper. Students prepare lessons by reading and browsing through books and papers and make annotations on copies or write their own summaries. In tutorials and lectures they have to write down what is written on the board and they have to compare their notes with reference books and papers. In the time of collaborative learning it becomes more and more difficult for the students to lively participate in discussion groups and, simultaneously, to write down necessary facts for the following exams. Additional successful and effective forms of learning need student-centered structures of teaching. Student-centered forms of learning are defined as presenting different
views on the subject to allow students to develop a personal and more sophisticated way of understanding. This may be achieved by the use of electronic media, called multimedia and hypermedia, with the help of new educational didactic concepts and infrastructure requirements.

Therefore, modern electronic learning environments offer possibilities to enhance a student-centered approach for learning. In this concept the student himself is responsible for his/her personal learning progress. Socially embedded learning processes are the necessary precondition for effectiveness of teaching. To achieve better success in the understanding of the presented material, and in order to let students develop their own insights into the topics, it is necessary to offer a wide range of high quality information. The student has to extract the very essence of the many facts provided and, in addition, learn to see the bigger picture, i.e., the connections between the various facts. In conventional forms of learning the students get the information (portions of the presented subjects) step by step and is required to produce his / her knowledge and to show his / her understanding during the examination. The students do not feel responsible for the selection of necessary information. Modern forms of learning require the willingness to accept responsibility for the selection and filtering of fundamental knowledge. The process of extracting the real essence may be defined as the real achievement of learning. The goal of the mechANIma project is to reduce the reliability and portability in the use of electronic media, and to create an interactive learning environment that can actively be used by the students.

Such an integrated approach cannot be accomplished by a single research group that creates a high-tech learning island within the of the university. The term “Alltagspraxis” (every day practice) [BrKeil95] has been used to illustrate the objective to set up an infrastructure for suggestive learning and teaching that can be used under the typical constraints of normal day-to-day teaching at a university.

Conclusions

We have described and illustrated the underlying philosophy and integration of animation tools and hypermedia course material into the mechANIma hypermedia system. Our key concepts are to increase the reliability and portability in the use of electronic media, the setting up of an infrastructure for suggestive learning and teaching, the achievement of collaborative structures through and with the development of hypermedia materials, and the use of visual programming environments for the programming of animation and simulation systems. We expressed our positive experiences with our students who use Visual Basic as one of the very popular visual to programming environments.

We try to develop new methods and didactic concepts of teaching mechanics in many different courses to students at the university of Paderborn ([BreKeil97], [Keil97], [Keil90]), [HaFeMu98]. Especially the evaluation of new teaching environments and didactic arrangements for the daily use of new media in lectures, tutorials and student assignments is an important part of our research work. One goal of the mechANIma project is the achievement of a continuous flow of information between the students and the lecturers.

DEVELOPING an IMS COMPLIANT DATABASE for WebCT

Nimat Haque
Department of Electrical and Computer Engineering, University of Central Florida, USA
e-mail: nha@bruce.engr.ucf.edu

Abstract: This paper discusses about adding meta-data tags to courses created using WebCT, an online course authoring material. The reason to add meta-data is to facilitate the searching of learning materials over the World Wide Web. A database is going to be created to save the information about the courses and serve as a repository for the learning sources. The database will be replicated to several sites. The replication feature will be added so in case of site failure there will a backup site and also it will reduce network traffic.

Introduction

The growth of Internet and World Wide Web (WWW) has a huge impact on learning at all levels of education. But there is no standard approach of managing online course materials, locating and using educational content. To mitigate these obstacles the Instructional Management Systems (IMS) Project was created to facilitate the growth and viability of distributed learning in the Internet. IMS is working towards providing a common framework for generating and leveraging information integral to the process of learning[IMS]. To provide a purposeful and effective searching of online resources, IMS is developing specifications for Meta-data. Meta-data, which is “data about data”, will add labels to the educational materials. Examples of meta-data for learning materials are the title, the author, educational objectives, targeted learning level, publication date etc. People who are searching for learning resources will use the common meta-data fields to describe the type of resource they desire, use additional fields to evaluate whether the resource matches their needs, and follow up on the contact or location information to access the resource. Similarly, people who wish to provide learning resources will label their materials and/or services with meta-data in order to make these resources more readily available to interested users.

WebCT

World Wide Web Course Tool (WebCT) is a web based educational tool that facilitates the creation of internet based education materials[WebCT]. WebCT uses a World Wide Web (WWW)-based graphical user interface (GUI) as a course building environment and provides course enhancing tools like quiz creation, on-line chat, forums etc. The course author connects to a WebCT site using any browser such as Netscape. Usually the server is maintained centrally at the educational institutions. WebCT uses a flat ASCII file format to store data about courses. Each course has a directory on the server into which is put all of the HTML, text, image or audio files created by, or downloaded by the course author. For example, if the course-author defines a set of multiple-choice questions that are to be associated with quiz, files are created by WebCT containing these questions. The file is named by WebCT to indicate its relationship with that quiz. WebCT does not add meta-data to the courses according to the IMS specifications. Also it is not possible for an instructor to locate resources of similar kind. For example, an instructor is offering a course on calculus. If the instructor wanted to create a quiz for the students, he could make a query on the questions so far created on calculus by other instructors. These questions would give him an idea and he can use these resources. Also he could add his own resources so that others could use later.

Scope of Work

University of Central Florida has an agreement with the creators of WebCT that we will work together to add more features to WebCT. One of the proposal is that to add a IMS meta-data fields to the courses offered through WebCT. Also we want to save course information, such as title, creator, subject, questions etc. in a database so that any instructor will be able to query the database for resources.
Implementation

I have used Oracle Enterprise Edition 8.0.4 for Windows NT 4.0 to design the database. I found that WebCT allows an instructor to create five types of questions to add in a quiz. They are: Multiple Choice Questions (MC), Matching Answer Questions (M), Calculated Questions (C), Short Answer Questions (S), and Paragraph Questions. The prototype only considers first four types of questions. Each course can contain several quizzes consisting of combination of the type of questions described before. I created the following tables:

<table>
<thead>
<tr>
<th>Table Name</th>
<th>Important attributes</th>
<th>Constraints</th>
</tr>
</thead>
<tbody>
<tr>
<td>Questions (information related to a question)</td>
<td>ID, Title, Text, Type</td>
<td>Primary Key: ID</td>
</tr>
<tr>
<td>Meta-data (IMS meta-data added to a course)</td>
<td>Subject, Description, Title, Creator, course_id</td>
<td>Primary Key: course_id</td>
</tr>
<tr>
<td>MC, MATCH, CAL, SHORT (required to save answer information for each type of question)</td>
<td>Ans_text, Question_ID</td>
<td>All these tables reference to the Questions table using Question_ID</td>
</tr>
<tr>
<td>Course_link_question (information about course and related questions)</td>
<td>Course_id, question_id</td>
<td>Course_id references to Meta-data table, Question_id references to Questions table</td>
</tr>
</tbody>
</table>

An instructor will be able to search the database based on course number, creator, publication date, question type etc. This database will be local to the user. Duplicate copy of the database will be kept on remote servers. These databases will be linked through TCP/IP. Whenever new information is added to one database, all the tables in remote databases will be replicated at certain interval (for example every night). As a result the instructors will always be able to get updated information and will not be required to connect to remote servers. The whole system is shown in figure 1.

Abstract: The Internet: Communicating, Accessing & Providing Information is a University of Alberta credit course which is delivered completely over the Internet. This paper: 1) discusses the primary development and delivery phases of this course, while also providing a general account of the time spent on each of the phases, 2) compares the costs of this course with those of similar face-to-face courses, and 3) offers an interpretation of these results and the possible implications for similar courses.

History of the Course

The Internet: Communicating, Accessing & Providing Information (http://www.quasar.ualberta.ca/nethowto) (henceforth referred to as "the course") has been offered since 1995. The purpose of this course is to help students understand what the Internet is (and isn't), and learn to use Internet tools. This course prepares students to operate effectively in our knowledge-based society, to learn to use electronic communications, to access electronic resources, to prepare electronic resources for the Internet, and to understand and examine critical issues related to electronic communications (Privacy, Security, Copyright, Censorship, and others). The course was delivered for the first time in a face-to-face (F2F) mode September-December 1995. A number of Web pages were developed to support this delivery. The course was offered a second time January - April 1996, again in a F2F mode. During this session, students were asked to provide information on what would make the course more amenable for use by distanced students; this input resulted in a constant revision of the Web pages.

During the second offering of the course, a few students who, for a number of reasons, could not attend the lectures were encouraged to take the course and to rely on the Web pages for their information. They were asked to communicate with the instructors by telephone or electronic mail if they had questions. During May-August, 1996 the course was pilot tested completely over the Internet to over 100 students. Over 500 students have completed the course since it has been offered through Web-based Instruction. A complete discussion of the structure of the course can be found in [Montgomerie & Harapnuik 1997].

Development

The course was developed over a period of slightly more than one year. Four different phases of development occurred, with three different people involved in this development: a graduate student and the first two authors. [Tab. 1] presents the time spent (costs') in developing this course. Times for the F2F delivery are not included in [Tab. 1] but times for delivering the pilot test of the course during the May - August 1996 period are included. The first time this course was offered via web-based instruction (WBI) (and probably the first time any WBI course is offered) can more properly be considered as development time rather than operation and delivery time because real students encounter problems and request clarification that the course authors did not anticipate.

1 Throughout this paper we present the time spent on a task and call these "costs." Conversion of these times to dollars (or yen) using arbitrary values would obfuscate, rather than clarify the issues.
Following the initial delivery, the course has undergone major updates prior to each session. Because this course is about the Internet the subject matter is constantly changing; thus the course materials need to be updated on an ongoing basis, even during course delivery. Similarly, we needed to use the latest features on the Internet to model appropriate use of the best technology and instructional methods (i.e. "walk the talk"). Taken together, these two situations mean that this course has required a higher level of upgrading than most other WBI courses. The dynamic nature of the Internet demands that content, links, and entire technologies must be continually upgraded. Ironically, perpetual change has been one of the unchanged aspects of this course and we do not expect to see a decline in the rate of change for some time to come.

Course Operation and Delivery

The course has now been offered via asynchronous delivery mode for seven complete sessions. [Tab. 2] shows the time spent on operation and delivery of the course once it had reached "steady state," that is once major development and pilot testing was complete. As indicated previously, the times for the pilot test (May - August 1996) are included in [Tab. 1] rather than [Tab. 2].

The instructor and the teaching assistant (TA) recorded the time spent on six specific course operation and delivery responsibilities in a daily journal. The course operation and delivery responsibilities included updates (revising links, adding news & announcements, etc.), development (adding material or incorporating changes in technology), interacting with students in the Issues & Help conferences, providing email and phone support, and marking. [Tab. 2] summarizes these results for six steady-state offerings from September 1996 to April 1998.

An average of 415 hours was spent delivering and supporting this course each session. During the Fall and Winter Sessions the course is delivered over a 13-week semester while during the Spring and Summer Sessions the delivery time is approximately 6 weeks.
The time devoted to the Issues & Help conferences decreased after Winter 1997 as a result of the implementation of a more efficient conferencing system and a course management system [Montgomerie, Harapnuik & Palmer 1997]. These two improvements have streamlined the management aspects of the course. A great deal of development time was spent creating and implementing these systems, but because they were not directly related to the instruction of the course, they do not appear in these tables.

Marking times increased significantly in the Fall and Winter sessions. This may be attributed to the fact that Fall session students were granted extensions until April 1 to complete their work. Similarly, Spring session students were granted extensions to September 1, and Summer Session students were given extensions to December 31. The cumulative effect of these extensions is that more students were handing in assignments than the enrollment for the Fall and Winter sessions would indicate.

**Development & Upgrading**

The ever-changing nature of the Internet requires that constant updates and upgrades must be made to URLs, course content, and assignments. Change has been the one constant throughout the development and delivery of this course. The updates/upgrades and development tasks are closely related. Most course development and upgrades are a result of technology advancement. One of the most tedious tasks is keeping hundreds of URLs current. The time consuming aspect to keeping the links updated is not in finding the broken links, software is available to do this, but a substantial amount of time can be spent finding the new URL for the moved site, or finding (or developing) a replacement for a site that has completely vanished or has become outdated.

Since there is no F2F instruction in this course, students are kept apprised of new information and announcements via an "Announcement" page. Another update is the addition of projects prepared by students enrolled in previous course sections to the course resources database. Other upgrades or course modifications are the result of student suggestions received through email, phone, or the conferencing system. Our policy is that when a student submits an email message directly to the instructor asking for clarification on a particular section of the course, that section is immediately examined and, if necessary, changes or clarifications are made immediately. When a student posts a question to the Help conference, we wait for 24 hours to respond or to make changes or clarifications to the course. Twenty percent of a student's mark is allocated to his/her participation in the Help and Issues conferences; hence it would be inappropriate for the instructor or teaching assistant to respond immediately. Implementing rapid change can be time consuming, but it dramatically improves the content and structure of the course. In addition, students gain a sense of significance or community by seeing that their feedback has immediate results.

In addition to upgrades, time is spent integrating new technology into the course. New technologies like CU-SeeMe™, CoolTalk™, NetMeeting™, HTML editing tools, new browsers, and anything else that is new on the Internet must be tested to see if it can and should be included in the course. For example the Fall 1996 and Winter 1997 sessions saw the integration of CU-SeeMe™.

More time was spent in upgrading and development during Winter and Summer sessions [Tab. 2]. The increase in time spent on development and upgrading in the Winter session is in preparation for the upcoming Spring and Summer session. Similarly the increased time spent on upgrading and development in the Summer session is in preparation for the upcoming Fall and Winter sessions.

**Support and Interaction**

Direct student support includes instructor and teaching assistant time spent working on the Issues & Help conferences and phone and email support. These three components of a web-based course are crucial to the course's successful delivery and to the students' learning experience. In addition, each plays a major role in offering students who do not have the opportunity to meet F2F an opportunity to interact with the instructor. A variety of support opportunities must be presented because different students have different learning styles that

---

often require a different level of interaction. Some students insist on using the telephone to make a more 
personal contact. Other students are satisfied with the conferencing system and others seek a middle ground by 
using email.

The instructors and teaching assistants spent more than half the course delivery time in some form of 
interaction. [Tab. 2] shows a significant decrease in time spent responding to questions on the Issues & Help 
conferences after the Winter 1997 session. This difference was the result of the implementation of a much 
superior conferencing system for Spring 1997. With the conferencing component playing such a substantial role 
in replacing F2F interaction it is imperative that the most effective, efficient and economical conferencing 
system be employed.

It can be argued that the current levels of interaction are higher than in a traditional F2F setting. Participation in 
the Help and Issues conferences is required of all students and makes up 20% of the final course mark. Because 
of this, total class interaction is very high, and virtually all students participate. Some students keep their 
interactions to a minimum and others go well beyond the required interaction levels on the conferences. Many 
students acknowledge that the conference system offers a level playing field and makes interaction much more 
comfortable. A major portion of the time spent on the course for both students and the instructors is spent in 
some form or interactive communication.

Different sessions have had different levels of interaction. For example, Spring session of 1997 saw an average 
of 47.9 interactions per student [Tab. 3]. More than 50% of those interactions were in the form of email 
communication directly with the course instructor or TA. On average there have been over 38 interactions per 
student. It must be stressed that more than 50% of these interactions were between the student and instructor. 
This is a high level of interaction for any type of course.

Marking

Evaluating student work is always an important part of any course. Depending on the content and assignments, 
marking can either be very time consuming or it can involve very little time and even be automated. The 
andragogical foundation to this course is that people learn by doing. All assignments deal with actual skills 
needed to function on the Internet. The course has no exams and except for two small assignments the student 
evaluation is project based. Students are required to build an HTML portfolio, worth 25% of their final grade, 
which demonstrates their Internet skills. They are also required to do a final project, the development of a Web 
site on the topic of their choice, which is worth 50% of their final mark. Grading these projects can be very time 
consuming, however. To assure objective marking, a template has been developed, which gives students 
detailed feedback on the two major projects in the course. A major portion of the marking time deals with the 
writing of these detailed evaluations.

The proportionally higher marking times in the Winter and Fall sessions [Tab. 2] can be attributed to the higher 
number of students working on extensions in these two sessions than the number of students working on 
extensions in the Spring and Summer sessions.

A Cost Comparison with F2F Courses

[Tab. 4] shows the number of hours the Instructors and TAs spent in each area of the course for the six “steady state” sessions and [Tab. 5] summarizes that data. An examination of [Tab. 4] shows that the time spent monitoring the electronic conferences was inordinately high for the first two sessions. Replacement of the conferencing system following the Winter 1997 session reduced this time by approximately half. Corrected times, which reduce this time by half for the first two sessions are included in [Tab. 5].

[Fig. 1] displays a graph of the number of hours that the Instructors and the Teaching Assistants worked on the course by the number of students enrolled in each session. The corrected times (reducing the time spent monitoring the conferences for the first two sessions by half) are also plotted. A linear regression has been plotted for each series. The intercept and slope for each regression line are given in [Tab. 5]. As can be seen, the intercept for the corrected values for the instructor is 192.7 (that is, if there were no students enrolled in the course, the instructor would spend approximately 193 hours on the course). The slope of the line for the corrected values for the instructor is 0.221 (that is, each student adds a load of approximately 0.22 hours to the instructor). The intercept for the corrected values for the TA teaching assistant is 120.9 (that is, if there were no students enrolled in the course, the teaching assistant would spend approximately 121 hours on the course). The slope of the line for the corrected values for the teaching assistant is 0.106 (that is, each student adds a load of approximately 0.10 hours to the teaching assistant).
At the University of Alberta, where we teach, each course is allocated approximately 35 hours of lecture time. If we assume that for each hour in the classroom a professor spends another hour in preparation or marking (likely a low estimate); an average course would require approximately 70 hours of instructor time. Normally graduate courses are limited to 20 students (this was originally designed as a graduate course but due to a strong demand, senior undergraduate and unclassified students have been allowed to enroll in the course). Furthermore this is a laboratory course which would require teaching assistant to monitor a 3-hour lab of about 25 students (the size of our computer labs) each week for 12 weeks (a total of 36 hours).

[Fig. 2] overlays estimated time allotments for F2F Instructors and F2F teaching assistants on the WBI (corrected) regression lines from [Fig. 1]. Note that resources expended on students enrolled in WBI courses can be considered to be incremental, while expenditures on students enrolled in F2F courses should be considered to be a step function due to limitations such as the number of seats available in classrooms and laboratories. We have used a step function of 20 students for the instructor and 25 for the teaching assistant. An examination of [Fig. 2] shows that the WBI instructor spends more time per student up to 40 students at which point the amount of time spent by the F2F instructor becomes greater. Similarly, the WBI TA spends more time per student up to 75 students where the amount of time spent by the F2F TA becomes greater.

Some may dispute the choice of a class size of 20 students. In our course there is a high degree of interaction between the instructor and the students; this would be more similar to a seminar than to a lecture. If someone wished to deliver a WBI course with substantially fewer interactions, it might be comparable to F2F instruction in a 100-seat lecture theatre. If that were the case, then the time spent by the WBI instructor monitoring electronic conferences should be reduced close to zero. In the case of our course, the average number of students enrolled in each session has been 63.3 which means a time savings was incurred by offering the course by WBI rather than in a F2F mode.
Figure 2: Comparison of Times Delivering WBI with F2F Instruction

When considering these costs, one must remember that the nature of both the content and delivery of this course is likely changing more rapidly than in most other courses. However, the costs for courses taught by WBI which deal with less rapidly changing subject matter are still likely to be higher than for an equivalent F2F course when there are low enrollments. When considering costs, however, one must also consider the level of success that has been achieved. Over 50% of the time spent on the delivery of this course has been spent on some aspect of interaction (email, conferencing, and phone). This high level of interaction is a major contributor to the 90% completion rate that we have experienced since the course has been delivered.

The times discussed so far in this section are for the ongoing delivery of instruction. None of the development time identified in [Tab. 1] has been included. The time spent preparing a new course is substantial for both WBI and F2F instruction, but before the course begins, WBI instructors need to prepare all materials in a form that the student can access on-line. In the case of our course, this preparation was 1440 hours, which is likely substantially more than is required for the development of a new F2F course. This development time should be prorated over some of the “steady state” delivery sessions. Further, Instructors and administrators must recognize the time involved in developing a WBI course and budget time for this development.

Conclusions & Recommendations

When implemented properly, WBI can offer a quality instruction with a much higher degree of interactivity for relatively large classes than may be possible in traditional F2F settings. It is clear from this study that, at least in this specific case, this course took less person hours to deliver than it would have if it were offered in a F2F mode. Of course, if the course had not been offered via WBI, we would have had a much smaller enrollment because the students in Singapore, Freiburg, Pender Island and Teepee Creek would not have been able to take the course.

Students took advantage of e-mail and conferencing systems to communicate directly with the instructors. Some would suggest that we could ask TAs to assume a considerable portion of this workload, but we would argue that it is important that students have this access to the instructor. Further, the offering of this course through WBI rather than F2F meant that University facilities like classrooms, washrooms and those very expensive computer laboratories were not used by these students.

560
On the other hand, WBI has substantial costs. The development of a new WBI course requires the allocation of substantial time. The high degree of instructor/student interaction in this course puts substantial strain on the instructor; there are no office hours, but the instructor must read and respond to e-mail, phone and conference messages at least once a day. Further, courses with a low enrollment will cost more to deliver via WBI than would an equivalent F2F course.

University administrations need to look seriously at the economics of implementing WBI. If instructors are given the time that is actually required to work using this form of delivering education, then it can be a very educationally effective and cost-effective method of instruction. However, if instructors are expected to develop, maintain, and support this type instruction with the same time expectations of F2F delivery, the quality of education will be in jeopardy and instructors will run the risk of burnout.

Inquisitivism or "The HHHMMM??? What Does This Button Do?"
Approach to Learning

Dwayne Harapnuik, MLS

E-Mail: dwayne@oanet.com

Abstract: Inquisitivism or "The HHHMMM??? What Does This Button Do?" approach to learning is a synthesis of cognitive theories that provide a novel approach to technology related adult learning. It gives learners the freedom and opportunity to control, construct and take responsibility for their learning experience rather than force learners into following a strict and often confusing set of procedures or instructions. Learners using this approach quickly gain confidence and overcome the debilitating fear that often accompanies technology-related learning.

What I mean to discuss in this paper is the need for a new approach to adult learning. That is to say, I wish to discuss the development of a learning approach based on the unique needs of adult learners who are required to learn and use new information technologies. More specifically, I will establish how a learning approach I have labeled Inquisitivism has evolved from a synthesis of key cognitive learning theories into one cohesive approach and how its implementation in the development of learning environments, curriculum and courses, can meet the needs of today's adult learner.

To successfully fulfill the task that I have laid out I will: 1) Explain why there is a need for a new approach to adult learning. 2) Identify contemporary cognitive learning theories that this new approach will be based upon. 3) Finally, establish the learning approach of Inquisitivism. A practical application of the Inquisitivism in Web-Based Instruction (WBI) will be the basis of discussion of a subsequent paper.

The Need

A central theme of many papers presented at recent educational conferences and published in educational journals is that many of our instructional systems are failing or are in need of repair. In addition, many articles call for a complete change in the way we design and deliver educational material. Objectivism vs. Constructivism: Do we need a new paradigm? (Jonassen, 1991), Web-based distance learning and teaching: Revolutionary invention or reaction to necessity (Rominiszowki, 1997), and The Learning Revolution (Dryden & Vos, 1994) are only three of the many articles or books that call for a significant change in learning models. Some argue that there is a common basis for many of the current problems in education discussed in these and similar books. There are claims that the deficiencies in the outcomes of learning are strongly influenced by underlying biases and assumptions in the design of instruction (Rand J. et al., 1991). The systems approach to instructional design which has no substantive theory content, no user domain content and is arguably the primary factor contributing to the poor outcomes of instruction, is still the predominant instructional design assumption used throughout most of education (Carroll, 1990; Dryden & Vos, 1994; Jonassen, 1997; veder Meij & Carroll 1995).

Another theme revealed in recent work calling for change deals with the limitations of instructionism. This dominant method used in most instructional settings is based on the notion that students are passive receptacles for information that the instructor (teacher or instructional media) relays (Jonassen, 1996). Carroll (1990) titled his polemic against the systematic approach to learning and instructionism, the Nurnberg Funnel. The legendary Funnel of Nurnberg was said to make people wise very quickly by simply pouring knowledge into them. In the Nurnberg Funnel, Carroll presents the results of ten years of empirical research that shows that newer methods of instruction based on Constructivism and other cognitive theories perform much better than the commonly used systems approach to instruction. This literature points out that there is a need for a substantial change in the way instruction is developed and delivered.
Cognitive Learning Theories

It can be argued that cognitive theory is a reaction against behaviorism. By going beyond the information given and focusing on the mental processes that are involved in knowing and learning, cognitive theories offer a much larger view of human capability and potential (Bruner, 1973). In general, cognitive theories place an emphasis on higher order thinking and look at the processes that are involved in all aspects of knowing and learning. Constructivism is perhaps the most well known cognitive theory and represents much of the current emphasis of the cognitive movement (Di Vesta, 1987). In addition to constructivism, the following theories discussed will form the basis of the Inquisitive approach.

Constructivism

Constructivists posit that learning is an active process in which individuals construct knowledge based on their interactions with the world. Learners rely on their cognitive structures, their needs, beliefs and prior knowledge to transform new information into new knowledge. It could be argued that Constructivism is a theory of knowing as opposed to a theory of learning.

Bruner (1966) states that a theory of instruction should address four major aspects: (1) predisposition towards learning, (2) the ways in which a body of knowledge can be structured so that it can be most readily grasped by the learner, (3) the most effective sequences in which to present material, and (4) the nature and pacing of rewards and punishments. Instruction should be concerned with the experiences and contexts that make the student willing and able to learn, structured so that it can be easily grasped and designed to go beyond the information given (Kearsley, 1997).

Social constructivism focuses on socially co-constructed knowledge that is based upon a groups interaction with the world. Vygotsky's social learning theory is often used as an example of social constructivism.

The theory of andragogy is specifically for adult learning. Knowles (1975, 1984) posits that adults are self-directed and expect to take responsibility for decisions. Therefore, adults can be expected to take responsibility for their own learning. Instruction for adults needs to focus more on the process and less on the content being taught. The designer of adult learning must keep in mind that: adults need a valid reason to learn something, they learn experientially, they often approach learning as problem-solving, and they learn best when the subject they learn can be immediately applied. In addition, instructors should act as facilitators and allow learners to discover things for themselves, but still provide guidance and help when mistakes are made.

Discovery Learning

Discovery learning refers to obtaining knowledge for oneself (Bruner, 1961). This does not mean that students are allowed to do as they wish. Rather, students are directed by the instructor to either solve a problem or gather information and develop a hypothesis. Meaningful learning is promoted by discovery because the learner uses inductive reasoning to formulate general rules, concepts and principles. Discovery learning is especially useful and beneficial in the training and instruction of teachers. The discovery learning process requires a learner to focus more on the process than the content. This emphasis on process allows prospective teachers to better understand the dynamics of learning helping them to become more effective instructors.

Activity Theory (Active Learning)

Activity Theory is based on the notion that human learning is mediated through practical activity and activity is mediated by cultural signs: language, tools, media, and conventions. As the products of learning change, activity changes along with the consciousness of the participants in a continuous, evolving cycle of learning. Activity is fundamental to learning. Proponents of activity theory would argue that it precedes knowledge and there is no understanding apart from it.

Functional Context

Making learning relevant to the experience of the learner is the key to the functional context approach. New information is related to existing knowledge (information in long term memory) and transformed into new
knowledge. This transformation is facilitated by cognitive processing skills including language, problem-solving, and learning strategies. Instruction that utilizes this approach strives to use the same materials in the training that will be used in the "real world".

The functional context approach was developed specifically for adult technical and literacy training (reading/writing/mathematics) in military programs, but it has implications for learning of basic skills in general (Sticht, 1976) and reading in particular (Sticht, 1975). Functional context theory shares a similar emphasis with Situated Learning theory which also stresses the importance of context during learning (Kearsley, 1997).

**Minimalism**

Minimalism should be referred to as a descriptive approach to designing effective instruction. "One of the key ideas in the minimalist approach is to present the smallest possible obstacles to learners' efforts, to accommodate, even exploit, the learning strategies that cause problems for learners using systematic instructional materials." (Carroll, 1990) The minimalist goal is to get out of the way of the learner and let them get more out of their training (learning) experience by providing a less overt training structure.

Unlike many of the other learning theories and approaches minimalism has been developed from the empirical process. Carroll's research at the IBM Watson Research Center in the 1980's revealed that traditional systematic instructional materials were very ineffective and often hindered the learning of new technologies by trapping the learner in error loops within the instructional material. Learners often experienced more problems working through the support and learning material than they did by simply attempting to learn the new system through discovery exploration (Carroll, 1990).

In the first of many experiments Carroll and his associates reduced 94 pages of the systematic training manual of the IBM DisplayWrite to 25 cards. The cards did not include any step by step procedures, but provided general information for completing a task. The cards were intentionally created incomplete so that learners would focus on the task at hand and fill in the missing details which ultimately facilitated the construction of their own understanding. The learners were encouraged to work directly on the DisplayWrite system and use the cards for direction or guidance.

Out of a group of twelve participants, six used the guided exploration (GE) cards and the other six were given the traditional systems-style manual (SM). Both groups were expected to complete their respective training by working through either the drill or practice of the systems-style manual or the twenty five GE cards. Both groups were evaluated by being required to complete a real task of transcribing a one-page letter into the word processor and printing it out. The participants were asked to think out loud and their thoughts were recorded by research associates. In addition, the session were video taped so that all the data could be collated and taxonomized to develop a qualitative picture of how GE learning was contrasted by SM learning.

The guided exploration cards allowed for much faster initial learning and more successful performance in the achievement task. The learning time for the GE participants was less than half of what it was for their SM counterparts; 3 hours and 55 minutes vs. 8 hours and 5 minutes (Carroll, 1990). Similarly, GE participants spent half the time on the achievement task as did their SM counterparts and the GE group achieved much greater success than the SM group. The GE group spent more time working on the actual system trying out more operations than the SM group who spent most of their time reading about the system. Not only did the GE group work effectively with the operations they need to complete their task, they experimented with many more aspects of the system.

The GE group had much more success because they worked with the system itself and took responsibility for their own learning. They demonstrated much more initiative and used errors as learning experiences. In contrast, the SM group often became trapped in error loops created by the systems-style manual. The problems the SM group experienced with the instructional material hindered, or in some cases, prevented the learner from working with the system they were attempting to learn.

Additional experiments were conducted over a 10-year period that demonstrated the minimalist approach to be much more effective than the traditional system approach in virtually all aspects of technical training involving adults. It is from this body of research that Carroll has developed the rubric of minimalist instruction. The nine concepts listed below make up the primary principles of Carroll (1990) minimalist approach:

1. **Training on real tasks.** This is one of the key differences from the systems approach. All training must take place on the actual system that is being learned.
2. **Getting started fast.** Adult learners often have other interest than learning a new system. The learning they undertake is normally done to complement their existing work. The "welcome to the system" prefaces and other non-essential layers in an introduction are simply a waste of the learners' time.
3. **Reasoning and Improvising.** There is no single correct training method or procedure. Allowing for self
directed reasoning and improvising throughout the learning experience requires that there is a substantial reduction in the verbiage and volume of learning materials.

4. **Reading in any order.** Materials designed to be read in any order cannot be read in the wrong order. This will eliminate the common problems that arise from material read out of sequence.

5. **Coordinating System and Training.** The most effective way to coordinate the system and training is to conduct the training on the actual system being learned.

6. **Supporting Error Recognition and Recovery.** Much of what learner does is "error". Since there is such a pervasiveness of errors in most learning, it is unrealistic to imagine that errors can be ignored. Error recognition and recovery strategies need to be implemented to enable learners to learn from their mistakes instead of being trapped by them.

7. **Exploiting Prior Knowledge.** Most adult learners of technology are experts in other areas or domains. Understanding the learners' prior knowledge and motivation and finding ways to exploit it is one of the keys to effective adult training.

8. **Using the Situation.** The learning situation itself can provide many details. In many traditional cultures, "teaching" never occurs. Children are not shown how to perform skills or rituals or understand myths, but are shown in context how to participate (Brunner, 1996a: 151)

9. **Developing Optimal Training Designs.** Instructional models are not deductive or prescriptive theories; they are descriptive processes. There is no "deductive theory of minimalist instruction" that given a set of minimalist principles, will allow us to crank out a minimalist training manual (Carroll, 1990: 91). In contrast the design process should involve the actual learner through empirical analysis so that adjustment can be made to suit the learners needs. "Develop the best pedagogy that you can. See how well you can do. Then analyze the nature of what you did that worked." (Brunner, 1960)

A secondary key to the minimalist approach is the need to discover and support the learners sense-making efforts. This discovery is a dynamic approach that will not only involve the instructional designer, but also the learner. There is no minimalist checklist that a designer can use to create effective instruction. Carroll (1990) states that taking checklists seriously is perhaps the most typical and debilitating design fallacy.

The minimalist approach to learning offers one of the best theoretical foundations from which adult instruction can be designed. Like many other approaches, minimalism is a synthesis of many other theories that propagate the educational psychology landscaped. Despite offering many sound concepts for instructional design, the minimalist approach lacks a number of key components that are required for today's adult learner.

**Inquisitivism**

While Constructivism and many other cognitive theories and approaches examined in this investigation do stress that learner must be motivated, or at least have a predisposition towards learning, most do nothing more than state a variation of this fact. Experience in the past five years of instructing a variety of technology related courses face2face or online, has revealed that you can have an adult learner who is motivated to learn or, at minimum, predisposed to learning, and yet these same people have difficulty with the simplest of tasks and procedures. They want to learn; they paid their fee for their course, have shown up for the class or accessed the information online, yet they seem to be paralyzed. Why?

Fear! Fear of wrecking the computer; fear of breaking the system; fear of loosing their data and a whole host of related or even unrelated fears. Helping adult learners overcome their fear of technology is one of the first steps in creating a successful learning environment. Convincing an adult learner that there is nothing to be afraid of can be achieved through either explaining or demonstrating that the system cannot be broken or wrecked. In addition, it is just as important to demonstrate that mistakes will happen, the system will eventually crash, but it can be restarted. Finally, implemented effective backup procedures at the system level can help reduce or eliminate the fear of loosing data. Letting the learner know that working with technology can, and will, at times be frustrating will help reduce the amount of paralysis that can occur when things go wrong.

Dispelling the learners' fear is only one part of the challenge in adult education. The second and often more difficult related challenge is stimulating the natural curiosity or inquisitiveness that decades of traditional formal education have so successfully squelched. There have been numerous studies conducted over the many years that clearly demonstrate the first six to ten years of a child's life (the actual period depends on the study) are the most critical period of development.

A young child is a natural scientist. This can be easily demonstrated by giving an infant a piece of paper or a toddler a stick. The toddler's natural inquisitiveness will motivate him to see what kind of an instrument the stick will make by shaking it or hitting it against another object. Next the child could check out engineering, mechanical
or tensile strength of the stick by seeing if they can break it. The economic value of the stick is assessed by offering
the stick to another person. By placing the stick in their mouth the child is determining the chemical composition of
the item. New parents find out very quickly that anything within reach become objects of investigation. This natural
inquisitiveness is what adults need to adopt in order to not only succeed at learning new technologies, but also enjoy
the experience.

For the past five years I have been using this example of the child as an investigative scientist to motivate
adults to become inquisitive. In addition to the child scientist example, I also ask my new class of adult learners to
think of their children; nieces, nephews, or family friends, when it comes to learning computer games. Within
minutes of handing a computer program or game to a child they have it installed, clicked on every menu item and
button on screen, and are well on their way to racking up a score that most adults could never dream to achieve.
Children excel at the computer and other technologies because they follow the "HHHM MMM? What does this
button do?" approach to learning. Adults can have almost the same level of success with technological learning if
they allow themselves to be inquisitive.

Inquisitivism is a proposed learning theory that is based on a variation of the Constructivist learning theory
of Minimalism. Since "inquisitive" is defined by Websters as: 1) given to inquiry or research; eager for knowledge;
curious. 2. unduly curious; prying; the label of "Inquisitivism" has been used to describe this approach. Much like
Minimalism, Inquisitivism is a synthesis of other learning theories and approaches so many of the key concepts will
be adapted from other theories. The key concepts of Inquisitivism include:

1. **Fear removal.** Dealing with the paralyzing fear that many adult learners experience must precede the
stimulation of one natural inquisitiveness. Demonstrating that the computer or other piece of technology is
not easily broken, providing explanations, examples and solutions for common errors and problems and the
application of data backup will help quell the adult learners fear.

2. **Stimulation of inquisitiveness.** With the fear abated, encouraging adult learners to become like children
and enjoy the pleasure of inquisitiveness can be easily facilitated. Encourage the use of the "HHHM MMM? What
does this button do?" approach.

3. **Using the system to learn the system.** This is one of the key differences from the systems approach. All
training must take place on the actual system that is being learned.

4. **Getting started fast.** Adult learners often have other interests than learning a new system. The learning
they undertake is normally done to complement their existing work. The "welcome to the system" prefaces
and other non-essential layers in an introduction are often a waste of the learners’ time.

5. **Discovery Learning.** There is no single correct method or procedure. Allowing for self directed reasoning
and improvising through the learning experience will require the adult learner take full responsibility for
his/her learning.

6. **Modules can be completed in any order.** Materials must be designed to be read or completed in any
order. This will eliminate the common problems that arise from material read or completed out of
sequence.

7. **Supporting Error Recognition and Recovery.** Much of what learner does is "error". Since there is such a
pervasiveness of errors in most learning it is unrealistic to imagine that errors can be ignored. Error
recognition and recovery strategies need to be implemented to enable learners to learn from their mistakes
instead of being trapped by them. Use of Frequently asked Question lists (FAQ’s), Help Forums and other
help strategies must be implemented to deal the errors and problems that arise.

8. **Forum for Discussions and Exploiting Prior Knowledge.** Much adult education dealing with technology
is conducted through alternative delivery. Distance education, WBI and other alternative delivery methods
can isolate students. Providing a conferencing system for the replacement of F2F interaction is a crucial
component of any alternative delivery program. Most adult learners of technology are experts in other areas
or domains. Understanding the learner’s prior knowledge and motivation and finding ways to exploit it is
one of the keys to effective adult training. In addition, adult learners can share their expertise or assist each
other and should be encouraged to use conferencing system to facilitate social interaction.

9. **Real World Assignments.** "Make-work" (purposeless) projects are simply useless. All assignments must
have a real world application. Adult learners are often undertaking training to be able to work in their own
area of expertise more effectively. If possible, the assignments should be tied directly to the learner’s
personal or professional interests while at the same time challenging the learner to expand their current
knowledge base.

10. **Developing Optimal Training Designs.** Feedback facilities like online surveys or email should be used to
allow learners to immediately provide feedback on any aspect of a program. Problems with instructions,
assignments, wording or other problems should be immediately addressed and corrected. Instructional
models are not deductive or prescriptive theories, they are descriptive processes. The design process should involve the actual learner through empirical analysis so that adjustment can be made to suit the learners needs. "Develop the best pedagogy that you can. See how well you can do. Then analyze the nature of what you did that worked." (Brunner, 1960)

Like the minimalist approach, Inquisitivism is a huge departure from the familiar step by step procedures of the systems approach. Carroll's (1990) research has demonstrated the reason the systems approach is so ineffective is not that people are not capable of following step by step instructions, they just choose not to. Inquisitivism gives students the freedom and opportunity to control and construct their learning experience.

Perhaps it is the familiarity of step by step procedures that motivates people to choose this ineffective method of instruction. Even though guided discovery that has been implemented in the inquisitive approach as well as other learning theories and approaches has been shown to be a more effective way to learn, many students still seek the comfort and solace of traditional systems based tutorials and manuals. We truly are creatures of habit. Like the minimalist approach, inquisitivism has been showed to be successful. The successes and failures of this fresh approach to learning will be the basis of a subsequent discussion.

Abstract: California State University, Fresno is introducing core information competence skills to First-Year Experience students through its University 1 freshman seminar course. The University 1 web site is a major component in this effort. This panel describes the Information Competence initiative and the initial and subsequent efforts to utilize a web site to address information competence, support service information dissemination, and instructional content delivery.

1. Introduction

Information competence is becoming a key issue for the California State University (CSU) system as it implements sweeping educational technology initiatives designed to infuse technology into all phases of the University. For students this is both an opportunity and a challenge as their learning experience expands to include a variety of information technologies and methods. The ability to access, evaluate, interpret and utilize technology-delivered information is, therefore, critical for today's university student. Information competence then becomes an important factor influencing students' success in completing their college degrees. In the face of these high expectations, educators are concerned about the informational and technological obstacles and negative consequences for students who have limited information competence. At California State University, Fresno efforts are underway to insure student success by integrating information competence, facilitated by a curriculum specific instructional web site, within the University 1 First-Year Experience course.

The panel will discuss the California State University Information Competence initiative and its implementation at CSU Fresno's through the University 1 First-Year Experience course and its related web site. Panelists will include a case study discussion about the University 1 web site project from its initial implementation through the evaluation and subsequent redesign of the site.

2. Background

2.1 Overview of Information Competence in the California State University

Since 1996, the CSU Commission on Learning Resources and Instructional Technology has supported a system-wide initiative on Information Competence. This is defined as the ability to find, evaluate, use, and
communicate information in all of its various formats. The initiative is guided by a workgroup comprised of librarians, teaching faculty and administrators.

A major effort of the workgroup has been the publication of a document that defines and recommends basic competence levels on “the use of recorded knowledge and information and processes for assessment of student competence” [CSU 1995]. This document, entitled “Information Competence in the CSU: A Report,” sets standards and recommends ways of implementing information competence in the curriculum.

A particularly important part of the report is the premise that information competence, like any other competence, is achieved through a systematic process of increasingly sophisticated levels of exposure throughout a student’s academic career. Optimally, information competence should be introduced in First-Year Experience or orientation courses, developed in General Education classes, and reinforced in Capstone or interdisciplinary courses.

For the past two years, California State University, Fresno has worked with the Commission to embed this process in the curriculum and to infuse these levels of exposure in a number of course settings [CSU Fresno 1997]. University 1, a 3-unit credit course that focuses on the skills necessary for a successful academic career, is one of those courses.

2.2 Overview of University 1 at California State University, Fresno

First-Year Experience courses are rapidly becoming one of the most sweeping programmatic endeavors in higher education, given impetus by a marked increase in public demand for accountability and educational outcome. National statistics indicate that some 40% of entering college students will leave the higher education system without earning any type of college degree. Of this number, almost half of all students who leave college will drop out during their freshman year, often during the first few months of their first semester. A well-established body of research supports that first-year academic courses promote student retention by providing a foundation for effective learning and information processing.

University 1, a First-Year Experience course, has been offered at CSU, Fresno since Summer, 1996. The course emphasizes student involvement in adaptation to change, critical thinking, writing, information competence, priority and financial management, computer use, interpersonal communication, health and diversity issues, campus resources and career planning. A component of the course also includes more traditional content focused on studying, note-taking and test-taking strategies for success in academic coursework. The course is challenging, multi-dimensional, and develops student skills across many domains.

As a result of the recommendations of the CSU Workgroup on Information Competence, University 1 is addressing the identified core competencies that form the foundation of information competence in the CSU [Fig. 1]. In order to be able to find, evaluate, use, and disseminate information, students must be able to demonstrate these skills in an integrated process.

1. State a research question, problem, or issue
2. Determine the information requirements for the research question, problem, or issue
3. Locate and retrieve relevant information
4. Organize information
5. Analyze and evaluate information
6. Synthesize information
7. Communicate using a variety of information technologies
8. Use the technological tools for accessing information
9. Understand the ethical, legal, and socio-political issues surrounding information and information technology
10. Use, evaluate, and treat critically information received from the mass media
11. Appreciate that the skills gained in information competence enable lifelong learning

Figure 1: California State University Workgroup on Information Competence core information competence abilities.
The new University 1 Website was designed to help develop these competencies. It contains online course information, instructional supplements, a student handbook, and a continually evolving set of modules for information competence and interactive student activities.

3. University 1 Web Site Case Study

3.1 The Initial University 1 Web Site

The University 1 web site was initially developed in response to the need to provide students with information, in a manageable form, about the various student support services. During the first semesters of the program, the information was provided through guest lectures presented by staff from the various support services. When the projection for the number of courses reached 40-60 it became apparent that presenting this material in a lecture format for each section would be a tremendous burden on the staff of these services. Various formats (e.g., video) were investigated to provide these materials for the student without much success. It was felt that students would benefit more from an interactive approach while working with the material. This is when the abilities of the internet were first investigated.

The first attempt at designing a web site for the course was based on a metaphor of life enrichment. Students were directed to view the various components which make them a complete person. These included the intellectual, physical, emotional, and social aspects of a person. Students wishing to engage in enriching experiences in any of these areas were able to wander freely down any path to discover activities designed to develop that aspect of the person.

The life enrichment metaphor represented a grandiose and somewhat esoteric approach to the web site that presented an abundance of materials for students to choose from. Students were challenged by the maze of links and confused by the life enrichment metaphor. For many students this made it difficult for them to stay focused on the information goal that was the reason for their visit to the web site. This was especially challenging for the first-year student who lacked internet experience or had not previously utilized the internet for academic pursuits.

After the first semester of implementation it was apparent that the site did not work well with the population it was targeted for. At that point the decision was made to redesign the web site to better meet the needs of the University 1 course and its students.

3.2 The New and Improved University 1 Web Site

Re-evaluation of the initial web site also coincided with the University’s participation in the California State University system-level Information Competence initiative. This led to the incorporation of the University 1 program within the Information Competence grant project undertaken at California State University, Fresno. The University 1 web site then became an important method for addressing the University’s information competence activities. As part of the project, a number of instructional modules that facilitated information competence were developed for inclusion in the University 1 web site.

One of the biggest problems with the original University 1 web site was that while it provided students with many information paths to explore, the lack of directed guidance through the web site and the life enrichment navigational metaphor made meaningful navigation through the site difficult for students. The design of a new interface that clearly categorized the site’s content then became a driving force behind the changes to the web site.

As development of the organizational structure of the site progressed it became apparent that the most effective approach was to design a new web site from the ground up. It was decided that the new site would utilize some of the information and resources collected for the initial site but would have a much easier, straight-forward navigational structure. Students would be channeled into more specific learning modules rather than the free-flow format of the previous site and would be very few mouse clicks from the information they sought. The organization of the content was centered around five areas: a Welcome to University One,
an Online Student Handbook, Course Topics, Special Opportunities, and Faculty information which were all listed as links found on the home page.

Along with the organizational changes, a new graphic look was designed for the web site. The new look simplified the page layout, eliminating the cluttered layout of the previous web site and adding more white space for easier readability. Color and graphic shapes were also used to provide a uniform design element for each page which included the category headings and navigational links to other parts of the web site.

4. Conclusion

The evolution of the University 1 web site has resulted in a number of improvements that are reflected in both the organization and content of the site. The clear and direct navigational structure has made access to the site's content easier and more understandable for students. The incorporation of learning modules has increased the site's instructional role in the course and served to provide content information in areas that were limited or non-existent in the textbook. And the University 1 web site continues to play a key role in facilitating the long-term goals of the state-wide Information Competence initiative.

The University 1 web site is an on-going project which continues to expand and evolve. Learning modules will continue to be developed that augment, enhance, or provide the course content and that facilitate information competence for students in the course.

The new University 1 web site is seen as the first phase in the utilization of World Wide Web resources for the program. Plans are underway for a faculty resource web site for University 1 instructors. This site would provide information that would assist faculty in their preparation and execution of the class. Information would include, the generic course syllabus, examples of course topic schedules, teaching strategies, learning activities, and an exam question bank. The third phase of web utilization will be the development of an online version of the course.

Visionary terrabytes

Nicholas Negroponte described a vision in his book "Being digital" (1995), his dream of the ideal interface: "Computers" that are human-like. Such a human-like interface would have the ability to communicate with men in a human manner. Negroponte is well aware that there is no computer that understands language as we do, up to now. Although in some restricted areas of language recognition some success has been achieved, no computer system incorporates something like "meaning" or "understanding" (see the "Being digital Cyberdock": http://www.obs-europa.de/obs/english/books/nn/bdintro.htm)

Vilm Flusser, the European philosopher of the Electronic Age, envisioned a world where no human being is working but all men are engaged in solemn cogitation, being part of networked human-computer brain (see the Flusser surfboard http://www.snafu.de/~klinger/flusslnks.htm). Hans Moravec, director of the Robotics Institute of the Carnegie Mellon University, states that in the year 2050 the evolution of computer systems will outperform the natural evolution having the capability of more than thirty million instructions per second (MIPS). Therefore, the human race will only survive as hybrid creatures, something between human being and computervirtuality (see Moravec's home page: http://www.frc.ri.cmu.edu/~hpm/).

Figure 1: Communication with the robot Xavier from Carnegie Mellon University is graphical, remote, and speech-driven. A real-time, speaker independent speech recognition system and a text-to-speech board provides speech generation.

Reality bites

Each user of the web search engines, like Alta Vista, Yahoo and Excite, experiences a reality that is far away from these far reaching visions: Relevant information is buried under thousands of irrelevant links - many of the links are not valid any more and information in the web tends to be of low quality. The situation is even worse, if content providers are concerned: As most content can only be found and accessed by world-wide search engines, the content
provider can hardly influence at what time, to what extent and in what kind of indexing his content will be provided by the search engines, that is, the broker governs the provider.

Whereas the Hypertext Transfer Protocol (http) based on TCP/IP indicates important progresses in computer networking and routing, the Hypertext Markup Language (HTML) stands for the stone age of structured data storage. Fixed links and HTML references elicit inconsistent and incomplete document and link structures. Even basics of data storage, such as normalization of data including data about links, are a 404: They simply do not exist! Therefore, it is not too surprising that maintaining large web servers leads to serious problems. A first solution is: Do not use HTML, use a database, which generates HTML. Up-todate web servers, such as the HyperWave server (which was developed by Hermann Maurer, program chair of the WebNet), help to maintain huge amounts of linked pieces of information easily. Basic concepts are: The use of object oriented databases in a multi-user environment, automatic link generation and management, a variety of navigational and managerial tools for the web master and tools to engage the user, such as annotations and flexible content views (see http://www.hyperwave.com).

I don't want to address other important problems, such as the storage and linkage of audio-visual media, which are facing important progresses through the definition of MPEG-4 (see Motion Picture Expert Group: http://www.cse.ttu.ut/ufm/leonardo/mpeg/index.htm). An adequate database and technical concepts for audio-visual media form the technological platforms for the Electronic Age. But: Technology solves only technological problems. The accessibility of information depends on the ability of the users to navigate through the knowledge space, to understand texts, images, videos, and to understand how to use the navigational tools.

The myths of multimedia and hypermedia

Most of the hypertext systems are implemented by computer scientists and technical staff. Therefore, they focus on the technological side of the site and not so much on the psychological and pedagogical aspects. This may be the reason, why several multimedia and hypermedia myths managed to survive more than fifty years of psychological and pedagogical media research (I let this kind of research start with Edgar Dale's book "Audiovisual methods in teaching", 1946, New York: Holt, Rinehart & Winston). Here are the three most popular misunderstandings:

Myth 1: More media leads to a better understanding

As of today, empirical research has not been able to support the enthusiastic visions of multimedia. In their most recent meta-analysis, Chen-Lin and James Kulik (1991) examined 248 research studies about computer-supported learning. 150 studies failed to show any significant effects. The other studies showed only a slight advantage of multimedia over textbooks or lectures: Error rates of simple retention tests were reduced between 5% to 15%, problem solving was hardly enhanced, and study time was reduced between 20% to 70%, with an average reduction of time about 30%. Considering all studies included into the meta-analysis, multimedia produced only a small effect (Hasebrook, 1995a). Although, multimedia seems to save some time and reduce simple learning errors, it has not been found be very effective as a problem solving tool. Clark and Craig (1992) reviewed several meta-analysis about the efficacy of multimedia supported learning. They draw the following conclusions: (1) Multiple media are not the factors that influence learning, (2) the measured learning gains are most likely due to instructional methods, (3) the aspects of picture superiority and dual coding of texts and images have not been supported.

Fortunately, however, there are also some promising studies showing that multimedia could potentially facilitate the learning processes. The Software Publishers Association (1995) reviewed the effect of instructional technologies in 133 school studies from 1990 to 1994. They stated that there were better test results, an increase in self-reliance, and a closer interaction between students and teachers. Similarly, Boettcher (1993) collected 101 success stories in higher education in his book. Thus, multimedia can help people to enhance communication, motivation, and self-efficacy. This, however, does not necessarily lead to better learning rates but it could potentially facilitate the everyday life in schools and universities.

Myth 2: Hypertexts help to convey structural knowledge

Picking (1994) observed users of a hypertext stack about Jazz music while solving different tasks: To get a brief overview users stick to the paging facilities and the subject index; to perform a goal directed search they rely on key
words and indices; only if the users are free to get an impression of the system, they use hypertext links more frequently. Retterer (1991) tested whether the use of hypertext features leads to better understanding. He compared three conditions: The first group read a written text, the second group read the same text on a computer screen, the third group studied with a hypertext, which contained links between that parts of the text where names and cities are mentioned and that parts where they were explained. Retterer (1991) found that learning with hypertext leads to the best results. Crain (1994) compared lectures, video, and hypertext in a course about public relations. She found video to be the worst learning condition when tested immediately after having finished the course. She found no differences, however, four weeks later.

Many authors claim that hypertext studies convey different or contrary results, because study setting and user skills are not sufficiently regarded. Glowalla and Hasebrook (1995) conducted studies about the effect of user skills and study setting on the use of hypermedia courseware. 52 students participated in a hypermedia learning course, that consists of five consecutive lessons. All of them were novice hypermedia users. In the first lesson they are "unskilled learners", in the fifth lesson they were "skilled learners". Four month later, 43 of these 52 students attended a relearning course. All students received exactly the same course materials and configuration of features of the hypermedia system as in the learning sessions. The students practiced different relearning strategies in the lessons 2 to 4. Therefore, in the first lesson they were skilled learners, but "unskilled relearners". In the fifth lesson, they were "skilled relearners".

Hypertext links and maps were used most frequently by skilled relearners, informational tools, such as a glossary and a table of contents, were used more often during learning than during relearning. Many other studies have confirmed that hypertext enhances learning, only if the individual skills and - especially verbal - abilities match the demands of the learning task and the hypertext system (Reynolds & Danserau, 1990; Barba & Armstrong, 1992; Barba, 1993; Mayer & Anderson, 1992). In conclusion, it is necessary to teach users strategies and concepts to use a hypertext. Additionally, it is necessary to adapt the system to individual abilities and the overall learning environment (Lajoie & Derry, 1993).

There are only few empirical studies which evaluate the on-going use of hypermedia in higher education. One example is the report of Berg and Watt (1991) who compared hypermedia in competition to a classroom lecture, hypermedia supplementing a lecture and hypermedia replacing a lecture. They draw the conclusion (pp. 119): "Objectively the academic performance of (hypermedia) users was not different from those attending classroom lectures... Although positive about (hypermedia) technology, they indicated that they would prefer to use it as supplement to lectures and books."

**Myth 3: Web is easy, print is tough**

As web-based training refers to multimedia and hypertext, it is clear from what has been said before that appropriate learning results will not be achieved easily. Salomon (1984) showed that audio-visual media does not lead to better retention automatically: Children considered television to be easy and printed matter to be tough; therefore, they learned from television, only if they were instructed to prove how much they could learn watching television. Therefore, it is important to activate and engage the learner into the knowledge building process. The learner, who is not engaged, does not learn: This is the lesson that Jonassen (1993) learned when testing several hypertext indexes and maps. Although he provided well structured hypertext links, maps and tables, the users were not able to grasp the main concepts and to transfer them to related fields. Only one group was superior to all other groups: They had used a hypertext generation tool, called LearningTool, that allowed them to develop their own hypertext map.

How can the effectiveness of multimedia over any other form of learning be improved? There are three important factors: (1) Interactivity, (2) communication, and (3) individualization (or adaptability). An enormous amount of information can be stored and accessed easily. Interactive systems can support the responsible use of electronic media and international communication, such as language learning when students from different countries communicate via e-mail or computer conferences. Computer applications can adapt to preferences, knowledge, and abilities of single students (Hasebrook, 1995b). On-line databases can provide up-to-date information while books tend to be out-dated as soon as they are printed. Homework assignments, such as read the next 50 pages until Monday, do not make a lot of sense anymore. Instead, students may be more motivated to measure the air pollution in their hometown to find out that it is higher in the center of the town. Carefully designed animation, feedback facilities, and simulations can help teachers overcome the weaknesses of study materials and to focus more on the
learning and communication processes. The learning places of the future won't be dim places filled with computers and isolated students in front of the machines. There will be an intensive interaction and communication between teachers, students, and other learning places from all over the world. Computers and multimedia applications are important tools to support this development but they are not the solution to all problems.

When the model is more complex than the reality

Most graphical user interfaces do not support the capabilities of our perceptual and cognitive systems. For instance, the popular three dimensional statistical charts cannot be inspected very quickly, because our visual system focuses on small details or gives an overall impression: Certain details pop-out of the scene, a Gestalt, is projected into a scene. But 3d statistical graphs, diagrams and hypertext maps, like moving maps and fisheye views, need a continuous flow between details and general figures which have to be linked to certain meanings. But our mind did not evolve in rectangular block worlds and meaningless linkage maps. Natural scenes support understanding, if the scene is appropriate for the meaning of the data displayed in the scene.

The Institute of New Media (INM; http://www.inm.de) and the Bank Academy (http://www.bankakademie.de) are co-operating in the development of innovative web-based learning tools. One project of the INM is SkyLink, a model of the city of Frankfurt which contains the skyscrapers of the major banks. An avatar allows to float around in the scene and to choose different content views, such as the cash flow between the banks. While a real building is always more complex than the architects plan, the usage of virtual models tends to be more complex than the plan. We aim to connect VRML models and the interactivity of MUDs (Multi-user dungeons) in order to provide the students of the Bank Academy with a deeper insight of real (but partly invisible) processes (visit the SkyLink browser: http://www.inm.de/people/bernhard/skylink.html).
This hypertecture differs from the desktop metaphor by its immersion. Additionally, there have to be immediate system responses: If it takes more than 10 seconds to understand the basics features, the user moves on to the next site. Known architectural elements can be used and transformed to semantic symbols of information: For example, the skywalk is not meant to stroll on but is used as a semantic element promising some interesting events to go along with. A door like the skystation entrance has to be visible from far away and has to be big enough to float through it - even if the visitor is not well trained. In this way, architectural elements become icons, and natural environments become virtual learning environments.

**SHOEs for the web walker**

Obviously, we have to use a proper technological base and to engage the user if learning, understanding and problem solving is the objective of information sharing in the web. But we have to understand what understanding means in order to come up with tools to support understanding. Understanding certainly refers to internal activities like to grasp the meaning of something. How has meaning brought to the web, so far? There are three prominent ways:

1. Keyword subject indices.
2. Catalogs painstakingly built by hand.
3. Private robots using ad-hoc methods to gather limited semantic information about pages, such as Everyone with links to me. It is easy
to see the disadvantages of all three techniques. All recent searching and indexing techniques come with about 25% relevant items responding to a retrieval query. Projects from the University of Stanford and the University of Maryland, for example, try to overcome the semantic barrier in the web information technology.

The University of Maryland developed the Knowledge Query and Manipulation Language (KQML), a language and protocol for exchanging information and knowledge. It is part of the ARPA Knowledge Sharing Effort which aims to develop techniques and methodology for building large-scale knowledge bases. KQML is both a message format and a message-handling protocol to support run-time knowledge sharing among robots. A related approach is Simple HTML Ontology Extension (SHOE) which allows to give HTML authors the ability to embed knowledge directly into HTML pages, making it simple for user-agents and robots to retrieve and store this knowledge. SHOE is set of HTML tags that adds a knowledge markup syntax; that is, to enable the publisher to use HTML to directly classify the web pages and detail the web pages' relationships and semantic attributes in machine-readable form (for an overview see: http://www.cs.umd.edu/~seanl/kr.html). Similar projects are Harvest (see http://harvest.transarc.com/) and the ontology servers of the University of Stanford (look up the ontology frame editor: http://www-ksl-svc.stanford.edu:5915/FRAME-EDITOR/). Similar projects are run at several institutes (e.g. the MIT: http://www.medg.lcs.mit.edu/doyle/projects/ontology/; an overview about web ontology is given by Doeben-Henisch at: http://www.inm.de/kip/lit-inf-retrieval.html).

The new traveling agents: Knowledge Robots

The INM and the Bank Academy are currently implementing a knowbot scenario to enhance learning and working in banks. To fulfill the requirement that knowledge (explained in a certain language) can be learned by an intelligent user's interface, two strategies are near at hand: (1) Robots are built, which are like human beings (the vision of Hans Moravec) or (2) virtual agents are constructed within appropriate environments which will be similar according to a functionality based on the establishment and usability of verbal meaning. Strategy one is followed in the Real World Computing Program of the Japanese MITI. Strategy two forms the basis for the Knowbotic-Interface-Project (KIP) of Gerd Doeben-Henisch from the INM and myself. We think, that the hypothesis is valid that sufficient isomorphy of the data-structure and the functions are enough to achieve interesting results (see http://www.inm.de/kip/kip.html).

Within the context of the Knowbotic-Interface-Project the virtual agents are called knowbots. This term has been coined by Doeben-Henisch in order to establish a distinction between knowbots and the robots of the Real World Computing program, and to avoid the still diverse use of the term 'agent' within the context of AI (an overview is provided at: http://www.inm.de/kip/KBOOK/models-others.html). Crucial for the knowbots within the project's context is their ability to learn knowledge about the virtual world they live in. They must also be able to learn an intelligible language in relation to this knowledge. Since the exact functionality of human ability to learn and human usage of language is still impenetrable, all varieties of modeling experiences have a hypothetical characteristic. Considering this the following draft of a knowbotic interface can only be seen as one possible suggestion among other promising alternatives.
Knowbots in web-based vocational training

The research on constructivism and situated cognition support the idea of a new roles for teachers and interactive learning systems. The main ideas of constructivism and situated learning are: Learning as active construction of knowledge instead of passive absorption of knowledge. Additionally, physical and social aspects of the learning situation have to be considered. Central theories of situated cognition led to corresponding instructional models such as „anchored instruction” (overviews are provided in CTGV, 1990; Collins, Brown & Newman, 1989; Duffy & Jonassen, 1992; Gerstenmaier & Mandl, 1994).

State of the art in pedagogical and cognitive research provides a number of key concepts: (1) Constructivism, (2) situated cognition and situated learning. Cognitive apprenticeship - especially in vocational training, (3) knowledge transposition, that is the transformation of expert knowledge in practical knowledge and in practical competencies, (4) enhancing the learners’ motivations (although the role of intrinsic motivation seems to be overestimated in the recent literature), (5) definition of the teaching process as an active coaching and guidance process; immediate feedback based on adequate evaluation criteria.

We reviewed rule-based expert systems, neural networks, genetic algorithms, fuzzy logic, and advanced statistical systems in order to check their appropriateness for vocational guidance and education:

(i) Neural networks are superior to many statistical methods because they provide an easy way for non-linear forecast. They are effective in recognizing patterns in noisy or incomplete data. Therefore, neural networks are suited for career counseling where clear rules cannot be formulated. Unfortunately, it is impossible to explain the reasoning of neural networks to users. Explanation of the underlying reasoning, however, is a crucial point in counseling and education.
Genetic algorithms are successful in searching huge databases and large optimization problems including timetabling, job-shop scheduling, and data-mining. Moreover, genetic algorithms can provide explanations of the decisions they produce. The performance of genetic algorithms, however, is strongly affected by the representations schemes employed. Additionally, setting the parameters such as mutation rate and crossover need extensive experimentation. This contradicts our goal to develop a simple to use and simple to maintain algorithm.

One of the obvious advantages of fuzzy systems is their capability to deal with imprecise data using a rule-based knowledge base which is easy to understand and explain. This advantage, however, turns out to be a problem if clear rules can not be elicited.

While interviewing 118 experts for career counseling, we learned from the interviews that the experts use rules to guide the counseling process, but they do not rely on any detectable rules when matching career options and personal traits. Thus, we had difficulties to translate their expertise into simple If-then-rules (Hasebrook & Gremm, 1996). Our statistical analysis of the expert data revealed that only very few statistically significant factors are discriminating hundreds of career options. We aimed to take advantage of this fact and reviewed statistical methods to match multi-dimensional data sets. We implemented an algorithm which allows easy explanation of reasoning, easy updating and maintenance, and incorporation of precise and imprecise data. Above all, no paradox system responses could be observed (Hasebrook & Nathusius, 1997; see http://www.medialog.de/t0.html for a German implementation).

In a study with seventy-five students we were able to show that individualized information provided by a brief test followed by system generated suggestions lead to better retention of relevant information than multimedia elements, like digital video and photo: Our subjects recalled 45% of the information after having used the testing facility but only 33% after having watched videos and photographs accompanying the explanatory texts.

Statistical methods, however, represent a static set of factors. Thus, it is impossible to set up a dialogue between human users and the computer system. Moreover, static systems do not learn from users interactions and do not adapt to the communicational needs of the users. Knowbots may help to overcome such obstacles by representing relevant aspects of the users needs and knowledge. They may be able to provide individualized communication with the user and - by communicating with each other - to optimize counseling and learning systems.

Little is known, however, about the effects of tele-cooperation on corporate culture, learning behavior, and communication processes (Sproull & Kiesler, 1991; Hasebrook, 1996). Electronic conferences can provide several advantages as Sproull and Kiesler (1991; Kiesler, 1992) discovered: Personal communication takes less time but leads to agreements less frequently. Additionally, electronic conferencing allows for a more symmetrical participation than personal discussions, mainly because social cues and social status are less important. We expect to enhance these advantages by using knowbot technology (a demo is provided at: http://www.inm.de/kip/APPLETS/KIP_2.061/applet_no 2.061.html).

Bank Academy and INM are implementing Intranet-based learning environments that allow for synchronous and asynchronous communication within learning groups and support workshops. Two evaluation studies are conducted in March and May this year: The first study examines the impact of Intranet-based testing and simulation tools within a bank training framework. The second study examines the communication behavior of learning groups in banks using web-based training systems based on HyperWave servers.

We are aiming to conduct a study which comprises all relevant factors, namely the user engagement, the user interface design and the accessibility of relevant information. The design of the study is based of three factors, each of them in three versions:

- User engagement: Factor users task - (1) get overview, (2) learn for test, (3) solve work problem.
- User interface: Factor GUI - (1) text based hypertext, (2) hypermedia maps, (3) hypertecture.
- Information access: Factor Index - (1) keyword index, (2) catalog built by human expert, (3) knowbots.
There will be three different groups of 60 users each working with different versions of the bank training system. We hope that the results of study will give us a closer look on how human beings interact with different kinds of meaningful information displayed by different user interfaces embedded in different contexts. First results from the pilot studies and this comprehensive study will be presented at the WebNet conference. We are sure that more than recent visions will come true: Computers wont be like humans, but they will be partners in an on-going communication and learning process. Rules and systems for a real men-computers dialogue will emerge in the near future. This will not result in a simple extension of the anthropomorphism that can be observed, if tools like hypermedia, virtual reality or AI-based dialogue system are used. Inter-connected computer systems will learn to support understanding in the human users, and they will bring meaning to the World Wide Web.

"With Performance Outcomes in Mind: Embedding Performance Support Elements in Web-based Course Design."

Elizabeth L. Haslam, Ph.D', Drexel University, School of Education, USA. 
Phone: (215) 895-6770; Fax: (215) 895 5879; Email: haslamel@drexel.edu

Abstract: This paper describes a case study currently in progress of how a Web-supported course in Multimedia and Instructional Design was designed, implemented and evaluated using performance support elements aligned with performance outcomes for one section of teacher education students. The evaluation results of this case study will be based on a course survey questionnaire, the themes of the students' journal analyses, a profile of the student projects, and the performance outcomes' data.

1. Performance Outcomes

The exponential growth and information and the rapid development of technologies is transforming education as we have known it for the last fifty years moving from a teacher-centered model of tell and test or a "transmission" view of knowledge to a student-centered model of constructivist teaching and learning. This shift is occurring because the new realities of the knowledge age are changing not only how we view learning (Slattery, 1996; Wheatley, 1994) but also what students will need to know and be able to do. Now when our students graduate, they must have much more sophisticated skills and abilities, such as creative problem-solving, accessing and managing vast quantities of information, communicating effectively, working on teams, and learning how to learn.

With performance outcomes in mind, web-based curriculum design can embed "performance support" elements that provide scaffolding, support and functions at the critical moment of need for the learner. The result is a better fit between the learner and what the learner needs to do in the context of a performance. Current thinking in lifelong learning stipulates that the most powerful learning is that which occurs in response to challenges being faced by the learner and that allows for immediate application, experimentation, and adaptation (Sparks and Hirsch, 1997, p. 52).

2. Performance Support

Electronic performance support systems (EPSS) is both a way of thinking and a set of strategies for using technology to augment work. Gloria Gery (1991) defines EPSS as the use of technology to provide on-demand access to integrated information, guidance, advice, assistance, training, and tools to enable high level job performance with a minimum of support from other people. As schools and universities implement educational reforms that include performance outcomes and benchmarks as assessments, the students have similar needs to workers who need specific resources to complete their tasks successfully.

Web-based curriculum can be designed to support the learner's performance and assessment so that the emphasis is on gaining expertise as part of the learning experience rather than having students fulfill the course requirements and hope for the best. As Larry Friedlander points out,
“This technology invites us to embrace process, to enjoy the journey as much as the goal. Because it asks its users to intervene with their own choices and opinions, it can challenge authority and help deconstruct received, standard forms of knowledge” (Friedlander, 1997, p. 174).

3. Designing in the Performance Support Features

Designing in these features takes time, but the support provided for all the students is well worth the effort. Now students can use the materials, work on design teams, and discuss their learning far beyond the allotted class meeting times.

3.1 Course Syllabus, Schedule, Bibliography, and Instructor Link

The course syllabus, schedule, a bibliography, design templates, and instructor’s Email address and other information can all be downloaded.

3.2 The Learner Profile

Students take a learning inventory profile and see how the class is made up of many different learning styles. They become more aware of how styles influence multimedia software designs.

3.3 The Performance Outcomes

These outcomes are based on the content, procedural, cross-competency process and lifelong standards. These include instructional design principles, learning research and pedagogy, multimedia design principles, teamwork, communication, reflective analysis, and others. For each of the assignments in the course, a set of criteria and rubrics is provided so that students know exactly what is expected. Rubric levels range from novice to expert.

3.4 A Learning Community Environment

Students and teachers build a communal knowledge base similar to ways that scientists and researchers communicate. This helps support the learning experience and the communication performance outcomes. Learning takes place as students write, discuss, annotate, describe, and reflect on their learning in their journals. This reflective process balances the “doing” process in the curriculum. A leading educator, Ann Berthoff reminds us that: “Our job as teachers is to devise sequences of assignments which encourage conscientization, the discovery of the mind in action” (Berthoff, 1990, p. 25).

Providing State-wide Access to Information Resources: Indiana’s INSPIRE Project

Mary-Elise Haug, INSPIRE System Administrator, INCOLSA, USA mehaug@incolsa.in.gov

INSPIRE (Indiana Spectrum of Information Resources) is Indiana’s Virtual Library on the Internet. Its successful launch on January 15, 1998 represents a milestone in the evolution of statewide virtual libraries. INSPIRE debuted with commercial periodical databases and encyclopedias from EBSCO, a handful of z39.50 compliant library catalogs, and an opportunity for information professionals to bring added value to traditional library services. While publicity has been limited to the library community, the number of database searches reached nearly 1.4 million in the first six months of operation, with over 425,000 full text articles downloaded. The mission of INSPIRE is to provide residents of Indiana with equitable access to electronic information resources that enhance the quality of their everyday lives, the depth of their educational experience and the economic prosperity of their communities; to provide high-quality information resources that have been evaluated based on criteria that include richness and authority of content, reliability of source, ease of use, and suitability for Indiana residents. To ensure access to these resources for all residents of all ages, in all economic circumstances, in all walks of life and in all regions of the state of Indiana through Internet connected computers in homes, businesses, schools, and libraries. Guaranteeing this level of access with a limited budget has lead to creative ideas and solutions for user authentication.

What distinguishes INSPIRE from other statewide information access projects is the intention to provide access to home users. Traditionally, library projects have authenticated users via IP addresses/domain name or library barcode. There were no models available for extending access to any state resident without requiring a person to register with a local library. At the same time, future plans for INSPIRE, purchasing additional databases that may be available to some but not all libraries in Indiana, interlibrary loan/document delivery, and reference services, require sophisticated authentication schemes for implementation.

When INSPIRE was first available nearly all the public schools and libraries in the state as well as homes and businesses with connections to Indiana-based Internet service providers had access to the service. IP addresses and domain names had been collected from schools, libraries, and local Internet Service Providers. A proxy server, Squid, was set up. Access to a z39.50 web server, SiteSearch, and hence the commercial databases were limited to IP addresses/domains entered into an access list for the proxy server. While this mechanism has worked well in the early stages of the INSPIRE project, it offers no opportunity for expansion. For example, an institutional name could not be linked to an IP address for purposes of controlling a list of available databases or setting up interlibrary loan properties.

As INSPIRE evolves, a major challenge is to develop a user authentication system that makes the system accessible to all Indiana residents and allows services that are available only to particular institutions, while maintaining a modicum of security. Additionally, it is not desirable to limit access to INSPIRE web pages in any way. Planning for access needs involved considerable research into existing authentication options. Most of the newer technologies seemed to rely on an existing database or at least the idea that an organization had an identifiable user groups, usually employees or students or, in the case of commercial enterprises, would register folks, regardless of geography. The more realistic solutions, notably username/password scheme (htaccess or database), cookies, and proxy servers, failed to address how to identify that someone was from Indiana in the first place. It became clear that there are two issues at work for establishing an authentication system for statewide access. The first one is how to verify that a user is a resident of a particular state and the second one is how to maintain information about valid system users once residency is verified.

At first glance, digital certificates appeared to address both issues as we could contract with a vendor that issued certificates with locality information. The problem was with base level certificates only check a person’s email address, so the state/province would not be part of the certificate. Address information is provided with class 2 digital ids; however, that level of security was out of our price range and was overkill for our security needs. Another high tech idea for verifying residency was to make arrangements with the division
of motor vehicles to use their database, which is available online. While this idea has merit for the long run, both systems need to be more fully established before trying an interface. It also has limitations for authorizing K-12 and college students. The most reliable, albeit slowest, means for verifying an address seemed to be the U.S. Postal Service. A user will fill out a registration form on the Internet. The data will be captured to a file and manipulated so it can be printed onto a self-mailer form with a one-time-use password. The password will allow someone to generate an entry into a permanent database entry.

With the verification issue resolved, there were still lingering questions about the best way to maintain user information as well as periodically re-check the validity of a person's residency. The later was solved with the requirement that database entries had to expire. (A plan for re-validating can wait until other components are in place). Further discussion and planning centered on whether to use a more traditional SQL based database or digital certificates. The latest release of SiteSearch software is developed to use a mini-SQL database for authentication. Certificates were intriguing as a state of the art technology and what looks to be a lower cost per user in staff time. Since the x.509 standard includes fields for organization and organization unit, it would be possible to setup institutional access parameters based upon data in a certificate. Ultimately, digital certificates could meet all our authentication needs. To speed up implementation IP addresses/domain names with institutional information will be stored in the SQL database.

Options for issuing certificates were evaluated with the idea that they would be used primarily for home users that would be allowed access to Inspires core services. Due to budget constraints, the only way to proceed was to become our own certifying authority (CA). The drawback is that web browsers do not recognize the CA making downloading a certificate more cumbersome, particularly for Internet Explorer users. After setting up software from Xcert, Netscape, and the free SSLeay tools, the Netscape Certificate Server was chosen. Xcert was eliminated because the certificate database it created was not accessible to the SiteSearch server. SSLeay required significant programming expertise to implement a backend database. An understanding of United States encryption law helps too. Netscape uses an Informix database and has hooks directly into its LDAP server product. Product literature indicates that later releases of Netscape may work with additional database products. If so it should be possible to use mini-SQL for both types of authentication. The web interface makes the server setup almost trivial.

While the ideal is to have one system for authenticating all users, lack of time for development work has forced to use of two distinct systems. At the moment the proxy server is still used to authenticate IP addresses/domain names. This will be replaced by a SQL database in the coming months, which will allow for institutions to access different databases, etc. Those entering the system with a digital certificate for authentication will be able to get to the core services. It individual libraries will be given a choice about patron access to additional databases and referring URLs will enter the mix of authentication options.

With digital certificates the way the process works is that once a user fails the IP authorization check, he/she will be given an opportunity to fill out a web form with basic information—name, address, email—. Perl scripts will be used to capture the form data, generate a one-time-use password, and output data for a self-mailer. The user will also be given the URL for the INSPIRE digital certificate server. The password will be required for a user to automatically generate a digital certificate that can be downloaded into her browser. The web server associated with the SiteSearch software will check for the digital certificate before allowing access to commercial databases.

The digital certification application for INSPIRE is still very much a work in progress, with testing set to begin in August 1998.
A Networked University as a Joint Venture - Challenging the Trad. System

Harald Haugen, Dep. of Teacher Training, Stord/Haugesund College, Norway; Harald.Haugen@hsh.no
Bodil Ask, Agder Research Foundation (SENTEK), Norway; Bodil.Ask@hia.no

Abstract: Internet and WWW challenge higher education to re-think traditional, academic ways of organising universities and colleges, and require new pedagogical approaches to the provision of knowledge. This paper presents organisational and pedagogical arrangements for a joint, networked university, established by four Norwegian institutions - and also open for other institutions to join in.

Among the organisational aspects, attention is drawn to formal arrangements, commitment and objectives related to national demands and joint activities within ODL. Tasks like economical, technical, professional and pedagogical organisation, are specified in a partner contract, signed by each partner institution.

Pedagogical aspects are discussed with a focus on professional collaboration between university researchers and teaching staff for the development of ICT based learning environments. Different pedagogical models are presented, from the simple 'electronic correspondence school' to more advanced ICT supported, problem based learning and collaborative learning where students share responsibility for support and learning activities.

Background

Industrial leaders as well as public administration claim that universities and the traditional, higher educational system are not able to meet the demands of required, up-to-date education. They express clearly a lack of faith in the system to meet new challenges, and tend to look for other solutions and resource centres, outside the existing academic system, in order to develop and offer courses and studies that fill their needs. New, private enterprises are more flexible to adjustments and tailor-made training programmes and packages, than are the large, public universities, which are bound by traditions and regulations.

National white papers and international reports point out needs and sketch different solutions to the present situation and future requirements. The growing demand for lifelong learning and increasing requests for new competence can only be met by developing open and flexible learning systems. Companies can not release all their workers, technical and administrative staff for lengthy periods of time in order to upgrade their competence or raise their formal, professional level. Such education and training should be available at their desk, as a complementary activity in their daily routines. This requires flexibility and availability of learning at the workplace.

Typical for the situation in Norway is a very strict labour market, with an extreme lack of qualified personnel in several fields, and particularly in areas related to new information and communication technology (ICT). Politicians and governmental agencies do not see any immediate solution to the problem, and can only recommend import of skilled staff from abroad. In the long run, however, this is far from a desirable situation. Experiences from different ODL projects, both nationally and as part of international programmes (DELTA, Socrates etc.) has during the past 4 - 6 years created a basis for further development in the area of ODL. It is believed that this is a possibility of both offering industry and public services the learning facilities they are asking for, and for making higher education more attractive to individual students at all ages and stages of life.
NOL - Networked Open Learning
Based on experiences from the European DELTA project, JITOL\(^1\), four Norwegian institutions, in 1994 made a joint, national offer of higher education through ICT based NOL. This project is known under the acronym NITOL\(^2\), and has proved very successful with respect to popularity among students around the country. The diagram below illustrates the impressive growth of an activity that was mainly initiated for R&D purposes, and not for mass attendance. Marketing was close to nil at the start, and has continued at very low cost.

![Graph showing growth of students registered for NITOL courses]

Fig 1: Students registered for NITOL courses

The rapidly growing number of learners attending the program clearly indicates a market and a demand for courses and training. Since this is outside the regular university activities, students have to pay fees to cover the costs of delivery and tutoring. Nevertheless, lots of people see the advantages of availability of higher education when and where it suits them, so important that they will rather pay than attend regular study systems free of charge.

Observing these preferences in the population, the project group of NITOL has concluded that it is necessary to improve and extend the services of ICT-based NOL. The restriction of limited resources also makes it necessary to look for rational and efficient ways of providing these services. Collaboration between institutions with similar or complementary competencies and specialities, exchange of products and knowledge, openness in research and development work, all seem to be possible strategies to obtain the set goals. The limited project initiated by a few persons within four geographically separated professional environments, would therefore have to be raised to an institutional level in order to expand further. This is the background for now embarking on an intentional agreement between the four institutions to establish a networked university (NU), or a virtual learning institute (VLI).

Organisational aspects

\(^1\) JITOL = Just In Time Open Learning, aimed at upgrading of professionals in different fields through electronic networks

\(^2\) NITOL = Norway-net with IT for Open Learning, where Norway-net refers to the national network of higher education
Institutions
The 4 institutions involved are all part of the same national network, Norway-net. This expression was introduced through a governmental white paper in 1990 (Stmeld.nr 40, 1990/91), describing a professional network of higher educational institutions in Norway, in order to share responsibilities for the different academic fields and subjects. The 'net' did not necessarily imply electronic or digital connections, but did rather denote professional and human relations between academic societies in the country. Now, since the mid-90's, Internet and modern IT have gained such popularity that it is quite natural to include ICT as an important infrastructure to facilitate the Norway-net. This is also a natural link to previous experience from the JITOL project, where new ICT was a strong feature. [Haugen & Ask, 1996b]

Characteristics and specialities of each of the four NITOL institutions are basically complementary,
- a large university (NTNU, 20 000 students) with a wide spectre of subjects and professional study programmes, from undergraduate up to Ph.D. level, well known for their specialities within technology and science, represented in NITOL by their Department of computer technology and information science
- two fairly big regional colleges (HiST & HiA, 4-6000 students), both with strong departments of engineering and computer science, a wide spectre of other professions and subject areas, and represented in NITOL respectively by their departments of telematics and computer science
- one smaller college (HSH, 2000 students) with a more narrow spectre of professions, a strong department of teacher education, and represented in NITOL by the division of educational information science

Fig. 2: The four NITOL institutions in Norway

The strong representation of ICT personnel in the project was partly a heritage from a previous project (JITOL), but also intentional to choose subjects and courses involving students and tutors that would not back away at first encounter with technical difficulties. When the project started in 1994, ICT was not as customised and user-friendly as it is now in 1998, and represented a major challenge in itself.

After taking an initiative for establishing the Networked University (NU), the original four partners have invited other universities/colleges to join the organisation in the next phase. Rules for this expansion are discussed between leaders of the new organisation.

Objectives
The intentional agreement specified three groups of objectives,
- international goals, including positioning our country in the global society of education, research and development, and contributing to international exchange and understanding as a basis for lifelong learning
- national goals, like improving access to education, filling gaps of knowledge in industry and society, raising the general level of competence, and developing new courses and lines of study that are asked for by industrial and political leaders and employees
- institutional advancement in pedagogical and professional activities, renewing the study programmes, researching new ways of learning - and defining a common policy of academic and educational service development.
The objectives concern both research, development and creation of practical learning environments, stressing contacts with professionals from all walks of life, exchange of products and knowledge, and networked open learning offers to those who want, when and where they want it.

**Economy and technical solutions**

A common belief, particularly among politicians and administrators, is that networked open learning (NOL), or 'distance education' - will be a less expensive way of providing education. This is probably true when it comes to total costs for the society. Experiences so far, however, indicate quite strongly that in order provide equivalent quality of learning, NOL, it requires a lot of effort for initial development and maintenance of learning material, and that tutoring on the network takes more time than simply performing a lecture in a classroom or an auditorium. Students on the net - whether they are local, on campus, or at a distance - have a strong urge to ask for individual guidance e.g. through e-mail in stead of contributing to discussion on a conference.

On the other hand, the total cost for society, including costs of transportation, student housing, costs of living etc., will be lower for NOL provided to the individuals at their home or workplace, compared to the cost if they would have to attend regular day-studies at a university. So the possible extra costs of providing higher education in the form of NOL, is more than compensated by the savings for the individual learners. In addition they are likely to have a better opportunity to meet other obligations in their lives, with respect to family, work and geographical location, in parallel to education.

Technical solutions for providing NOL should be kept at a balanced level, not the most advanced and expensive, and not too old and out-dated for professional use. Both for NITOL and for the planned networked university, the intention is to apply the present standard of ICT at any time. In 1998 this means Internet connections with standard WWW browsers and Windows-/Office software or the equivalent.

**Formal organisation**

The new NU will start as a joint project, based on a partnership agreement between the four institutions. The intentional agreement suggested some lines of structure in the new organisation, and some ideas on how to share rights and responsibilities between the partners, a board and a secretarial function. Details are now specified in a preliminary partnership agreement, a document signed at the highest level of authority at each institution.

The contract specifies the organisational structure of the networked university (NU). When the organisation is formally established, it is open for other institutions with similar and complementary study programmes to join in or associate. Among the issues that are specified in the contract, we find the following issues:

- Goals and objectives
- Formal status of the NU as a collaborative project, formal management of the project, i.e. with a representative steering committee and its mandate
- Practical administration, i.e. a secretariat for general information, marketing, student registration, invoicing, accounting, updating of the common course catalogue and web-pages, etc.
- Specification of joint responsibilities and tasks, and relations to the individual institutions
- Contract formalities, such as joining/withdrawal by institutions, start and end of contract etc.

The already existing NITOL organisation will most likely continue as a joint forum for research and development, exchange of experiences and academic discussions related to NOL.

**Pedagogical aspects**

A networked university depends upon inter-institutional collaboration on organisational issues, but it is also a challenge for collaboration between professionals on pedagogical issues.

**Collaboration between professionals**

Inter-institutional collaboration between professionals can be looked upon from different angels; from collaboration in distribution of limited and well defined learning material, to collaboration in creating a total learning environment.
Collaboration in distribution of learning material is relatively easy to implement in a networked university. This might be as simple as just putting courses together in a common course pool, making a common catalogue of offers etc. [Ask & Haugen, 1996].

Another way of dealing with learning material is to join forces in development of course material. An example here can be when professionals from two or more institutions - even across boarders - join forces in creating a course where no single person or environment has the necessary knowledge or resources to develop it. A NU can really profit from this way of sharing workloads [Retalis, Skordalakis, Haugen, Ask 1997].

A third option is to develop single modules that can be building blocks in several combinations of courses or studies within the collaboration. One may look upon single modules as units to compose a course, or look upon different courses as fragments in a puzzle of a degree programme, independent of which institution the building blocks or fragments originate from. This kind of arrangements requires strong co-operation for recognition of credits and academic level.

The many different ways of collaboration between professionals seems to be a strength for a networked university, and is also a main idea and reason for establishing this kind of virtual institution.

Models of learning environment ‘inside’ a networked university.

It might be a contradiction in terms to talk about a learning environment inside an open, virtual organisation. Nevertheless, it is important to create a learning environment, especially when students are more or less ‘off-campus’ as most of the students attending the NU possibly will be. Normally we think that students attending a NU are adult people, employees in a work situation, individuals looking for up-grading in their spare time etc. We also use to think about adult learners as mature persons taking responsibility for their own learning. Even if this is true, we as professional academic staff members, have a responsibility for making the learning environment for our students as rich as possible. How may we create the best learning environment for our net-learners?

If we look upon a NU as one institution, even though it is virtual, we also may think that the learning environment we create belongs to this institution and is a part of the pedagogical work going on inside the institution. We can of course differentiate between one learning environment for on-campus students, and second one for off-campus students. But since a lot of teaching and learning activities apply the same tools and resources, it is both convenient and rational to include all students into the same learning environment. We may have difficulties if one student group have access to learning environments that are out of reach for another group, whether it now be the classroom attendance or the network resources.

Intentionally, a learning environment should be dynamic, adjustable to circumstances and content. It shall evolve and develop according to the environment and the persons involved. It is difficult beforehand to tell how an environment is going to develop, but different models create different opportunities to the environment. We will look at a couple of models for a learning environment which have been practised within the NITOL networked university [Haugen & Ask, 1996a]. The two models reflect activities where each institution acts independent of the others in the network. We will also look at the design of a more complete learning environment for a networked university, where the two models can be ‘subcultures’.

The electronic, networked correspondence school

The main purpose for this framework as a learning environment is to have a smooth and simple pattern for electronic delivery of learning material and for return of exercises from the students. The structure is well defined, with a fixed time schedule for distribution of material and deadlines for return of exercises etc., presented in the start of the course. The basic model gives little space for creative or spontaneous student activities or discussions of any sort.

If we add E-mail and electronic conferences to this model, it opens up for a learning environment that supports discussion groups, sharing of experience etc. It brings ‘interactive’ characteristics from the classroom into the
virtual environment. Students are allowed to ask questions ‘directly’ to the teacher or tutor through e-mail. Responses will normally come either as soon as the tutor reads the mail, or at pre-defined times.

Another dimension that is now commonly available, is the concept of hyperstructures and links to other sources of information. With this included, we are far beyond the potential of a traditional correspondence school.

Experiences from use of this model as a learning environment have been amazingly positive. Amazingly because we thought that this way of using the network could be a bit boring for adult students and that they would not care about using these added facilities. On the contrary, it turns out, they like to stay in touch with the professional tutor - and with each other. The teachers' experiences from using this technique vary from one group of students to another. Even within the same framework, it is hard to tell how the environment will evolve. An example of this net-correspondence model using e-mail and conference facilities may be found at http://www.idb.hist.no/fag/LO303D-GrunnkursEDB-NITOL/index.html

The interactive learning environment model
In this model we use more of the services and facilities that Internet offers. An example here can be the problem based learning (PBL) environment where students attending the same course are ‘forced’ to work together in order to bring forward interesting literature and articles on how to solve a defined problem, e.g. by using electronic hyper links to relevant material, which in turn becomes part of the study material or curriculum. This model has moved the learning situation from a classroom or group discussions and reference lists to a workplace on the net where all the students' activities are visible for every other student in the group. In this environment students discuss, contribute in the learning process, submit their own thoughts and ideas of how to solve a problem, analyse each others’ solutions and so on. The net is not only a ‘transfer medium’ for learning material, but it is also the place where the learning activities occur (http://hugin.hsh.no/home/lv/mfag97/home2.htm).

The networked learning environment
A complete model of NOL can contain the two previously mentioned models and all combinations of them, which more or less represent the specific way a tutor and the students create an environment for the actual course. When institutions establish an inter-institutional collaboration, a virtual university, it is important to agree on a common platform or learning environment for the students attending this university. One way is to establish a common home page for this virtual institution, where students get all the information they need e.g.: how to register, costs, equipment needed, exams, courses available, names of teachers, etc. Further more, it is important to make paths from this common arena to the specific course environments. If a specific course is developed by joint efforts from two or more institutions, it is natural that the actors involved in the development also take part in running the course. At least they should have access to a common learning environment where all of them contribute together with the students. An example of a jointly developed environment model can be found at http://hugin.hsh.no/nitol/DoODL/classroom98/PiOL/.

And an example of the virtual institution learning environment you can find at http://www.idb.hist.no/nitol

Other models of learning environments
The European Socrates project MECPOL (Models of European Collaboration and Pedagogy in Open Learning) has surveyed and developed several models of interest in this area. They may be studied through the printed publications of the project outcomes ('deliverables') [MECPOL, 1998], or may simply be downloaded from Internet, where they are listed on the MECPOL homepage, http://www.idb.hist.no/mecpol/. Of particular interest should be the Guidelines for networked open learning in a virtual learning institute (Product 3), and the shorter version of Guidelines for ODL - a Virtual Learning Institute (VLI). More extensive experience in this field is available as the on-line course in Pedagogy in Open Learning mentioned above, and is described in a paper, Learning by doing - an Internet course on methods for ICT-based ODL [Ask & Haugen, 1998] at the BITE conference (Maastricht, March '98).

Distributed Information Storage and Retrieval Agents for Web Information Gathering and Recommendation (DISRAWIGR)

Hans-Ludwig Hausen GMD FIT.CSCW Sankt Augustin Germany hausen@gmd.de

Abstract In DISRAWIGR the classical information and storage retrieval features are distributed across the different agents and sites where information might be stored and requested. For the retrieval so-called hybrid query and document feedback is proposed taking into account the excellent results obtained in our experimental system. For the implementation of DISRAWIGR a distributed agent platform is necessary, as it is given by the Java abstract engine.

0 Preface

On the worldwide web each day a large number of information entities is added and consequently an arbitrary user exploring the net get lost soon. So called search engines have been introduced and used in the last couple of years, but even those search engines are not providing the necessary means to get structured effective access to the relevant information sources. In the following a brief discussion is given on whether and how mature information storage and retrieval techniques can be used to help both the technical expert as well as naive user to navigate through the web.

1 The Basic Information Storage and Retrieval Process Model

The task if an information gatherer on the web is to get efficiently the most precise response to an information request. In general we have to distinguish two kinds of request. The first type of request is given when an requester ask for information containers (e.g. web sites) identified by some formal descriptors, such as author of an article. When the requester is not aware of the formal descriptors (or part thereof) a content description has to be used to identify and retrieve the requested information content (e.g. description of the BeOS, What are the decision of the WTR on the R&D programmes of the GMD). In the first case the retriever has to look for the information containers that exactly match the relevant terms of the request. A semantic matching is necessary when the requester poses an informal request. The scenario for information storage and retrieval comprises several components to get hold of the information containers as well as to manage the contents. In order to make both the information containers as well as the information container contents available several features to store and retrieve them have to be provided.

Following [2], [5], [7], [10] a basic information storage and retrieval model therefore has to comprise:

set I of input features applicable to get the information into the site, set E of entities e in natural language, e = <e'1, e'2, e'3, ....e'n>, set R of requests r' in natural language, r' = <r'1, r'2, r'3, ....r'm>, set L of terms l to be used to index the items of E and R ( - which might be subdivided into set LE of terms le to be used to index the items within E and a set LR of terms lr to be used to index the items within R - ), set T.1 of transformations to map E' on its internal representation leading to the set E of internal entities e in index language L (or LE), e = <e1, e2, e3, ....en>, ei are elements of L (or LE), set T.2 of transformations to map R' on its internal representation leading to the set R of internal requests r in the index language L (or LR), r = <r1, r2, r3, ....rm>, ri are elements of L (or LR), LE, LR and L are integrated into a coherent consistent thesaurus, such a thesaurus might be obtained by extending standardized index term lists (e.g. US Library of Congress Term List, ACM computing review categories), search function s on the Cartesian product of E and R which defines the result of the search as a partial ordering of E, threshold function t which cuts of the non-relevant search results based on a threshold value, which indicates the lower limit of match value. Based on this components of the basic retrieval model a basic retrieval process works as follows:

1. Each entity e' and each request r' is transformed by the input features into the corresponding e and r. The e as well as the r are represented as n-ray vectors. The components of the vectors are defined as binary values (leading to Boolean storage and retrieval), numerical values (leading to linear storage and retrieval) or relevance functions (leading to functional storage and retrieval). As both Boolean and numerical values can be defined as constant functions we need only to consider the functional storage and retrieval, which we will call just information storage and retrieval or IRS for short.

2. Each request vector has to be checked against each entity vector. A correlation coefficient is computed for each pair <c,e>. Based on the comparison the entities are ranked from worst to best match. The ordinal number of the matchlist defines the rank of a particular entity with respect to a given request.
3. A threshold value is used by the threshold function to separate the relevant from the irrelevant entities. In case no threshold value is given the partial ordering resulting from the comparison is used to generate the response vector. (Remark: In order to save space and communication the entity objects as well as the requests are captured in inverted file organization IFO. In an IFO a thesaurus is enhanced by references to the names and locations where the particular thesauraus item appears).

2 Typed Agents for Information Gathering on the Web

In order to achieve an extensible and adaptable agent one needs to separate the following issues i) Agents being typed declarative or procedural procedures or programs, ii) Agent engines or Agencies providing the execution environments, iii) Intercommunication between agents defined via agent interfaces or protocols by using the services of agencies as well as, iv) Intercommunication between agent engines (or agencies), which are defined via the agent model and the agent interface model.

As a consequence an agent is to be viewed as defined by its: (e.g. Software quality and productivity model Y7), location (e.g. http://www.scope.gmd.de), function specification of agent service e.g. semantics), type of agent service (e.g. book, report, program), environment of agent definition and application (e.g. HotJava), store of the agent to keep information objects, interface of the actual agent to other agents.

Assuming that our information gathering scenario comprises: a set of Individuals (sometimes called users): I1, I2, ....... In, a set of Representatives of Individuals: R1, R2,.......... Rn, a set of Agents A (such as A01, A02, A03,....A0k0 to be used to implement the agent engines, A11, A12, A13,......, A1k1 to be used to implement the user agents, A21, A22, A23, ...., A2k2 to be used to implement the agent interfaces, A31, A32, A33, ...., A3k3 to be used to implement the engines interfaces, ...., Ai1, Ai2, Ai3, ...., Aik to be used to implement the agents for dedicated tasks (e.g. retrieval agents), An1, An2, An3, ...., Ank to be used to implement agent management (e.g. monitors, schedulers, etc.). An agent engine provides the operational environment for the agent enabling them to conduct their tasks or to communicate with each other. A user agent provides the storage and the features of agent that acts on behalf of a particular individual. In other words, a user agent implements the representatives of an individual. The agent interfaces define the operations and the information exchange between agents as the agent engine interfaces define those for the operational environment. A baseline for the implementation of the agent model therefore has to comprise an interaction protocol, and a minimal, extensible content language that can be used by agents or agencies to support the operation as well as the interaction. At present Java seems to be an appropriate candidate for such an agent base line. A promising approach for an agent environment might build on both agents conducting on-site information storage and retrieval and on resident agents conducting remote information storage and retrieval.

As there are no statistically valid data available on cost and benefit of each at present both approaches might be worthwhile to be explored. The mobile agent approach might be appropriate where huge amounts of data has to be explored whereas the resident agent approach seems to be right in case where large amounts of different types of content explorations (e.g. as in data mining) have to be conducted. Taking into account the experiences from classical information retrieval a hybrid approach interleaving the mobile and the resident agent approach might be the most effective. For this case we need to have guarded agents in the form of:

\[
\text{if guard then agent or guard pl: agentl; p2:agent3; p3:agent3; \ldots; pn:agent.n draug}
\]

As the agents are used not only to define tasks or procedures but also to store information they have to have a typed storage. As a consequence an agent might be viewed as a high level named and located procedure with defined typed functionalities and typed data types for the storage. For a baseline web information gatherer one might start with a set of user agents, each representing an individual, set of dedicated tasks agents, each acting on behalf of one or more user agents, as well as a starting set of so called information brokers, which provide remotely references to the web sites to be considered in an web information gathering process.

3 On the description of Web Site Content

As in traditional library systems information entities on the web might be catalogued using standardized dictionaries and thesauri or lexica. But at the present point in time information is provided in a variety of forms on web sites. As there is no standard or norm for web sites each web site designer defines at least on web site scheme or let's say web site data structure. Even when there will be a standard (like SGML, MCF, etc.) there will be more than one metacommend schema as well as at least a couple of content schemes. On the other hand one has to respect freedom of each user in the net to use a specific scheme considered by that particular user as appropriate. Effective and efficient information gathering on the web therefore will require means to handle a couple or even all the so called metacommend schemata as well as all content schemata at the same time. This is different from classical storage and retrieval procedures on single engines, where a dedicated schema for both the meta content and the pure content is only necessary. As a consequence one needs an extensible and
enrichable agent and object description scheme. For a base system on might start with a flexible schema like the following:

\[ \text{object} := \langle \text{object-type} \rangle \]
\[ \quad \langle \text{object-id-type: object-id}, \right. \]
\[ \quad \left. \text{object-location-type: object-location}, \right. \]
\[ \quad \text{object-author-type: object-author}, \]
\[ \quad \text{object-neighborhood-type: object-neighborhood}, \]
\[ \quad \text{object-content-type: object-content}, \right. \]
\[ \quad \text{object-extra-type: object-extra} \]

To identify the set of relevant descriptors a standardized thesaurus has to be used, such as the one available from the US Library of Congress. In general one gets a declarative object scheme as the following:

\[ \text{object} \leftarrow \text{oname, olocation, ofunction, oauthor, oneighbourhood, ocontent, oextra} \]

4 An Information Storage and Retrieval Process Model for Distributed Agents

For the realization of a web based IRS we assume to have available the following agents: user agents to handle the interaction between the user and the agent engine as well as to manage the user agent itself, task agents to conduct dedicated functionalities, such as indexing, transformations, correlations, aggregations, assessments, etc., and broker agents to keep gathered information on users, websites, tasks, and agents.

An agent based information storage and retrieval model can be defined now by the following components:

A) The user i.e. a provider invokes an user agent to get access to the agent environment as well as to provide access to the user's store for other agents. As a result one gets:

\[ \text{provideragent} \leftarrow \text{providername, providerlocation, providerfunction, providerstype, providerenvironment, providerstore, providerinterface, providerextra} \]
\[ \text{providerobject} \leftarrow \text{providername, providerlocation, providerfunction, providerauthor, providerneighbourhood, providercontent, providerextra} \]

B) Information provided by a web site is indexed by so called indexing agents which take the respective language LO or LR (or just L) as defined by a standard thesaurus. The result will look like:

\[ \text{indexagent} \leftarrow \text{indexername, indexerlocation, indexerfunction, indexertype, indexerenvironment, indexerstore, indexerinterface, indexedextra} \]
\[ \text{indexedobject} \leftarrow \text{indexedoname, indexedolocation, indexedofunction, indexedoauthor, indexedocontent, indexedoextra} \]

If all websites are indexed one gets the set of indexed websites:

\[ \text{indexedwebsites} \leftarrow \text{indexedobject1, indexedobject2, indexedobject3, ..., indexedobjectnn, indexedagent1, indexedagent2, indexedagent3, ..., indexedagentnn} \]

C) Requests posed by a user are indexed by so called request indexing agents which take the respective language LO or LR (or just L) as defined by a standard thesaurus. The result will look like:

\[ \text{requesteragent} \leftarrow \text{requestername, requesterlocation, requesterfunction, requestertype, requesterenvironment, requesterstore, requesterinterface, requesterextra} \]
\[ \text{requestedobject} \leftarrow \text{requestedoname, requestedolocation, requestedofunction, requestedoauthor, requestedoneighbourhood, requestedocontent, requestedoextra} \]
If all requests are indexed one gets the set of requests

\[
\text{indexedrequests} \leftarrow \text{requestedobject1, requestedobject2, requestedobject3, ..., requestedobjectN}
\]

D) The match of the requests against the provided objects is conducted by a dedicated **match agent** which is parameterized to execute the following focused matches: indexed request against indexed objects, indexed request against class-indexed objects, class-indexed request against class-indexed objects, indexed request against object-class-indexed objects, class-indexed request against class-indexed objects.

The **total retrieval process** comprises:

\[
\text{match agent(agent environment, requests, objects, final response) \leftarrow}
\]

\[
\text{totalmatch(response, objects, request, assessment(response, final response, assessmentobjective))}
\]

\[
\text{totalmatch(response, objects, request) \leftarrow}
\]

\[
\text{mpii((response, indexedobjects, indexedrequest), mpdcii(response, descriptorclassindexedobjects, indexedrequest), mpdcidci(response, descriptorclassindexedobjects descriptorclassindexedrequest), mpocii(response, objectclassindexedobjects, indexedrequest), mpocioci(response, objectclassindexedobjects, objectclassindexedrequest)}
\]

or any subset thereof (i.e. any combination of the individual match processes).

5 Feedback-based Information Gathering within an Agent Environment

As the ultimate goal is to get short response time and a minimum user effort one has to investigate the procedure and the response to elicit that. In order to achieve this goal one might assume the following approaches:

- Viewpoint one (request feedback): user to the universe i.e. change of user request towards relevant objects to be found will ensure increase in recall and precision.
- Viewpoint two (object feedback): universe to the user i.e. modification of the objects to be found towards the user’s request will lead to higher recall and precision.
- Viewpoint three (hybrid feedback): universe and user towards each other i.e. modification of user request space and objects space are intertwined.

To automate the feedback one has to make use of the request response relation. As defined above we get from an assessment of an retrieval process amongst other the following assessment measures:

\[
\text{objectsfoundandrelevant(response), objectsfoundandirrelevant(response), objectsnotfoundandrelevant(response), objectsnotfoundandirrelevant(response)}
\]

and the aggregated measures

\[
\text{coverage(response), recall(response), precision(response)}.
\]

The aggregated measures can’t be used directly to modify request space or object space, since the aggregation functions applied are not bijective. Our goal, therefore, has to be to directly exploit the vectors representing the request space, the vectors representing the object space and the vectors representing the responses to obtain change vectors. Using the non-aggregated measures we can obtain change vectors by separating discriminating indexes from non-discriminating ones. The frequency of both then is used to change the respective vectors in the respective spaces.
6 Bookmark Repository: Storage and Retrieval of Bookmarks

In this section we discuss a typical application of the DISRAWIGR techniques. The bookmark domain is selected as this is considered an attractive example from the individual users point of view. In the following we assume to have available structured bookmark lists as provided by today's web browsers or editors, i.e. we have a tree over a set of (composed) terms, each denoting a category, a phrase or just a basic term. The leaves of the tree are bookmarks, denoted by its name or identification, location, author, links to related bookmarks, description, list inclusion date and bookmark visitation date. In case we get access to a relevant number of bookmark lists one might want to integrate them in a common framework in order to exploit the knowledge represented in that set of bookmark list. As we consider it impossible to create the one and the only bookmark list we aggregate the bookmark list provided by different bookmark list managers into one bookmark repository by taking the terms used in the bookmark trees to index the individual bookmarks and insert those indexed bookmarks into an bookmark information storage and retrieval agent.

We can pose requests against the bookmark repository by using the terms used in the aggregated bookmark lists or just by using the terms to be found in the individual bookmark lists. From use of terms in the individual bookmarks we might generate weights for the terms in the aggregated bookmark repository, which can be viewed as a set of bookmarks, where each term appearing in the description of a particular bookmark gets a dedicated weight. A bookmark requester might use the aggregated set of terms or only those terms used in a particular bookmark list to query the repository.

There are several benefits for the owner of a bookmark list to be involved in the bookmark repository. The first is to be able to reflect a personalized bookmark list with respect to an aggregated set of qualified bookmarks provided by the repository. The most attractive return might be that the bookmark lists of each participating bookmark list manager is to be enhanced by bookmarks obtained by the aggregation. This will allow to update the bookmark list upon request, in defined intervals or continuously.

The bookmark updating service works as follows. Conducting a match of bookmarks of a bookmark list with the set of bookmarks in the repository by our vecfieldvecfieldmatch procedure one gets the set of relevant bookmarks by picking those with match with respect to a defined threshold, which is in our case an element of $[0,1]$. The bookmark repository provides means to aggregate arbitrary tree-structured bookmark list into the vector model for bookmark storage and retrieval. In employs the frequency of terms to weight the terms used to describe the bookmarks. In this respect the repository in a way filters individual bookmarks into a coherent network of bookmarks. The aggregated views are used to update the bookmark list at the individual bookmark authors site.

7 Conclusions

DISRAWIGR provides a model for distributing the storage and retrieval functionalities across internet clients and servers by introducing the agent concept. An agent in this context is much more than a sequential or parallel procedure or a distributed object system. The agents are communicating across internet sites, thus making it unnecessary to load the internet with all the sites to be transferred to and back to search engines or data bases. In this concept the actually required information is transferred at the end of the process. During the retrieval process

8 References and Further Readings

Selected Literature on Information Retrieval Fundamentals

1. Introduction

The aim of the study was to develop a WWW based course feedback system that covers all the about 800 courses at Tampere University of Technology (TUT) serving both university students and teachers. The basis for the new web system was an existing UNIX based program which is daily used by the students.

2. Development of the system

The new feedback system includes generation and analysis of course feedback pages, giving course feedback and summary of course feedback. Course feedback pages include different questions; general questions (the same for all courses), free feedback, and teacher's questions, which the teacher can choose from the question list or make his own questions. The teacher needs a password for this function. Teachers can also study the given feedback of their own courses and analyze the gathered information. In the second part students give feedback for selected courses. The third part (summary of course feedback) is meant for common use. All willing persons can study the summary of all course feedback of different departments. Information about course feedback from all students is automatically collected. The system consists of 1034 files (46 Perl files and 988 html files).

3. Testing of the system

In the first step, the feedback system was tested by the programmers. In November 1997, all institutes were delivered their own userIDs, passwords and instructions for the system. After that the interested institutes could test the system. Teachers have created customized feedback pages to about 20% of courses. Generally the system has been working well. The system has not collapsed even once. Students have given feedback since December 1997. No special publicity campaign in which students would have been encouraged to use the system has been carried out. The old Unix based program is still used at the university, and the new system is used besides it. The feedback in the system was asked by e-mail. By the end of May 1998, the administrators of the system have received 23 comments about the system by e-mail.

The comments gave many new ideas. The benefit of the system is that everybody can easily use the WWW system, and the answers are anonymous. The feedback system also helps to improve the quality of education. The drawback of the system is that the same user can give feedback more than once for the same course because currently the system is open to everybody. In the further development after the testing it may be necessary to move the system to Intranet and use some encouragement methods for students.

4. Conclusion

In this project a new course feedback system in the Internet has been developed and tested successfully. The study shows that it is possible to create this type of a web system using Perl. Based on the testing results there is some need to improve the system. Students can somehow be encouraged to give feedback about the courses. Then the number of answers will increase and the statistical reliability of the system improves. So far the experiences from the system are so good that the use and development of the system will be continued.

Abstract
A recent master's level course pushed the envelope on using instructional Internet technologies. This course utilized several in-person sessions (both on- and off-campus), extensive use of e-mail, and a dedicated web site. The majority of classes were held over the Internet using CU-SeeMe client and server software. Certain experiences (e.g., installing and configuring new software, training students to use the software, and back-up methods of instruction) were anticipated, while others had to be dealt with on the fly (e.g., incompatible hardware, Internet propagation delays, and synchronizing audio and video). Instructors contemplating this mode of content delivery need to be aware of the benefits and the costs, especially in terms of time for instructor and student training, multiple modality and error-alternative preparation, and practice.

Background
The Department of Educational Administration and Foundations, a graduate-level unit of the College of Education at Illinois State University, has as one of its primary missions the preparation of educational leaders in public schools. Accomplishing this mission often requires teaching courses off campus. One off-campus cohort draws students from a school district located in the town of Wheeling, Illinois, approximately three and one-half hours drive from campus. The distance from campus made weekly travel impractical. Intensive, multi-day weekend sessions were examined although some courses do not adapt well to this delivery format. Dedicated-line compressed video is a popular alternative, except that the district did not have the facilities for a remote site connection. Neither were facilities available for delivery via satellite. Asynchronous Internet-based (web) instruction has been used in other subject areas, although there was some concern about teaching a master's level, research and statistics class solely asynchronously. Compressed two-way audio and video over the Internet had been used experimentally, but never as a primary means of delivering instruction. Could this new technology be used for primary instruction for this off-campus group?

By mid-summer of 1997 the necessary software (Cu-SeeMe version 3 and Reflector version 2.1) were purchased and installed at both the University and on three computers at the school district. The Instructor's computer was a Dell XPS/H266, and Pentium-II class computer with a 266Mhz processor, 64Mb of memory, a 21" monitor with 4Mb of video RAM, and a high-speed token rink connection to the Internet running under Windows 95. A Panasonic Egg-Cam was used to capture the live video and audio, while a sound card built into the computer provided audio to the stereo speakers. The reflector software as run on a Dell XPS/H233 machine, a Pentium-II class computer with a 233Mhz processor, 64 Mhz of memory, a standard monitor with 2Mb of video RAM, and a high-speed token ring connection running Windows NT version 4. Three computers were purchased for the district—all were Hewllett-Packard Vectra machines; however, these machines proved incompatible with the then-available Panasonic Egg-Cam and had to be replaced with functional clone computers. These machines were Pentium 133Mhz computers with 32Mb of RAM and 15" SVGA monitors, each having an audio board, speakers, and Panasonic Egg-Cam.

The first task facing the instructor was the setup, installation, and testing of the various hardware and software components. Different transmit and receive bandwidths, audio and video codecs, and connections strategies were
experimented with over the course of almost two months of trials. During the same time the instructor was reformatting courseware for this new model of delivery. To facilitate the evaluation of this course the instructor kept a daily diary, recording his observations and experiences. Students were encouraged to e-mail the instructor detailing their impressions, as were the technical staff assisting with the project. These written records, along with the materials developed for and used in the course, were examined as the record of the course activities.

Results

The class began in mid-August of 1997 with two days of on-campus orientation sessions. During this time students were introduced to the technology of CU-SeeMe, along with a review of basic computer operations and WWW/e-mail over the Internet. Students also received the first six hours of content instruction in the research and statistics course. Three weeks later the first class over the Internet using CU-SeeMe was held. Technical problems with the Hewlett-Packard computers prevented the students from utilizing all three computers, with the result that all of students had to crowd around a single screen. A projection system was hastily put together, although the degree of class interaction initially suffered since the instructor was unable to see or hear all of the students in the class. When the HP machines were later replaced with other, compatible computers this problem went away, and later sessions were able to utilize all three student computers (with three to four students sharing a computer) running simultaneously.

Start-up problems continued to abound, however. Early sessions were plagued with difficulties in transmitting audio, and many times the back-up system of a speaker telephone (and long-distance call) had to fill in for the non-transmitting audio (even though this put the audio badly out of sync with the video). While several computers could be placed in one room to receive and send video, out-of-sync audio necessitated that only one machine be used for sending or receiving audio. During one class the server crashed, resulting in a 15 minute break while the server was rebooted and the reflector software reinitialized. Another session had to be canceled entirely when an MCI telephone switching node, located between the campus and school district, was experiencing difficulties and holding packets in excess of 400 milliseconds. [NOTE: while this might not sound like a long time it dramatically degraded the audio and video transmissions to the point where neither was intelligible.] One session was ended early when the Whiteboard application, which had been running perfectly for almost two hours, crashed right before the final example was to be completed.

By the end of the fourth month operations were running relatively smoothly. Reliable connections could be established between the university and the school district, and audio and video were configured to allow reasonable communications under almost every network circumstance. Although minor software glitches continued to occasionally crash programs (or disconnect computers from the conference) the instructor and students had learned to take these problems in stride, rebooting the computer and/or application or reconnecting the computer with only minimal downtime. The simultaneous chat window proved to be quite useful, with students able to ask questions of the instructor without interrupting the flow of a lecture or discussion. To manage the instructor had to learn to respond (by typing or in voice) to these queries while continuing with a simultaneous audio and video presentation! It was observed that chat was used as frequently for content related needs (e.g., “what was the web address again”, or “could you give us an example of what you just said”) as for non-content related needs (e.g., “the audio is too low”, or “I will miss class next week”).

Conclusions

1. Both instructors and students need a lot of time to become familiar and comfortable with the technology – hardware and software – used in this kind of distance education. The initial orientation session was critical, although we found that additional time still needed to be spent throughout the course to refresh and expand knowledge.

2. Instructors need to plan for the unexpected, and have alternative and backup methods for delivering course content in the event of a failure of the primary method. The speakerphone provided an instant link between the university and the district, critical at the start of each session and when technical glitches severed the connection. Having additional session dates and times written into the syllabus, as well as alternative modes of information presentation (whether over a web site or in person) provided flexibility not normally found in the typical college class.
3. Instructors need to create multiple and repetitive modes of content delivery. We discovered, for example, that CU-SeeMe was not an appropriate vehicle for delivering videotaped presentations. While the program could handle this type of input it would often fail to keep audio and video synchronized. Rather than deliver videos using CU-SeeMe it was decided to encode the videos for streaming presentation from the web site. Real Media's video encoder and plug-ins for Netscape and Internet Explorer provided a more reliable means of video presentation to the remote class. Likewise, content shown on the Whiteboard was mirrored (using PowerPoint shows) on the web site, providing students a secondary means of viewing this content and protecting against unexpected program or system failure during class.

4. Finally, the current state of this technology requires that potential instructors and students be relatively technically savvy as well as highly fault tolerant. The emergent nature of these new technologies, together with the unpredictability of the Internet (and, in some cases, the unexpected failure of software components) will require a need for the instructor to be able to think and act relatively quickly. Although not yet mature enough, in our opinion, to be relied upon as the sole means of distance education instruction, Internet-based audio and video conferencing can fill a developing niche for off-campus student needs.
An Integrated Methodology for Designing Web Applications

Abstract: This paper describes a system for the design and implementation of distributed Web applications. A distributed framework to access and update databases based on the Java serialization and Java beans frameworks is explained. Java Beans are used to compose light weight applets that interact with such a database. The objective was to have a truly flexible way of implementing distributed database or knowledge base systems, making maximal use of automatic code generation and component technology.

The broad outline of the system is as follows:
- A CAD tool is used to design a domain model, with constraints and queries.
- The tool's output is used to generate (a) a (relational) database and (b) Java classes implementing the model.
- A generic client and server can communicate the objects across the network using the built-in Java serialization mechanism.
- An extendible Java beans framework is used to compose client applications to query, insert and update objects.

1. Introduction

The appearance of the Web, and more recently of Java applets and JDBC have made it a lot easier to develop distributed information systems. The problem with using JDBC to access remote databases through the web is however that it tends to create two-tier client-server systems. The main problem of the two-tier approach is that the client application code is riddled with references to fields and tables of the database, making the code difficult to maintain and debug, especially when the database is modified later. The result usually is that, when the database is changed, all client applications have to be completely re-written.

A better, but more complicated method is to use a three- or multi-tiered architecture. In a three-tiered application, the client communicates with the server not in terms of SQL, but in terms of the objects and classes. This usually leads to a system that is a lot easier to evolve, because any incompatibilities in the client applications are detected by the compiler.

The problem is that developing a three-tiered application requires a lot of expertise and effort from the developer. This is because the different technologies used: a relational database, a programming language and a network protocol like web forms do not integrate well.

We have tried to create a system than encapsulates most of the complexities of three-tier application development, and in which a single object oriented paradigm is used for all of the layers.

In the remainder of this paper, we describe the model and system which we have used to implement distributed database applications. This includes:
- an object model known as EROOS;
- mapping rules to automatically map the EROOS schema to a (relational) database implementation;
- coding rules to automatically map the EROOS schema to Java classes and interfaces;
- a generic server that instantiates objects from the database and stores new and modified objects;

2. The EROOS Object Model

Figure 1 shows an example of an EROOS schema [Steegmans 95]. Notable difference with other object models are:
1. Relationships are modeled by separate relationship classes, or by relationships embedded in a class.
2. Attributes are of a simple atomic domain. Lists have to be modeled by a separate class.
3. Attributes and relationships can be immutable. Mutability is indicated with a curly line. E.g. a person's name or birth date can not change, his salary can.
4. Relationship classes (indicated with a small circle in the center) can relate to at most two other classes.

These limitations are mainly meant to limit the number of ways in which a particular situation can be modeled. Generic object models usually allow many equivalent models for a given domain, which is why many people find object modeling difficult.

We use EROOS to define a domain model that excludes any transactions or user interface specifics.

![Figure 1: EROOS model of the company database](image)

3. Mapping Objects to a Relational Database

To implement the schema on a relational database, we have to devise a mapping of object classes to tables. To do this a few decisions have to be made. We need to (1) implement object identity (2) map names of classes and attributes, (3) map inheritance relationships and (4) enforce the implicit constraints of the model.

3.1. Object identity

The fact that traditional relational theory does not recognize object identity is a major obstacle to a more object oriented perspective to database design. This deficiency illustrates the data-driven nature of relational database design. One might suggest to use a key attribute as an object identifier, but this will not do for the following reasons:

- Some entities or classes may not have unique attributes, but the objects do have an identity (e.g. dependents in Figure 1). Normal practice is to include a copy of the key of a related entity and use a composite key. This introduces more maintenance problems, as the keys must be kept consistent.
- Keys with a business meaning introduce inflexibility, because over time, business meanings change. Keys with business meaning create dependencies in other tables or classes.
- Attributes usually can change value, but the identity of an object may never change.
So the object identity should be implemented by an artificial field with unique values, generated by the database. Because database administrators do not like artificial keys, we must be careful when deciding on naming and values of these artificial keys, and be consistent. It is best to use a key that is globally unique, but from which the object's class can be derived.

3.2. Naming

We use simple rules to map class names and attribute names to table names and field names that avoid problems such as name collision and reserved words.

- Each model or subsystem has its own name, and this name is prefixed to all class names to form table and view names.
- An attribute's name is prefixed with the name of the class declaring it to form a field name.
- Relationships are given the name of the relationship alias if there is one, or the name of the class referred to, prefixed with the name of the class defining the relationship.

Using a strict naming scheme will make it possible for developers to automatically map attributes to fields, and moreover, it allows automatic code generation for interaction with the database.

We also distinguish between a physical and logical storage at the database level. Logically some classes are represented by views that join a number of subclasses. Physically only non-abstract classes are stored in tables.

3.3. Class Hierarchies

A class can be mapped to a relational table, with a field for each attribute of the class. For inherited attributes there are two possible solutions, generally referred to as horizontal and vertical mapping.

a) Vertical mapping means that the declared attributes and the inherited attributes are stored in separate tables. Each class is mapped to a table containing only the attributes declared in that class. A great advantage of this approach is that a change to a class only means changing one table. Another advantage is that existence dependency constraints can readily be implemented as foreign keys in the database, even for relationships that refer to an abstract class. A serious disadvantage is that it becomes difficult to insert and update objects manually through SQL.

b) In horizontal mapping both the declared and inherited attributes are stored in one table. This means that an object is stored in exactly one table, so insertion and retrieval can be done relatively quickly. We don't need a table for an abstract class, but a view that joins the specializing class tables or views. A disadvantage is that if one class changes, all the tables for its specializing classes have to be changed, which would lead to inflexibility. As our objective is to automatically generate the table definitions and code from a formal schema description, this disadvantage largely disappears. Therefore, and because this mapping generates tables that are easy to manipulate manually, we choose to use this mapping.

We do however need a safe solution for existence dependency of abstract classes. To provide this, we will create a table for each abstract class that will contain only the identifiers of the objects of the derived classes. It is updated by insert and delete triggers on the derived class tables. Integrity is maintained by assigning the foreign key constraint to that table.

3.4. Enforcing Constraints

The first and foremost constraint to enforce is the uniqueness of identifiers. This can be done by requiring that identifiers are unique within each table and requiring that the identifiers within the class map to the actual class.

The immutability of attributes and identifiers can be enforced by disallowing updates of the identifier field in update triggers. Alternatively the update privilege can only be granted to a view that contains only the mutable attributes. Existence dependency constraints are implemented by referential constraints. This means that when an object that is reference by other objects is deleted, either an exception is raised, or the referring objects are deleted also.

It is very important to make sure that as many as possible implicit and explicit constraints are enforced by the underlying database itself, because otherwise inconsistency will sooner or later begin to creep in. For many
manipulations it will be convenient to use SQL scripts instead of using some other programming language. This is where thinking or programming errors will create inconsistent data. If constraints are enforced by the database itself, these errors will not easily go by unnoticed.
4. Generation of Java Domain Classes

Instead of writing client applications using a database protocol like ODBC or a proprietary database protocol, we will write them in terms of classes generated from our domain model. This is very important for reasons of flexibility:

- Client application writers need not concern themselves with the technical details of the database mapping or database protocol. The client applications are effectively independent of the mapping and protocol.
- Subsequent changes in the model and database are easily located in the domain model classes, and adapting the client application is straightforward. The compiler will detect most of the inconsistencies.
- Multimedia data types such as images can be mapped to the database independently of the client application.

In principle any object oriented programming language can be used, but as it turns out, Java is particularly suited for the described approach.

4.1. Interfaces

For each class in our model we generate an interface with the same generalization/specialization hierarchy of the model. For each attribute a selector method is declared, and for each mutable attribute a mutator method is declared. For relationships a method is declared that simply returns the related object. For inverse relationships at the many-side, a method is declared that returns an enumeration of related objects.

4.2. Domains

The domain names used in the EROOS schema are mapped to a RDBMS domain and a Java domain. The database access layer must have a method to convert the Java domain to the RDBMS and vice versa. If our database access layer has a method getImage() to get an image from a database field, we can use image as an attribute in our Java domain classes.

4.3. Classes

For each domain interface we generate a Java class that implements it. Delegation is used to implement multiple inheritance.

- Each class only has private data members. All access has to go through the selector and mutator methods.
- Object identifiers are implemented by a class representing the identifier. The only public constructor will create a new identifier. The serialization engine creates the existing identifiers from the database and makes sure that within the same run-time environment no two identity objects exist that represent the same object.
- Relationships are represented by the identity of the related object. Inverse relationships (many side) are represented by a list of identity objects. These lists are kept up to date by the constructors and destructors of the related objects.
- It is also the responsibility of the Identity class to retrieve the remote object from the database and cache a reference to it. We have used a so called soft-reference implementation (Java runtime class ‘sun.misc.Ref’) for this, which allows caching constrained by the garbage collector.
- Each class has a public constructor that takes the immutable attributes to create a new object. There is also a package protected constructor that also takes an identity object parameter. This constructor is called within other constructors when a member for delegation is created.
- Relationships are passed to the constructor by passing the related object. The constructor then has to call a method in the related object to update the inverse relationship.

4.3.1. Queries and Constraints

Certain queries and constraints expressed in the model are implemented in the Java code level. Queries that return a list of objects that can be expressed as a SQL query are implemented by a Java method returning an enumeration of objects.
Constraints that can be expressed in Java can be implemented as selector methods that are checked in constructors and mutators. If a constraint is broken, either an exception is thrown, or a designated event is called to recover.

4.3.2. Functionality

It is essential that the generated code is never modified, because these modifications may hinder the evolution of the system later. Therefore, when specific functionality is to be added that could not be generated from the model, it should be implemented in a class that extends the domain model class. The serialization layer can be configured to use the derived class instead of the original class. It is even possible to let the client application do this configuration at run-time, so that different clients can use different versions of classes with different functionality. This also allows the implementation of what has been called 'application facades' [Fowler 97], classes that further encapsulate the behavior of the underlying domain model classes for the benefit of specific applications.

There is one instance in which it may be useful to modify the generated class, and that is to remove unneeded reverse relationships. Computing the inverse relationships from the database can be relatively expensive. The serialization layer is implemented so that it will not attempt to reconstruct inverse relationships if they are not declared in the Java class.

5. Java Beans Framework

Java Beans [Sun 97] are a promising new technology for visual programming environments for Java. A Java Bean is a Java class that is implemented according to a specific pattern regarding:

- The naming and signature of selector and mutator member functions.
- The use of a specific event model to communicate with other Java bean objects.

A Java beans enabled programming environment allows a programmer to drag Java bean objects onto a canvas, and manipulate them without programming. Event paths are drawn from one bean to another, allowing the beans to interact. An interesting and important feature of Java beans programming is that is allows that programmer to design a program while it is running.

A Java bean is highly reusable component. It is written once and used in many applications. Java's object serialization [Sun 96] and introspection make Java beans frameworks more flexible and simpler to implement.

5.1. Basic Beans

Basic generic beans are display/edit fields containing a number, text, a date or a time value. A date can be represented by text, or by a visual representation of a calendar or clock. A number can be displayed as text, or by a dial or slider. We intend to include Beans that allow formatted (HTML) text and images to be displayed and edited. Other media type handlers such as (streamed) audio and video, speech etc. will be included as new media API's become available for Java.

These basic objects represent one member field of a domain model object. The view objects use Java introspection to access the proper methods to get and set the target field, so they can be written independently of the domain model classes.

Other beans are used to display a list of objects that are retrieved from an inverse relationship or a query.

5.2. Bean Dialogs

A number of basic beans are assembled on a bean panel. A bean panel can be used in four different ways:

- To display a domain object.
- To edit one or more of an objects' fields, or delete the object altogether.
- To create a new object.
- To select an object from a list.

Note that in our object model, the creation of a reference between object is encapsulated within the constructor of a relationship class, so all possible interactions are combinations of these four.
6. Web Access

We have also created a Web Servlet that can be used in conjunction with a World Wide Web server to visualize objects in HTML pages. To do this, the XML-Data [XML Data] specification is used to convert Java objects to an XML file. This XML file contains part of the object graph in a computer readable form. This XML file is then converted to HTML (or another human-readable form) either by the client or the server using a style sheet mechanism. The style sheet used is determined by the client (e.g. by the language) allowing some user-specific formatting of the information.

This allows us to implement large well-structured information webs that are easier to maintain [Hendrikx 97][Elen 95].

This approach is similar to other approaches using databases and e.g. SQL to generate and maintain web pages [NewSome 97] [Houben 97][Microsoft 96]. We do however believe that our current approach allows better integration with applet technology.

7. Conclusion and Future Work

We have developed a design method supported by automatic generation of a relational database definition and Java client application code that can be used to create client-server information systems with no or little programming. The information is served either by dynamic generation of HTML pages, or by Java applets graphically composed using a number of generic Java Beans.

We are currently developing a generic XML viewer that uses the Java Activation Framework [Sun 97] to register Java beans that perform operations on data elements at different levels of granularity. This will allow a user to view and edit any XML file regardless of its data type.

We are also working on an object oriented persistence layer on top the relational database that will allow faster access, while still having the benefit of ad-hoc querying and data independence.

Specification of Distributed Multimedia Applications in the MUSE Environment: QoS and Adaptation Issues

Ana Carolina Hermann
Luciano Paschoal Gaspary
Janilce B. Almeida
Federal University of Rio Grande do Sul - Informatics Institute P.O. Box 15064 - ZIP 91501-970 - Porto Alegre, RS, Brazil, E-mail: {hermann, paschoal, janilce}@inf.ufrgs.br

Abstract: An important element of network support for distributed multimedia applications is the supplying of quality of service. In this paper we present the definition of quality of service at user and application levels in MUSE (interactive networked Multimdia applications Specification Environment). The behavior of the application during execution is also described, as well as a strategy that allows the adaptation of the application to adverse situations in the network.

1. Introduction

Quality of Service (QoS) is an important aspect of the support for multimedia applications; however, the diversity of these applications difficults the establishment of a QoS standard. Besides, adaptation methods need to be defined to handle quality variations. This paper presents the definition of QoS and adaptation in the MUSE specification environment.

The user usually does not have conditions to specify low level parameters, like bandwidth, or even characteristics of the media objects, such as an audio sampling rate. Therefore, the system must offer an abstraction level so that users can define what they consider acceptable. Besides, the properties of a media object are not enough to define its quality. The purpose of the application is also important, or more specifically, the context in which the media object is inserted. For example, any noise, like that of an airplane landing, can be considered excellent even if it has been recorded in conditions that would be bad for speech.

The quality level may change for several reasons, even in networks that supply QoS, like ATM or Internet with reservation protocols (RSVP, etc.). Problems may happen in a node, deallocating the resources that an application had been using, and they may not be available in a new route or may not be reserved due to a matter of priority [Gecsei 1997]. In an environment like the Internet, however, one cannot even obtain QoS guarantees from the network, nor that the end systems have the same capacities. This leads to the creation of adaptive applications. Multimedia applications are particularly appropriated for adaptation, since media objects can be presented in several ways, adjusting factors like delay and throughput. A video, for example, can have its frame presentation rate, resolution or number of colors decreased without the quality loss exceeding acceptable limits.

2. The MUSE Environment

In the MUSE environment (Figure 1), the author defines the way media objects should be presented in terms of order, synchronization, position and quality, creating a specification that is later interpreted and presented to the end user [Gaspary 1998]. The user cannot define the quality with which each media object should be shown, since he does not know the presentation's content. The author, however, knows which information is more important and therefore should have a higher quality. Thus, the end user may take advantage of the QoS suggested by the author.

In order to avoid the author's need to work constantly with a series of parameters, the program works with QoS levels, going from Very Good to Bad depending on the perceived quality loss. For instance, an audio recorded at 44 kHz with 16 bits of sample and two channels is considered very good. This information is kept on mapping tables, which the author can customize. It is possible to create templates, allowing to specification of the most appropriate QoS for the author's purposes.
The author can also specify alternative media objects that will be used if the main ones cannot be presented. For example, a video can be substituted by an image or by another video, recorded with lower quality. These secondary media objects offer an alternative when the network does not have enough resources (e.g., slow connection), and also when the end system lacks a device necessary to present the primary media object (e.g., absence of a sound card). At run-time, it is verified if there are enough resources for the presentation, based on the media objects' characteristics and on the network's condition. The aforementioned audio would require 172 kb/s of bandwidth, for instance.

Figure 1: Interface of the authoring environment

3. Conclusions

The MUSE environment allows the author of the application to specify the presentation quality of each media object. The media object's content properties are used for the automatic calculation of presentation parameters. Because the specification of QoS is done in a flexible way, each user's preferences are taken into consideration and applications aimed to several purposes can be created. The author can define alternative media objects that are used when the main ones cannot be presented. This allows the application to adapt itself to environments with different capabilities and to fluctuations in the QoS level.

Tests are being performed in order to verify if the users can specify their applications properly and obtain the desired results during the presentation. Future works include studies of environments like ATM, and consequent changes in the module that guarantees QoS during the execution of the multimedia application.

Abstract: This paper compares the integration of technology into two university curricula at the same institution over a three-year period. By year three in both fields, undergraduate students were 100% technologically literate. However there were differences at the graduate level in Economics and Education. Generally computer literacy at this level was effected by ready access to a personal computer either in the workplace or at home.

1. Introduction and Background

This paper compares the integration of technology into two university curricula at the same institution over a three-year period. Both instructors teach undergraduate and graduate students in a public university serving commuter students from approximately a 50-mile radius. The authors believed that technology could support many of the cooperative learning activities used in their classes and was a significant way to minimize some of the problems associated with students finding time and more effective of ways working together. Also we understood that cooperative learning would allow those students who were more proficient in the use of technology to instruct their less technologically proficient peers.

2. Findings and Conclusion

Having access to online computers has been and continues to be a significant factor in determining the effectiveness of our efforts. Initially we found that campus computer laboratories were crucial in our work with undergraduate students who generally spent more time on campus than did our graduate students who as part-time students only came to campus for evening classes. Undergraduate Economics students were initially more familiar with computers than Education students. Because of this in the first two years a decreasing amount of class time was spent in the Education classes introducing students to computers. This included actual instruction in the use of email and the WWW in order to utilize course WebPages to complete assignments. However by year three such instruction was no longer necessary as all undergraduate students had the technological competency to effectively utilize course materials, which in some cases were totally online. We attribute this development to student exposure to email and the WWW in earlier classes and required courses for computer literacy in both Economics and Education. By year three in both fields, our undergraduate students came to our classes 100% technologically literate.

However at the graduate level we continue to find a very different and problematic picture. The graduate class in Economics is required for students in the MBA program. These students are generally employed full-time in area businesses. As a result, over all three years most of these students used personal computers in the workplace. They used email and had at least some experience with the WWW. These students responded well to having all course materials and assignments totally available online. Since there were frequently occasions when they would be out-of-town on business, such access allowed them to continue and even participate through the use of technology.
Our biggest concern is the continuing lack of technological literacy among graduate Education students. The majority of students enrolled in Education master's degree programs are full-time teachers whose undergraduate degrees predate any technological literacy requirements. They are a distinctly bi-polar group who can be distinguished by whether they have a home computer or not since for the most part few, if any, have convenient access to computers in their schools. Those with home computers generally have WWW access and regularly use email. Instruction still needed for these students is very specifically focused on accessing educational research materials via the web.

The other larger group of graduate Education students are those with no home computers. These are practicing teachers who, for the most part, have never owned a home computer, have never seen an email, or know what the WWW looks like. Despite all course materials being available electronically, some of these students prefer to walk to the library and pay to photocopy materials rather than learn to access them electronically. We have recommend technological literacy requirements for all of our graduate Education programs in order to begin to remedy this situation. This is a serious concern for school districts as well since we are finding that about 2/3rds of our graduate Education majors fall into this category. This is the majority of the people in the field in our geographic area. We would highly recommend that the computers in school computer labs be distributed to any interested teachers over summer vacations in order to give them the time to become familiar with computers. Teachers need to overcome some of the technological fears we see in order for them to be willing to make, which for them is a significant investment, the purchase of their first home computers. Only then will we begin to see the full integration of technology in the public school curriculum.

Abstract: The World Wide Web is in constant renovation, with new technologies emerging every day. Most of these technologies are still incipient, and there are few de facto standards for this "new Web". There is a need for tools that can run with current standard support, but which are flexible and extensible enough to be eventually ported to new APIs and to incorporate new technologies. On the other hand, many Web developers cannot keep pace with the fast track of Web technologies. Therefore, it is important for new tools to be simple enough to be mastered quickly by the average programmer. This paper presents CGILua, a Web development tool that matches these requirements. The paper also discusses why this tool is being adopted in many commercial and academic projects, focusing on issues such as flexibility, extensibility, simplicity, and portability.

1. Introduction

The World Wide Web has gone through a big change from its initial goal. The electronic publication of static documents, read-only and file-based is being replaced by a more complex environment, where dynamic and interactive pages are produced by components of a distributed system. In this setting, some of its adopted technologies cannot satisfy the new requirements, driving the search for many alternative technologies.

Unfortunately, embracing any new technology at this time may be premature, since there are no de facto standards for this "new Web". It is well recognized that the Web standards are key factors in its success [Hadj. 97]. Currently, many new proposals are tied to a specific vendor or operating system, compromising the openness that allowed the Web to grow explosively. Another problem is the lack of robustness, since many of the technologies are quite new, and they often have incompatibilities with different versions of hardware, operating systems, HTTP servers and browsers [Hadj 97][Everitt 96][Duan 96].

Finally, as noticed by [Everitt 96] and [Lazar 96], Web applications are frequently written by casual programmers, following a rapid prototyping approach. To tie new technologies to the knowledge of complex languages such as Perl, C++ or even Java may put a heavy load on these programmers.

Considering all these aspects, three points emerge as requirements for a Web site development tool:
1. Suitability to work based on common Web standards (like CGI [CGI 96]), being portable to different platforms and servers.
2. Openness to incorporate new technologies, in a gradual way.
3. Flexibility to accommodate different uses, from the "quick and dirty" approach of casual programmers, to an object-oriented structured approach of a skilled team.

CGILua is a Web development tool based on CGI and the extension language Lua ([Ieru. 96] [Figueiredo 96]). Although based on an "old" technology (CGI scripts), it differs from other tools by its set of features:
- a flexible and simple scripting language (Lua);
- the ability to mix different paradigms (templates and programming);
- and an extensibility mechanism to dynamically load libraries written both in Lua and in C/C++. 
This set of characteristics makes CGILua unusually portable, flexible, and extensible, while being simple to use.

2. The Extension Language Lua

Lua is a general purpose extension language that arose from our group's need to use a single extension language to customize industrial applications [Ieru. 96][Figueiredo 96]. Currently, Lua is being used in more than a hundred products and prototypes, in many academic institutions and companies. The whole package is written in ANSI C, and compiles without modifications in all platforms that have an ANSI C compiler (DOS, Windows 3.1-95-NT, Next, Solaris, Mac, Linux, OS/2, etc).

Lua integrates in its design data-description facilities, reflexive facilities, and familiar imperative constructs. On the “traditional” side, Lua is a procedural language with a Pascal-like syntax, usual control structures (whiles, ifs, etc.), function definitions with parameters and local variables, and the like. On the less traditional side, Lua provides functions as first order values, and dynamically created associative arrays (called tables in Lua) as a single, unifying data-structuring mechanism.

There is no notion of a “main” program in Lua; being an embedded language, it only works embedded in a host client. Lua is provided as a library of C functions to be linked to host applications. The host can invoke functions in the library to execute a piece of code in Lua, write and read Lua variables, and register C functions to be called by Lua code. Moreover, fallbacks can be specified to be called whenever Lua does not know how to proceed. In this way, Lua can be augmented to cope with rather different domains, thus creating customized programming languages sharing a single syntactical framework [Beckman 91].

Functions in Lua are first class values. A function definition creates a value of type function, and assigns this value to a global variable. Like any other value, function values can be stored in variables, passed as arguments to other functions, or returned as results. This feature greatly simplifies the implementation of object-oriented facilities. A more complete treatment of Lua's object oriented facilities may be found in [Ieru. 96].

Lua is dynamically typed. Variables can handle values of any type. Whenever an operation is performed, it checks the correctness of its argument types. Besides the basic types number (floats) and string, and the type function, Lua provides three other data types: nil, with a single value, also called nil, whose main property is to be different from any other value; userdata, that is provided to allow arbitrary host data (typically C pointers) to be stored in Lua variables; and table.

The type table implements associative arrays, that is, arrays that can be indexed not only by integers, but by strings, reals, tables, and function values. Associative arrays are a powerful language construct; many algorithms are simplified to the point of triviality because the required data structures and algorithms for searching them are implicitly provided by the language [Bentley 88]. Most typical data containers, like ordinary arrays, sets, bags, and symbol tables, can be directly implemented by tables. Tables can also implement records by simply using field names as indices. Lua supports this representation by providing a .name as syntactic sugar for a["name"].

Unlike other languages that implement associative arrays, such as AWK [Aho 88], Tcl [Ousterhout 94], and Perl [Wall 96], tables in Lua are not bound to a variable name; instead, they are dynamically created objects that can be manipulated much like pointers in conventional languages. The disadvantage of this choice is that a table must be explicitly created before used. The advantage is that tables can freely refer to other tables, and therefore have expressive power to model recursive data types, and to create generic graph structures, possibly with cycles.

3. CGILua overview

The simplest form of a CGILua script is as a Lua program; when the page is accessed, the program is ran and its output is interpreted as the final HTML page sent to the browser. The majority of CGI scripts are written this way, as with Perl [Stein 97], Tcl [Libes 96], C [Weber 96], Python [Vanaken 97] etc. In CGILua, these programs are written in Lua.

The main advantage of writing a script as a program is its flexibility. The full power of the language is available in the creation of a page. This includes all abstraction facilities of a programming language, plus pre-defined functions for pattern-matching and the like. Also, some programmers find it convenient because they can still use a conventional programming style. Nevertheless, this approach is quite difficult for non-programmers, and even for programmers it is not very effective, since it operates in a very low abstraction level.
An alternative, and more interesting, way to write CGILua scripts is to use an HTML template of the document to be generated. When the page is accessed, the template feeds a pre-processor that creates the final page. These templates use special marks to indicate fields to be handled by the preprocessor. CGILua supports three kinds of fields: statement fields, expression fields, and control fields. Statement fields contain Lua statements to be executed by the preprocessor; they generate no implicit output, although they can explicitly write anything to the final page. Such fields are written between the marks `<!--$` and `$--->`. Expression fields contain Lua expressions, which are evaluated by the preprocessor, with the result used as the final text of the field. Such fields are written between the marks `$!` and `!$`. Finally, control fields indicate parts of the document to be repeated or conditionally inserted.

It is interesting to notice that all marks have been carefully chosen so that a template has a sensible appearance in a browser even when it is not preprocessed. Statement and control marks, which do not generate any implicit output, are handled as comments by HTML syntax, while expression marks appear literally in the browser, acting as a place-holder. In this way, a template can be edited as a regular static HTML page. The main advantage of this approach is that it allows the use of conventional HTML editors, such as Microsoft's Front Page, for building the template, requiring no programming knowledge.

Traditionally, templates are used for more declarative, static uses, while programming is used when there is a need for control structures and dynamic descriptions. CGILua allows a reverse in this conventional use: A template can be used as a kind of subroutine, while Lua is used as the declarative language. [Fig. 1] and [Fig. 2] illustrate this style.

```html
<html>
<head><title>Example Form</title></head>
<body>
<form method="POST" action="validate.lua"
!--$ LOOP start="i=1", test="field[i]", action="i=i+1" $-->
  $|field[i].label|$
  <input type="text"
    name="$|field[i].name|$
    value="$|cgi(field[i].name)|$"><br>
<!--$$ ENDLOOP $$-->
<input type=submit>
</form>
<font color="#0000FF">$|error_message|</font>
</body></html>

Figure 1: File form.html

field = {
  { name="project", label="Project" },
  { name="year", label="Base year" },
  { name="code", label="Project code" }
}

cgilua.preprocess("form.html")

Figure 2: File form.lua

Function cgilua.preprocess provides a degree of reflexivity: It allows a Lua script to process a template explicitly, as if the user had accessed that template. Notice that the file form.html describes how to show a generic form. The abstract specification of the form, on the other hand, is given in script form.lua, in the format of a table (field). The same table (field), which gives the abstract specification of the form, can be used to drive the creation of other pages.

Notice how CGILua can improve the management of Web sites even when used for static pages, since the use of parametric pages allows a developer to work in a higher abstraction level. For instance, the same template shown in [Fig. 1] can be used to create many different forms, when fed with different values for table field.

4. CGILua Architecture

Like many programs that use a scripting language, CGILua has two main modules: a kernel, written in C, and a configuration script, written in Lua. The kernel is the program called by the HTTP server when a user...
accesses a CGILua page. It creates a Lua environment, defines some new functions to Lua and then runs the configuration script. The configuration itself is almost 70% of all CGILua code. It decodes the data in the query (using Lua's built-in facilities for text handling), redefines some Lua functions to provide a secure environment where the user script will run, locates the user script and then runs it. Since all these steps are done by a script, they can easily be adapted to local needs by the system administrator. In addition, a site may have several configuration scripts, allowing differentiated environments for different projects. For instance, personal user pages may have a stronger security policy than the one enforced on institutional pages.

4.1 Portability

The tool's portability is ensured by the standards upon which it is based: Lua is fully implemented in ANSI C, which makes it portable for every platform that has a C compiler. The CGILua kernel is implemented following the POSIX standard and uses CGI as the interface with the HTTP server, since this is the only current standard for interfacing servers with external programs. These features allow the use of CGILua in different platforms without modifications, with the same source code. Currently, CGILua is being used with different servers in MS-Windows 95 and NT, and most popular Unix flavors, such as SunOS, Solaris, Linux, IRIX and AIX.

Despite its name, CGILua does not depend on the CGI standard. It has been developed in a way such that the interface with the server is totally done by the kernel. This architecture allows the porting of CGILua to other APIs, for example Microsoft's ISAPI or Apache API, improving the script's performance.

Since CGILua scripts communicate with the server only through the kernel, they are independent of the kernel's interface with the server. This allows the use of the same scripts, even with different kernels. At the time of writing, only a CGI kernel is available, with an ISAPI kernel under development.

4.2 Extensibility

Both the configuration script and the user script file can run other Lua files. In this way, Lua libraries can be loaded before or during the execution of the user scripts, offering new facilities. Sometimes, however, such extensions must be written in C, either for efficiency reasons (like a cryptography package), or because a pre-defined C interface (like a database) is accessed.

Again, the solution adopted by CGILua has the same general pattern: The kernel implements a generic mechanism for dynamic library loading, and the configuration script specifies which and how each package will be loaded. After this step, the script erases these loading facilities, thereby restricting the use of any unauthorized extension.

For instance, Lua itself offers no database facilities. Its standard libraries offer only access to files in conformance to the ANSI C facilities. DBLua is a Lua library that interfaces Lua with a standard database API, called DBGraf [Mediano 96], which offers access to different database systems, like mini-SQL and ODBC. This library is dynamically loaded by the configuration script, thereby offering all database facilities of CGILua.

In another example of its extensibility, CGILua is also being used in a network management system based upon SMNP. Again, a C package has been built to offer SMNP facilities to Lua, allowing a CGI application to get and set SMNP variables. In this way, different management applications can be built over the Web by writing simple CGILua scripts.

Another package that can be used with CGILua is LuaOrb [Jerum 98], a binding between Lua and CORBA that allows a Lua script to manipulate CORBA objects in the same way as it manipulates local objects. LuaOrb is based on the CORBA Dynamic Invocation Interface, mapping its dynamic character to the dynamic type system of Lua.

These feature brings another level of utilization to CGILua, allowing different instances of the tool for different domains. Upon this perspective, CGILua is not only a tool for the creation of Web sites, but also a supporting tool for fully distributed applications.
4.3 Security Issues

A CGI script has the same security problems of any network server [Garfinkel 96], since it is invoked by remote requests; from this point of view, any CGI script can be considered a mini-server. Since CGILua activates user's Lua scripts, all security concerns must be extended to these scripts.

Lua is a language with secure semantics. There are no language constructions with undefined behavior. Lua programs are translated into byte-codes, which are then interpreted in a protected environment. There are no instructions to do real memory access or to call arbitrary C functions; the stack is fully controlled. Besides pure resource consumption, the only way a Lua program interacts with the external environment is through function calls. Therefore, in the realm of a Lua program, security issues can be focused on how to control the use of insecure functions.

In Lua, functions are first class values; Lua programs can freely create, redefine or erase functions at runtime. Therefore, a simple solution for a secure environment would be for the configuration script to erase all "dangerous" functions before calling the user script. This solution is clearly too simplistic, since most of these functions can be used in restricted ways without security risk. For instance, a generic open function, which allows a script to write to any file, may be dangerous, but it can be restricted to open files in a pre-defined directory tree.

The solution adopted by CGILua has two parts. The kernel introduces a single generic facility that allows a Lua script to erase a global function while keeping a private access to it. With these facilities, the configuration script redefines the "dangerous" functions to more secure versions. Notice that the original functions are still accessible by the configuration script, and are used in the implementation of the restricted versions. With this solution, the whole Lua environment is configured in Lua itself, with the usual benefit: Flexibility. System administrators can change the configuration script to adapt the protected environment to their specific needs.

5. Final Remarks

Unlike many other Web tools, CGILua follows the same "minimalistic" principle adopted by Lua: Instead of providing a myriad of mechanisms for specific purposes, they provide a few generic meta-mechanisms to address general issues. In this way, they can handle rather diverse application domains, such as database query applications, document formatting, and Web gateways.

At a glance, the main features of CGILua are:

flexibility: The use of an extension language in the architecture of CGILua (and not only for writing user scripts) makes the tool highly flexible. Many characteristics, from error handling to security policies, can be easily tailored by the system administrator. The use of a scripting language greatly facilitates rapid prototyping, an important methodology for Web applications [Everitt 96]. Moreover, there are no fixed roles for what is written in Lua and what is written in HTML templates.

extensibility: Applications can load libraries written both in Lua and in C. Lua libraries allow the extension of internal CGILua facilities and C libraries allow the construction of Web gateways, as illustrated by the SMNP example.

simplicity: The whole system has less than ten thousand lines of code (~1500 lines for CGILua plus ~8000 for Lua). All its sources and binaries can be put on a single floppy disk. Its use is also simple. Most users are able to start using CGILua in less than half an hour. Lua is a small language, with a simple Pascal-like syntax and a simple semantics.

portability: CGILua runs on Windows NT, Windows 95, Linux, IRIX, Sun-OS, Solaris, AIX, HP-UX, FreeBSD, Unixware, SCO, OSF, and other platforms with essentially the same source code. Applications are fully portable: Any script written in one platform runs without changes in any other platform.

Despite its inherent academic nature, CGILua has also achieved industrial relevance, being employed in many commercial web systems, such as the dynamic pages of the Brazilian site of Xerox (in its system for choosing products and services). Another major example of industrial use is SIGMA (Sistema de Gestão do Meio Ambiente). SIGMA is a WWW system being developed for PETROBRAS (the state-owned Brazilian Oil company). Its function is to manage the procedure of obtaining environmental licenses and to inform users about rules and technical procedures. The system is part of a strategy to obtain the ISO 14000 certificate. Around one hundred people use SIGMA as a work tool on a daily basis. Moreover, parts of the system will be available to the general public. The system generates and collects information by an active communication with a database. DBLua is used to provide the connection through ODBC to an SQL Server database. A group of six people has been developing the system, having produced, to this date, around ten thousand lines of HTML templates and
Lua code. Approximately 85% of the system is built dynamically by CGILua templates, 5% are programs in Lua and the remaining 10% are static HTML pages. The large disproportion between HTML templates and Lua programs mirrors the emphasis given to the visual design: HTML components are intensively employed to fulfill layout constraints and requirements.

This work was developed at TeCGraf/PUC-Rio (Group of Technology on Computer Graphics at the Catholic University of Rio de Janeiro), and it has been partially supported by CNPq (The Brazilian Research Council).
Abstract: VRoom is a 3D-visualization system which transforms the structure and navigation of existing WWW documents into three dimensional spatial representations. It takes as input the URL of any existing HTML page, and explores outward, converting individual web pages and entire websites to a Virtual Reality Markup Language (VRML) based representation. The generated representations of the internet's structure, logical and functional relations, content and metacontent, can then be examined and interacted with in three dimensional space.

Introduction

Despite recent advances in VRML language standards and software, VRML and 3D information navigation is not widely used. Creating a large VRML web site is both difficult and expensive, while creating a HTML based web site can be done with a common text editor. The creation of a HTML to VRML translator would allow the public to make use of the advantages of VRML and three-dimensional visualization without learning a new language or sophisticated 3D modeler, increasing VRML's mass market appeal.

VRoom, a prototype HTML to VRML converter, is designed to be intuitive and easy to use. The end user is not expected to have any knowledge of VRML syntax or of three dimensional content creation. VRoom is designed to be used by anyone who would like to visualize the content of a web page or site using a variety of three-dimensional spatial metaphors.

Background and Related Work

The World Wide Web has become an environment that we interact with daily, yet navigating the web continues to be through a 2D magazine-like interface [1]. There is very little work being made on simultaneously visualizing structure, interconnectiveness, content, and meta-content of a site. Hollywood, through popular culture, represents the future of the Internet as being a fully 3D, immerse, interactive, animated, and exciting experience. Movies like Johnny Mnemonic, Disclosure, and The Lawnmower Man represent what the mass market has come to expect the future of the Internet and data navigation to be. Science fiction literature, such as Neuromancer and Snow Crash, push the concept of a completely immerse world of data driven visual representations. VRoom automates the creation of a prototype of that experience from existing data, visualizing the content and structure of the World Wide Web.

There are many systems that represent existing data in a three dimensional environment. Judith Donald's "Visual Who" demonstrated both the simplicity and potential of intuitive three-dimensional interfaces to existing data [2]. "Web Ciao" is one of several data-representation systems, abstracting content from the web and redisplaying the information in a condensed and useful form [3]. Projects such as "Stretch" demonstrated clearly that with the proper level of detail controls, vast amounts of structural information could be represented simultaneously without overloading the user interface [4]. There currently exists data specific VRML representation tools, such as representing web usage logs in a VRML graph, but none have been generalized yet.

The VRoom System

VRoom is designed to be completely intuitive. Through a web submission form, VRoom is passed the URL of a page and several optional parameters. All that is required by the end user is a target URL and a VRML capable web browser.

VRoom Sequence of Operations
VRoom uses standard VRML navigation techniques including walk, rotate, and zoom to object navigation. There are also several preset camera perspectives that the user can jump between. VRML 2.0 specifications will allow for much richer interactive content: nodes that react to a user's proximity, three-dimensional sound, and collapsing node trees are all in the process of being implemented in VRoom.

Representation Techniques

VRoom uses two methods of visualizing the structure of a web page or site. "Tree" mode, in which a site is explored using a breadth-first search, returns a cone-tree like structure of interconnected nodes, each page of HTML represented as a single node. Meta-information about each page and the site as a whole is abstracted and presented with the tree. In "Immersive" mode, each page of HTML is represented as a hallway. The hallways are connected by doors, while images and textual headings are presented in compressed form within each room. Having entered the Immersive corridor, the user can travel from page to page indefinitely.

The goal was to provide the user enough information for navigation without overloading the visual display. Titles of HTML pages are used, while images smaller than an arbitrary cutoff are ignored. The choice of what information to display, as well as what detail to go into, can be overridden by the user. VRoom is not meant to provide more than an overview, or a sense, of the content of a page or site, allowing for fluid navigation until the user reaches the desired information and returns to traditional viewing methods.

The media type of the node is represented by geometric shapes. Brightness represents how current the given data is, causing older inactive sections of the web to appear faded while recently updated sections stand out. The texture of visual media nodes, such as images or movies, are mapped with a compressed thumbnail, either from a preexisting source or generated on the fly.

In the tree representation, the branching structure represents the interconnection of different pages. The width of the branches linking the nodes represent the relative dominance of a link, using the font characteristics or area of a web page that a link would normally cover. Errors, such as missing or broken links, are highlighted. Outdated sections of the web would appear as dark, broken areas, where new sections would be brighter with less broken links, allowing a user to "cruise" the more recent information. At any point the user can jump back to regular hyperlinked navigation by clicking on a "HTML Cube."

System Implementation

The tree representation is generated through a depth-first search of a web site using a web crawling CGI script. Once the sites are tagged and their interconnectiveness determined, the CGI script returns to each page and gathers metadata. The architecture of the "Immersive" single room is based on the number of links leading out of the room. The size of the room expands accordingly. All links are positioned in front of the user in a semicircle of hallways leading out of the room.

VRoom's CGI is written entirely in Perl. The target pages are fetched into a CGI script using the lib-www extensions to Perl, then parsed using regular expression matching. The resulting extracted information is analyzed, and then returned in VRML format. For textures and images, the VRML is linked to a second "thumbnail" generating script, which loads the image or other media from the web page, and returns to the user a compressed version of the media. The result is a highly compressed version of one page or an entire site, downloading extremely fast over a variety of bandwidth speeds.
Currently, VRoom is a proof-of-concept that creating a VRML immersive user experience from preexisting online hyperlinked information is possible. Much work remains until it is ready for mass-market use, however, it is a useful tool for exploring currently existing web pages in a variety of representations.

The Blake Digital Text Project

Prof. Nelson Hilton
Department of English, University of Georgia, USA
nhilton@english.uga.edu

1. Blake Warp

On-line since February of 1996, the Blake Digital Text Project (www.english.uga.edu/wblake) offers the text of *The Complete Poetry and Prose of William Blake*, an on-line dynamic concordance to that text, and a continually expanding hypertext edition of the Romantic poet and artist's *Songs of Innocence and of Experience*, which he first published in 1794. As a quintessential multimedia author living through a time of revolutionary expectation and transformation, Blake offers an exemplary pertinence to current developments in the world-wide WebNet.

First of all—to the extent that a search of over 1,500 authors in the Chadwyck-Healey Literary Database can signify—it is appropriate to note for this conference that Blake's combined use of the words “web” (30 times) and “net” (21 times) prophetically exceeds that of any other major English poet, indeed, any other altogether with the exception of that later text technologist, William Morris. (Among other romantics, Wordsworth, for instance, uses “web” 4 times and “net” 8; Shelley, 6 and 10.) For Blake, a “net” or “web” is one of the signature productions of his embodiment of abstract reason, an unhappy giant form named “Urizen” who criss-crosses our horizons while a “cold shadow” follows him, “like a spiders web, moist, cold & dim”—this results at length in “a Web” which binds everything and is at the same time “twisted like to the human brain” and seen also as “The Net of Religion” (*The Book of Urizen*, 1794). The positive associations of “Web” stem from from the “fabrication” and “textile” production of weaving associated with the work of Blake’s figures for imagination, “Los[s]” and “Enitharmon” who on looms with global warp and woof “Joy’d in the many weaving threads ... / Weaving the Web of life for Jerusalem. the Web of life” (*Jerusalem*, 1821). Blake’s use of these words is deeply marked by his training and daily labor at engraving, the technology, so to speak, of making form and adding dimensionality by casting a net or web of lines onto a single plane.

2. Hyper Blake

Blake’s anticipation of hypertextuality appears in his various experiments in bookmaking. His best-known work for instance, *Songs of Innocence and of Experience*, which he wrote, illustrated, etched, printed, and published, exists in two dozen copies whose 54 poems and designs are ordered in widely varying sequences. Indeed, some poems which first appeared in the 1789 *Songs of Innocence* move to *Songs of Experience* upon its publication five years later and then return back to *Innocence* in still later versions. The different sequences with their radically different juxtapositions can create very different readings. Before the advent of hypertext, appreciation of *Songs* was hampered by the usual decision of editors to follow a particular order which Blake happened to adopt late in his life for the last six copies. The limitation of this practice is evident when one figures that this order represents less than fifteen percent of the total number of copies. Even printed editions which supply information on alternative sequences do so in a cryptic fashion too time-consuming for most readers to decode.

The *Songs* hypertext obviates this difficulty by making the various links from a particular poem dramatically visible and instantly accessible. Links to detailed bibliographies and and to annotations and interpretation for each stanza are readily available. This electronic edition also makes possible the incorporation of audio into our experience of *Songs*, a capability appropriate for the work of an artist who composed his own melodies and whose work has frequently been set to music. From a pedagogical point of view, the musical interpretations are desirable for the power to make obvious almost instantly the reality of different yet convincing “interpretations” and that reading itself is as much a matter of such effective performance as the determination of some final truth.
A second large concern of the Blake Digital Text Project is to make available the text of Blake's writing in a scholarly and comprehensive fashion. To this end the Project was inestimably fortunate to obtain the permission of David V. Erdman, as the copyright holder, to use his standard, complete edition. This text has now been digitized and proofread several times and is freely available at the site. As an electronically archived text, the edition is available for significant enhancement in the form of SGML-TEI markup (now underway) and the inclusion of useful collateral texts. An important part of Blake's writing, for instance, includes his vigorous and provocative annotation of other texts; while the Erdman edition attempts to include enough context to situate each particular comment, the excerpts are perforce limited and local. The intention of the Project is to provide full text and collateral material for the relevant works so that the reader can branch from an annotation to the entire context. Obviously context ramifies infinitely, and material relevant to Blake's life and surroundings are a future goal of the Project.

The availability of Blake's text in electronic form enables the third major concern of the site, an on-line searchable concordance. The one previous concordance to Blake reproduces computer-generated output of more than thirty years ago, an age when big iron communicated in monospaced capital letters. That effort lists only words and not all words at that, as it omits those which occur very frequently and supplies only the whole line in which the word occurs, regardless of the word's position in the line. The Project's Perl-CGI scripts offer greatly enhanced search capabilities, including search for strings as well as words, wildcards, optional case sensitivity, link to surrounding context, alignment of search results in the central field, and Boolean searching. The digitizing of the Erdman text made possible its rearrangement so that concordance results are returned in a roughly chronological sequence.

For an artist who argues that his "Every word and every letter is studied and put into its fit place" (Jerusalem pl. 3), the ability to cross-reference instantly his entire oeuvre can open new insights. We begin to see, what is known already of oral-formulaic poetry like Homer's, that verbal artists think not just in words, but with them through their associated links. For Blake, who etched his own words, we will have in time the ability to cross-reference his various material renderings or calligraphy of particular words, to explore ways in which he toys even with single letters to play with signification.

As we move into the age of information and new concepts and practices of education it will entail, the idea of some self-reinforcing and self-regulating canon of Literary Masterpieces proves its own downfall as the time demanded for the return evidenced is generally perceived by the student to be disproportionate (i.e. "a waste of time"). Highest value goes now to those works that offer the most information and, more importantly, the most information (as practice) about using information, in the most accessible manner. Paradoxically, as previously normative literary acculturation disappears from much undergraduate experience, the prospective student's vision of the capacities needed for strong reading can be in itself so intimidating as to reinforce a defensive devaluing of literature. But Blake, in part owing to his contestation of previously normative literary culture, can engender value with compelling ease ("I am happy to find a Great majority of Fellow Mortals who can Eludicate My Visions & Particularly they have been Elucidated by Children" letter, Aug. 23, 1799).

Blake offers an exemplary text for the "creative reading" which Emerson urges (in "The American Scholar") and which we might encourage in our students. For aside from its curatorial function, the art and practice of what Emerson termed "creative reading" is what literature in the age of digital text has best to offer and what students must need or, at least, what teachers of those students need most. In the age of information, Matthew Arnold's canonical principle of "the best that has been known and thought" yields to a more pressing drive for high heuristic value, for cognitive development, for practical experience with semiotic potential or, in Blake's words, "what rouzes the faculties to act." So we might agree with Northrop Frye's argument of half a century ago that in understanding how to read Blake we understand "how to read the Bible, Milton, Ovid, and the Prose Edda" not just because, as for Frye, Blake offers a "beginner's guide to the understanding of an archetypal vision of which it forms a part," but because Blake's work offers an "archetypal" experience of the making of meaning, an experience all the more intense in the contemporary multimedia environment toward which that work points. He is our first great hypertextualist.
COLLABORATIVE LEARNING IN ASYNCHRONOUS LEARNING NETWORKS: BUILDING LEARNING COMMUNITIES

Starr Roxanne Hiltz
Distinguished Professor of Computer and Information Science
New Jersey Institute of Technology
Newark, NJ 07102
Email: roxanne@vc.njit.edu
Homepage: http://eies.njit.edu/~hiltz/

ABSTRACT: One of the potential negative effects of online courses is a loss of social relationships and of the sense of community that is usually present on a traditional campus. Evidence is presented that collaborative learning strategies, which require relatively small classes or groups actively mentored by an instructor, are necessary in order for Web-based courses to be as effective as traditional classroom courses.

1. INTRODUCTION

The use of the Internet to deliver “anytime, anywhere” education is frequently referred to by the name “asynchronous learning networks” (ALN). There are two possible models for the use of ALNs. One model is the “mass market:" emulate the previous, primarily “one way” distance learning delivery modes of sending material to students, receiving back individual assignments or test materials, and providing some means of limited one-to-one communication between the student and the instructor. Web pages might replace video for lectures, and email might replace surface mail for student-teacher correspondence, but it is basically the same pedagogical model. This does have the advantage to educational institutions that education can be very “cheap;” hundreds or even thousands of students can be accommodated in a single course. Inexpensive adjuncts can be hired to do the grading and communication.

A very different model is to use the technology to try to create the kind of learning community that can arise in a good graduate seminar. Typically this is where the students learn with and from one another, collaboratively, and the faculty member structures the topics, provides expertise, and works closely with students preparing their projects for presentation to the group. In this model, the faculty member is directly and actively involved in facilitating collaboration and group interaction among the learners, on a daily basis. There are limits to the number of students who can be successfully accommodated in such a “learning network” [Harasim, et. al. 1994] format. Though the numbers are approximately double the 10 to 15 that face to face seminars can easily include without making it difficult for everybody to participate actively in all the sessions, they nevertheless make the “learning network” or “learning community” a relatively expensive educational delivery choice. The question is: is it worth it? Is online collaborative learning really superior to using the web for students to individually interact with educational materials? How do both compare to traditional classrooms of various types (the small seminar style classroom, and the mass lecture hall)?

Our evidence on these matters is limited, but this paper will briefly describe some studies that have been conducted which provide some data to answer these questions.
First, however, it will review the nature of collaborative learning vs. other models, and some of the issues raised by Web-mediated education.

2. THE END OF COMMUNITY?

The issues raised here are not just of "academic" concern; they have been increasingly raised in the mass media, and have become issues of general public concern. Consider, for instance, the rather sensational headlines used to describe the release of some preliminary findings from a study of Internet users in Pittsburgh. "Researchers find sad, lonely world in Cyberspace (The New York Times, see figure 1) and "Study: Internet Causes Depression" (The Washington Post- see http://search.washingtonpost.com/wp-srv/WAPO/19980831/ V000514-083198-idx.html ) certainly would make a prospective faculty member or student pause before signing up for an online course.

The issues raised in the Carnegie Mellon study of Pittsburgh Internet users are serious ones, but the sensationalism is troubling. As my colleague, John Sener of Virginia noted in an online commentary, "I think the creator of this headline should be sent to the blackboard and made to write 100 times: 'Correlation does not necessarily imply causation.' ... More importantly, statistical significance has been confused with substantive significance. Since when does a decrease from 66 people to 63 people in one's active "social circle" constitute a "sad lonely world?"

Computer-mediated communication can be the basis for people with shared interests to form and sustain relationships and communities [Hiltz and Wellman 1997]. Compared to communities "offline," computer-supported communities tend to be larger, more dispersed in space and time, more densely knit, and have members with more heterogeneous social characteristics but with more homogeneous attitudes. Despite earlier fears to the contrary, online communities can provide emotional support and sociability as well as information and instrumental aid. However, for this to occur takes both the right software to support group communication (a topic beyond the scope of this paper), but also an emphasis upon collaborative learning approaches rather than individual learning.

Exhibit 1: Excerpts from a Recent News Story

Researchers Find Sad, Lonely World in Cyberspace  By Amy Harmon

In the first concentrated study of the social and psychological effects of Internet use at home, researchers (including Robert Kraut) at Carnegie Mellon University have found that people who spend even a few hours a week online experience higher levels of depression and loneliness than they would have if they used the computer network less frequently... the new study... raises troubling questions about the nature of "virtual" communication and the disembodied relationships that are often formed in the vacuum of Cyberspace... Participants in the study reported a decline in interaction with family members and a reduction in their circles of friends that directly corresponded to the amount of time they spent online...

In measuring depression, the responses were plotted on a scale of 0 to 3, with 0 being the least depressed and 3 being the most depressed. Loneliness was plotted on a scale of 1 to 5... By the end of the study, the researchers found that one hour a week on the Internet led, on average, to an increase of .03, or 1 percent, on the depression scale, a loss
of 2.7 members of the subject's social circle, which averaged 66 people, and an increase of .02, or four-tenths of 1 percent, on the loneliness scale.

The subjects exhibited wide variations in all three measured effects, and while the net effects were not large, they were statistically significant in demonstrating deterioration of social and psychological life, Kraut said. "Our hypothesis is there are more cases where you're building shallow relationships, leading to an overall decline in feeling of connection to other people," Kraut said.

The study tracked the behavior of 169 participants in the Pittsburgh area who were selected from four schools and community groups. Because the study participants were not randomly selected, it is unclear how the findings apply to the general population. It is also conceivable that some unmeasured factor caused simultaneous increases in use of the Internet and decline in normal levels of social involvement. Moreover, the effect of Internet use varied depending on an individual's life patterns and type of use...

3. WHAT IS COLLABORATIVE LEARNING?

Passive approaches to learning assume that students "learn" by receiving and assimilating knowledge individually, independent from others [Bouton and Garth 1983]. In contrast, active approaches present learning as a social process that takes place through communication with others [Mead 1934]. The learner actively constructs knowledge by formulating ideas into words, and these ideas are built upon through reactions and responses of others [Bouton and Garth 1983; Alavi 1994]. In other words, learning is not only active but also interactive.

In particular, collaborative or group learning refers to instructional methods that encourage students to work together on academic tasks. Collaborative learning is fundamentally different from the traditional "direct-transfer" or "one-way knowledge transmission" model in which the instructor is the only source of knowledge or skills [Harasim 1990].

In collaborative learning, instruction is learner-centered rather than teacher-centered and knowledge is viewed as a social construct, facilitated by peer interaction, evaluation and cooperation. Therefore, the role of the teacher changes from transferring knowledge to students (the "sage on the stage") to being a facilitator in the students' construction of their own knowledge (the "guide on the side"). Some examples of collaborative learning activities are seminar-style presentations and discussions, debates, group projects, simulation and role-playing exercises, and collaborative composition of essays, exam questions, stories or research plans [Hiltz and Turoff 1993]. This new conception of learning shifts away the focus from the teacher-student interaction to the role of peer relationships in educational success [Johnson 1981].

3. THE IMPORTANCE OF COLLABORATIVE LEARNING IN AN ALN ENVIRONMENT

There is no question that ALN's have disadvantages as well as advantages in comparison with traditional classrooms. The major advantage is convenience ("anytime/anywhere"), which in turn facilitates students being able to have more total interaction each week with the teacher and with peers, and being able to learn at the pace
and the times best suited to their individual needs. The major shortcomings are (1) limited bandwidth or "media richness" [Daft & Lengel 1986] and (2) the frustration of waiting an unpredictable amount of time to receive any reaction or feedback. The weaknesses of ALN as a mode of communication is the decrease of the feeling of "social presence" of the teacher and the other group members. In turn, this can severely decrease feelings of motivation and involvement, and thus negatively affect the learning outcomes. However, an emphasis on collaborative learning can emphasize the advantages and overcome some of the disadvantages of asynchronous computer-mediated communication.

Several studies have shown that collaborative learning strategies result in more student involvement with the course [Hiltz 1994], and more engagement in the learning process [Harasim 1990]. Collaborative learning methods are more effective than traditional methods in promoting student learning and achievement [Johnson 1981], and enhance student satisfaction with the learning and classroom experience. The next few pages briefly summarize some recent studies that provide evidence that collaborative learning is very important to the success of ALNs in creating positive outcomes for students.

3.1. Field Trials on the "Virtual Classroom®" at NJIT

In an ongoing project at NJIT spanning more than a decade, data have been collected not only on all students in sections using its ALN system, the Virtual Classroom® (VC), plus web pages and videotapes or CD ROM's for lecture type material, but also in sections of the same course taught by the same instructor or set of instructors, using roughly the same syllabus, in three other modes: traditional face-to-face, "traditional" distance mode of all video, and a combination of face-to-face and VC. The results for the post course questionnaire for a recent three year phase of the project (over 600 responses from students who used the system) and grade data for all three years will be summarized here. In the post-course questionnaire, students were requested to compare their experiences in their course which used VC, to that in other college courses delivered face-to-face. Generally, the results of these subjective evaluations were positive. For example:

- Over half of the students in the VC + video experimental sections felt that having this option available enabled them to complete more courses that semester than would have otherwise been possible (and thus make faster progress toward their degree).
- Subjectively, the majority of students feel that the VC improved the convenience of course access (73%), access to their professors (65%) , and the quality of learning (58%).
- Correlation statistics support the theoretical premise that active participation online by both faculty and students, and the use of group or collaborative learning strategies in ALN, are positively related to desirable outcomes.

A multi-item scale was constructed to measure perceived degree of collaborative learning, which correlated significantly (p=<.001) with scales measuring overall course outcomes (R=.31, N= 749) , and overall rating of the virtual classroom experience (R=.30; N= 632).

Outcomes as measured by grades in the courses show no significant differences between modes. Only two courses showed significant differences, one in each direction. Course grades are only weakly correlated with most variables measured, except for overall grade point average (R²=.21, N= 1531, p = <.001).
Though the degree of perceived collaborative learning in the course correlates significantly with perceived outcomes, as noted above, “correlation is not causation.” Being online is confounded with collaborative learning. In addition, all of the courses supposedly used collaborative learning approaches (though this was implemented better and more consistently in some courses than in others). We need a more experimental approach to test whether collaborative learning is a key mechanism in making ALN's effective, and the extent to which collaborative learning groups can be as effective as face-to-face collaborative learning groups.

3.2 A Field Experiment on Collaborative Learning at NJIT

Recently completed dissertation research [Benbunan-Fich 1997] is based on a field experiment that compared groups and individuals solving ethical case scenarios, with and without computer-mediated communication support. A 2x2 factorial design crossing two modes of communication (offline with a task time of two hours vs. asynchronous computer conference with a task period of ten days; these times were established as optimal in pilot studies) and two types of teamwork (individuals working alone vs. individuals collaborating in groups) was designed to assess the separate and joint effects of medium of communication and collaborative vs. individual learning strategies. In both conditions, undergraduate students in a Computers and Society course received an ethical case scenario comprising the task one week ahead of time, and were permitted to use whatever written or other materials they wished while discussing the case. In the individual offline condition, students solved the case individually, in an in-class exercise like an open-book quiz, and received individual grades based on their own performance. In the individual online condition, students simply posted their individual responses online. In the group offline condition, team members discussed and solved the case by interacting face-to-face and prepared their report. In the group online condition, team members interacted asynchronously using a computer conference as the only means of communication, and submitted a group report.

Assignment of the 136 subjects to experimental conditions was done as close to randomly as possible some students were truly “distance” students and could not be assigned to come to campus. Students randomly assigned to a group condition were then randomly assigned to a specific group. Perceived learning was measured immediately after the experiment in the post-test questionnaire, using a seven item scale adapted from Hiltz (1994; Chronbach’s alpha = .92). Quality of the analysis produced was rated by three expert judges on a number of dimensions, including the extent to which the correct legal principles were identified and applied to the scenario. “Actual” learning was measured in the final exam with two similar ethical scenarios, two weeks after the experiment ended.

The results indicate that working in groups, instead of alone, significantly increases motivation, perception of skill development and solution satisfaction. In terms of self-reported learning [Hiltz & Benbunan-Fich 1997], there is, as hypothesized, an interaction between medium of communication and group vs. individual learning. According to the results, conditions with (or without) both factors, i.e., individuals-manual and groups online, perceived higher learning than conditions in which only one of the factors was present.

The implications for ALN are that putting individuals online to interact with course materials is not as effective as the traditional classroom, but that using collaborative learning approaches can make online learning at least as effective as the traditional classroom.

3.3. A Field Experiment at Penn State
A total of 43 graduate students participated in a recent experiment at Penn State Harrisburg conducted by Ocker and Yaverbaum [1998]. The vast majority (40) were part-time students with full-time employment (38). All students were enrolled in the core information systems class required of all MBA and MS/IS students. The authors point out that although there has been more than a decade of literature on computer-mediated communication in education, the research has been unclear as to whether it is an effective replacement for FtF collaboration.

This study sought to add to this body of research by exploring the effects of two modes of collaboration on student groups. Following a repeated-measures experimental design, each student group collaborated on two case studies, one using face-to-face collaboration and the other using asynchronous computer conferencing technology as a means of collaboration. The findings indicate that asynchronous collaboration is as effective as face-to-face collaboration in terms of learning, quality of solution, solution content, and satisfaction with the solution quality. However, students were significantly less satisfied with the asynchronous learning experience, both in terms of the group interaction process and the quality of group discussions.

4. SUMMARY AND CONCLUSION: CREATING AND SUSTAINING LEARNING COMMUNITIES

Collaborative learning designs are more effective for online learning than pedagogical approaches that emphasize individuals working alone with materials posted online. Software structures can be constructed which will support group collaboration. However, they can only facilitate the desired behavior, not produce it. For the group to adapt a structure of interaction that is collaborative in nature, the instructor must mold, model, and encourage the desired behavior, and the students must be able and willing to participate regularly.

A number of studies indicate that when collaborative learning is used in ALN delivery, “objective” results in terms of mastery of material and efficiency of education tend to be equal to or better than traditional face to face classes. However, even when collaborative learning is used, the current “state of the art” of systems plus pedagogy seems to lead to less feeling of community than is typically obtained in face to face small group interaction. The question of how to build and sustain online learning communities is thus a prime area where researchers on ALN ought to be focusing their efforts.

The most basic premise from which all online teaching should begin is that the goal is to build a learning community and to facilitate the exchange of ideas, information, and feelings among the members of the community. Every “electecture” (electronic lecture) should be designed to include questions for discussion or response among groups of students, rather than simply representing one way transmission of “knowledge.” The students, as well as the instructor, should be encouraged to raise new topics and ask questions of the class; and to respond to one another’s contributions. This kind of daily interaction does demand constant attention from the instructor, and thus is a labor-intensive mode of course delivery.

Colleges and universities ought to be concerned not with how fast they can ‘put their courses up on the Web,” but with finding out how this technology can be used to build and sustain learning communities. This does have fiscal implications: using collaborative
learning approaches requires relatively small classes or sections of courses, which need daily attention from a faculty member.

Abstract: Just as technology trends improve and we approach the next millenium, so have our abilities to perceive farther and visualize new methods of testing. With the assistance of learning technology consultants in the Technology Teaching and Learning Center (TTLC) at University of Houston-Downtown, professors have shifted their paradigms and are taking the leap to use more high-risk web technologies in their courses. One that has become an instant hallmark is delivering exams via the Internet.

1. Introduction

A new state of consciousness has taken form – the reality that learning can take place outside the confines of a classroom. This is not meant only in terms of the ever-evolving distance learning and video conferencing, but also by using web technologies as a supplement.

In one of the nation’s most diverse institutions of higher education, the University of Houston-Downtown (UHD) in Houston, Texas, students are grasping ideas and concepts through non-traditional teaching methods. For example, faculty members incorporate electronic mail, listservs, and World Wide Web home pages into their classes to provide more innovative ways of delivering instruction. Professors have the opportunity to incorporate the latest computer technologies into their courses with the assistance of learning technology consultants like us who work inside the UHD Technology Teaching and Learning Center (TTLC). The TTLC provides resources and support for the university community to explore new technologies and capitalize on their potential to improve learning. It offers a wide range of programs, tools, and activities that enhance the education and opportunities available to the diverse student body of this dynamic university. By including such learning facets, students are ready to venture into the “real world” being more confident, prepared, and capable of using technology. They are ready to surpass their competitors and end up on top.

Just as technology trends improve and we approach the next millenium, so have our abilities to perceive farther and visualize new methods of delivering instruction. With this in mind, professors at UHD have shifted their paradigms and are taking the leap to utilize more high-risk web technologies in their courses. One that is becoming an instant hallmark is delivering exams via the Internet.

2. Planning and Preparation

Throughout the 1997-98 school year at UHD, faculty members took the leap of developing online exams to be delivered via the Internet as a supplemental method of giving examinations during instructional television (ITV) courses. A great deal of planning and preparation took suit before the initial test taking, but ultimately the exams were successfully administered and conducted.
After assessment of the current software titles available in the TTLC, Asymetrix’s ToolBook II Instructor 5.01 was the software of choice.

ToolBook II Instructor is a high-end authoring tool designed for the flexible creation of content-rich online learning applications. Its wide array of tools and predefined content includes wizards, widgets, and templates. It comes with a catalog full of preprogrammed interactive objects that can be dragged and dropped into applications. The authoring tools provide for a range of distribution options that are sure to meet many users needs. Because it was necessary to deploy over the Internet, we decided to use the HTML & Java export option built into the ToolBook II authoring environment.

Using the ToolBook II “Export for Web” feature, the online exam was converted directly to an Internet-ready format (a combination of HTML and Java) for delivery on the World Wide Web. Anyone with Internet access, a web browser, and Uniform Resource Locator (URL) of the exam can take the test without having to install a plug-in.

After determining the software application to use, we (the technology consultants) then had to provide training for the faculty members. This involved familiarizing the professors with the information needed to create a ToolBook II Instructor Book (examination), which includes learning how to add:

- a title page
- duplicate pages
- text fields
- question widgets
- navigation widgets
- an exam summary page
- a scoring button

In addition, time management was very important in the development of the online examinations. Given that faculty members participate in a number of activities including teaching courses and attending conferences, we wanted to make sure they learned the skills necessary to build successful exams. As technology consultants, it is our responsibility to train the faculty specifically on a need-to-know basis. This included providing one-on-one hands-on training, detailed documentation, and constant support.

3. The Components and Risks

During the online exam development process, there were a number of unexpected factors discovered. These factors are what allowed us to learn that online testing is indeed a high-risk web technology.

3.1 Question Widgets

All of the ToolBook II Instructor 5.01 question widgets are created from ToolBook II objects. Many, particularly multiple-choice question widgets, consist of groups of objects in fours. The question widget behavior is specified using scripts. If a question widget’s default does not meet the needs of your application, you can customize it. The question widget in the Standard Widget Catalog are constructed from standard ToolBook II objects, so you can modify them easily if you are comfortable with OpenScript programming. However, the question widgets in the Internet Widget Catalog are implemented not with OpenScript, but with Java. These question widgets can not be modified in the same way the standard question widgets are modified. This proved to be a problem with high-risks involved. For instance, if a professor has a multiple-choice test with five answers rather than four, the question widgets (which are pre-programmed with four options) would need to be modified using scripting that the professor may not have time to learn.

3.2 Question Scoring

In one instance, we actually created an exam with 50 questions using a question widget with four choices. We manually duplicated one of the choices before setting the question properties for each question. So, instead of having only options a, b, c, and d, we had a, b, c, d, and e. After setting the scoring properties for each question widget and exporting the test as HTML, we were faced with the problem of answer e being scored correctly even if the correct answer was defined as a, b, c, or d in the scoring properties. This was discovered when we took the exam and selected e as the answer for each question for testing purposes. We found that a solution would be to create the test with four multiple-
choice questions. This allowed us to avoid working with any scripting and gave us time to focus on the exam development.

3.3 Java Class Files

Before the exams could run effectively, ToolBook II Java classes needed to be downloaded from the Asymetrix web site (http://www.asymetrix.com) and then installed in a designated area on the web server where the exam would be located. If an exam were accessed during a time when the necessary Java class files were not installed on the server, then the test would not function properly.

![Figure 1: Screen view of the window one must access in ToolBook II Instructor 5.01 in order to indicate the Java Class Location.](image)

3.4 Scoring the Exam

Scoring properties were setup for the examinations. This was configured in the Instructor’s Book Properties. When these settings were defined correctly, it allowed for the scores to be sent to the student. When the student entered the exam, he or she was prompted with the login window to enter the correct name and email address in order to receive the score.

![Figure 2: Screen view of the window students must fill out so they may receive their scores and so the instructor will know is taking the examination.](image)
In the Instructor Book properties, there is also an option to send a log to the professor so that he or she can find out more information, like the computer machine name from which the student took the exam. This is excellent information to have for security purposes.

![Image of Instructor Book properties with options for logging and tracking student exams.]

Figure 3: Screen view of the Scoring, Tracking window in the Instructor Book Properties.

During an actual examination we discovered that some student logs were not emailed to the professor. Though tested continuously, we were still unable to determine the reason why they were not received.

3.5 Web Browser

Before deploying the exams over the Internet, it was important to know what computer software the students enrolled in the courses had access to at their locations. The ToolBook II Instructor 5.01 requirements specify that tests should be accessed using the Netscape Navigator Gold 3.01 web browser. Through trial and error, we discovered that exams could occasionally be accessed using a lower or higher version of the Netscape browser. However, during the actual testing situation we required that students access the exams using Netscape Navigator Gold 3.01.

4. High-Risk Precautions

4.1 Security Issues

Before and during the examinations, security was an important issue. The security precautions we took included setting restrictions on the time students could access the exams and having a proctor available at distant locations during the tests to verify that the students taking the test were actually registered in the course. In addition, we set up restrictions which enforced students to provide usernames and passwords before entering the online examination web pages.

4.2 Back-up Plan

When setting up online exams it's also important for the instructor to have a back-up plan in case the technology fails. We prepared for this by instructing the students to bring scan-trons on the exam date and enter their answers on them as they selected their answers on the computer. Also, it was important to have more computers ready than students registered in the class in case one or more computers experienced technical difficulties during the examination.
5. Conclusion

By including such a high-risk web technology as online testing into courses, professors are able to evaluate the effectiveness of incorporating this type of testing in their distance learning courses and in turn recommend this use of the technology to other faculty members. In our organization, we learned that the professors as well as the university and technology department benefit in this process. By addressing and accessing the online testing issue through the development of tests created with such products as Asymetrix ToolBook II Instructor, individuals see that the worth is invaluable to the entire university from the administration to the students.

6. References

Acknowledgements

The authors wish to extend special thanks to the faculty members who took advantage of the opportunity to utilize the technology available in the University of Houston-Downtown Technology Teaching and Learning Center. Their willingness to break the barriers and build online test to deploy over the Internet helps set the standard for the technology department and the university at large. This allows for so many individuals to win, especially the students.
Toward Context-Sensitive Filtering on WWW

ISIR, Osaka Univ. JAPAN

1. Introduction
Browsing is one of the most popular ways to gather information in WWW. To support a user to browse WWW pages, modeling of the user's interests is an important issue. Although there are several promising methods to infer the interests from the user's browsing behavior, they assume that the interests are consistent during the information gathering. However, during browsing, the user's interests often shift depending on the local context of the browsing. We have proposed a method to model the user's shifting interests from the browsing history. An information filtering facility using the model of the interests has been implemented for CD-ROM encyclopedia. We call the filtering method "Context-Sensitive Filtering," CSF for short. The effectiveness of CSF for browsing in CD-ROM encyclopedia has been confirmed by an experimental evaluation by real users [Hirashima 98].

In this paper, we report a work-in-progress project to apply CSF for browsing in WWW pages. Pages in CD-ROM encyclopedia follow basic guidelines to design hypertext. Therefore, one page has one topic and the content is concise to be able to read through it briefly. Modeling of user's interests of CSF depends on the characteristics of the page. In WWW, however, pages often don't follow the guidelines, for example, one page has several topics, or the volume of the content is too much. Therefore, modification of WWW pages is necessary to use CSF effectively. In this paper, first, framework of CSF is described. Then, we report results of preliminary experiment to apply CSF to WWW pages directly. Based on the results, we propose modification methods of WWW pages following HTML specifications.

2. Outline of Context-Sensitive Filtering
Figure 1 shows an example of browsing history. Here, an ellipse is a node: letters included in the ellipse are indexes which characterize the node. BN means an already browsed node in browsing history and CN means a candidate node as the next browse node. Assuming that a user browses BN-1, BN-2 and BN-3, in order, the user will then browse the next node through Index-g. Here, there are three candidate nodes, CN-I, CN-II and CN-III, each of which includes Index-g.

We model user's interests as the pairs of an index and its weight. It is assumed that when the user visited and accepted a node, the user was interested in the indexes of the browsed node. It is also assumed that the user is more interested in an index included in more nodes and more recently browsed nodes. Based on these assumptions, each node is weighted depending on the time order. Then, the weight of an index is calculated as the sum total of the weight of nodes in which the index is included. By using the weight of the indexes, the weight of each candidate node can be calculated. In the browsing history, the three candidate nodes are ordered CN-I, -II and -III. Here, if the user browsed nodes BN-2, BN-1, and BN-3 in order, the weight of Index-b is heavier than Index-d, conversely. Then, the order of CN-I and CN-II is exchanged. Thus, this method is sensitive to user's browsing history.

![Figure 1. An example of browsing history.](image)

3. Context-Sensitive Filtering on WWW
3.1 Framework of Context-Sensitive Filtering on WWW
We have confirmed that CSF is effective for free browsing in CD-ROM encyclopedia [Hirashima 98]. In this
section, a browser for WWW pages with CSF is introduced. The browser consists of three windows: Page Window, Search Window and Selection Window. Page Window shows the content of selected page. There are two ways to select a page. The first is selection of URL, like usual WWW browser. In this case, CSF doesn't work. The second is selection with CSF. The selection procedure with CSF is as follows. First, a user can set an index as a keyword for retrieval in Search Window. Here, the index should be included in the page shown in Page Window. Then, WWW pages which share the index are retrieved. Here, the WWW pages should be already gathered in local database. This is the same way with usual search engines. CSF monitors the user's browsing history and models the user's interests continuously. Based on the model, CSF orders the retrieved results in Selection Window.

3.2 Preliminary Experiment
To implement CSF for WWW pages, there are two apparent problems: (1) gathering WWW pages, (2) indexing WWW pages. These are common issues for search engines. For the first problem, we gathered users' browsing histories by using proxy function of CERN httpd. For the second problem, the pages were analyzed by Japanese Morphological Analysis System: JUMAN (http://www.forest.dnj.ynu.ac.jp/~jun/jum_chaframe.html) and every noun was used as an index of the page.

In the preliminary experiment, two thousand five hundred WWW pages were gathered. Ten users were asked to browse the WWW pages with the browser shown in Figure 2. However, we couldn't confirm that CSF is effective. Pages in the encyclopedia follow basic guidelines to design hypertext. Therefore, each page has one topic and the volume is adequate to read through a page briefly. These characteristics are necessary to apply CSF effectively because it is assumed that when a user visited and accepted a node, the user was interested in the indexes of the browsed node. In WWW, because one page often has several topics or too much volume to read through it briefly, the assumption isn't adequate.

3.3 Modification of WWW Pages
The purpose of modification of WWW pages is to give two characteristics to the pages: (1) one page has one topic, (2) one page has adequate volume to read through briefly. To realize the modification, partitioning methods of WWW pages are described in this section. First, partitioning following HTML specifications is described. Then, partitioning by heuristics is reported. Here, although CSF uses the divided pages to models user's interests and to order search results, Page Window deal with the whole page. So, in Page Window, the part of the divided page is shown first, but the user can see other parts in the whole page in the same way as usual browser.

Because WWW pages written by HTML, every page has the structure defined by HTML specifications. By using the specifications, the content of the page can be divided into several document blocks. The Headings in the BODY elements represents hierarchical structure of HTML document. The TITLE element in the HEAD elements represents the title of the document. Following HTML specifications, Headings and the TITLE element compose a tree structure. Each Heading divides a document into several smaller document blocks. Then, the lowest Heading makes the leaf document block. This leaf document block is a divided page which is dealt with a page in CSF. The divided page is characterized not only by the content of the divided page, but also by the upper structure in the tree structure. Therefore, indexes of the divided page consists of indexes which come from the content of the page and come from the upper structure of the page.

However, WWW pages are often written not following HTML specifications. For example, font specifications sometimes used as headings. In such case, the largest font part is regarded as H1 level, and so on, is an useful heuristics. The leaf document block generated by Headings, often include too much content to read through briefly. In such case, paragraph tags can be used to divide the document block again. In order to realize CSF for WWW pages, such heuristics to divide HTML documents are important.

By using the above modification, divided pages are listed in Selection Window. As the explanation of a page in Selection Window, a summary of the hierarchical structure of the page are shown. The summary consists of the first one line of TITLE element, H1 element and so on. When a user selected a divided page, the whole page is provided to Page Window and the part beginning with the divided page are shown.

4. Conclusion Remarks
This paper described a work-in-progress project to apply CSF for browsing in WWW pages. Currently, partitioning facility by using HTML specifications are implementing. We will prepare much more heuristics to divide WWW pages, implement partitioning facility with the heuristics and evaluate CSF for WWW pages. To deal with multimedia, such as pictures, is our future work.

Abstract: The last few years have seen a growth in interest in the concept of distance-learning in the field of education and in the use of teleworking to provide a way of conducting work from home. Current predictions suggest that these could become very significant ways of learning and working in future.

The contention of this paper is that distance learning will continue its early adoption of many of the existing techniques and technologies used for teleworking. It therefore starts by describing an investigation into the working environment of teleworking, examining the currently debated issues associated with it, and laying out the potential advantages and drawbacks.

Views solicited from workers currently operating within a teleworking regime in a large UK organisation are presented. A small-scale experimental study of the psychological and sociological effects associated with teleworking is then described, and the results discussed. Finally, the implications for tele-education are considered.

1. Teleworking

The term teleworking is not one that is clearly defined, and it is often used to encompass a number of different styles of work. For example, it includes people working at home (such as programmers), people working from home (such as salespeople), and people working at workcenters (such as telecottages and satellite offices).

[Gray et al 1995] defines teleworking as 'a flexible way of working which covers a wide range of work activities, all of which entail working remotely from an employer, or from a traditional place of work, for a significant proportion of work time.' He goes on to point out that teleworking may be on either a full-time or a part-time basis, and that the work often involves electronic processing of information, and always involves using telecommunications to keep the remote employer and employee in contact with each other. Whilst this is a useful working definition, it should be noted that it excludes traditional 'outworkers' as well as those who work at home only occasionally. Other terms commonly used in place of teleworking are telecommuting, networking, remote working, flexible working, and homeworking.

Gray (op cit) classifies as full-time homeworkers those who work at home for most of the working day, visiting an office occasionally for meetings or to pick up material. Computer programmers, systems analysts, catalogue-shopping telephone order agents, and data entry clerks fit into this category. Part-time homeworkers he defines as those based in an office but spending two or three days a week working at home. At present these tend to be managers and professionals who can justify the additional expenditure on information technology equipment at home and work, but as hardware prices continue to fall dramatically it will increasingly become an option for a wider range of workers.
Mobile or location-independent teleworkers are those who spend most of their time out of the office or home, either 'on the road' or in customers' premises. Salespeople, service engineers and consultants are typical of this grouping. Throughout the world, location-independent teleworkers represent one of the most populous and well-established groups of teleworking.

Another identifiable group of teleworkers is those who work at a work center. These can vary from a rural telecenter or telecottage to a company satellite office - a small office remote from the company head office that is not self-sufficient but relies on communications with the head office. Retaining some of the ethos and work patterns of the conventional central office working, the work center may be more attractive to workers who may find it hard to adapt to full homeworking and to managers who might find difficulty with managing a set of geographically dispersed individuals. At the same time, telecenter working offers some of the benefits of homeworking.

2. Claimed Advantages and Disadvantages of Teleworking

Teleworking can bring advantages for the employer, the employee and the environment. It may also provide new job opportunities for the disabled, alleviating some of the effects of immobility.

[Reid 1993] suggests that cost savings can be achieved through teleworking by reducing the need for centrally maintained offices in expensive locations. Further, [Gray et al 1995] and [Heap 1995] find teleworkers to be more productive than office bound staff who have to travel to work and tend to suffer a higher level of stress. Teleworking is generally regarded as a 'green' activity, primarily because of the reduction in travel, the consequent fuel savings and lessening of pressure on congested city centers and overstretched public transport.

Against this, Reid (op cit) cites loss of status and professional isolation as potential dangers for workers moving into teleworking. There will need to be considerable change in management attitudes in many organizations and contractual arrangements for teleworkers will have to strike a careful balance which allows them to feel an integrated and valued member of the workforce as opposed to an inferior and exploited individual.

Worse, teleworking could be seen as a halfway house to redundancy. For many workers, the social interaction of the workplace is all-important, and were the isolation of teleworking to be enforced on these workers, they could find the job no longer worthwhile.

3. Psychological Aspects Associated with Social Isolation

For the individual, the disadvantages of becoming a teleworker are predominately psychological. In some teleworking scenarios individuals may be totally isolated from interaction with society. This may be either through their own choice as in the case of a writer or musician retreating alone to the mountains to compose, or else through necessity such as a research scientist who is required to take seismic readings for an oil company in a desolate environment such as Antarctica. In the latter case the only contact with others may be through infrequent e-mail messages detailing instructions, and it is in such situations that the effects of social isolation on the individual are likely to be at their most severe.

[Myers 1996] draws a distinction between loneliness and aloneness, pointing out that an individual can feel lonely in the middle of a crowded party, and yet not feel lonely when working alone in an office on an absorbing piece of work. It would seem vitally important for a socially isolated teleworker that they should be in regular contact with others on a social level and not just through their working environment if they are to stay mentally healthy and continue to perform their work duties efficiently. This social contact could be achieved through using modern technology such as video-conferencing, cellular telephones, fax and electronic mail, all of which should help to lessen the individual's feeling of loneliness.
Perceived loss of status can be another major problem for some individuals both inside and outside the workplace. [Messe, Kerr and Sattler 1992] note that in many everyday and laboratory situations, people assigned a superior status come to see themselves as meriting favorable treatment or as capable of superior performance. [Humphrey 1985] showed this effect in a simulated business office in which subjects were arbitrarily assigned as ‘managers’ or ‘clerks’. After the role-play exercise, ‘managers’ and ‘clerks’ alike judged the randomly created ‘managers’ to be more intelligent, assertive and displaying leadership qualities. Similar effects of assigned status on performance have been found in experiments with elementary school children [Jemmott and Gonzalez, 1989] and [Musser and Graziano 1991], and demeaning roles were found to undermine self-ability by [Myers 1996].

It would seem vitally important, therefore, that if an employer were to decide to deploy some of their employees in a teleworking environment they should ensure that they help them overcome these dangers and make a smooth transition into the teleworking environment. For example, prestigious sounding teleworker job titles could be created, and teleworking employees could receive special mentions in company bulletins or newsletters.

4. Teleworkers’ Views

In order to ascertain views of teleworkers themselves, a questionnaire was devised and sent to teleworkers working for a UK telecommunications company. The workers held a variety of job titles such as teleworking systems engineer, technical advisor, technical officer, development engineer, and teleworking technician.

Length of teleworking service was found to vary from two to eight years with an average of four years, and the number of days spent away from the office/workplace environment ranged from three to five days per week with an average of four days per week. The teleworkers themselves commented favorably on the flexibility which their style of working allowed, particularly in terms of travel between work locations, but also in terms of scheduling the work. There was relatively little response when asked to list disadvantages, and was confined to the loss of the social banter of the traditional office. The general feeling was that it could be extremely difficult to return to the more rigid traditional workplace after having experienced teleworking.

5. Teleworking Experiments

One of the major debates revolving around teleworking in the present day working climate is whether the quality of work using modern teleworking methods such as electronic mail is to the same standard as that produced using more traditional working practices [Gray et al 1995] and [Reid 1993].

To investigate this controversial issue further, two experiments were devised to allow the observation of a team of three subjects while they worked together in trying to solve a problem. For comparison, they were firstly observed working in a traditional working environment around a table, and then working in isolation from each other using only electronic mail for communication as in a typical teleworking environment.

Both experiments had a set time limit to generate a realistic level of stress as might be found in this situation in the real world. As a measure of the stress levels experienced by the subjects under the two working environments, their pulse rates were taken before and after completion of the tasks in both experiments.

In the first experiment, the three subjects were isolated in a room together with a standard survival-type problem-solving exercise - the establishing of importance ratings to fifteen items to a space crew stranded on the moon. The aim was to observe how quickly and successfully the team worked their way towards NASA’s recommended solution.
Initially, after having read the problem description, a balanced discussion involving all three participants took place. However, after six minutes of the allotted twenty had passed and the first five most important items had been identified, the discussion changed dramatically. The team began to have difficulty in deciding how the remaining items on the list were to be rated, and by the ten-minute mark, one subject had taken the role of a leader whereas another had withdrawn from the discussion.

With five minutes left, the silent member began to contribute again and a more balanced discussion ensued, with voting where necessary, through to completion of the task with thirty seconds to spare.

Although the team’s solution was not identical to NASA’s, it was very close and acceptable. Pulse rates were found to have increased by eight beats per minute for the two most active subjects, a sizeable increase, probably a reflection of the degree of heated discussion they undertook, and by four beats per minute for the less active one.

All three subjects indicated they enjoyed the task and the environment of close proximity working. The less active subject claimed he had felt overpowered by the personalities of the other two when the discussions ran into disagreement declaring ‘... they seemed oblivious to my suggestions so I decided to take a back seat role and leave them to argue it out’.

The second experiment was based around a desert survival exercise which again required identification of important items for a team stranded, this time, in the desert. It was devised to ascertain how the three subjects could work together while being isolated from each other and using only electronic mail for communication as in a typical teleworking environment. Subjects worked at networked PCs, each in a separate room so that no visual or verbal communication was possible. A slightly extended time limit of twenty-five minutes was set to allow for the poor performance of the computer network being used.

After reading the problem definition, the subjects started to exchange their initial thoughts via the email system. They soon established the key features of the problem and offered each other suggestions for the items that should rank high in the importance rating. Within eleven minutes they had correctly identified the five most important items. They then moved onto items lower down the list at which point it soon became apparent that they had strongly differing views and some considerable time (eight minutes) was spent with each justifying his own judgement. Eventually one member drew attention to the limited time left, and within the remaining six minutes agreement was finally reached on each item’s degree of importance. Apparently this process was aided by the extensive reasoning which had already taken place earlier.

Again, the team was found to have developed a good solution when compared to that of the ‘expert’. This time, pulse rates were found to have risen by only two beats per minute for two subjects and by three for the third, a result that suggests the teleworking environment was less stressful, perhaps by being less confrontational. Indeed, no leader emerged throughout this problem solving exercise, and there was generally equal participation. Indeed, the previously less active subject commented that he felt he had had a better opportunity to express his opinions using e-mail.

All three subjects again enjoyed working on the task, but two reported that after the novelty value had worn off they did not like this working environment, one of them stating that he did not like the feeling of being isolated and by himself. The third did not mind the environment but nevertheless did not feel he would wish to work for long periods of time under those conditions.

6. Analysis of Experimental Findings

As far as completing the tasks was concerned, both environments proved to be highly successful in achieving the solving of the problems. The second experiment showed that the teleworking environment facilitated an even distribution of ideas and contributions from all three subjects. Whereas in the round table working a leader
had emerged to dominate the discussion, and one member had become overwhelmed by the force of debate, in the teleworking environment the quieter subject was able to contribute on a more equal basis. This might suggest that the teleworking environment encourages broader, more democratic discussion.

The face-to-face working environment of the first experiment appeared to be more stressful for the participants, although on balance, this was the style of working that the subjects finally felt they marginally preferred.

7. Implications for Tele-Education

The educational systems across the globe are coming under increasing pressure to become more efficient and more flexible to the needs of the learners. In particular, people are increasingly requiring and seeking education or retraining beyond the traditionally assigned ages. Distance education is seen as a possible solution for many of these in that workers can receive in-time training without having to leave work to travel to an educational institution, and foreign students may study in another country without the expense of having to leave their own.

This study coupled with the experimental work suggests that certain guidelines could be proposed in order to increase the success of a transition towards a tele-education environment for students and trainees. For example, the success of an educational homeworking arrangement is largely dependent on the course tutor and the homeworker, and it is therefore important that both are enthusiastic about teleworking, aware of potential benefits and disadvantages, and clear about how the arrangement will operate.

If a tele-education arrangement is to be a success it is important that the potential student has appropriate personal qualities that allow them to work unsupervised or be supervised remotely. These include self-motivation, self-discipline, commitment to learning, adaptability, self-organization, and ability to work with little social contact.

More generally, working, reporting and communication arrangements between the student, tutors and other students will need to be established, as well as any attendance requirements on the part of the student. Ensuring that the student does not become isolated from the educational institution and other students will probably be a priority. The experimental evidence described above provides some anecdotal evidence that collaborative problem-solving, such as often found in group assignment work, can take place adequately or even more effectively using a distance technology such as email. However, occasional attendance at class meetings will go some way towards preventing isolation if this is feasible.

8. Conclusions

The driving forces that have motivated teleworking are unlikely now to be halted. Likewise the pressures on education worldwide are also unlikely to abate in the near future. Against this, the costs of telecommunications are falling, as is the cost of bandwidth hungry technologies such as video-conferencing. These factors are likely to hasten an evolutionary change in working and learning practices as a long-term consequence of the information technology revolution.

However, in both cases, rather than a sudden change, it is more likely that there will be a gradual, evolutionary change in working and learning practices as a long-term consequence of the information technology revolution. In all probability, teleworking will increasingly be absorbed into the mainstream of normal working practice and tele-education gradually phased in for appropriate groups of students. More flexible, location-independent working and study practices will emerge. It will become accepted practice for workers to spend part of their time working outside the traditional office or studying within it.

Environmental Discovery Online: A Case Study

Elenor Hodges, Educational Outreach Department, National Wildlife Federation, USA, hodges@nwf.org

The National Wildlife Federation (NWF) has developed an online strategy to provide the K-12 classroom audience environmental education resources and training. Through online programs including an in-depth web page, a monthly list-serv, an annual cyber-festival, and distance learning courses, NWF has combined its decades of experience in delivering high quality environmental education content through the more traditional means of print materials and workshops with a need to reach a broader audience and provide ongoing support for classrooms interested in integrating environmental education into their curriculum.

The goals of NWF's online educational programs are to increase environmental awareness by providing educators the skills and resources they need to complete community-based environmental activities and projects. The programs have been successful: the emphasis is on hands-on learning, the materials are free and can be accessed in many forms at any time, and the use of technology engages students.
Using Web Assignments to Foster Critical Thinking, Communication, and Problem Solving Skills

Abstract: In an attempt to enhance student responsibility for learning and increased student class participation, the two authors, from the SUNY Cobleskill Social Science Department, have developed an instructional method which utilizes constructionist learning strategies, critical thinking skills and the World Wide Web to evaluate contemporary issues and problems in their respective fields (i.e. psychology and sociology). This instructional method produces different cognitive and affective outcomes for students and increases the level of classroom discussion and student connections between the texts and the material. This presentation will demonstrate how students can learn to think more critically, write more precisely, and learn to solve problems and use the Web to learn research skills.

Based upon the classroom discussions, the evaluation of WWW critical thinking critiques written by students, and instructor observations, we have found that there are educational benefits for using technology as a learning tool. Student classroom participation has increased significantly and student learning appears to have reached a deeper level than found in previous class discussions. We believe that these instructional strategies empower students to take ownership of their learning.

We will show how these strategies can be implemented in any introductory course. Every instructor can expect to get increased participation, enthusiasm and interest from the students in their class utilizing these methods. Each participant will leave with practical suggestions for application in the classroom.

Abstract: This paper presents the modular training system MTS, the PLATINUM ¹-Net, a worldwide network for innovative learning and advanced training, and distributed collaborative training on demand as well as cross-media delivery of course material as demanding application scenarios. The MTS system anticipates tomorrow's learning scenarios by providing flexible, on-demand, user-adaptive, co-operative, telematics-based, distance learning services. MTS allows efficient and effective co-authoring of courseware and flexible, personalized, cost-effective learning for users. Based on a flexible modular courseware concept, the MTS fosters the collaboration of multiple authoring teams in the development of global courseware domains.

1. Introduction

Traditional training focuses on teaching in either classroom-like settings at fixed times and places, or in individual learning settings which lack teacher guidance, feedback, and the opportunity to apply the presented information. The upcoming information age demands new training concepts and infrastructures for life-long, high quality training. The learners need to be able to access on-demand and goal-oriented training from their workplace or at home. Training should also be adapted to the individual knowledge and learning style of the user. Even within a high quality learning environment, the human factor will remain vital to allow expert consultation, teacher guidance, and user co-operation.

These environments introduce additional requirements. Training providers need applications by teams of experts, pedagogues and media designers for efficient multimedia courseware production. The accumulation of knowledge in such environments demands efficient management concepts to enable the multiple use of existing courseware.

Computer-based distance learning satisfies this need by providing flexibility with respect to place and time. Today we can identify steps towards integrated solutions based on the Internet which enables access to the learning material independent of the learner's time and place. In contrast to stand-alone learning, distance learning led to a trend to merge the whole world of education into one global network where the learners could study virtually and access innovative multimedia courseware combined with (adapted) traditional learning approaches.

Learning and training can be characterized by four parameters: the people executing the learning and training tasks, the places where those people act, the systems providing the technical infrastructure, and the knowledgeware as the underlying courseware material.

[¹] PLATINUM stands for Presentation, Learning and Training in the Internet using MTS.
Nowadays, learning and training systems provide local solutions and are realized as black boxes incorporating all these components. In the Web-based future scenario, all components will be distributed via global networks (Fig. 1). This paper addresses all the issues above and presents MTS as a substantial step forward towards effective and flexible Internet-based learning and training.

2. Concepts of Internet-based Learning and Training

2.1 Roles involved: People

Traditional computer-based training (like CD-ROM based CBT) consists of two strictly separated phases: courseware production and courseware delivery. The underlying paradigms are based on the assumption of single authors and single learners not interacting with each other.

![Author Learner](Image)

**Figure 2: Human Networking in Traditional Computer-based Learning and Training**

This situation changes completely in Internet-based learning and training systems. Here, worldwide distributed collaborating *communities* are considered instead of single actors. Cooperative authoring and group learning are obvious usage scenarios in network environments. Moreover, learners can give direct feedback to the authors, which, in return, is leading to shorter courseware innovation cycles.

Besides this, new roles arise which are specific for Internet-based learning and training: online tutoring, information brokering, and knowledge tailoring.

Online consulting describes the concurrent usage of courseware by a teacher and a student, to which both may have different views and access rights to the underlying course. The real advantage of online consulting as compared to traditional educational approaches is the network-presence of tutors: the Internet allows users to find the best-suited tutor worldwide for a specific question.

Internet-based learning and training is based on worldwide distributed knowledge domains (see below). As the available amount of information explodes, the configuration of appropriate individual courseware becomes more and more important. The *knowledge tailor* fills this gap. He serves as a mediator between producers and customers by transforming raw material into high-quality knowledge products.

The *information broker* mediates between supply and demand of knowledge products. As in the brokering of real goods, appropriate brokering becomes important in large-scale markets.
In summary, Internet-based learning and training changes the way we interact with knowledge in two main ways: unidirectional static chains are being replaced by highly interactive networks and many different knowledge mediators are arising.

2.2 Learning Environments: Places

Traditional learning and training takes place at fixed locations and at predefined times. In stand-alone learning scenarios, the learner works isolated and, in general, using entry-level environments. The available material is restricted, and there is no possibility for tutoring or reflection about the lessons learned.

Electronic classrooms overcome these problems by providing access to multimedia courseware, yet still supporting the learning in groups and the direct interaction with the teacher. Moreover, advanced infrastructures such as collaborative virtual environments allow for new approaches to computer-based education and training.

Web-based learning and training environments go even one step further. Here the notion of place makes no sense and is replaced by ubiquitous computing, i.e. worldwide transparent access to courseware domains independent of their physical location. Moreover, since in the Internet application logic and access via user interfaces are separated by default, individualized access becomes more prevalent.

2.3 Worldwide distributed Knowledge Domains

The creation and usage of Internet-based knowledge differs completely from traditional courseware with respect to the following aspects:

- Use of references instead of copies
- Availability of multi-author domains
- Separation of structure and content
- Provision of data and metadata
- Support of dynamic and active courseware

Internet-based courseware is used on demand; it is no longer prefabricated and then delivered. Moreover, a community of users accesses the same courseware material. On the one hand, this facilitates the reflection about the learned knowledge. On the other hand, additional methods for individualizing the common course (e.g., by personal annotations) have to be provided. Moreover, the user has to pay for usage instead of ownership of courseware.

The Internet provides new means of collaboration. Large courseware domains cannot be provided by single individuals anymore but instead need to be created by teams of authors. Therefore, appropriate mechanisms for collaborative work on courseware domains have to be provided.

The reuse and adaptation of information stored in knowledge domains requires strict modularization. Courseware structures incorporating, for example, didactical principles have to be strictly separated from the content used. This separation allows the reuse of already proven material in different contexts or learning scenarios.

Courseware material is always used in certain learning contexts. Therefore, metadata describing the semantics of the data in the courseware domain have to be provided. Since a single material can have diverse meanings in different contexts, varying metadata may exist to a single data entry.
The fact that courseware is referenced instead of copied decouples the lifecycle of the courseware and the lifecycle of usage. This enables the usage of actual information. Only Internet-based courseware can incorporate actual and dynamically changing information.

2.4 Systems

Traditional courseware systems are based on proprietary authoring environments producing executable course blocks.

Internet-based learning and training systems, however, can be seen from two perspectives: the extension of traditional local authoring systems to the WWW or the availability of learning and training as an application on top of generic Internet-based architectures.

The first approach is pursued by systems like Macromedia [Macromedia 1998] or Toolbook [Asymetrix 1998]. In the first stage, HTML-export was made available to support the delivery via Web-Browsers. Next, server-side administration tools were provided. However, these approaches require proprietary solutions.

The provision of generic learning and training platforms has been undertaken, for example, by the Deutsche Telekom in the Global Learning system [GlobalLearning 1998] and by Oracle's OLA [Oracle 1996]. These architectures focus on the provision of distributed servers providing generic support for user and courseware management. However, the courseware modules still remain proprietary.

The MTS-system combines the strengths of both approaches. Designed on top of a three-tier Web-architecture, it provides both kinds of distributed courseware servers, an innovative courseware concept, as well as support for traditional courseware.

3. The Modular Training System

In this chapter, we describe the Modular Training System MTS as an example of an Internet-based learning and training architecture. We will explain what solutions the MTS system provides to the challenges of Internet-based learning and training as mentioned above.

3.1 Architecture of the MTS

The MTS System is based on a state-of-the-art, three-tier WWW architecture, encompassing a client layer, an application server layer, and a remote resource layer (Fig. 4).

The Client Layer contains the WWW browser and the MTS client. It defines the top level of a virtual learning environment and offers graphical user interfaces to the learner. While the WWW browser is used for the presentation and interaction of the course material, the MTS client is implemented as a Java-based extension (plug-in). The MTS client supports functionality such as graphical authoring and interactive group management. As an add-on to the WWW client, the MTS client is implemented with Java to complete the learning environment, e.g., to start the video-conferencing software to support the online tutoring.
Figure 4: Architecture of the MTS System

The Application Layer contains the WWW server and the MTS server (CBT server). While the WWW server provides the standard components for the network connection between client and server side, the MTS server contains the application logic to steer learning and training sessions. This mainly encompasses the course control, but also includes components for session management and group work.

The Resource Layer consists of database and compute servers. A database server contains material and user data, and a compute server executes applications (simulations and microworlds) to effectively support training applications. Both the database as well as the compute servers can be distributed themselves.

3.2 The MTS Server

3.2.1 Overview

The MTS server is a CBT server, which communicates on the one hand with the WWW server to exchange the WWW-based information and, on the other hand, with the database server to get and store the course material and user data. The user sends requests through the WWW browser to the WWW server using the HTTP protocol. The WWW server redirects this request to the MTS server via a CGI program. The MTS server preserves the different information from permanent user data to user interaction, from course contents to individual course flow, and exchanges this information with the MTS database.

Every request from a client can be identified through the 'cookies' mechanism. The behavior of learners will be stored in the user profile. During the operation of a client request the user profile is used to determine the course flow individually for every user. The fixed 'links' of normal WWW documents are replaced by the flexible course structure, considering the interactions made by users, as well as the users' knowledge states.

The compute server is connected by CGI calls, if a course unit contains such requests. The results from a compute server, such as graphical images or video stream, are sent back to the WWW server and presented in the course online. The other possibility for connecting the compute server is the IOP (Internet Inter-ORB Protocol) architecture. Figure 5 shows an exploration unit which calls a ray-tracing teleservice with different parameters to get the illumination effects online.

Figure 5: Exploration Unit Using a Remote Compute Server

3.2.2 Login and Session Creation
The user of the MTS system always starts with a login message. This message identifies the user and its role: administrator, author or learner. The session management handler checks the input with user data stored in the user database. Dependent on the role, the executive then creates a new instance of the course runtime handler or the course-authoring handler. Next, a session ID is created which uniquely identifies this session. The executive uses this ID for passing further requests. The session ID is passed back to the WWW client using the 'cookies' mechanism. This returns a unique identification of the WWW client to the MTS server. The according handlers then process all subsequent requests.

3.2.3 Course Authoring

In authoring mode, the authors first select a course, then the authoring environment is started and the authoring client, implemented in Java, is downloaded. This tool supports the interactive graphical design of course nodes and units, while standard editors are used to produce course material. In authoring mode, both virtual and direct references can be created. The authoring clients send messages describing the creation, modification and deletion of nodes and units. These messages are passed via the executive to the course-authoring handler. The authoring handler then uses the mapper for mapping virtual references onto direct references and calls the component management services for accessing the database.

The author can preview the course using the course runtime handler.

3.2.4 Course Runtime Handler

The course runtime handler is used either in learner mode or in authoring preview mode. The user starts the course runtime handler when selecting a course node. This node is loaded and the course runtime handler executes it by interpreting the CDL script.

The course runtime handler distinguishes between virtual and direct references, and between references to nodes and references to units. All virtual references are passed over to the mapper service, which returns a set of direct references. Next, direct references to units are passed to the converter which, by means of the component management service, returns an HTML page. Direct references to nodes are accessed directly via the component management service. This node is then interpreted directly in a recursive manner.

The actual course component (node or unit) may return a value via a Java applet. This value is passed via the executive to the course runtime handler, which updates the user profile and, based on the actual value of the user profile, determines the next course component to execute.

3.2.5 Group Management

The group management functionality is available after a user is logged in, yet it is independent from the actual session management. A user can watch active user groups, join user groups, and communicate with other users, such as via email. Moreover, synchronous communication and teletutoring are supported.

3.3 Personalities

The MTS integrates course presentation, course production, and administration into a single system using three different operation modes: the course runtime handler mode, the course authoring mode, and the administration mode. These operation modes are used by the different kinds of users, such as learner, author and administrator, to support the different kinds of MTS usage. “Authors” will typically be teams of specialists (educators, scientists, programmers, and media designers) which all have their dedicated tasks. In the course runtime handler mode and the course authoring mode the users use the remote client to connect to the LTC, while in the administration mode the LTC administrator uses the administration tool locally to manage the course configuration and the user data stored in the MTS database. For the different kinds of usage, the MTS
offers the responsible modules and tools, both at the client site and the LTC site, which are integrated smoothly to a complete MTS system.

### 3.4 Learning and Training Centers

The integration of various learning aspects is the goal of the Modular Training System (MTS). From the users' point of view, the MTS is like a virtual classroom or virtual training center which offers a complete multimedia distance learning environment including course presentation, course production, user and course administration, group learning, and online tutoring (Fig. 5).

![Learning and Training Environments](image)

**Figure 6: Learning and Training Environments**

Learning and training takes place in MTS according to the following model. First, two main types of sites should be distinguished: the Learning and Training Center (LTC) and the user's workplace.

Learning and Training Centers are composed of a standard WWW server, a MTS server, and a MTS database server, and provide management functionality for distributed courseware and administration functionality for users. The LTC is the central infrastructure element since it is the access point to all training facilities. Each LTC offers its training facilities to registered users. It administrates access rights to courseware, assigns experts for consultation, and aids the formation of virtual learning groups. The LTC is responsible for guaranteeing the quality of new courseware made available to the entire Virtual LTCs by their local authors, and it is the owner of a distinct subset of the distributed courseware domain.

On the client site, the main components of the MTS are the WWW browser and its add-ons. The client runs a course front-end at the trainee's and author's workplaces. It handles the user's input and edits, downloads, and displays the course framework and the different kinds of courseware material.

Since the material is stored in the Learning and Training Center, each LTC must run a WWW server to connect the WWW client. The MTS server provides all the necessary functionality to control the course, and the database provides the multimedia courseware and user information.

LTCs are interconnected via terrestrial and satellite links to form a global Virtual LTC that provides transparent access to all courseware for users from arbitrary locations with different networking bandwidth and client configurations.

### 3.5 MTS-Courseware Concepts

MTS strictly applies the paradigms of modularity and reusability to courseware. This leads to two design concepts: a modularity concept composing courses out of different, clearly separated components, and the strict separation of the content of these components from their description using metadata.

#### 3.5.1 Structuring Courseware
Courseware is broken down into three different categories: course nodes, course units, and course material. These categories form a hierarchy of abstraction and support the design of modular and flexible courseware (Fig. 7):

**Course Nodes** define learning goals. A course node does not contain any information about how this learning goal can be reached. Courses are arranged as networks. Each course unit delivers a return value indicating the learner's success. Dependent on this value, the appropriate "next" course node can be chosen. Herewith, a complete course can be described on an abstract level. The content of a course node is a script in the special language CDL (course definition language). This script describes the implementation of the course node and may reference either other nodes or units. It never references material herewith supporting the clear separation of structure and content.

**Course Units** are implementations of specific steps in the learning and training process. Course units may either be presentation units, exploration units or test units. Each of these unit types can be implemented using characteristic templates. Course units are self-contained. They contain only references to course material, but neither reference other units nor nodes. In this sense, course units form containers of course material. They are implemented as an extension of HTML, the so-called HTML-M (for MTS-HTML). This extension includes special tags for referencing (see 4.2). Course Units deliver a return value indicating the learner's success when traversing this unit.

**Course Material** describes the material used in the course units and, herewith, the visible parts of a course. The course material consists of Internet standard formats like Text, Audio, and Video.

In order to enable reuse and multiple use of courseware on a large-scale, each module is stored as a separate entity, is self-contained and implements a common interface. This also allows course adaptation to the individual needs of the trainee by using the best fitting modules.

The flexible linking between the course documents requests the separation of the course framework and the course contents. The MTS server controls the structure of the course, independent of the WWW documents, which represent the course content. This allows the reuse of the course material in different courses. For a special user group, the course can be produced with a special course framework, yet can reuse the course material available. In this context, the database server plays an important role: In order to use the existing course contents the domain must be efficiently browsed to retrieve the suitable material. For this domain browsing, the self-description of material and catalogues must be stored in the MTS distributed multimedia database.

### 3.5.2 Referencing of Courseware

An orthogonal concept of the MTS courseware is the referencing of courseware. The different courseware components introduced in section 4.1 are never embedded directly, but are always referenced instead. Moreover, to every courseware component there exists a separate description containing metadata of this component.
in the form of characteristic attributes. Even more, constraints on the attribute—value pairs—can be defined. Herewith, the following hierarchy of references exists in the MTS system:

- direct references, pointing to a course component's data and metadata directly
- virtual references, describing a constraint set of direct references

While a direct reference points to single component, a virtual reference defines an open set of characteristics and, therefore, of course components.

This design principle allows the concept of late binding to be introduced in courseware. While a direct reference is bound at authoring time, virtual references are late bound. They either can be bound at a special configuration step before course delivery, or they can be bound at runtime. The binding at runtime allows users to choose the best-fit course component depending on their learning progress.

4. Applications and Demonstrations

4.1 Usage of MTS in Learning and Training Projects

The MTS system has been developed, enhanced, and demonstrated in large-scale projects in Germany (COBRA-3) and on a European scale (IDEALS).

4.1.1 COBRA-3

In the COBRA-3 project [Borgmeier et al. 1996] sponsored by the Deutsche Telekom, the MTS-system has been used as basis for the development of advanced courseware by Fraunhofer institutes to teach employees in small and medium-sized enterprises. Courseware in such different areas as logistics, development of ASICs, and introduction into CAD systems has been developed and taught in Germany via ISDN-networks.

4.1.2 IDEALS

In the IDEALS project [Borgmeier & Beyer 1996] sponsored by the EU Telematics Application Program, a European-wide network of LTCs has been installed demonstrating different usage scenarios in small and medium-sized enterprises as well as in institutes of higher education (Fig. 8). The university pilot is the basis for the Computer Graphics courseware domain2 [IDEALS 1997].

[2] The available courses can be executed on the TUD LTC at URL http://ltc.gris.informatik.tu-darmstadt.de/.
4.2 The PLATINUM Network

Based on the experiences gathered in these projects, the PLATINUM network is currently set up. It connects the different branches of the INI-GraphicsNet and, herewith, defines a worldwide network of excellence in learning and training in all areas of computer graphics (Fig. 9). The different branches are connected via high-performance networks (ATM, satellites) and provide state of the art learning facilities such as collaborative virtual environments.

![Figure 9: The PLATINUM Network](image)

PLATINUM forms a global learning and training network and will serve as a common platform for the development of different kinds of demonstrators in areas like training on demand, collaborative simulation of complex technical systems, teaching and tutoring at universities, or qualification for workers in industry.

4.3 Cross-media Delivery of Educational Material: A PLATINUM scenario

Within the CAMPuS (Cross Application and Media Publishing Services) project, Fraunhofer CRCG targets the unification of two of its R&D areas—Cross-Media Publishing (CMP) and Distance Education: While CMP is targeting the preservation of concepts throughout the distribution of information using diverse publication media, efficient distance education faces a rather different task. It has to reuse information entities for different educational purposes and audiences (applications), such as for entry-level education, advanced training on the job, or even high-level overview presentations. Obviously, each of these applications puts different demands on the underlying media, yet they can also be used for non-educational publication purposes. On the other hand, CMP needs to consider various publication purposes as well. Therefore, the exploitation and development of MTS as a platform that supports the integration of, and common R&D for both areas, provides a promising approach to support a variety of applications and customers. In this sense and supplementing the Computer Graphics courseware domain mentioned above [Klein & Encarnação 1997], Fraunhofer CRCG’s distance education efforts additionally include cooperation with the Computer Graphics Lab at Brown University, the Computer Algebra group of the University of Rhode Island, the Rhode Island School of Design (RISD), and Bryant College. Furthermore, in cooperation with RISD and the Distributed Publishing Lab—an international collaboration of institutions from Germany, the US, Portugal, and South-East Asia focusing on CMP over high-speed global networks for business, scientific, and educational purposes—Fraunhofer CRCG has established a Lab for Cross Media Publishing in which the CAMPuS project is pursued.

5. Future Work

The current MTS system is based on currently established Web-technologies. The server side is implemented mainly in C++, while the clients use Java and Javascript. A future version of the MTS system will be based entirely on Java and will use advanced techniques, such as RMI, JavaBeans, and EnterpriseJavaBeans. Herewith, a better distributability and scalability of the system will be reached.

Another focus of future research is the sophistication of user-adaptation mechanisms in MTS. A few adaptive, Web-based educational systems demonstrate the possibility to use adaptation technologies from the area of adaptive hypermedia in the Web context. Two of these systems, InterBook [Brusilovsky & Schwarz 1997], developed at Carnegie Mellon University (CMU), and ORIMUHS [Encarnação 1997], developed at the University of Tubingen, Germany, provide particularly suitable approaches towards developing adaptive interface technology for Web-based courseware. InterBook’s strengths lie in its embedded adaptive navigation support (ANS) rather than its sophisticated user-modeling. ORIMUHS qualifies through its history-based user-evaluation mechanisms, although it focuses on adaptive presentation rather than guidance. Both systems have been investigated in laboratory settings and have demonstrated encouraging results. The challenge is to combine and further develop these promising approaches within the PLATINUM framework in the context of real-world, Web-based university courses. This research has already been targeted by Fraunhofer CRCG and CMU’s Computer Science department in the form of a joint proposal to the National Science Foundation.

On October 16, 1998, the PLATINUM Network will hold an international workshop on Internet-based Life-long Learning involving all of its geographically distributed sites. Throughout this workshop, the participating groups will show MTS-demonstrations from various application areas and fields.

6. Conclusions

Internet-based learning and training will not replace the traditional approach to learning abruptly, rather it will have to prove its advantages over the traditional forms. It is expected that it will become an indispensable supplement for lifelong high quality training soon. The multimedia distance learning system MTS concatenated the up-to-date CBT features to the Internet to satisfy the important pedagogical and didactic demands with its concepts of multi- and reusability, modularity, and adaptability. MTS is open for new media types and running in a heterogeneous computer environment. Its modular, scaleable, open system architecture is designed to support reuse of courseware and to meet the challenges of global, life-long learning for the future.

7. References

Abstract: This paper reports on work in progress on the generation of hypermedia (Web) presentations for the results of arbitrary queries to multimedia databases. In [Houben & De Bra 1997] we have proposed a heuristic algorithm for generating navigation structures for multimedia database output, based on ideas from RMM [see Isakowitz et al. 1995]. We have shown that only part of the RMM design methodology can be automated deterministically, and have provided both heuristics and a way to override them through additional specifications in a database query. This paper describes our approach to automatically generate a presentation for multimedia database output, in addition to the generation of navigation for such output described in [Houben & De Bra 1997].

1. Introduction

In [Houben & De Bra 1997] we have shown an approach to generating World Wide Web applications for volatile database output. The motivation for this approach is that the use of a hypermedia platform such as World Wide Web can help to represent the less structured and not purely textual information one typically finds in applications such as employee databases, museum databases, geographic information systems, and mail-order catalogs and services.

Since the design and construction of a hypermedia application involves the representation of relationships between information objects, the approach for generating the navigation structure is based on the ideas of RMM [see Isakowitz et al. 1995]. RMM combines elements from the Entity-Relationship model [see Elmasri & Navate 1990] and HDM [see Garzotto et al. 1991] to effectively manage relationships between objects. The core of our approach is to use as much as possible the relevant aspects that are embedded in the data definition (of the volatile information) and in the query specification. In [Houben & De Bra 1997] we have shown how we can deduce the navigation structure for the hypermedia application from the data definition and query specification.

The subject of this paper is the generation of the presentation (through WWW browsers) of volatile database output. This includes the presentation of the records (from the query result) and the presentation of the relationships with other records. The information contained in a query result generally depends on the data structures underlying the volatile information, and on the given query specification. We have shown that RMM and its supporting tool RMCase [see Diaz et al. 1995] do not help in the case of results of arbitrary queries. The main problem is that the dynamically generated structure of a query result cannot be (trivially) translated into a hypermedia presentation.

2. Record Presentation

Based on the concepts of RMM, the lowest level of representation of information is the level of the slices. Just like a pizza may be too large to eat all at once, an object may be too large to present all at once. It is therefore divided into slices, which are essentially groups of attributes that belong together (semantically). This grouping is used to divide a record into information chunks that can be elegantly displayed by a World Wide Web browser, without too much information becoming "invisible" due to a lack of space on the screen.

It is obvious that a designer of a hypermedia application would specify the presentation of all slices explicitly contained in the data structures. In order to do so, our approach asks the designer to do two things:

1. Attribute presentations are chosen for every attribute contained in the slice.
2. A slice presentation is constructed using the chosen attribute presentations.

We assume that the attribute presentations are specified in a way that enables the layout algorithm to measure or estimate what (size) rectangular screen area is needed for an attribute. The presentation of a slice can be
encoded in HTML using tables. However, such an encoding does not specify what the relationship is between attributes, and thus what the possible reasons are for positioning attributes the way they are. Therefore, we propose to generate the HTML code from an internal representation which specifies relative positions of attributes. For instance, we can specify that a "subtitle" attribute must be positioned under a "photo" attribute (and that it must be centered under the photo), and that a "description" attribute must be positioned to the right of the "photo". A translator script will combine size information and these positioning constraints into a layout that is then converted to HTML code.

Both size information and positioning constraints may be hard or soft. An image may have a fixed size and the subtitle really must be positioned immediately under the image. But a text paragraph may be presented in a wider or narrower column and if there is no room we may allow the description to be positioned under the image and subtitle. See [Borning et al. 1997] for the use of constraints for automatic user-interface layout generation.

Another issue involved in the attribute presentation is the choice and presentation of index attributes that are used to provide navigation to slices. We propose to provide two presentations for index attributes:

- a compact presentation used to help the user in identifying the records he is searching for;
- a complete presentation used to supply the user with all the information available on the selected record.

These two types of presentations can be used to handle different sizes of query results. Our typical target user wants to obtain an efficiently "browsable" set of records. Using the compact attribute presentations first, it becomes efficiently possible to identify the records that are (potentially) interesting. Asking for the complete presentation for those records makes a subsequent thorough inspection of the information possible.

3. Relationship Presentation

In [Houben & De Bra 1997] we have defined the generation of access structures for a query result. This includes the definition of record relating structures (index, guided tour, indexed guided tour or grouping) and the relationships between slices. It did not include any specification of how these relationships are represented.

In some situations the user asks for information that is represented by slices involved in multiple relationships. For example, the representation of a "multiple join" means in general that a slice can give access to other slices contained in multiple guided tours. For the presentation to the user it is essential that the presentation of the navigation and the presentation of the actual record contents are generated simultaneously because both parts of the presentation share (fight for) the same screen real-estate.

We have therefore augmented our approach with practical guidelines to specify how navigation and actual contents are displayed together. The basic idea is that the designer specifies:

1. How the browser page is divided in different frames for navigation and contents;
2. Which navigation information is displayed (not all navigation information is accessible at all time);
3. How this navigation information is displayed.

The presentation of new slices must always be generated, when we deal with new slices (parts of existing slices or combinations of existing slices). Sometimes, the presentation of access structures can be designed, whenever we can use presentation aspects defined for existing slices. For instance, if a query results in a single indexed guided tour through a set of new slices, the page layout for that result can probably be the same as that for single indexed guided tours through a set of existing slices. But for complicated multiple joins generation of the presentation of the navigation structure may still be needed.

4. Conclusion

In this paper we have discussed two important aspects extending our approach. The first aspect is the attribute presentation and the composition of attribute presentations into record (or slice) presentations. We have shown what elements need to be added to the approach to facilitate the proper design of applications for ad hoc query results. The second aspect is the presentation of relationships that represent navigation mechanisms. We have shown how the designer can fix a number of details in order to produce an effective application. The presentation of navigation structures is more an issue of design than of automatic generation.

Abstract

The purpose of this research was to study the effects of selected characteristics of a Java simulation on students' conceptual development, problem solving and transfer. A two-pronged research study was conducted using students enrolled in a beginning meteorology course at Iowa State University.

For the experimental design, the performances of three groups were compared on posttest scores and a weather forecasting activity. No statistically significant differences were found between the groups on these measures. However, follow-up interview data obtained from five diverse students in the treatment group supported the design and future use of the simulation. Although multiple representations were used by the students to construct knowledge, of the five students interviewed, only one had used an effective problem solving strategy. This student also demonstrated a better understanding of how to transfer newly gained knowledge to weather forecast exercises. Four of the five students interviewed saw the task as being authentic.

Introduction

Theoretically, computer-based simulations are very powerful learning aids. They can improve motivation and enhance learning by providing students with an appropriate cognitive and affective context for learning (de Jong, 1991; Snir et al., 1995; Kaput, 1995). Since computer-based simulations emerge from authentic tasks, they can engage the learners in meaningful, problem-based thinking (Jonassen, 1996). Yet, the research on computer-based simulations is inconclusive. Much is still to be learned about their design and use. Strategies for helping students construct knowledge from the simulated environment are in need of development and evaluation.

This study serves as a preliminary investigation of one Internet-accessible simulation. The purpose of the study was to address the impact of the simulation on students' actions and problem-solving strategies. For this research, an Internet-accessible simulation was developed using Java and HTML. In order to analyze students' learning patterns, students' actions with the simulation were recorded through a web management system, called ClassNet.

Simulation

The simulation (MtnSim) modeled the adiabatic process of an air mass passing over a mountain. Students could set the initial values of temperature and vapor pressure of the air with the goal of causing precipitation at a specified altitude. When set in motion, the simulation animated the air movement and any precipitation that occurred. Two graphs were also displayed. One graph plotted temperature and vapor pressure for the air movement and the other showed temperature and altitude (See Figure 1). A deep understanding of the process involved the ability to cause precipitation at a specified altitude and to interpret and use the graphical representations.
Research Design

This study used Web courseware as learning materials. de Dinan and van Shaik (1993) suggest courseware include the following elements: textual material, simulation models, exercises, problems, and feedback information. In this study, the Web courseware was integrated into a traditional course. It included a simulation model (MtnSim), a real-time weather forecast exercise and a Web management system (ClassNet). Textual materials and feedback were the responsibility of the instructor. This Web courseware created an exploratory environment for students.

Students enrolled in a beginning meteorology course were assigned to three experimental groups. Student performance on a five item pretest was used to determine strata and an equal number of students from each strata were randomly assigned to each group. One group was designated the control group and the other two were with-log and without-log treatment groups. The control group did not use the simulation. The with-log group used a version of the simulation that recorded and displayed on demand a history of the trials and results while the without-log group used the simulation but did not have access to the reporting feature (See Figure 2).

![Figure 2: Example Experimental Results Log](image)

Two methods were used in this research, experimental and interview. All groups made assigned weather forecasts, attended the same lectures, and completed the same posttest. In addition, the experimental groups used the simulation of adiabatic phenomena. Based on their simulation performance, the researcher further divided subjects in the with-log group into five subgroups based on their problem-solving patterns (Goos & Galbraith, 1996) and their degree of success in working with the simulation. One student from each group was randomly selected and interviewed. This method of selection identified a very diverse group of students and provided multiple perspectives of the simulation and its value. The student's protocols in using the simulation were used as a memory aid in helping them respond to the prepared questions.

Results

For the comparison of students' conceptual development, it was hypothesized that the groups using the simulation would score significantly better on the posttest. There was no significant difference among the groups in overall posttest
scores \(F=1.32, P < 0.27\). Detailed analysis revealed a statistically significant difference on only one item of the posttest \(F=5.54, P < 0.01\). That item was directly related to the simulated phenomena but did not appear to be more closely related than other non-significant items.

For the comparison of students' transfer ability, it was hypothesized that students using the simulation would be more successful in making weather forecasts where the simulated principle was applicable. On all measures the groups experiencing the simulation had a higher mean score than did the control group, but there was no statistical significance on the scores of weather forecasting \(F= 1.44, P < 0.25\) for the adiabatic warming case and \(F=2.80, P < 0.07\) for adiabatic cooling cases).

Overall, the results did not show any significant difference between experimental groups on scores from a posttest and weather forecast exercises. The posttest results are not surprising, based on previous research (Thomas & Hooper, 1991; Upah & Thomas, 1993), but the lack of a significance in forecasting is inconsistent. Failure to observe significant differences on this measure may be due to the complexity of the forecasting process and the numerous extraneous factors, such as wind direction, which must be considered.

Interview data was more revealing, showing how the simulation design impacted students' learning with the simulation. Multiple representations, (digital display, animation and graphical), affected learners in two ways: allowing them to construct knowledge across representations and to choose their own mode of representation to explore the simulation. For the student who was able to readily take advantage of the information contained in the log and graphs, the simulation exercises were quickly completed and a sufficient understanding of the concept was developed to transfer the newly-gained knowledge to a new situation. For others the simulation was less effective. For example, four of the five interviewees reviewed the logged histories of simulation activities to determine if they had reached the goals of the exercises, but they did not use this feature as a tool for reflection on their actions.

Student difficulties in interpreting graphs were documented by Leinhardt et al. (1990) and McDermott et al. (1987). Three of the five interviewees in this study had difficulty understanding the meaning of graphs. As a result, they ignored this information and chose either digital displays or animation to explain the phenomena in the simulation. Thus, multiple representations in the simulation provided options for students to choose that built on their previous knowledge but these options also provided an escape from learning new and important tools.

The analysis of the interviewees' problem-solving episodes showed that only one interviewee's protocol showed the features of the three stages of problem solving defined by Goos and Galbraith (1996): "Careless Grabbing of Information and Data Analysis (CGI)", "Exploration Episode (EE)", and "An Orderly Progression of Activity (OPA)". He had reached the last stage of problem solving: using an orderly progression of activity for finding a successful solution. After trial and error, this interviewee tested his plan, searched information, analyzed relevant data, verified his answers, and found a successful solution. Then, he described how he used the logical structures that he discovered in the simulation, such as the wind direction and the location of cloud formation, to forecast the weather in a mountain area. Two other students were poised for improvement, having the basic strategy but needing refinement. The other two students were in serious need of basic instruction and guidance.

Conclusion

The major success of this project was not in improving student's learning as was expected, but in revealing the enormous deficiencies in the students learning skills. More than half of the students failed to employ the most basic tools and strategies for learning elementary science. Thus, supplementary methods must be devised which will support the cognitive and metacognitive development of a very diverse learner population. Perkins (1992) noted that meeting the learning needs of individual students is the job of the constructivist teacher using technology and Vosniadou (1992) advised promoting problem-solving and conceptual change required taking into account the learner and the learning process. From these perspectives, the simulation with authentic tasks and recording facilities can serve as a valuable learning environment for students to develop and improve their learning strategies and for instructors to observe and support that development. However, considerable research on classroom integration is needed before this goal will be reached.

For future research, the MtnSim simulation appears to be a good model. It contains multiple tools of the discipline which students must use to achieve success and it records their actions for further study. In addition, it is an authentic model of an important, complex, and difficult to understand process. In using the simulation, students must be mentally active, focusing on factors basic to the discipline, as they manipulate the model to achieve the desired state. Using this rich
environment, constructivist teachers should be able to take the next step of developing appropriate supporting strategies to aid students in constructing their knowledge.

Abstract

A new simulation (Mtn Sim) was developed by merging constructivism and technology to create a learner-centered environment. Mtn Sim was written using Java and put on the World Wide Web for students’ use. With the features of embedding an authentic situation, providing multiple-linked representations and displaying input-output data, Mtn Sim can be used as an interactive environment conducive to fostering conceptual understanding of the meteorological concepts of condensation and adiabatic processes, and the development of problem-solving skills.

Introduction

Recent developments in computer technology are providing new support to the learning environment (Wilson, 1995). These developments make complex human-machine interaction and multimedia products possible and powerful and make accessing structured information sources much easier. The wide range of delivery and access methods accommodate a myriad of learning styles so teachers can use computers to create learning environments for different students’ needs.

Computer based applications must not be restricted to the delivery of educational content. They must also be grounded in some model of learning. In contemporary theories of learning and instruction, learners act as active agents in the learning process. From the constructivist perspective, technology should be used to deliver computer based applications emerging from authentic tasks with multiple representations in order to engage students in exploratory learning (Collins, Brown & Newman, 1990; Roblyer, Edwards, & Havriluk, 1997). Constructivist learning benefits from support provided by computer applications because the complexity of world situations can be presented in a flexible and versatile format to accommodate the diverse individualized processes of constructing knowledge.

One promising environment for constructivist learning is computer simulations. In order to promote learners’ cognitive processes, simulations need to be designed to engage them in meaningful, problem-based thinking so learners can understand the role that hypothesis testing plays in knowledge generation. In other words, simulations not only need to allow learners to construct and manipulate screen “objects” for exploring underlying concepts, they also need to provide learners with the observation and manipulation tools necessary for exploring and testing hypotheses (Jonassen, 1996). The purpose of this study was to investigate design features which may support specific pedagogical strategies for constructivist learning and cultivate the development of thinking skills. To accomplish this goal, a computer simulation (Mtn Sim) was developed for fostering conceptual understanding of the meteorological concepts of condensation and adiabatic processes.

Design Features of Exploratory Computer Simulations

Thomas and Hooper (1992) stated: “A computer based instructional simulation is a computer program containing a manipulatable model of a real or theoretical system.” (p. 498). Simulation differs from a flexible tutorial environment in that instructional simulation does not provide explicit feedback, but alters the state of the model in response to students’ actions in accordance with rules governing the simulated system. This definition of simulation by Thomas and Hooper is used in this paper.

The features proposed in this paper for simulation design integrate learning theories and design techniques for the purpose of meeting learners’ needs in constructing understanding. A computer-based simulation with realistic (authentic) situations, multiple representations, and the capability of reviewing previous actions, aids learners in constructing their own
knowledge and cultivating their problem-solving skills. Additionally, by recording the students' actions while trying to solve problems, much information about the students' thinking can be obtained (Smith et al., 1993). This also provides an opportunity for students to analyze and reflect on their thinking. Simulations with a recording function display input-output data and replay the sequence of students' trials so students can review their actions and alter the problem-solving strategy or try another approach when difficulties are encountered. Metacognition can be fostered when a student is engaged in a learning environment where hypothesis testing is facilitated and reflective thinking is encouraged.

An Example of Exploratory Computer Simulation: MtnSim

By using the MtnSim simulation (see Figure 1), students can explore the various physical characteristics of air that has been lifted over a mountain. When MtnSim is executed, digital displays and graphs provide immediate, visual feedback of the current state of the simulation. Students can directly manipulate initial conditions and immediately see the impact. This interactivity may provide opportunities for students to modify their mental models, by comparing the outputs of the model with their expectations (Jackson et al., 1996). This interactivity is intended to engage and motivate students to explore and couple actions with effects which will lead to understanding.

As an added feature, MtnSim provides the actual sounds of wind and thunder to evoke the learners' stimuli of perception. This may motivate learners to engage in extended exploration of this simulation. The special function of displaying summaries in MtnSim is designed to help learners recognize the relationship between input-output and improve their problem-solving methods by reflection on previous trials.

As the students work through MtnSim, their actions are recorded and made available for researchers. The program is used to track learners' progress and to identify patterns of success and failure in selected learning activities. This method of data collection also provides a window for instructors to determine student learning processes. Based on an understanding of student action in using a simulation, instructors can select appropriate instructional activities to anchor student learning, facilitate the development of problem-solving skills, and make links to related knowledge for the further transfer of concepts learned from the simulation.

![Figure 1: The MtnSim Simulation](image)

Conclusion

The strength of a simulation is to force students to retrieve or discover relevant knowledge, experiences and problem-solving skills under authentic situations. Exploratory simulations require students to take more responsibility in learning processes (de Jong & Njoo, 1992; Thomas & Hooper, 1992). Active learners are most likely to benefit from this kind of use of computer-based simulation. For non-engaged learners, it is suggested this kind of simulation be used in small groups. Through cooperative learning and social interaction, some students will overcome difficulties which occur when they use simulation by themselves. The features proposed in this paper for simulation design integrate learning theories and design techniques for the purpose of meeting learners' needs in constructing understanding. In the future, appropriate learning activities need to be integrated into these exploratory simulations so that optimal learning will occur.
