We have several experiments of observation with some high schools by the remote control system of the telescope. However, we are so unfortunate that they were always cloudy or rainy days. To get real time image, client users have to contact observatory and make reservation of day and time of observation previously. Because the telescope server program has to be started before operating the telescope from remote site. The day and time cannot be changed easily, since the telescope has other many schedules of research and public use.
[Fig.6] shows the scene of telescope movement and a classroom of Tonan high school in Kyoto city. Although it was clouded day and students cannot see real time image of celestial bodies, they are strongly interested in real time image of telescope moving in accordance with their requests from web user interface. The distance between the school and the observatory is about 120 km. The telescope started to move in a few seconds, after the CGI program sent request of a student. We had some other experiments to move telescope from remote site from National Astronomical Observatory (Tokyo), University of Calgary CANADA, and California.

5. CANES

Every celestial body such as a star, galaxy, nebula, and cluster has its own position values on the equatorial coordinates. Also, our remote control system always keeps position values of the direction of the telescope on the equatorial coordinates. Therefore the system can know which part of a celestial body a student is observing. Sometimes a student gets lost when he/she is traveling around a celestial body by using the slight motion buttons. So we suggest new idea of navigation and explanation system for a student to observe a celestial body. The system is called CANES (Computer Assisted Navigation and Explanation System). CANES is now under development, it is not completed yet. Here we explain the mechanism of the CANES, using observation of the Andromeda galaxy as an example.

![Diagram of CANES](image)

**Figure 7:** The mechanism of CANES (Computer Assisted Navigation and Explanation System)
[Fig.7] shows the mechanism of CANES. It has two databases, explanation database and navigation database. Both databases have many frames called explanation frame and navigation frame. Every explanation frame has an explanation about a part of the celestial body. Every navigation frame has navigation information around the field of view of the telescope. Every explanation frame and navigation frame has its own values of equatorial coordinates. CANES retrieves adaptive explanation frame and navigation frame by the direction of the telescope, and shows them to the student. The student can know much about the part where he/she is watching by the explanation, also can know where to move the telescope to catch a part he/she wants to observe.

6. Conclusion

In this paper, we described the concept, architecture and a prototype system of our remote control system of a telescope with CANES on WWW. The purpose of our system is education use. Therefore the system does not need to realize full-remote control, although a telescope for research use needs it. In the full-remote control system for research use, dome is also controlled from remote site, but it is not so necessary for education use. The main reason why we try to realize remote control, is to increase student's feeling as "using telescope by oneself", and to increase student's interest. Only a part of the celestial body is observed at a moment by a high magnification, if the celestial body is large, such as the moon, Andromeda galaxy, or Orion's nebula. In such a case, it is important that the student can control the telescope according to his/her desire, since the remote control brings him/her the feeling of voyaging in the space. CANES helps such a voyage. On the other hand, if a staff is in the dome, it is possible to move the telescope by the staff according to the request from a student by phone call or e-mail. However this kind of system is not so interesting for the student, since it has less interactive feeling.

It is desirable that remote telescopes for education exist as many as possible in all over the world, because weather condition is not always good in one observatory. If there are many remote telescopes, some of them can catch the target in a good weather condition. For another reason, the view of celestial phenomena by the moon, is dependent on the location on the earth. For instance, a total solar eclipse can be seen in a narrow zone where the umbra by the moon passes on the earth. In neighbor area of the zone, partial eclipse can be seen. Therefore, if there are many remote telescopes on the earth, from an observatory in the zone of totality, the real time image of total solar eclipse can be sent to remote clients. On the other hand, from another observatory in neighbor area of the zone, the real time image of partial eclipse can be sent. If a remote client student receives some real time images from some observatories on the world, he/she can understand the difference of view of the eclipse. Also he/she can understand the umbra and penumbra passes on the earth as time passes.

Eclipse of the sun is quite rare phenomenon, but occultation of stars by the moon can be often seen. As well as the eclipse of the sun, the view of occultation of a star depends on the location of the observatory. The point and time of disappearance and reappearance of the star against the moon differ according to the location of the observatory. Therefore if a student compares some real time images of occultation of the star from some different observatories, he/she can understand and measure parallax of the moon. By the parallax, it is possible to make an education program to calculate the distance between the earth and the moon. This kind of education program is a desirable science program. Because it includes observation phase of real objects and consideration phase of the observation. It enhances ability of observation of real objects and ability of consideration and study.

CANES is our original idea, that gives some explanations and navigation information of the target. It helps the student to drive the telescope. It is also possible to put in questions instead of explanations in the explanation frame. In this case, CANES becomes another type of CAI system, that consists of questions and answers. It will be an excellent CAI system that utilizes real time image as teaching material. It is our future work.

Abstract: The basic philosophy and current developing status of Distance retraining system for teachers in Korea is presented. The system was planned and has been implemented by the Korean Minister of Education and Korea multimedia education center. The target the system pursues is to minimize teachers' retraining cost and provide more chances to teachers who need to get new information through retraining programs. The exhibition system was designed and has been partially implemented. The proposed system will be the basic retraining system in Korea in near future and comparing with the cost for retraining teachers under the existing retraining system, it is expected that the proposed system reduce the cost more than twenty percents.

I. Introduction

Every year more than 100,000 teachers participate in a variety of retraining programs held in forty five institutes in Korea. To take the programs, teachers who are geographically distributed throughout Korea always have to attend the classes in the institutes. This kind of retraining scheme continuously increases the retraining cost and gives many difficulties to teachers who are always struggling with time. In addition to that, the facilities in very limited number of institutes are not enough for providing good quality of retraining service and accommodating many teachers. But what makes the matter worse is that even though many rich courses are offered, teachers are not able to get the courses, depending on their major fields and levels, due to the limited resources and uniform training programs. [Choi 1995]-[Jin 1997]

With the help of the current communication infra-structure which can overcome time and space limitations, and make remote retraining system feasible, the Minister of education and Multimedia education development center in Korea has been developing “Distance retraining system” to resolve the above problems. They utilize “Edunet”, a global service system for education information in Korea which is accessible by everybody [Lee 1997]. They expect that the Distance retraining system removes many problems associated with the current retraining programs and makes it feasible for the teachers to participate in the programs from anywhere and in anytime. The Distance retraining system aims at enhancing the specialties of teachers and lets them prepare for intellectual and informational society of the 21st century. The system may also extend retraining chances by amortizing time and space limitations, and reducing retraining cost.

The Minister of education established the Distance retraining system with 10 million dollars in 1997 and has run the exhibition system for a limited number of retraining programs in two provincial retraining institutes since April, 1998. As the network, “Edunet” is being utilized. The Edunet was installed in June 1996 and is running successfully. [Lee 1997]

Section two describes the procedures for developing Distance retraining system. In section three, the implementation plan of the Distance retraining system is presented. Finally section four addresses the expecting effect and future plan, and wraps up this paper.

II. Procedures for developing the Distance retraining system

The procedures for developing the Distance retraining system has included modeling a remote training
system with considering the current situation and expected future environment in Korea, establishing a practical system based on the model, and developing a platform which will serve as the management system for all retraining programs. Creating coursewares for retraining programs and installing the infra-structure were also included.

In modeling procedure, a basic model was developed. The model includes the scheme for setting the relation between distance and in-class retraining, the credit system for distance retraining courses, the grading system, and the future improving plan. In establishing step, running the retraining programs and supporting the prototype system were considered. For these activities, the materials for distance retraining were developed and the strategy for utilizing the materials was set up. To verify the performance of system, three institutes were selected and have run the system. And the future plan for extending the number of the institutes which are going to use the Distance retraining system was also set up. The complex retraining management system is a web-based application for running the Distance retraining system. The components for performing the retraining system consist of lecturer, student, and manager. And the complex retraining management system is a platform to support the components according to their roles. The platform includes the following sub-systems: 1) authoring sub-system served as an authoring material pool, served for establishing course types, designing lectures, and creating the contents for lectures, 2) remote lecture support sub-system for supporting distance retraining, controlling classes, and the activities of lecturers, 3) retraining support sub-system for searching retraining materials, and supporting classes, 4) management and evaluation sub-system for managing credits, securing the system, counseling, and evaluating statistics.

III. Implementation of the Distance retraining system

Distance training using computer and communication can be classified into two types: Non-realtime system and Realtime system. BBS(Bulletin Board System) type and VOD(Video On Demand) type are included in non-realtime system. Considering the fact that it is hard for teachers to make enough time in daytime for participating in extra training programs besides their normal classes, the proposed system has been developed as a kind of non-realtime system. Therefore, teachers can take programs they want when they are free. Since the current communication environment is not enough to fully support VOD system which requires extremely high data bandwidth and sophisticated equipments, it's not easy for teachers in remote places to get high quality retraining programs. Therefore, a Web-based instruction system which is a kind of multimedia BBS type is hired in the proposed system. We have a plan to move for VOD system in near future, expecting that communication environment is improved.

For the first stage of running the Distance retraining system, teachers who wish to take retraining programs attend cyber-classes after class hours through Edunet and get credits. The classes use training materials made by typical multimedia authoring tools. The classes offered in the current exhibition system are very limited. The number of the classes is eleven and they are all liberal arts courses. The other classes are held in the previously mentioned 45 institutes. To get the credits, teachers have to attend the classes held in the institutes. The number of cyber classes is going to be larger and eventually all retraining programs will be done through the proposed distance retraining system.

To diversify retraining programs, six basic courseware databases are being developing. The number will be increased and the field will be extended. The coursewares are developed in four class models. They are basic courseware model, lecture model, problem solving/information searching model, and seminar model. They have different class scenarios which were developed with considering the characteristics of the models. And thus the scenarios provides friendly interactive environments to teachers in remote places.

For the exhibition system to be worked, Korea multimedia education center cooperates with two other institutes: Education center in Korea national university and Kyoungnam teachers training institute. Korea multimedia education center serves as the central center. It installed Web server, DB server, and Mail server. It also loaded the coursewares which had been developed in the early stage of the proposed system development. And the coursewares could be accessed through Edunet. The two cooperating institutes manage the teachers in retraining programs using the DB server and monitor the offered courses. For the communication network, dedicated 256Kbps network is utilized currently. But it is
going to be replaced with 465Mbps fiber network in 1998. Figure 1 shows the configuration of the exhibition Distance training system for teachers in Korea.

The teachers who want to take the courses in the retraining program register via PSTN or PSDN. Any questions during the classes are asked by teachers and the answered are supplied by lecturers on-line bases. For supporting this scheme, a FAQ utility is provided. A complex retraining management program is also provided. It includes an authoring system, a lecture support system, a learning support system, and a total management and evaluation system.

To monitor the efficiency of the proposed system and give the chances to comment on the future improvement, the Ministry of Education, Korea multimedia education center and sixteen municipal and provincial education offices are connected through a teleconferencing system.

Figure 1. Configuration of the Distance training system for teachers in Korea.

IV. Effect and future plan

The following effects are expected by running the proposed system. First, retraining cost will be reduced. About 20 percents of the traveling cost to attend the institutes and the charge for board and lodging is expected to be reduced. In addition, the replacement cost occurred due to the absence of teachers can be reduced. Second, it becomes possible to immediately collect the information on the organizations of retraining institutes and the management for running retraining programs. Recognizing the current state of retraining programs becomes easier. Therefore, the time for dealing with the dirty works associated with retraining programs may be utilized efficiently for other purposes, since everybody can access the information on retraining programs via public network. Third, the proposed system can contribute to installing a lifelong-retraining structure because every teacher can take the chance to participate in any courses which are offered by any institutes in any time. Especially in the case that an emergent program should be propagated to all teachers throughout the nation urgently, the proposed system will be a very strong and only way to get the job done.

To improve the efficiency of the proposed system and make the system work smoothly, thirty institutes are going to utilize the proposed Distance retraining system by 2000. Along with that, more than a hundred more cyber coursewares are going to be developed. To encourage teachers to use the system,
there is a plan to provide the well graded teachers with merits. And other media such as TV, CATV or satellite are considered for the future implementation. The proposed system utilizing Edunet will be connected with the existing Korea educational network and Information superhighway which is going to be installed by 2005, allowing everybody to access the system from anywhere in anytime.

Abstract: "Music: A Listening Experience" is a computer mediated, college introduction to music course. The course was designed for self-paced, individualized instruction with all learning taking place in a computer lab. This course has now been redesigned into a hybrid Web/CD computer mediated course. The Web functions as a communication vehicle between students and instructor, as well as, between students and their peers. Students use the Web to upload files containing test results and to communicate with the instructor. The instructor downloads test results and poses discussion topics on a conferencing program. The principal educational objective is the development of skills for attaining music cognition through auditory perception. It is a hands-on listening course intended for learners with none or limited musical preparation. All learning occurs off the Web and thus requires no connect time. A final exam is presented on a floppy disk.

1. Courseware Design

The multimedia program, *The Anatomy of Music*[^1], was designed as stand-alone courseware for individualized instruction. Its principal objective is to develop in the learner skills for auditory perception of musical forms. Programmed with HyperCard, it is currently available for the Macintosh platform (with CD-ROM drive) only and the packet includes a floppy disk containing the program to be installed on the hard disk, a student disk that stores data of test results and also serves as key disk, three specially created CDs containing all the music needed for the course, and a workbook.

The main task preceding the development of the courseware involved selecting appropriate musical examples to suit the purpose. These examples had then to be analyzed into such syntactic units, or musical strings, that the average learner could be expected to perceive auditorily. Obviously, the dissected syntactic units had to correlate with the actual forms, so transferability of what is learned in the course to real-world situations would be enabled. Consequently, the analyses represent each form at its most general or inclusive level, its metaform.

The actual program development began with the preparation of graphic representations of the musical forms to be used in the course. In the program, these are called form-maps. The following is an example of the form-map of a minuet (Figure 1).

![Figure 1](image)

The program was then designed to synchronize animated highlights on the form-maps with the appropriate music played over a CD-ROM drive. Thus, each highlighted box serves to visualize the location of the

various musical statements that make-up the forms as they are heard; guiding the learners in their perception and classification of the musical statements. Parallel inputs from auditory and visual modalities reinforce conceptualization and categorization of the discerned musical events.

The program is designed for interactivity. By clicking on anyone of the boxes of the graphic, the music will instantaneously synchronize with that location on the form-map. This enables the student to learn by experimentation. Comparing various sections and listening repeatedly to those sections experienced as being unclear will reinforce the learner's auditory understanding.

2. Other Items in the Program

The software also includes listening exercises and relevant historical background information. Listening exercises are available for every composition in the program. They permit students to select the composition on which they wish to assess their listening skill. Once a composition is selected, the computer screen presents the selected composition's form-plan. The form-plan is presented without highlighted boxes. After the music is started, the student is expected to click in real time on a box that represents the music heard. If the box clicked is in sync with the music it represents, the box will highlight and a positive score will show. These scores are for practice only and are not saved. The purpose of these "Listening Exercises," as they are called in the program, is to build-up the learner's self confidence.

The historical background information is presented in several scrolling text fields that can be read on the screen in the context of a chapter studied. The information is also available in hard copy in the provided workbook. The information relates directly to each particular form class and this information represents the basis for the question part on the final exam.

Finally, the whole program was compiled as an application, an option provided by later versions of HyperCard. This makes it unnecessary for users to have HyperCard on their computer.

3. The Web as Communication Vehicle

The Anatomy of Music is the basic "text" for a computer mediated course entitled "Music: A Listening Experience." The course has a Homepage on the Web and its URL is http://multimedia.dac.neu.edu/aom/.

The Homepage contains several links to other locations such as university administrative centers for registration, etc., or to other related sites, as well as to the publisher of the text materials for the course.

The four credit course is offered as a free elective at a college of Arts and Sciences. Designed as a self-paced course, students can study at any location and almost without fixed schedules. They can study and experiment in any order or sequence though, chapter-tests have to be taken in sequence. To pass a test, students have to accumulate a predetermined number of score points. They cannot proceed to a subsequent chapter test before the previous chapter-test has been passed. All test results are accumulated on the student disk, which, as was mentioned earlier, also serves as a key disk needed to access the program.

The Web functions as a communication vehicle between students and instructor, as well as, between students and their peers. In its function to communicate between student and instructor, the Web is used for the periodic uploading of test results accumulated on the student disk. Space on a server at the University has been set aside for this purpose. The instructor can download student files from the server and save them with a separately designed course management program.

In addition to its up and downloading of homework function, the Web is also used for e-mail communication between instructor and students for answering student questions, prompting, or for providing additional information or explanations when needed.

To encourage "class participation," the instructor poses periodically questions on the conferencing program which is accessible from the Homepage. Ability to answer these questions requires task oriented listening. Students are not graded on these questions. After seven to ten days, the instructor posts the answer. All who participated in a meaningful manner between the time a question was posted and the answer provided will be
credited for class participation. The same conferencing program is also usable for discussions between students and can thus be used for cooperative learning.

3. Testing Instrument

Tests are considered learning experiences and designed to probe and monitor progress in the learner’s skills and understanding. The learner can call up questions until the needed score has been attained. And since feedback is immediate, learners can self assess their performance continuously in a non threatening environment.

Testing modules includes form-plans with randomly selected highlighted boxes. The music, also selected randomly from among several examples for each chapter, is then started and the learner is asked to identify the musical events highlighted on the form-plan by clicking on the appropriate boxes in real time.

To be able to do this successfully, the learner has to track the music mentally, discriminate and categorize musical events as they occur, and have committed to memory sufficient data for comparison and orientation.

Each chapter includes a context related auditory test unit. As students answer each question, they accumulate score points. Once the required minimum score for passing the chapter test is reached, the program informs the student by flashing a congratulating dialog screen with an option for printing it for the student’s record.

4. Final Exam

After students complete successfully all tests for five chapters, they are ready to attempt the final exam. This exam contains listening questions as well as questions drawn from the historical background information provided both on the computer screen and in the workbook. The listening part is based on a chapter that differs from the others by not having listening exercises or tests. The chapter contains form-maps and commentaries for Beethoven's 3rd symphony, the Eroica.

The final begins with the listening part. The program selects randomly one movement from Beethoven’s Eroica symphony. The work has three of its movements in forms that were studied earlier in the program and one movement in a modification of a form studied. The learner can prepare for this exam by working and experimenting with the form-plans and the recording provided in chapter six.

Five locations on the presented form-plan are highlighted by random selection. The learner has to be able to locate these in real time as s/he listens to the music over the CD-ROM drive. Unlike in the chapter tests, no feedback is provided as to whether an answer given was correct or not.

After the listening part is completed, a set of randomly selected questions is presented in multiple choice format. Each question is followed by four possible answers and the learner has to respond by selecting one of these. A review of all answered questions with allowance for changes is available as long as all is done within the time limit.

Because all questions, listening as well as verbal, are randomly selected from a significantly sized pool, the possibility of two finals being identical is extremely remote. The obvious reason for this design is to discourage the transfer of information from one student to another.

The final is provided on a floppy disk and obviously several security issues had to be addressed in the programming. For example, the design makes it impossible to attempt the final more than once. Also, it has to be taken in one continuous period and within a set time limit (controlled by a time bomb). Once the time limit has elapsed, the final program is no longer usable.

After completion, the file containing the results of the final is uploaded in the same way as were the regular home work results, and again the instructor can then download the data and includes it in the student’s file with the course management program.
5. Fundamental Educational Consideration

One of the learning theories that permeate this hybrid Web/CD computer mediated course pertains to mastery learning. Students have to attain a certain level of mastery before moving on to the next stage. But unlike the classic application of this theory, students are free to learn by experimentation and may select objects of study out of any prescribed sequence. This brings the didactic strategy closer to the Constructivist approach. It is assumed that most students can learn the materials if they are permitted to do so at their own pace and in their own manner.

Another instructional theorem underlying the design of this courseware is that learning a general principle is of greater value than learning specific instances of it. As applied here, the focus is on comprehension and perception of a form and not on any number of compositions in that form.

Assessments are performance based. It matters not how much time was needed to complete a chapter test. Grades for this course are determined by number of chapters completed, class participation, and performance on the final. Currently, the course is available only to students of this university and adheres to its college’s time schedule and therefore has to be completed within one term. Future plans call for making this course available to students outside this university. This may make its scheduling more flexible.

6. Ordering the Content Hierarchically

The five basic forms included in the program are: minuet, rondo, theme and variations, sonata-form, and concerto - modified sonata-form. They represent most of the forms found in compositions of the selected period. In most larger, aggregate, forms such as symphonies or concertos of the period, each separate movement is cast in one of another of these forms.

The forms were ordered hierarchically according to levels of difficulty for auditory perception. These levels were based on results from an earlier performed items-analysis study.

7. Complexities in Teaching Music Listening

For this course, music cognition is defined as being made up of three related elements: a) knowledge of several of the most common composition plans - the forms - of musical masterworks composed between ca 1720 and ca 1920, b) ability to discriminate by auditory perception between discrete musical events that define these forms, and c) ability to categorize these musical events according to their proper location and function along a known musical form.

Given the ineffability of the emotional and aesthetic qualities of music, this college introduction to music course, designed for the non-major in music, applies a novel approach by utilizing musical syntax as the central didactic strategy for the achievement of music cognition. The aim is for the student to attain skills in perceptual categorization of sonic data into coherent musical statements.

The historical period selected contains composition representing some of the greatest human achievements. And one objective of this course is to make these masterworks accessible to anyone who is interested but feels intimidated for lack of musical knowledge in general, and music theory and music reading skill in particular.

Composers of the period under consideration composed their works for amateurs and not for the professional musician. They took great pains to create compositions within the accessibility limits of their listeners by following established norms. One of these norms related to the syntactic order, or forms, all composers adhered to.

Many who listen frequently to Classical music, including most professional musicians, are unaware of their own mental processing as they listen to music. They already have attained the necessary skills and possess the required knowledge, and thus, listen to music as one listens to language, i.e., without paying attention to
its syntax or grammar. Many others, however, need instruction to attain the needed skill and knowledge and it is for those that this course was designed.

Although an understanding of musical form and possessing the skill of becoming aware of it by listening can provide considerable satisfaction, the course aspires a broader objective. Most written accounts of music, weather in program books for a symphony concert or in music appreciation books, refer to specific musical events in a composition discussed. To locate these events, the reader has either to have the work completely memorized in every detail, be able to read the musical score, or know the form of the work and have the skill to follow it auditorily. Thus, since the achievement of the last of these presents the main objective of this course, its approach and content are intended to provide a solid basis for the continuous accumulation of musical knowledge that reaches beyond the limits of this course.

In music, form has several meanings. Its definition depends on whether one speaks about a small detail of a composition or the entire composition. For example, we can say that the form of a typical concerto has three movements. This is probably the broadest use of the term form. In contrast, theorists discuss at times the form of a fragment of a melody. For the purpose of the current discussion, we use the term form as it applies to the composition plans, the mappings of entire movements of a composition.

The number of different musical forms used by composers of the selected period is astonishing small considering the infinite possibilities. Hence, a comprehension of these forms on a purely intellectual level is not much of a challenge and would not require the devotion of a whole term to their study. The real challenge lies in the auditory perception of these forms.

Musical information reaches the listener in both serial and parallel modes. To perceive a coherent cognition of music's syntactic structure requires the listener to engage in "thoughtful" listening. Obviously, there are different modes of thinking. We are so used to thinking in words that it seems to us to be the natural and perhaps the only thinking mode. But of course we also think in numbers, in symbolic representations, and in images; and some of us also think in music.

However, to most of us, thinking in music does not come naturally and we have to acquire it by learning and practice. To be able to follow at least some of the composer's intellectual organization of his/her compositional materials, we have to discriminate between numerous musical events as they are perceived via auditory input, categorize and recategorize these, since continuous new inputs may affect our conception, and commit enough to memory for comparison with future inputs. This is the challenge and it requires learning and practice.

The style of all compositions of the selected period is characterized by a shared common theoretical foundation. This style can be elucidated by using a concept borrowed from a different discipline. The psychology of visual perception uses the figure-ground concept to explain the mechanism by which we manage to discern a figure embedded in a background.

Gestalt psychologists maintain that we grasp the world in complete configurations and not in minute components. When we look at a representational painting for example, we see the objects represented and not the brush-strokes. Also, we focus our attention primarily on the figures and less so on the background. When we listen to music we do essentially the same thing. We listen to complete musical statements and we do not listen to individual tones. We pay more attention to the themes than to the harmonic progressions in the background or the accompanying events.

When we listen to a composition sharing the common theoretical style mentioned, we have to discriminate between figure (musical statement) and ground (musical background) and remember enough of both to recognize them when they recur. This is essential because if we limit our listening to a continuous present only, we are limiting our perception to what is called low-level. Everything we hear is immediately replaced with something new and nothing of the past is ever stored even temporarily. To achieve any level of music cognition requires to do some mental mapping of the form with at least a vague memory of the discerned musical statements.

Most, if not all, composers who created their works during the period discussed here worked mainly in a kind of musical figure-ground style. The musical term for this is homophony. It is defined as a style having prominent musical statements embedded in a less pronounced accompanying environment.
This style made it possible to create musical forms by assembling musical statements in various arrangements or mappings. Once a musical statement was created and embedded in an appropriate musical background, a composer could decide whether to repeat it or follow it with another statement. The manipulation and the arranging of these statements determined the form of the composition.

Let’s continue with the visual metaphor a little longer. Figures can be clear and have obvious boundaries, or they can be rather blurry with less defined contours. On occasion, the background will be made purposely to obscure the figure so it gets lost within. The same applies to music. The musical equivalent term for the visual figure is theme or subject. It is the musical entity that is usually the easiest to commit to memory.

Once stated, a theme becomes something like fiber which the composer will use to spin the fabric of a work. The musical theme is the basic intellectual material for creating a whole section\(^2\) of a composition. The composer will draw from the theme many different elements such as rhythmic figures, melodic fragments or elements from the accompanying events, and use these to expand and elaborate the section. Hence, think of a musical section as an entity that in most cases will contain a quite easily discernible theme, and that this theme will be followed by a strain of related musical material. In most cases, the theme will appear at the start of a section.

At times, the strain that follows the theme will contain some elements that protrude more than others and eventually develop a life of their own. They can be considered sub-sections.

Themes can be short and simple, and they can also be extensive and very complex. A complex theme may contain several "themelets" that are clearly discernible. This can make it difficult at times, especially for the novice, to distinguish between a short theme followed by a strain with several sub-sections and an extensive, complex theme.

The end of a section may or may not be defined by a clear boundary. Sometimes, it will be noticed only by the introduction of a new theme at the head of a new section.

Once the learner has developed the skill to discern a musical section and to discriminate between one section and another, s/he has taken an important step toward auditory cognition of music. Being able to isolate musical sections, enables the learner to tell, for example, if two adjacent sections are similar or different; an important observation for the perception of form in music.

Themes, sections and sub-sections are some of the smaller structural elements the learner has to deal with. Musical forms contain many more group levels, and the auditory perception and categorization of these requires much trial and error experimentation by the learner. But it will ultimately lead to a firm foundation for attaining music cognition.

This brief description of the complex nature of even a limited level of music cognition was intended to underscore the difficulty in teaching music cognition by auditory perception. It should be quite obvious that doing so in a traditional lecture recitation class-setting would not be appropriate. It is questionable indeed, whether it would be possible to do so at all without the availability of the new technological tools.

\(^2\)There are no generally accepted terms for the various elements of musical syntax. The terms used here were selected for the purpose of elucidating the discussion for the lay reader.
Interaction: What does it mean in online distance education?

Abstract: Evolution of communication technology has now enabled us to interact synchronously or asynchronously with almost equal ease. Many instructors feel that synchronous interaction is the epitome of learning while others feel that asynchronous interaction offers better learning opportunities. This paper uses the Delphi Technique in an attempt to arrive at an indication of whether instructors favor one interaction mode above the other. Eight experienced Distance Education instructors were interviewed for their opinions on the interaction types that are considered essential in online learning environments. The results show a predominant preference for the asynchronous mode for all types of interaction and a strong preference for teacher-learner interaction in the synchronous mode.

1. Introduction

Distance education is defined as education that “takes place when a teacher and student(s) are separated by physical distance, and technology is used to bridge the gap (Willis, 1993, p. 4). The separation of instructor and learner is sometimes viewed as a problematic issue in learning because it poses a barrier to interaction. Bates (1995, p. 13) asserts that high quality interaction with learning materials, between teachers and learners, as well as among learners, is essential for effective learning.

Within the constructivist framework and the learner-centered theory of learning, there is the notion of students creating their own meaning when they learn. If meaning is to be constructed, then the learner is central to the learning process in that personal experiences constitute what the learner comes to realize as “real” or viable. Interaction is crucial to student learning as the learner’s experiences come from the interactions he has with the learning environment. The social negotiation of meaning is emphasized where interactive collaboration is seen as central to the learner testing the viability of his understandings in interactions with others (Duffy & Bednar, 1992). However, while everyone is in agreement as to the significance of interaction to student learning, the concept itself may have different interpretations for the online learning community.

2. The nature of interaction

Moore and Kearsley (1996) noted that the nature and extent of the interaction that would be deemed appropriate for any learning environment vary according to the teaching philosophy, the nature of the subject matter, the maturity of students, and the media used in the course. Given the large number of variables included, it is not surprising that it is difficult to agree on what is interaction. Moore and Kearsley
got around the problem by categorizing interaction into three types: learner-content interaction, learner-instructor interaction and learner-learner interaction.

**Learner-content interaction** is the interaction the student has with the subject matter that is presented for study. Interaction between learners and content refers to learners constructing knowledge through a process of accommodating new understanding into their cognitive structures.

**Learner-instructor interaction** refers to the assistance, counsel, organization, stimulation and support that the instructor provides to the learner in helping the latter construct new understanding of the content. When the learner "applies" his new understanding through his interaction with the instructor, the instructor serves as a representation of the expert knowledge with which the learner can test the viability of his new understanding. Moore and Kearsley see this type of interaction occurring even when there is no face-to-face contact between the instructor and the learner, for example, in correspondence courses. When the correspondence instructor sits with a set of student papers, he enters into a silent dialogue with each individual learner-writer.

**Learner-learner interaction** refers to the interaction between one learner and other learners, whether alone or in group settings, with or without the real-time presence of an instructor. This is particularly important during application and evaluation of new knowledge as the learner's peers serve as a touchstone for his understanding.

**Learner-self interaction** refers to the learner's reflections on the content, learning process and his new understanding. Many educators would agree that an important goal of instruction is to develop skills of self-regulation in an effort to make the learner an independent and self-directed learner. This can be done by supporting the learner in reflecting on his learning and his learning strategies. In addition, we see reflection as conversing with oneself - a sort of "inner dialogue", where the learner takes on both the protagonist and the antagonist roles sequentially in an attempt to reframe his understanding. As such, learner-self interaction is very much a type of interaction and because of its importance to learning, it is included in this study.

3. **Method**

The study aims to clarify what types of interaction are considered essential for online distance education. To do this, this study attempted to capture the informed judgments of experts in the field of distance education.

Using the Delphi Technique, a total of three questions was sent, one at a time, to eight experts in distance education. These respondents were anonymous to each other. Their responses to each question were analyzed and used to generate the next question. With each question, more data were elicited to form a comprehensive picture of the issue. The Delphi Technique has the added advantage of being an established tool for generating a reliable ranking of options, in this case of the types of interaction deemed essential to online distance education.

4. **Results and Discussion**

The responses to the questions generated are presented in the tables below. These results are also discussed with regard to their implications for instruction in and design of online learning environments.

**Table 1:** Experts' responses as to types of interaction essential in online learning

**Question 1: What type(s) of interaction is(are) necessary for learning in online distance education?**

**AM** We feel that extensive interaction is needed. On the Internet, we have unique opportunities to incorporate all types of interaction. Our institution creates a virtual classroom that allows all participants to interact in real-time discussion. However, the most important thing about online interaction is that the technology used to enable such interaction is *easy to use*. Some good tools...
are listserv and bulletin boards.

CB  Good quality learning requires discussion, debate, team exploration, role-playing, competition, and project work. This level of interaction can only be gotten from peers. Since the teacher cannot respond to all requests for assistance, students have to depend on their peers. Such a range of interaction would require private chat tools, email, fax, and asynchronous conferencing. Basing a portion of final grades on peer responsiveness and dialogue depth will enhance interaction.

CS  For students to interact with each other, using a listserv is sufficient. However, such interaction must be mandatory or it would not happen.

DM  The types of interaction necessary range from interacting among themselves as needed in student-based learning to just receiving information as in teacher dominated learning. At a minimum, a chat room is necessary and ideally, a video link at each site.

EC  Students need to interact with each other. Chat lines, email, and moderated newsgroups will enable the needed interaction.

JH  Both synchronous and asynchronous interactions are necessary. Asynchronous interactions are needed to set up conferences and sub-conferences to organize interactions between participants and for sharing and manipulation of educational material. Synchronous interaction is needed for private and public discussion. A chat room serves this purpose.

JS  Real-time interaction in medium-sized groups is most important. That is the chief advantage of classroom instruction. Video-conferencing captures this edge better than email, computer conferencing, or any type of one-to-one communication.

The responses in Table I show that a range of interaction types is deemed necessary although learner-learner interaction seems to be more prominent. An interesting finding is the prominence of tools in the minds of the respondents. Interaction seems to be inexorably linked to technology tools and their uses. This is indeed one of the distinguishing features of distance education. Technology appears to be the factor that both enables and constrains the learning we want to instill in these online environments. As educators, we should, indeed must, begin our inquiry from the kind of learning and by extension, the types of interaction that we want. However, the second step is to refer to the technologies that exist to see if they support the interaction and learning we want. It is possible that not all the types of interaction we want can be supported by the technologies available in our instructional environments. Instructors are then faced with the choice of whether to accept running a program with limited interaction capabilities or eschewing distance education until the technology supports the range of interaction we want. It is not the purpose of this paper to explore the match of technology and interaction. However, it would be useful to rank the types of interaction mentioned in this study according to their perceived importance to enable educators in this dilemma to make a more informed decision.

To enable ranking of the types of interactions, we first grouped them into the six categories listed below:

**Synchronous Learner-material interaction** - refers to student learning from instructional events such as live broadcast or doing a scientific experiment. The learners are not interacting with other people even though the event he is watching may be happening in real-time.

**Synchronous Learner-self (reflective) interaction** - refers to reflection. Editing stuff one has just written is one example. Only one party is involved here - interacting with one's own thoughts. Sometimes this takes the form of a debate with oneself, taking on both the roles of protagonist and antagonist.

**Synchronous learner-learner(s) interaction** - refers to interaction between learners that occurs in real-time such as in face-to-face communication, IRC, or computer video-conferencing. This is particularly valued for group collaboration.

**Synchronous teacher-learner interaction** - refers to interaction between instructor and learners. Teacher-centered instruction over the web will be one extreme of this category, while two-way question-and-answer sessions will be the other extreme. In most instances, interaction between learners is not included.

**Asynchronous Learner-material interaction** - refers to students learning from instructional materials such as web-pages and books. Again, the learners do not interact with other people although materials may be animated.
Asynchronous Learner-self (reflective) interaction - Reflecting on one's work may not occur instantly. Some people will deliberately put aside stuff they have written and go back to it some weeks or months later, with a fresh perspective developed in the intervening period.

Asynchronous learner-learners interaction - refers to students interacting with each other but not in real-time. Email and newsgroups are the most common examples.

Asynchronous teacher-learner interaction - refers to interaction that is broken by a time lag. There is no immediate conversation-style interaction. An example would be when the teacher emails the student or puts out an announcement on the listserv.

Having established our categories, we posed the second question.

**Question 2: How would you rank the following types of interaction?**

(A ranking of 10 denotes "most important" while a ranking of 3 denotes "least important". Each ranking can be given only once, for example, there cannot be more than one category ranked 10 by the same respondent.)

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

Asynchronous learner-learner interaction was rated the most important type of interaction for online distance education, as seen in Table 3. The three top-ranked categories are asynchronous interactions and the three lowest ranked categories were synchronous interaction. This indicates that real-time interaction is not highly valued by distance educators. Two other features stand out. Both types of teacher-learner interactions are in the top half of the table, ranking second and fourth respectively out of eight. This indicates the respondents think the teacher has a fairly important role in online learning environments. However, as noted before, the respondents obviously believe in learner-centered learning since they rated learner-learners interaction as most important. Both types of learner-self interaction are in the bottom half of the table, ranking fifth and seventh respectively out of eight. Reflection has relatively low priority in the scheme of things in this learning environment.

The findings above reflect an artificial averaging of disparate ratings by individuals. It is not a true consensus. While we think it is unlikely to achieve a true consensus in this matter, we feel that it is beneficial to narrow the divergence between the individual respondents and elicit information about why they ranked the categories in the ways they did. To achieve this aim, we posed the third question.

**Question 3: Considering the averaged rankings (in Table 1), indicate why you would, or would not, agree with the ranking given for each category of interaction** (You may revise your original rankings if you wish).

This question gives the respondents an opportunity to reflect on and justify their original positions. To facilitate this, Table 1 was made available to them and they were asked to revise, if necessary, their original rankings. However, only three of the eight respondents responded to this question. Table 3 shows the revised rankings of the categories based on the ranking of these three respondents.

</tbody>
</table>

The revised rankings do not differ from the original rankings. Due to the relatively few responses, some categories were ranked as equally important. Asynchronous learner-material interaction is rated 7.333, as is Synchronous teacher-learner interaction. Synchronous learner-self interaction is rated 4.000, the same as synchronous learner-material interaction. The experts' reasons for their ranking in Table 3 are discussed below.

**Asynchronous learner-learners interaction**
From their ranking, it is evident that the experts regard learners as the most important aspect of learning. Thus the learner is central to any learning that may take place. Distance learners are generally mature learners with commitment to careers and families and busy schedules. Hence, asynchronous interaction is often regarded by instructors as the most productive and appropriate form of communication in online courses.

**Asynchronous teacher-learner interaction**
While learners are central to the learning process, guidance from teachers is still necessary. This partnership in learning explains why this interaction is ranked second. In fact, the experts are mindful of not using the teacher-centered approach and they see the asynchronous mode as the best way to ensure that teachers become less domineering and improve thoughtfulness in their responses to the learners.

**Asynchronous learner-material interaction**
Students eventually will need some content material to dwell on. The asynchronous mode allows them to read and react in a manner that is independent of time and place in this mode of interaction.

Given these perceived advantages, asynchronous interaction is deemed to be more prominent to the synchronous mode for learning. This is especially so since learners can make use of asynchronous interaction more conveniently, for instance, at home or in the workplace.

**Synchronous teacher-learner interaction**
Synchronous teacher-learner interaction is deemed slightly more important than asynchronous reflections. This is because reflection is deemed to have occurred as part of the first three categories and therefore need not be emphasized. On the other hand, real-time contact with a teacher might keep the learner motivated and involved.

**Asynchronous learner-self (reflective) interaction**
Reflection is critical to learning. In fact, this is ultimately where learning occurs as learners retreat from interaction to focus on individual and internal reflections. In fact, some experts consider this to be slightly more important than real-time teacher-learner interaction. However, most instructors regard this as occurring naturally as part of other interaction and therefore did not rank it highly.

**Synchronous learner-learners interaction**
Surprisingly, synchronous interactions are not highly valued, even interaction between learners. An expert felt it may be needed for some learning activities such as reflection on expert panels but is not really a necessity.

**Synchronous learner-self (reflective) interaction**

Revising one's thinking is regarded as one type of interaction wherein good learning occurs. The learner plays around with ideas and contemplates on his actions and thinking. However, as with learner-self reflection, the experts see this as occurring naturally and therefore did not see the need to rate it highly also.

**Synchronous learner-material interaction**

The experts see this type of interaction as more important in certain subject areas like physics and chemistry, and to a lesser extent in subjects like music, art, sports and so forth.

Overall, this is a composite image, that is, an average ranking of often sharply differing views. One expert refused to accept the overall ranking because he believes that real-time interaction is the key to effective learning. His institution has been committed to using the synchronous interaction mode since 1982. He believes that the other experts in the group rated the synchronous mode low because they do not have a way to do it easily and well. However, he also feels that the asynchronous mode is also important and a blend of the two is needed for effective online learning.

5. Conclusion

The reasons put forth by the experts show that the rankings were not given randomly. They had put much thought into the exercise, and much of that is supported by their experience in distance education instruction. It is unlikely that a consensus can be reached but it would appear that the majority supports the use of the asynchronous mode. Advocates of this mode feel that the use of this mode is more convenient for distance learners and meets learners’ interaction needs. On the other hand, the synchronous mode has an unassailable immediacy and this condenses communication in a way that cannot be duplicated fully online. The classroom is the foremost example of the synchronous mode and its continued prevalence even with a generally inferior cost structure shows that it is still the favored way to learn. That it has been often misused by a dominance of teacher-centered instruction does not detract from its inherent flexibility and compactness.

When it comes to the different types of interactions, there is a clear preference for learner-learner interaction followed by teacher-learner interaction. The surprise is the low ranking for reflection but this does not mean it is regarded as unimportant. Clearly, distance educators regard reflection as part and parcel of the other highly ranked interaction types. However, this situation should not be taken for granted and educators need to focus on learning strategies that would foster critical reflection to improve higher level thinking among learners.

Perhaps the question of what types of interaction and mode are needed in distance education should be answered by the learners themselves. While experts have a good perspective on these issues because of their close involvement with the field, it is the learner who knows best what works for him or her. Also we need to bear in mind that what is best for a learner can be the sum of many factors - accessibility and costs among them. It does the learner no good if we know what the best mode and types of interaction are for the learner but the learner cannot afford them.

Empirical Evaluation of Adaptive Annotation in Hypermedia
Marcus Specht
GMD - German National Research Center for Information Technology
Institute for Applied Information Technology (FIT-MMK)
D-53754 Sankt Augustin, email: specht@gmd.de

Abstract: Empirical evaluations of learning with hypertext have shown contradictory results. Adaptive hypertext was introduced to solve some problems when learning with hypertext. In the following paper two empirical studies comparing different forms of adaptive hypertext are described and the results are discussed. In the first experiment four treatments where realized by a combination of adaptive annotation and incremental linking of hypertext. Results show significant better improvements in knowledge tests for subjects learning with adaptive annotation and incremental linking. In a second study different forms of adaptive annotation where integrated in the WWW-based learning environment AST. Results showed a significant interaction between previous knowledge of students and the adaptive annotation of the learning materials. Students who performed well in an introductory knowledge test seemed to work more intensively and successful with a more supportive form of adaptive annotation, while students with less previous knowledge seemed to need more guidance and profit from a more restrictive form of adaptation.

1 Introduction
Empirical studies have shown contradictory results about the efficiency and effectiveness of learning with hypertext as compared to linear textbooks. The benefit of learning with hypertext seems to be dependent on various factors like previous proficiency in the domain, the complexity of the domain or the learners motivation. Arguments for better learning with hypertext are the cognitive plausibility and assumptions about the acquisition of meta-cognitive knowledge. However there are some problems with hypertext often mentioned in the literature. Students loose orientation or are overwhelmed by the mass of information presented to them [Conklin 1987; Conklin & Begeman 1988].

Adaptive hypertext was introduced as one possible solution to overcome these problems of learning with classical hypertext. Adaptive methods in hypertext try to make an adequate presentation and selection of content for individual learners. However, beside the argumentation that adapted hypertext must be a better learning medium because information and presentation is tailored to the student, empirical studies on the effects of learning with adaptive hypertext are rarely found. Furthermore differential effects between various adaptive methods are not evaluated in experimental studies until now. The need for differentiating between adaptive methods becomes obvious when considering the consequences of these adaptive methods for the learner. For example, the method of incremental linking hides hyperlinks that in some sense are not adequate for the learner. This restricts the learner's navigational freedom and can have important drawbacks on learning. On the other hand adaptive annotation like introduced in ELM-ART [Weber & Specht 1997] gives adaptive navigation support to the learner without any restrictions on the content or navigational level.

In this paper two empirical studies are presented which compare learning with hypertexts that were enhanced with adaptive annotation and incremental linking. The first study compares learning with adaptive hypertexts and a static hypertext in an experimental setting. The second study compares three forms of adaptive annotation in an WWW based learning environment on statistics: AST [Specht, Weber, Heitmeyer, & Schöch 1997].

1.1 Adaptive annotation as a learning aid
In his review of adaptive methods in hypermedia Brusilovksy [1996] distinguishes two major groups of adaptive methods: methods of adaptive presentation and methods of adaptive navigation support.

In this paper the focus will be on methods of adaptive navigation support, especially adaptive annotation and incremental linking. Methods of adaptive navigation support differ in their impact on learners freedom to navigate

---

1 The main idea of incremental linking is to incrementally introduce hyperlinks in a document depending on the knowledge a student has already acquired. Implicitly this method restricts the navigational freedom of a learner through hiding hyperlinks to complex contents.
in a hyperspace. Furthermore, combinations of adaptive methods can restrict the users of a system in varying ways. The amount of learner control seems to be a central variable when integrating adaptive methods in educational settings. In the literature there have been mentioned several arguments for and against learner control:

**Acquisition of metacognitive skills:** Devoper und Quintin [1992] stress the importance of learner control for the acquisition of metacognitive skills. They argue that the amount of learner control should be dependent from the age, the domain knowledge or the complexity of learning materials. Greer and McCalla [1993] criticize a surplus of confidence in the abilities of learners for self controlled learning.

**Acceptance:** Restricting learners in learning environments can be frustrating for them and therefore be rejected by the learners. The amount of control of a learner and the acceptance of a "teaching system" is dependent on the preskills and the knowledge state of a learner. Novices often want to have some guidance, while experts are just annoyed by restrictions.

**Additional mental load** through learner control: Beside the freedom for learners learner control requires additional efforts. Decisions about where to navigate and what is best to be learned next have to be made by the learner. This adds meta-tasks of monitoring and self-evaluation to the the learners tasks of learning the domain. Hammond and Allison [1992] showed that the improvements of learning through learner control depend on the previous experience of a learner the subject matter. Secondary and metaanalysis of learner control show disappointing results: although motivation and engagement of learners seem to increase through learner control, results in performance tests are mostly better in adaptive and systemcontrolled learning environments.

1.2 An experiment on adaptive annotation and incremental linking in hypertext

1.2.1 Method

In the following study learning with three different forms of adaptive hypertext and learning with a static hypertext were compared. The four experimental treatments where realized by a combination of the two adaptive methods of adaptive annotation and incremental linking.

**Adaptive annotation** of hyperlinks supplies the user with additional information about the content behind a hyperlink. The annotation could be adapted to the individual user by taking into account different aspects of the learner and relations of the contents to be learned. In the following study information about the learner's knowledge state and a didactic model of the domain concepts were used to adapt the presentation of coloured balls in front of each hyperlink. The knowledge state of a learner was represented in the learner model by simply storing if a concept was seen by the learner. The didactical model of the domain specified prerequisites (concepts) for each domain concept. Concepts which had been visited by the learner were annotated with a hook, concepts which the learner was not ready to learn (because of lacking prerequisites) were presented with a red ball, and recommended concepts were annotated with a green ball.

</tr>
</tbody>
</table>

**Incremental linking** can be considered as a special way of adaptive hiding. In contrast to adaptive annotation, adaptive hiding restricts the learners freedom to navigate in a hyperspace. While adaptive annotation just gives additional information adaptive hiding simply hides some information that is not adequate for the learner in the current situation. Based on the didactic model and the learner model concepts which the learner was not ready to
read are hidden. In the following experiment the information that was not adequate for the learner was not directly hidden from the screen but there was no way to get to this information. Concepts the learner was not ready to visit (cause of missing prerequisites) where not presented as a link in the hypertext.

From a combination of these two adaptive methods four different experimental treatments were realized, which are shown in [table 1]. In the experimental treatment *IncAnno* both adaptive methods were applied to present the hypertext. Consequently learners were restricted in their freedom to navigate the hypertext because of incremental linking. Learners had full transparency of the whole hyperspace because they could see where they need to go and where they will be allowed to hyperjump later on. [Figure 1] shows the hypertext in the treatment *IncAnno*. In the treatment *Inc* learners could not see where they will be allowed to jump later on, only concepts that were appropriate to their current knowledge state were presented as a hyperlink [Figure 2]. In the adaptive condition *Anno* all hyperlinks were presented from the beginning, learners were not restricted in their navigational freedom and had additional information about the adequacy of hyperlinks [Figure 3]. In the last experimental condition a static hypertext with no adaptation was presented to the learners [Figure 4].

![Figure 1: The main page of the hypertext in the experimental treatment *IncAnno*](image1)

![Figure 2: The main page of the hypertext in the experimental treatment *Inc*.](image2)

![Figure 3: The main page of the hypertext in the experimental treatment *Anno*.](image3)

![Figure 4: The main page of the hypertext in the experimental treatment *Text*.](image4)
The underlying hyperspace consisted of 16 concepts about prionic diseases. 12 concepts could be reached directly from the main page, while 4 only could be visited via another concept. The only static link in all treatments was the possibility to jump back to the main page from each concept.

1.2.2 The experiment

All subjects had to answer a demographic questionnaire and a knowledge test about prionic diseases. The knowledge test included 12 questions about central concepts of the curriculum with varying difficulty. Next a short introduction to using hypertext and information about the specific experimental treatment was given. When the subjects had visited all hypernodes the system automatically presented the concluding questionnaire. This included the knowledge test from the beginning and additional questions about the usability and helpfulness of the adaptive methods. As the main dependent variables the time to read all hypernodes and the number of correctly answered questions was measured.

1.2.3 Results

85 subjects completed the experiment. In the demographic questionnaire there were no differences in the experience with computers and the WWW experience between the four groups. In all experimental conditions there was a significant improvement of correctly answered questions from the introductory to the knowledge test at the end (F(1,81)=308 ; p<0.01). In the introductory knowledge test the treatment group Text had the best results, in the knowledge test at the end the group IncAnno showed the best results. For browsing the hypertext the group IncAnno needed less time than all other groups, subjects in the condition Text needed more time than all others. The means of the two knowledge tests and the time to browse the hypertext are shown in [table 2].

</tbody>
</table>

To be sure that the experimental groups didn't differ in their previous knowledge about the domain a variance analysis was computed on the data of the introductory knowledge test, which showed no significant differences (F(3,81)=0.37 ; p>0.05).

A variance analysis comparing the treatments for the second knowledge test showed a hardly not significant main effect for the adaptive annotation of hyperlinks (F(1,81)=3.91 ; p=0.052) and no significant effect for the incremental linking (F(1,81)=2.410 ; p>0.05). Significant effects for both adaptive annotation (F(1,81)=13.17 ; p<0.05) and incremental linking (F(1,81)=4.49 ; p<0.05) could be shown for the time to browse the hypertext. Comparing only the two experimental groups which had both adaptive methods (IncAnno) and which had no adaptivity (Text) showed a significant effect on the correctly answered questions (t(39)=2.38; p<0.05) and the time needed (t(39)=4.23; p<0.05) to browse the whole hyperspace.

1.2.4 Discussion

The results show better improvements in a knowledge test when learning with adaptive hypertext than learning with static hypertext. Learners which were restricted through incremental linking needed less time to read a hypertext and did not report problems with restrictions. By a combination of adaptive annotation and incremental linking learners got information about the whole hyperspace and the concepts that can be learned when progressing through the curriculum. This kind of transparency led to significantly better performance in a concluding knowledge test than learners in the static hypertext condition.

From our point of view the differences between the treatment Anno and IncAnno are interesting. Although there was the same navigational support available for learners in the two treatments, there were no restrictions to navigational freedom in the treatment Anno. Learners were not prevented from jumping to complex concepts before reading about the prerequisite concepts. On the one hand one may argue that this would evoke feelings of loss of control (which were not reported in a questionnaire). On the other hand the restrictions lead to a more
effective and efficient learning of the curriculum in the experiment. Of course this difference could be dependent on the complexity of the curriculum taught. We see two main conclusions from the results of this study:
1. The effects of adaptive methods in learning environments should be investigated in isolation and in view of synergetic effects between the methods.
2. The main criticism on integrating adaptive methods in educational hypertext are dependent on various learner features, the setting and the curriculum. Following a more instructional approach could be appropriate for learning small curriculums in an effective and efficient way. A more constructivist approach could be appropriate for complex curriculums and domain experienced learners.

1.3 A field study on adaptive annotation in a learning environment
In the second study different forms of adaptive annotation were integrated into the WWW Courseware "Adaptive Statistics Tutor" (AST). AST is an adaptive learning environment for learning introductory statistics on the WWW. Learners can read texts, look at examples, play around with concepts by manipulating interactive java applets or html-forms, or work on tasks and tests. Students can start from any point in the curriculum. When a learner selects a new section the system checks if all prerequisites for that section are already covered by the student. If a student lacks some knowledge for working on that section, the system presents some tests for the lacking knowledge. Depending on the result of the tests the system infers that the learner already knows about the prerequisites or recommends some hyperlinks.

1.3.1 Method
Similar to the experimental conditions in the first study three adaptive treatments were realized in the AST learning environment. The three treatments resulted from a combination of adaptive annotation and adaptive hiding.
1. ANNOTATION Annotation of Hyperlinks: With each hyperlink a colored ball was presented, which gave some information about the concept behind the hyperlink. The color of the balls was adapted to the knowledge state of a student. Green balls classified the corresponding link as a recommendation, orange balls were presented when all prerequisites to this concept were learned and red balls meant that the hyperlink leads to a hypernode with prerequisites that were not yet learned by the student.
2. HIDE Annotation of Hyperlinks and hiding of "red" hyperlinks: In this treatment adaptive annotation of hyperlinks was realized like in treatment 1. except that hyperlinks which lead to "not ready to be learned" hyperlinks were hidden. When a student had mastered all prerequisites of a concept than the hyperlink to this concept was made visible and presented with an orange ball. The annotation of hyperlinks with green balls was computed by the system taking into account the knowledge state of a student, the learning material that were already seen by the student and a didactic model for sequencing concepts and learning materials.
3. STATIC Annotation of learned and not learned concepts: In the third treatment all annotations were done with white balls and hooks, so learners only got information about what concepts they already had learned (hook) and what concepts they needed to work on (white ball).

1.3.2 A field study
In the field study the courseware was accessible to students of the University of Trier. Before working with AST students had to fill out a demographic questionnaire and work on a knowledge test about the statistics curriculum. The curriculum contained 23 concepts in 8 sections about descriptive statistics. With each section and concept 5 to 15 tests were stored. When learners mastered a certain amount of tests correctly the system assumed that the students had learned that concept. The students were allowed to work with AST as long and as much as they wanted and the system was able to keep the user model over multiple sessions.

1.3.3 Results
In a period of three months 180 subjects worked with AST. In the following study only 67 subjects are taken into account because they did more than 20 requests to the system. The number of requests and the requested type of learning material was dependent on the adaptive treatment.

Table 3: The mean number of requests splitted by type of learning material and the experimental treatment

<table>
<thead>
<tr>
<th></th>
<th>Introduction</th>
<th>Text</th>
<th>Test</th>
<th>Summary</th>
</tr>
</thead>
<tbody>
<tr>
<td>ANNOTATE</td>
<td>1.04</td>
<td>1.0</td>
<td>3.70</td>
<td>.64</td>
</tr>
</tbody>
</table>

1381
Subjects in the **ANNOTATION** group requested significantly more text material (F(1,2)=6.11; p<0.05) than the other groups, while the subjects in the **HIDE** condition requested more tests (F(1,2)=5.77; p<0.05) than the other groups. The mean number of requests for the different learning materials are shown in [table 3]:

<table>
<thead>
<tr>
<th></th>
<th>HIDE</th>
<th>STATIC</th>
</tr>
</thead>
<tbody>
<tr>
<td>Requests</td>
<td>1.13</td>
<td>1.01</td>
</tr>
<tr>
<td>Tests</td>
<td>.59</td>
<td>.62</td>
</tr>
<tr>
<td>Errors</td>
<td>5.39</td>
<td>2.17</td>
</tr>
<tr>
<td>Errors</td>
<td>.68</td>
<td>.40</td>
</tr>
</tbody>
</table>

The number of requests was not confounded with the preferences for different materials specified in the introductory questionnaire. In the knowledge test before learning with AST there were no differences between the experimental groups. After introducing a post-hoc split between students with good results and with bad results in the introductory knowledge test an interaction effect on the number of requests could be clarified. Students with good results in a preliminary knowledge test worked more intensive with the system when they were in the **ANNOTATE** group. Vice versa, students with bad results in the introductory test worked better (more requests) in the **HIDE** group. The interaction effect between the results in a preliminary knowledge test and the adaptive treatment is shown in [figure 5].

1.3.4 Discussion
The different learning materials requested by subjects of the different treatments could be evoked by the nature of the adaptive treatments. This becomes obvious when looking at the **HIDE** treatment: Students could only get to more complex contents when working on the tests of the visible concepts. Similar to the first experiment the restriction of learners to certain subparts of the hyperspace can have different effects which are reflected in the interaction effect with the domain knowledge of learners. Learners who have good working knowledge in the domain seem to prefer more navigational freedom like in the **ANNOTATE** treatment. Learners who do not have much previous knowledge of the domain seem to prefer more directive guidance and work better with restrictions of navigational freedom.

2 General discussion and further work
Two experiments evaluating the effects of adaptive methods in two different settings were reported. In the first study a combination of adaptive annotation and incremental linking showed the best improvements of the knowledge acquisition process. In the field study reported second the shortcomings of empirical investigations in complex learning environments prohibited as clear results as in the experimental study. Most of the students did not complete a concluding knowledge test. This made it impossible to compare the knowledge improvements in the different experimental treatments. Nevertheless, results showed that the type of adaptive annotation can have
Important impacts on the learning process and the style of learning. Different forms of annotation can have consequences on motivation and the acceptance of a learning environment. This is consistent with earlier results of Weber and Specht [1997]. In the future interactional and synergetic effects of different adaptive methods, learner features and characteristics of the educational setting have to be investigated in more detail.

Abstract: This paper discusses the problems of teaching statistics to engineering students and how multimedia and the World Wide Web alleviate and enhance many of the traditional limitations of teaching a "theoretical" subject to non-specialists. The paper presents examples of several multimedia and Internet projects and developments which help make statistics more accessible by reducing the theoretical demands of the subject and more effectively illustrating its practical applications.

Introduction

Multimedia systems offer great potential in engineering education in their facility to present concepts and applications in a highly interactive and visual environment. Traditional educational techniques are often limited in providing effective communication of engineering ideas to both undergraduate and practicing engineers.

Engineering is demanding both to learn and teach. It requires a broad base of background information, conceptual understanding and knowledge of practical applications. Traditional teaching methods often fall short in providing students with the all round appreciation necessary for an efficient and thorough understanding.

The teaching of statistics to engineering students is difficult for several reasons [Bisgaard 1991]. Many courses do not provide the time necessary to assimilate the concepts. The terminology philosophy and mathematics of the subject is therefore daunting to many engineering students. Statistics however is particularly important as applications abound in many engineering fields. More emphasis needs to be placed on a deep understanding and application of subjects such as statistics rather than just a theoretical underpinning. Traditionally this has been one of the major hurdles in teaching statistics to non-specialists. It in not just sufficient to say that these students do not have the proper background. The most significant shortcoming is if they do not appreciate the relevance and application of the subject to their particular field of interest.

At Nanyang technological University (NTU) in Singapore statistics is taught as part of several courses including:

- Quality Assurance and Quality Engineering
- Systems Modelling and Simulation and
- Manufacturing Management Decision Support
- Engineering Research Methodology

Multimedia offers a facility to enhance the learning experience of engineering students by providing interactive and visual support to teaching and an exciting way of linking the theory to the practice of the subject. [Norman 1997], [Lane and Atlas 1997]. This approach is particularly useful when teaching large class sizes, which are often a feature of university teaching.

Often similar topics in different disciplines have similar theoretical content in a different context. Multimedia offers an easy way to adapt the material by creating different examples depending on a particular subject and to develop a more relevant approach for courses that may emphasise either the technical or management aspects of the subject.
Naturally many resources exist on the World Wide Web (WWW). There are excellent examples of on-line textbooks (for example [Lane 1997]), tutorial packages and Java applets. A group of seven UK Universities, for example, established a consortium called STEPS (Statistical Education through Problem Solving) to provide tutorial modules for various statistical techniques which can be downloaded from the Internet [STEPS 1997]. These may be used in a tutorial environment or by the individual user.

One obvious problem of the World Wide Web is quality control. Developing a home page for the subject provides one solution to this problem. Home pages developed for statistics based subjects at NTU (as in other Universities) provide the student with on line access to course details, time tables, lecture notes and links to relevant and critically acclaimed sites. A second limitation of the World Wide Web is that it is not always possible to use these resources in a classroom environment if connection to the Internet is not readily available. Even where connection is available, access to the Web is often painfully slow which is not tenable in a teaching environment. However these limitations will almost certainly be overcome in the near future.

The next section examines some specific examples of multimedia developed for teaching statistically based engineering subjects at NTU.

Examples and Illustrations

The Central Limit Theorem is one of the fundamental theorems in statistics. The theorem is relatively easy to prove mathematically and it has far reaching in effects. However it is not always easy to put the concepts across to engineering students. The example shown in figure 2, developed in TOOLBOOK (Asymetrix), a multimedia authoring software, shows an animated illustration of using the central limit theorem to simulate the average waiting time in a bank. This particular example is used for business students. The same text is used with a different animation (average waiting time for a machining operation) when teaching engineering students.

Statistical Analysis software such as STATISTICA (Statsoft) provide useful interactive capabilities, colorful graphics, a downloadable demo version which can be used by students to solve simple problems and an excellent on-line manual with full hypertext and extensive references. Whilst STATISTICA and similar statistical software packages would not usually be termed as multimedia, they do provide facilities such as excellent on-line graphics for data visualization, multimedia tutorials and a fully linked hypermedia on-line help facility. A particular useful feature (figure 3) is interactive graphical exploratory data analysis, (an interactive method known as brushing which allows the on-screen selection of specific data points or subsets of data to identify their characteristics, or to examine their effects on relations between relevant variables. These sort of facilities offer an exciting challenge to the engineering student in developing an all-important visual approach to a subject, which is often considered theoretical and irrelevant, by engineering students.
Teaching decision trees as part of decision analysis illustrate a very simple innovation which can be performed easily in software such as POWERPOINT (Microsoft) – The sequence of building the tree and solving the necessary equations can be developed by displaying the diagram (and or equations) in a natural sequential order (figure 5). Recent versions of POWERPOINT allow diagrams and text to be built incrementally on the screen. This allows the students to visualise the sequence of the problem solving steps as well as providing opportunities for classroom interaction as the problem is solved. POWERPOINT is particularly easy to learn and it is fully integrated with Microsoft's wordprocessor and spreadsheet. The latest version of the software allows multimedia components to be seamlessly integrated with presentations.

Figure 2: Illustration of the Central Limit Theorem using TOOLBOOK™

Figure 3: Interactive graphical exploratory data analysis using STATISTICA

Figure 4 shows a simulation of the Funnel Experiment [Deming 1986] developed in TOOLBOOK. The experiment illustrates that if a process is in statistical control then tampering with it will increase the variation of the process. This is particularly simulation allows interaction in a classroom environment. The student volunteer is asked to run the multimedia presentation of the funnel experiment. The student is cajoled and persuaded by the lecturer and other students (as he would be in industry) to attempt to improve the performance of the system (without the opportunity to redesign the system). This realistic scenario quickly results in an increase in the variation of the system.
One of the most significant factors constraining the development of multimedia systems for teaching in the lecture theatre is the investment in development time. *POWERPOINT* offers the facility to develop a complete system in a relatively short time. Incremental development using the integration facilities provided by *POWERPOINT* allows a sophisticated multimedia presentation to be realised. This approach is particularly useful in situations where the lecturer wishes to adapt the system during the teaching cycle to incorporate particular subject material relevant to his student requirements. A complete *POWERPOINT* presentation can then form the blue print for future development on a more sophisticated multimedia platform [Spedding and deSouza 1995].

Discrete event simulation techniques demonstrate a host of statistical techniques and can be applied directly to the manufacturing environment or service industry. Usually discrete event simulation software have a powerful animation capability and so can be excellent tools for providing the creative link between statistical theory and the engineering application (Figure 6). Recently for example, the Promodel Corporation gave their discrete event simulation software (PROMODEL ) to 15 year old high school children as a mechanism for learning statistics. As part of the project these students took the software into local industry to solve real problems. The multimedia capabilities of such systems are becoming more comprehensive. This is not only important in teaching the concepts of simulation but also very useful in the industrial context where engineers can witness a realistic animation of their manufacturing system and have a multimedia interpretation of the statistical output [Spedding, deSouza and Chan 1995].
Figure 7 shows an interactive assessment of a student laboratory using TOOLBOOK™. This work is part of an ongoing project for developing a virtual laboratory environment. Students answer questions based on the statistical analysis of their laboratory results. The questions are designed to be visual and entertaining and test the student’s knowledge and understanding of the subject. If required an interactive help facility will lead the students to the correct answer but marks will be deducted depending on the extent of its use. Marks are stored on the database system for easy access by lecturers. A similar system in the University of Western Australia is used as part of a continuous assessment programme [Scott, Devenish, Entwistle, and Stone 1995]. Students are required to use the assessment system to answer progressively harder questions throughout the semester. One particular feature is an automatic tracking system which allows the lecturer to keep a watch on student performance thus making it possible to identify weak students at an early stage so that the can be offered the necessary help and encouragement.

Figure 7: Interactive Student Assessment using TOOLBOOK

Conclusions

This paper has illustrated several multimedia applications specifically developed to teach statistic to engineering students. Multimedia facilitates the transfer of knowledge which might not be inherently obvious to a student. It also provides a link between real applications and theory. Engineering is a multidisciplinary subject and so engineering students are forced to learn and develop an appreciation of many “non-engineering” subjects. Multimedia provides the mechanism and flexibility to communicate the essence and relevance of non-engineering subjects in a dynamic and interesting fashion.

Davies [Davies 1995] succinctly sums up the importance of using educational multimedia for teaching statistics:

Teeode is a project funded by the European Commission through the programme SOCRATES for Open and Distance Education.  
http://www.doe.d5.ub.es/te/teeode/

Introduction

Distance learning courses are an important way of meeting society's needs for more flexible ways of educating and training a modern work force. Supporting students at a distance raises new and interesting questions. Of particular interest to the TEEODE project were the methods of assessment and evaluation employed by the various suppliers of distance learning courses. The aim of the TEEODE project was to develop a representative survey of the models of assessment and evaluation used by institutions supporting distance learning. This survey endeavoured to cover all fifteen member states of the European Union.

For each of the member countries of the EU we attempted to survey up to 10 institutions on their formal procedures or framework for assessment and evaluation; and up to 10 tutors on individual courses within those institutions on how they conduct their assessment and evaluation.

In this part of the TEEODE project we have focused upon issues of Course Development and Assessment, and in particular, on how we achieve effective learning outcomes and how that learning is communicated to the learner. Other parts of the project have looked more closely at the institutional issues. The emphasis here is on the tutors' perceptions, teaching assessment and support-related issues.

If distance learning is to be seen as legitimate it must meet student, tutor and, in many cases employers', needs. In assessing their students, tutors should have a clear idea of their learning goals and they should also be able to match those goals to the assessment and evaluation instruments they employ.

Marton and Slåtjo (1976) showed that students that tackled their studies in a way which was called a 'deep approach' gained a through understanding of the material studied. On the other hand, students whose approach was labelled a 'surface approach', failed to gain a grasp of the material which had been studied. Ramsden (1988) provides a useful summary of 'deep' and 'surface' approaches to learning.

<td>Intention to complete learning task assignments</td>
</tr>
</tbody>
</table>

1390
In the tutor questionnaire presented here we were interested in identifying tutors’ perceptions of:
1. the learning goals of the individual course they chose to tell us about;
2. the modes of assessment they felt aided them in achieving those goals;
3. any mismatch that might occur between those goals and the modes of assessment.

1 The Course Tutor Questionnaire

The Course Tutor Questionnaire (CTQ) was based on interviews with tutors and administrators in ODE institutions, and the final versions (pilot as well as translations) were also checked for readability and understandability.

Translations of the English version were made into Finnish, French, German, Italian, Portuguese, Spanish and Swedish.

In the process of translating the English version, a number of problems were encountered which had to do with differences in the educational systems in the different European countries. What, for instance, is the equivalent of an English BA in other European countries? We endeavoured to approximate to the English original as close as possible to make results comparable across European countries.

The final form of the CTQ consists of seven parts which relate to
1. the tutor,
2. the course,
3. the students,
4. the assessment of the course,
5. production of the assessment material,
6. delivery of the assessment instruments,
7. staff development.

If the respondents were interested in receiving a copy of the results of the investigation, they were asked to provide their address.

The different versions of the CTQ were made available in the internet at http://www.doe.d5.ub.es/te/teode

The user was asked to type in his or her responses and these were then collected at the the University of Barcelona. Also, paper versions of the CTQ were sent to ODE institutions in different European countries.

2 The Sample
The initial sample of 10 tutors from each of 10 institutions for each of the member countries of the EU we attempted changed over time. One of the main reasons for this was the method of data collection (paper-based questionnaires sent out by regular mail and on-line questionnaires made available on the web).

There were two main benefits of the on-line questionnaire. The first was that it widened the sample beyond the initial fifteen member states, hence the inclusion of data from Israel, Mexico and the USA in our survey. It also proved highly efficient in gathering data together and the transfer from questionnaire to data-sets for analysis was achieved with efficiency through this route of data collection.

Unfortunately, however, there were some problems with accessing the on-line questionnaires and we have suffered data loss, thus some 25% of the UK sample is missing and we are aware that our Scandinavian contacts also had difficulty in initial access to the web questionnaire.

We tried to reach as many ODE institutions as possible, being well aware that, within the limitations of our budget, it was not possible to have neither a truly representative nor a purely random sample. We did hope, however, that we might achieve representativeness at least to some degree.

There were 224 CTQs returned. They were distributed across the different countries very unevenly. It is difficult to establish the reason for this, but one explanation that seems very plausible is that ODE institutions in Europe vary very much with respect to the extend and importance they have in the different European educational systems. In the UK ODE is well established but this is not the case for many of our European partners.

3 The tutors

Of the 224 respondents, 59 (26.3 % of 224) indicated they were course organizers and 175 of them (78.1 % of 224) declared to be course tutors. However, only 17 (7.6 % of 224) acted both as course organizers and course tutors.

Somewhat more than half of the tutors were employed on a full-time basis (125 versus 99 half-time, i.e. 55.8 % versus 44.2 %). An interesting finding was that all of the tutors were relatively new in their courses: none of them had worked for more than three years in his course, 99 (44.2 %) had given his course for less than three year but for more than one year, and 125 (55.8 %) had given his course for less than one year. This finding may reflect that rapid and recent rise in interest in ODE across our institutions or, it may be the case that tutors selected to talk about new courses rather than courses they have worked on for a number of years.

4 The courses

Table 1 gives an overview of the subject areas that were covered by the different courses. The single most cited category is languages (33.5 %), followed by literature (20.5 %). If we subsume the first six categories under the heading "Science of Letters", than almost three quarters (71.4 %) of the courses fall under this heading and a remaining 18.3 % (categories 8 to 12) under the heading natural sciences. This contrasts sharply with the findings of the Institution Questionnaire in which Business and Management Studies dominate the ODE field.

<td>9.8</td>
</tr>
</tbody>
</table>

Of the 224 tutors, 175 (78.1 %) rated their courses as academic and 45 (20.1 %) as professional or vocational. The length of the different courses varied substantially. 68 (30.4 %) of the tutors indicated that their courses lasted less than a year, 81 (36.2 %) had courses lasting between one and two years, 20 (8.9 %) were involved in courses lasting more than one year but with a time limit, while 55 (24.6 %) indicated that their courses did not have any time limit.

Table 2 shows how the tutors rated the level of their courses. As is evident, the vast majority of the courses (170 of 224, i.e. 75.8 %) lead to an academic qualification. This is very much in line with the tutors’ labeling the courses as academic versus professional or vocational.

<table>

Table 2: Level or courses

Cross-tabulating subject areas by course level shows that 63 of the 74 language courses (85.1 %) and 37 of the 47 literature courses (78.7 %) are academic while of the remaining subject areas in the sample, 23 of 58 are (71.6 %) academic.

5 The students

We asked for the age of the ODE students, but the results were rather inconclusive. 130 tutors (58 %) indicated that there was no set age and 69 (30.8 %) judged the age of their students to be more than 23 while only 25 (11.2 %) assumed their students to be younger than 23. It therefore seems that the age of the ODE students of our sample may be somewhat higher that that of "normal" college and university students. This is consitent with a view of ODE as an important way of gaining qualifications while working.
Concerning the entry qualifications of the students for the ODE courses, about half of the courses require no prior qualifications while requirements for qualifications are almost evenly distributed across the categories GCSE or General School Certificate (post 16; 15.6 %), A-level or Advanced School Certificate (16.5 %) and Bachelor Degree or equivalent (17.4 %).

6 Assessment of the courses

Of the 224 tutors, 92 (41.1 %) reported that formative assessments were undertaken during the course, 16 (7.1 %) indicated formative as well as summative assessments were being conducted while 116 (51.8 %) reported that formative as well as summative assessment was being done.

The most preferred mode of assessment turned out to be written assessment (208, corresponding to 92.9 %) followed by practical assessment (51 / 22.8 %) and oral assessment (43 / 19.2 %).

Please note: For this and the following questions in this part of our report, the alternatives were not mutually exclusive, i.e. a tutor might indicate that the assessment was conducted in written form as well as orally and practically; percentages are based on the 224 responses for each alternative.

With respect to the question of where the assessment was conducted, 84 tutors (37.7 %) named the host institution, 86 (38.4 %) a designated centre at a distance, and 49 (21.9 %) a place of the student’s choosing.

The tutors were given a number of alternatives which described the main objectives for assessing students on their courses and asked which of these they deemed most appropriate with respect to their own courses. Answers are given in table 3.

</tbody>
</table>

Table 3: Main objectives for assessing students

Evidently, the tutors consider application of knowledge and understanding as the most important objectives for assessing students’ achievements.

In order to learn more about tutors’ motives and beliefs with respect to conducting assessments of their students, we asked them to what extent different forms of assessment matched their educational goals. The forms of assessment were (1) multiple choice questions, (2) comprehension tasks, (3) problem solving tests, (4) practical tests, (5) project file or diary, (6) oral presentation or examination, (7) long essay or dissertation, and (8) written examination.

The tutors were asked to indicate to what extent the forms of assessment matched their educational goals on a five-point scale: (1) excellent, (2) good match, (3) satisfactory, (4) poor match, (5) no opinion. From these data, we computed two indices. First, we defined the degree of acceptance (DA) as the proportion of tutors (in percent) who chose to check one of the first three alternatives, i.e. who indicated that they perceived at least a satisfactory degree of match between the form of assessment and their educational goals.

Second, we transformed these categories (degree of match) into numerical values, assigning 1 to excellent, 2 to good match etc. We then computed a mean rating (MR) for those tutors who did rate the match between form of assessment and their educational goals. A low MR thus signifies a high degree of acceptance, and conversely, a high MR signifies a low degree of acceptance.
The most acceptable form of assessment (79 %) turns out to be the assessment by comprehension tasks, marked by
the tutor and conducted for formative assessment. This form is also rated highest with respect to the match between
assessment form and educational objectives. These results are in line with our former findings (see table 3) that the
tutors considered the assessment of understanding and the application the main objectives of their assessment
procedures. Interestingly, this form is less acceptable for summative assessment purposes (55 %) or with students or
peers doing the marking (38 % for formative and 22 % for summative purposes).

It seems that the question of who does the marking has a decisive influence on the tutors' ratings. For example, with
respect to multiple choice questions, the best match between form of assessment and educational objectives is
achieved when the marking is done by the tutor; students' marking obviously widen the gap between assessment and
educational objectives, while computers seem to be even less welcome as marking agents (the mean rating for this
combination is 3.11 - formative - and 3.16 - summative assessment). Preference for tutors' marking is also exhibited
with respect to the other assessment forms (indicated by the degree of acceptance as well as by the mean ratings).
Although our tutors are working in a new mode of teaching, they are still using very traditional approaches to
assessment.

Finally, with the exception of the „classical“ assessment forms of written examination, the assessment instruments
are considered more acceptable for formative than for summative assessment.

7 Production of the assessment material

In this section, we wanted to know where the assessment material that the tutors are using come from. More than half
of the tutors (126, i.e. 56.3 %) indicated that were using assessment instruments that were produced by course team
members. In most cases (98, i.e. 43.8 %) the instruments used were the result of a collaboration of the course team.

However, some tutors to some extent (57, i.e. 25.4 %) used assessment instruments that were not produced by course
team members most of which (67 %) came from commercial sources.

Concerning the type of the assessment instruments, 64 (28.6 %) of the tutors used instruments that were standardised,
80 (35.7 %) used instruments that were not, while 75 (33.5 %) did not know whether their instruments were
standardised or not.

8 Delivery of the assessment instruments

While in the section on the assessment of courses we had asked for the educational objectives that were being
persued in assessing the achievement of the ODE students and to what extent the instruments being used matched
these educational objectives, in this section we wanted to know what kind of assessment instruments were actually
being used.

When asked about the „traditional“ instruments, 61 tutors (27.2 %) reported using oral tasks and 206 (92.0 %), i.e.
the vast majority used written tasks. However, only in a very few cases was this assessment computer supported (in 3
cases for oral tasks and in 19 cases for written tasks).

Tutors were also asked if there existed a set interview schedule that must be followed in oral examinations. 33 (14.7
%) responded yes, and 30 (13.4 %) responded no, while 155 (69.2 %) checked the do-not-know alternative. This is
another indication that oral examinations do not seem to be used frequently as assessment tools.

In general, assessment criteria do exist, however. 90 (40.2 %) tutors declared this to be true, only 10 (4.5 %) denied
this, and 117 (52.2 %) preferred to check the no-answer alternative.

Finally, we wanted to know if computers were used in the assessment and in what ways. Very few tutors used
computer technology for assessment. Of the tutors that did so, 7 indicated that the system marked students’ responses
while 21 indicated that it did not. At the same time, 13 reported that the system provided feedback on responses to
students while 12 reported that it did not.
Of those tutors who used telematics, 6 conducted assessment in real-time and on-line while 16 did not conduct the assessment this way.

9 Staff development

In this last section, we wanted to find out in what areas there might be a need for further advice or training, and we asked the tutors whether they felt they might benefit from advice or training in the areas given. Frequency counts of the answers are exhibited in table 4.

</tr>
</tbody>
</table>

Table 4: Areas in which advice and/or training would be appreciated by the tutors

The data show clear variations in tutors' perceptions of their personal training needs for different modes of assessment. Few tutors felt that they needed additional help in marking, essays or in preparing formal examinations. However, significant numbers requested help in computer based assessment at both an introductory (16.5 %) and advanced (17.4 %) level. There was also considerable interest in obtaining additional training in the design (22.8 %) and assessment (17.4 %) of distance learning courses - but this need was for advanced level skills.

10 Summary and conclusions

The returns of the Course Tutor Questionnaire did not live up to our expectations. We invested a large amount of time and effort to contact ODE institutions in Europe and to distribute the questionnaire, but we received a relatively small number of responses. We only know that return quotas are in general relatively low with this kind of studies. Additional data has been received post this analysis. They will be incorporated in the year 2 report.

Nonetheless, from the tutors who did respond we received some very interesting data. It is clear that tutors aim at testing the application of knowledge and understanding when they conduct their assessments, and there is a preference for formative assessment, i.e. assessment that is done during the course. Traditional methods are being used, but tutors' preference is with comprehension tasks, multiple choice questions, and course essays. At the same time, tutors feel they would benefit from advice and training in the design of distance learning material and in the assessment of distance learning.

With respect to the computer, the results seem to be a bit paradoxical: On the one hand, tutors indicate that their educational goals can better be reached with multiple choice tests when marked by the tutor than when marked by the computer. This is difficult to understand because it would not at all be difficult to do the marking of multiple choice tests with a computer program in an “objective” manner. The objectiveness of multiple choice tests is in
general very high because the assessment of the results is independent of the person (or machine) who does the marking (given that there is a key for the correct alternatives). We therefore conclude that many tutors still do not feel at ease with the idea of letting the computer do the assessment simply because of lack of familiarity with this possibility. We consider this assumption to be substantiated by the fact that more than half of the tutors also were relative new in their teaching jobs (with an experience of a year or less with their courses) and that at the moment, there is indeed relatively little use of computers for assessment purposes in ODE institutions.

At the same time, tutors would appreciate advice and training in the use of computer based tests. Since they also exhibit interest in getting to know more about the design of distance learning materials and in the assessment of distance learning, we assume that their somewhat hesitant attitude towards computers would turn into a favourable one if they actually were given advice and training in using computer programs to develop distance learning material and instruments to evaluate the learning processes of their students.

Abstract: The traditional method of multimedia development is characterised by carrying out a number of processes in a linear fashion. This is an efficient method of development where a number of projects are occurring concurrently, but the lack of client pressure and the flexible skills base afforded by an academic environment provides an opportunity to develop multimedia in a unique, non-linear way. A review of the literature has highlighted the paucity of research pertaining to the development of multimedia programs and reveals the inadequacies of traditional systems design models for multimedia programs. This is particularly true for an environment where the development team frequently come from disparate backgrounds and are contracted from outside the University having little understanding of each other’s roles, leading to a breakdown in communications and misunderstandings resulting in an end-product at odds with the initial design concepts. Usually multimedia-based instruction is derived from a detailed preliminary analysis, but the instructional designer also brings personal assumptions to the design which are often not part of the analysis. These assumptions are evident in the way in which the program is designed, but may need to be re-examined and new strategies implemented in order to accommodate the ever increasing capabilities of the technologies. Two programs which demonstrate the results of different approaches of two instructional designers will be examined to illustrate some of these points.

INTRODUCTION

A grant of $20,000 was given to a project team to create a piece of instructional multimedia which could replace or supplement existing teaching within a unit in the Faculty of Business at Edith Cowan University. A review of commercially available instructional multimedia highlighted the fact that while the programs were aesthetically pleasing, they had a dry, unengaging feel to them. Analysis of these programs discovered that they were lacking in the areas of interface and interactivity design. When the decision was made to create a self-paced learning environment for students to learn about share valuation and investment, a review of the literature was undertaken in an attempt to determine what features needed to be included to motivate the students to use and engage with the program.

The team in question consisted of an instructional designer/project manager; a content expert and a programmer. Each member of the team was also skilled in at least one other area, for example each team member contributed to the graphics, and the programmer had a strong education background so had an immediate understanding of the needs and wants of the instructional designer, he was also primarily responsible for the production of the media.
At the outset the concern was primarily with initial and ongoing motivation, rather than learning outcomes, and once the elements to be included were identified, a concept map was developed and the program was designed. The resultant program, Principles of Financial Investment, was a microworld giving the students realistic insights into the world of share valuation and investment—a module within the introductory finance unit in the Faculty of Business.

Ten basic elements of program design modified from those identified by Duke (1980) were used to inform the design approach, with a focus on cognitive and affective aspects of the program's scenario, steps of play, and learners' roles to name a few.

This approach dictated many of the early design and development decisions where objectives were defined in terms of the program's interface rather than learning outcomes. The use of the term interface in this paper is used to describe the bridge between the content and the participant. It encompasses the organisation of the material, the screen design and layout, the use of the space and the way in which the participants moved through the program. Because of the complexity of the program, it was decided to break it into three main domains based on Gould's (1995) model. These domains are information design (content), interface design and interaction design.

The development model is illustrated in Figure 1. It shows the various stages the development team moved through when designing the program. Analysis and implementation are shown as being fairly discrete elements, but the information, interface and interaction design were done concurrently in an attempt to create a cohesive whole. In other words the team wanted an environment where the student moved effortlessly and seamlessly, with little cognitive effort expended on working out where they were, what they were doing there and how to move around. The authoring and media were created and constantly modified in conjunction with these three design domains, the whole process being iterative.

**INFORMATION DESIGN**

The first step in information design was to define the audience and plan and organise the content. A concept map was used to blueprint the content and to define the relationship between each of the elements. It was decided that a microworld would keep the context authentic while allowing the designer to incorporate some gaming elements necessary to keep the learners engaged and on-task. The potential of microworlds to combine didactic theory with simulated practice (Rieber, 1992) was viewed as advantageous in this product, and was difficult to achieve with other solutions.
A target audience analysis was conducted to determine the type of student who would be using the program and it was discovered that it had to appeal to both sexes, a variety of cultural groups, and an age range of 18 to 55. It was decided that it was important that the student be considered a participant in the process, rather than just as a user of the product. Considering the range and tastes of the participants was an important first step in the design of the program (Gould, 1995; Laurel, 1991).

Although storyboards were produced for Principles of Financial Investment, they were used more as a starting point. As the model shows, evaluation was an ongoing and constant process and minor adjustments were constantly made to the program. These were arranged mostly through emails rather than re-writing of storyboards. Archiving e-mail messages provided an audit trail for modifications made to the final product.

INTERFACE DESIGN

This process was guided by assumptions that best user interface demands the least learning effort” (Vaughn, 1994) and that the interface connects the learner and the content and helps to shape the interactive experience. “It is everything a user sees, hears, touches and feels. An interface must be functional and aesthetically pleasing and provide the information access and guidance that users need without hindrance” (Francois, 1996).

In this phase it was determined how the content and interactions would blend. The look and feel of the program was decided and the manner in which the content was accessed. A conscious decision was made to keep the interface simple, with cartoon style 8-bit graphics rather than realistically rendered images. This meant that the images took up very little memory and used minimal space, therefore being able to be used on fairly low level equipment. It also meant that the interface could be developed quickly and cheaply, allowing design efforts to be focussed on the educational elements of the program.

A first person approach was used, where the participant enters his or her name and they then become the “owner” of the share portfolio and the office. First-person sensory qualities are important in creating satisfying human-computer experiences and present experiences rather than information (Laurel 1991). As Laurel points out “Learning through direct experience has, in many contexts, been demonstrated to be more effective and enjoyable than learning through information communicated as facts” (Laurel, 1991: 119). This use of the first-person also overcame the problems of gender-bias and cultural and age differences.

A key step in the interface design was deciding upon a metaphor to use. In this case the form did infer the function in that the metaphor of a stock exchange building was an obvious choice, together with the attendant industries—a securities institute, broker’s office and participant’s office.

NAVIGATION

The navigational map outlined the connections or links among the various areas of the content and formed an “organiser” of the content and messages. There are generally four fundamental organising structures used to navigate around a multimedia program and often they are used in combination:

- **Linear**—the learners will navigate through the program in a series of sequential steps;
- **Hierarchical**—learners navigate along the branches of a tree structure that is shaped by the natural logic of the content;
- **Nonlinear**—learners navigate freely through the content;
- **Composite**—learners may navigate in a nonlinear fashion, but can be constrained by linear presentations of items such as movies or critical data which is logically organised in a hierarchy. (adapted from Vaughn, 1994)
Navigation is an essential component of interface design. In this program, it was essential that the students felt that they could move at will wherever they wished within each warp as "this empowers them within the context of the subject matter" (Vaughn, 1994: p 393). For this reason, a non-linear structure was implemented, allowed free navigation around the various 'rooms' of the microworld while diegesis and narrative flow was maintained by linear progression through financial quarters or 'Warps'.

Learners will often construct spatial mental models in order to move freely around a program and within the learning spaces and this has obvious implications for design (Sellen & Nicol, 1990). Designing a program which allows the learner to intuitively navigate using their mental model reduces their memory load and cuts down on the amount of time it takes the learner to learn to use the program. A navigational blueprint on the wall of each "room" in the program was used to assist in the users' construction of a mental model of the program structure and to provide an intuitive way of allowing the participants to move through the program. Clicking on doors in rooms allowed them to get into ante-rooms in a natural way.

INTERACTION DESIGN

Interactivity is the most recent component of IMM and has not yet evolved to the point where it is a communications device (Gould, 1995). Interaction design determines how the program works and how the learner acts within the program. Navigation and control are decided and outlined in the storyboard (Francois, 1996). "The storyboard is an extension of the concept map and is a rough approximation of what the end user will see and do on every screen. The objective is to keep the user oriented to the content through a system of controls and feedback" (Francois, 1996). As stated earlier, the storyboards were used initially and then supplanted by a more informal style of updating via the email. The nature of the interactions were carefully considered for Principles of Financial Investment and it was decided that the elements and techniques should be very different from those in mainstream computing systems. Buttons and menus were eliminated where possible as they denote a productivity device and this program aimed to keep the participant on task for as long as they needed in order to acquire the information, solve problems and make decisions; by engaging over time, the participant will experience a sense of change (Gould, 1995). Once the participants got used to the interface it was anticipated that it would become "invisible" to them so that they could get on with experiencing rather than using the program. In other words, the program should be simple but engaging.

A first-person perspective within an authentic setting provided for a more realistic and meaningful experience which encouraged users to take longer over investment decisions and problem solving, considering all the possibilities. The ability to view an expert and compare their own decisions with the experts in light of the theoretical foundations presented in the program would also impact on the nature of the interactions.

Usually in a computer system, the user must have a degree of competence in order to access the information in it. This program was designed for learners with a limited background in computing and was created to support browsing to permit a more flexible means of accessing the data. Although there was an optimum, primary path through the program, the non-spatial organisation permitted flexible browsing. Browsing is possible only if the
multimedia is interactive and non-linear. Due to the fact that the learner can move through the program in any order, they can use the simple navigation system to constantly check elements such as economic forecasts, theory elements from the Institute and company background information held in the Broker's office. This was considered to be important in assisting the students to achieve the learning objectives. Although a microworld was selected for the program design, a way of teaching the theoretical components without having the students wade through screens of text was necessary. The theory also needed to be presented in a way which was consistent with the authentic context of the rest of the program. It was decided to simulate an internet environment which allowed the use of hypertext links and slide shows if necessary. This environment also allowed the students to save their tutorial materials to disk, print them out and use the search facilities.

PROBLEMS OF THE APPROACH

The approach to development of Principles of Financial Investment was informal. This worked well for the three people in the team who communicated by email rather than in regular meetings and who worked collaboratively, sharing responsibilities and tasks. This approach would not work well in a team consisting of more people, or even in a commercial organisation where the responsibilities are more clearly delineated.

This approach is also fraught with danger. Should the programmer suddenly leave the team, there is no catalogue of media or programming style guide. So, although it worked well in this instance it is not the recommended method of development.

The use of this model is very dependent on the team members working together and working consistently. Some problems were encountered when the content expert became too busy to create some of the materials. In the more traditional approach, materials are created before programming starts therefore avoiding some of the bottlenecks experienced.

A "Waterfall" approach has benefits in that inconsistencies in style or content are weeded out much earlier. The team experienced some difficulties in changing elements consistently through the program.

This approach may not work as efficiently as the "Waterfall" approach for a straight presentation style program. Different approaches tend to produce different results.

ADVANTAGES OF THE APPROACH

One of the greatest strengths of this approach was the multi-disciplined nature of the team. This allowed an exchange of ideas and spontaneous development of the program not usually encountered in a traditional development team.

The speed at which the development took place was a distinct advantage. There was no need to wait for weekly meetings—all members of the team had access to each other at all times via the email system and turn around time on solutions to problems was therefore very fast.

CONCLUSIONS

In an academic environment, the method proposed here for Principles of Financial Investment worked well. A working model was produced quickly and cheaply and could start being tested with students within a relatively short period of time. However, it should be noted that this method may not have worked with other projects. This approach relies heavily on the synergy between team members and their iterative approach to design. If the aim were to develop a larger, maintainable learning system, the model adopted here may have proven to be too unstructured to support a necessarily higher level of management control. But it is likely that a program such as Principles of Financial Investment would have lacked many of the motivational features which made it successful if it were created under a linear development model. The multidisciplinary nature of the design team and evolutionary approach to development adopted for this project allowed for a unique organic synthesis of form and content into a more cohesive whole than would have been possible under traditional development models.

Abstract: This paper describes a study which formed part of a larger project exploring the motivation and engagement of adults using interactive multimedia for learning. In the larger project, it was hypothesised that adult learners would be motivated and engaged by educational interactive multimedia which is able to generate specific learner effects. The learner effects that were considered to be most important in influencing the motivation and engagement of adult learners were: immersion, reflection, collaboration, play, learner control, curiosity, fantasy and challenge. This paper describes the planning and development of an instructional landscape to generate and sustain these effects in learners and the results of a study to determine the impact and capacity of the various design elements employed to generate these effects.

INTRODUCTION

Motivation is well recognised as being important to student achievement (Walberg, 1981). However, there is a paucity of research concerning motivation and technology-based learning materials (e.g., Dempsey, 1994). Most IMM developers pay particular attention to the cognitive aspects of learning in their instructional design and attend in few ways to such affective aspects as learner motivation. The work that is described in this paper forms part of a large project involving an investigation of designing motivating and engaging interactive multimedia materials for adult learners.

Our inquiries suggest that for self-paced, resource-based learning materials to be motivating and engaging, they need to develop a number of effects in the learners, i.e.: immersion, reflection, collaboration, play, learner control, curiosity, fantasy and challenge. These elements are described in previous papers (e.g., Stoney & Oliver, 1997).

THE PROGRAM

In order to test the theory that these learner effects would have an impact on motivation and engagement, an interactive multimedia program was developed. It was quite a challenge from an instructional design perspective to plan an instructional program capable of supporting all these learner effects. We finally chose the form of a microworld as a possible framework for incorporating the instructional elements needed to provide the desired learner effects. The microworld has a number of inherent characteristics which appear to make it useful in this instance.

CREATING THE LEARNER EFFECTS

The following table summarises these desired learner effects and shows the instructional design that was used to enable each to be incorporated into the microworld design:
Table 1: Features of an engaging and motivating multimedia program

</tbody>
</table>

The coursework that was chosen for our project was a component of an introductory finance course in a Business degree. The chosen component involved share valuation and investment. The teaching and learning in this component was traditionally supported through reading and discussion. In an IMM environment, significant learning advantages were made possible, for example, student learning by exploration and inquiry, in their own time and at their own pace. The IMM program that was planned was carefully designed to incorporate not only the learning sequences needed to bring about specific learning outcomes but also the forms of affective components leading to the planned learner effects. The resulting program was designed in the form of a microworld.

THE STUDY

Having designed and developed the microworld, we explored the impact of the various design features in supporting the 8 learner effects which were seen to be important elements for a motivating and engaging learning environment. Twelve students used the program as an instructional aid across a period of 3 hours and in that time completed the various sections of the program to their own satisfaction. The students were videotaped and audiotaped whilst using the program, and interviewed at the conclusion. The students were asked a series of open-ended questions in order to elicit their feelings on the program and to identify which elements of the program contributed to their motivation and engagement. In particular we sought to have students discuss how they felt when they were using the program and the characteristics of the program which contributed to these feelings. The remainder of the paper describes the feedback from students describing their impressions in relation to the 8 intended learner effects.

IMMERSION

The students enjoyed the realistic interface which gave them a "graphical fix" on the content and context of the program, providing a strong link between visual and auditory modalities. Students mentioned several times that the realism of the program as well as the context, gave them a sense of being in the program which led to a feeling of complete immersion and engagement:

*We imagined ourselves in the situation, having to do something when you got somewhere... I felt like I was looking at a wall in the Stock Exchange. I could see how I'd use it in real life. I felt like I was there. The whole program immerses you, all the bits and the context. Buying shares and tutorials made it like real life.*
It is difficult to imagine how the students might have been immersed more than by the microworld setting. It was evident that this provided a strong framework for the program and created opportunities for many of the other learner effects to be developed.

**REFLECTION**

Reflection helps to engage learners by supporting higher order thinking and problem solving. The students recognised their reflective processes in a number of places in the program. For example, they were allowed to choose their own navigational paths and this led to thinking and pre-planning. Students found that they had clear, but implicit, goals and the program also made them stop and think at various stages. They enjoyed the conflicting advice they received and they all mentioned the ethical issues which they had been presented with by telephone. It is obvious that the students thought about what they had to do next, tried to balance the different information and make decisions on it, and related the theory to the practical aspects of investing.

_I thought about the investment mix, ethical considerations and media releases. Worked out a logical format by flicking through the program and deciding. The company summaries made us think, deciding what stock to buy and how much—so many combinations. Analysing information before investing—using forecasts and updates. Made me think about insider trading, ethical issues. Had to think about the approach to buying and selling, investigate the companies. I had time to sit back and think about what things meant. Can see things working, so can decide how to do something and imagine what’s going to happen._

All students recognised and commented on the way in which their reflection held their attention and engagement. The reflection was brought about by the open-ended nature of the instructional setting and the high levels of learner autonomy associated with decisions and actions taken as interactions in the program.

**PLAY**

Play is defined as a free and voluntary activity; a source of joy and amusement. The player is spontaneously devoted to the game, of free will and with pleasure (Caillois, 1961). Play is also an uncertain activity, doubt remaining until the end. An outcome known in advance with no possibility of surprise, is incompatible with the nature of play (Caillois, 1961). If the students are to engage in play, then elements of humour, novelty and fun must be present. These were evident in many places in the program and many of the items which students saw as sources of joy and amusement also had strong learning potential. Students’ responses clearly demonstrated the capacity of the program to provide a sense of play.

_I liked the humour, funny sounds, off-beat graphics and characters. The props, uncertainty and interface made using it enjoyable and fun. I enjoyed applying my learning, the funny characters, extra elements and the thrill of making or losing money. The combination of fun and theory made it unique. A more practical use of the material. I was attracted by the program—the graphics, colours, bits and pieces. The game makes things more interesting, stops you being afraid and bored. Easy interface, good graphics, fun sound effects._

The sense of play which students gained from the program were claimed to have been generated by the simulation and the task of share trading and facilitated by the many unexpected and chance elements associated with the microworld environment.

**COLLABORATION**

An emphasis on collaboration rather than competition is often seen as a supportive activity for effective learning. The program provided many opportunities for collaborative learning. Students were encouraged to provide
coaching to each other when they worked in pairs which helped all parties make decisions, and using the virtual 
experts as coaches meant that the students were collaborating with the computer itself. Student response 
indicated that they saw collaboration as an important and useful component of the learning environment.

I enjoyed working with a partner, we explained things to each other.
Helped me reinforce and remember the theory, discussed our investment mix.
Group decisions are good, conflict over decisions, sharing knowledge.
I like to work alone, to test the decisions, the consequences. The game let me know whether
I'd done well or not.
I worked alone, but I think working with a partner, I'd get to see both sides of an argument.
I think working with someone would be a distraction. I liked testing my decisions and
checking them against Wonda [the on-line character].

The students chose whether they wanted to work alone or in pairs and it seems that all were satisfied with their 
choices. They felt that they were able to test themselves in context and receive authentic feedback. The attributes 
of the program that fostered the collaborative efforts were related to the autonomy provided and the goal and 
problem-based activities that guided the learning activity.

LEARNER CONTROL

The literature suggests that students experience a much greater sense of control when they are guiding their own 
learning experience and a corresponding increase in intrinsic motivation (eg. Becker & Dwyer, 1994). Important 
elements supporting learner autonomy were incorporated into the program by creating a semi-structured 
environment in which the students had full control over time and direction in their exploration. A concerted 
effort was made to ensure that the students did not feel pressured or hurried and the interface design was an 
important part of this. Students were not only able to choose their working pace, but could choose the mode of 
navigation which suited their particular learning style—browsing or unstructured navigation following their own 
path, or a more structured progression following the hints and tips included in the program. Their responses 
suggested that they valued the levels of learner autonomy.

I liked the fact that I could skip the bits I knew and repeat those I didn't.
I could move around at will.
You don't just learn information put to you, you get to choose your own stuff.
I chose where to go for information and had to work out why something happened. I liked
being in control of this.
Could choose my approach, it was very clear how to do things.
If you can work at your own pace it's much easier.
If I was told where you had to go next it would take away a lot of the uniqueness.
More individualised, don't need any help, the visual thing helps, you can just click on
something and the information is there.

Students’ responses to questions about their autonomy in program made it quite clear that this attribute was seen 
as a critical part of the learning and the learning environment and one which contributed significantly to their 
enjoyment of the learning.

CURIOSITY

Arousing curiosity was sought by creating an experiential and exploratory environment which was optimally 
complex (not too difficult, not too easy) and which appealed to as many of the learner’s senses as possible. The 
gaming elements contained within the microworld were intended to pique the learner’s curiosity, particularly the 
random elements which changed from warp to warp. Once students began their investing, curiosity was instilled 
through a random element in the investment outcomes. Students were challenged to see if their investment 
strategies and decisions were successful and they were keen to explore the impact of extraneous events on those 
decisions.

I liked the uncertainty of what would happen next.
I couldn’t wait to see what would happen, I loved the surprise elements and the warping.
I liked buying shares and seeing what happens, exciting when the theory comes together.
We weren't sure what was going to happen next, went to TV and telephone to see what they had to say. Discovery of elements, especially information was exciting. It felt good because I kept wanting to see what happened next. Makes you make decisions. The phone made you feel involved in a small circle of people.

Personal curiosity was seen by students as an important part of the learning environment. It was supported strongly by the open-ended nature of the microworld and the authentic and realistic setting in which they were immersed. Other components which held their curiosity included the chance processes, the realistic outcomes and the referential and open navigation structures.

FANTASY

Having a realistic metaphor for the instructional landscape was intended to allow students the fantasy of believing that they were investing their own money. Many students of business traditionally have a fantasy of being financially successful. This program was designed to indulge that fantasy. There was also the added benefit of having an "autotelic" experience in which the students were able to prove their skill at forecasting future trends (Csikszentmihalyi, 1992). This was seen as an important component of the program as successful share investment depends very much on forecasting future events and trends.

Once again students' responses confirmed our expectations that the realism of the microworld combined with the authentic task of share trading would create a learning environment where aspects of fantasy were present.

Like curiosity, the microworld provided a strong setting for creating elements of fantasy in the learning which helped to guide and encourage students' exploration and use of the various elements of the program. The fantasy was supported by the metaphors employed to represent aspects of the authentic setting and the realism carried in the feedback and outcomes to decisions and actions.

CHALLENGE

By creating a program which necessitated a high degree of problem solving and higher order thinking with an appropriate level of difficulty, it was intended students would feel a reasonable degree of challenge. The reward structure was authentic and appropriate to the context and all students instinctively knew the goal of the program. Through a review of their strategies (by comparing with the experts and by reviewing their own portfolios) students could instantly identify whether their goals were being met and how successful they were at meeting the challenge. The students reported facing and dealing with a number of events they saw as challenges in the learning environment.

There were many challenging aspects in this program and students recognised their presence and the ways in which they encouraged their activity. The use of personal goals through the various gaming elements in the microworld were perhaps the most significant aspects influencing the challenge faced by the students. Once
again the feedback and performance measures supported the challenge by providing the cues needed to assess performance and to support further action.

CONCLUSION
The purpose of this study was to explore the potential and capacity of a microworld learning environment to support and create such particular learner effects as immersion, reflection, a sense of play, collaboration, personal autonomy, fantasy, curiosity and challenge. A program was developed in which the instructional design specifically considered these elements. The program was trialed with students to assess the extent to which it generated these effects among learners. Students were interviewed after a session using the program in which they completed the various learning activities and exercises.

The student responses indicated that all experienced each of the various learner effects in some way or another while using the program. It was evident that the microworld was a very suitable design strategy for our purposes and provided a strong setting for our study of the affective learning environment. Having established that the various design strategies can in fact create the various learner effects, the next phase of our study will be to assess the relative impact of the various affects on learner motivation and engagement. Tentative findings from this first implementation lead us to suspect that some of the effects possibly contribute more to engagement and motivation than others; further studies will look to see relative impacts of each of the learner effects.

Abstract: This paper presents an intelligent advisor for a discovery learning environment. The educational objectives of the learning environment are to learn fundamental rules of physics and to acquire ability of applying these rules to complex systems. In order to support the learning, the advisor has the student model that distinguishes between what a student knows and to what extent of complexity of physical systems the student can apply rules. The advisor provides assistance for the student according to the student model and the system structure that the student built freely.

1. Introduction

A process of the discovery learning consists of the following steps[Otsuki 1993]. Students learn a new concept inductively by observing an instance. Then they generalize the concept by observing several instances. Students examine characteristics of target objects by manipulating the objects through experiments in these steps. They may also solve problems by manipulating the objects. After that, the concept is generalized to a symbolic level and they acquire symbolic knowledge, with which they can solve problems by symbolic manipulation. In some cases, they may be taught symbolic knowledge, and then they understand meanings of the symbolic knowledge by trying to make correspondence between the symbolic knowledge and the instance objects through experiments.

Elementary physics is one of fields that students acquire knowledge by this scenario. For example, students learn concepts of gravity, velocity etc. by experiments, and try to find relations among physical parameters like forces and expansion of a spring. Or they confirm the Kirchhoff's Law by measuring electric currents of circuits.

There are three kinds of knowledge involved in solving physics problems[Anzai 1986].
1. Knowledge of fundamental concepts of physics like gravity, acceleration etc. and rules like Newton's Law.
2. Knowledge for applying fundamental concepts and rules. By using this knowledge, we understand the physical structure of a given system, and derives a set of equations that represents relations among physical parameters.

While the first and the third knowledge is thought as formal knowledge, the second one is empirical knowledge. Students will acquire fundamental concepts and rules by learning well-ordered materials step by step. Application knowledge will also be acquired by a systematic way in some degree. However they need training to apply fundamental rules to complex systems in order to develop their abilities.

Simulation based learning environments are effective for discovery learning of fundamental concepts and rules. However, because discovery learning costs burden on students, they sometimes reach an impasse. Hence we need an advisor to guide students. Simulation based learning environments are also useful to understand complex systems. When the purpose of learning is merely understanding a system structure, diagnosis and explanation by using qualitative reasoning plays an important role [de Koning 1997, Forbus 1994]. However when the purpose is to develop student's abilities, we should not simply provide explanation but provide a clue of understanding systems so that they may overcome difficulties by themselves. Students will polish their abilities during this process. The advisor should also provide this kind of assistance.

This paper presents an learning environment with an intelligent advisor. The advisor recognizes given physical systems and student's understanding states. Based on these information, the advisor proposes suitable learning objectives and gives advice tailored for each individual student. We first present the learning style in our environment and functions of the intelligent advisor in section 2. Implementation is described in section 3. In section 4, we present a result of evaluation. Section 5 concludes the paper with some discussions.
2. Characteristics of Intelligent Advisor

2.1 Learning Activities in the Learning Environment

Fig. 1 shows the user interface of our learning environment, which consists of a workbench, a parts box, tables and a dialogue box. Similar to many other learning environments, a student goes around the cycle of observation, prediction and verification for discovery learning. During the process, the student carries out experiments and collects data in the table. Student's activities in this learning environment are as follows.

(1) To construct a physical system by using parts prepared in the parts box.
(2) To decide physical parameters to observe and to fill the first column of the table with their names.
(3) To carry out experiments by changing the value of independent physical parameter of the constructed system.
(4) To fill the table by measuring values of physical parameters.
(5) To make a hypothesis and to predict values of dependent physical parameters for a value of the independent parameter after repetition of step (3) and (4).
(6) To verify the predicted values by carrying out an experiment.
(7) If the prediction doesn't match the result, go back to step (3).

The learning environment has two modes of learning: concept learning mode and training mode. In the concept learning mode, learning proceeds step by step according to a curriculum defined by a teacher. The curriculum restricts the complexity of systems that the student can construct. Hence a simple physical system is given to the student firstly, and gradually complicated systems are given. For example, when the student studies the domain of springs, a single spring and some weights are firstly given in the parts box. The student, therefore, has no other choice than building a system of one spring. The student will acquire concepts of the spring coefficient, Hooke's Law etc. in this first stage. After the lesson, lessons of parallel and serial springs follow. The educational objective of the following lessons is to generalize knowledge about springs and to acquire the ability of understanding complicated systems. The student follows step (1) to (7) in the concept learning mode.

In the training mode, students are allowed to create physical systems of arbitrary complexity. They challenge to understand physical structures of systems and they polish their abilities of applying physics rules during the process. Learning in the training mode basically starts from step (5) by solving a problem posed by the intelligent advisor. If the answer is incorrect, the student examines the reason by experiments.

![User interface of the intelligent learning environment.](image-url)
2.2 Assistance of Intelligent Advisor

Because discovery learning is not an efficient method of learning, students need trial and errors to achieve learning goals. Therefore, it is not adequate that an intelligent advisor helps students soon when they encounter difficulties. If students cannot achieve the goal after several trials, our intelligent advisor provides the following assistance.

(1) In step (2) described above, the advisor proposes physical parameters for measurement that are relevant to the goal. The advisor basically allows the student to experiment freely. However, if the student doesn't pay attention to goal parameters after several trials, the advisor proposes to observe values of relevant parameters. When the student failed to predict values, this advice is also given in order to collect more data that are relevant to infer functional relations of system parameters. Parameters to observe are decided according to the structure of the physical system and the student model. The system structure is used to recognize functional dependencies of system parameters and the student model is used to find a suitable level of difficulty for the student.

(2) In step (4), the advisor points out incorrect values in the table. Mistakes are mainly caused by misreading indication of measurement tools or confusing different physical parameters. Because the former error is not serious and this kind of errors usually occurs only a few entries of the table, the advisor points out the error only when the student failed in the prediction phase. It advises to check the value by experiments. The latter error is detected by matching the value of the table with values of other system parameters. The advisor directly indicates what the student confuses.

(3) After repetition of step (3) and (4), if the student doesn't try to predict values of system parameters, the advisor asks the student to predict values of dependent parameters without doing experiment by giving values of independent parameters. This advice persuades the student to think and to generate a hypothesis.

The following two assistance methods are used in the training mode.

(4) The advisor generates a problem that asks a value of a system parameter. This is a trigger to start the training mode. The problem is generated according to the system structure and the student model.

(5) The advisor proposes a system that is suitable to the student's understanding state. This advice is given when the student failed to work out the correct answer of the problem. The system that will be given to the student is generated by simplifying the original system that the student failed to understand. The purpose of the generated system is to bridge the gap between it and what the student has understood. The student will acquire the ability of applying physics rules to generalize cases by thinking about similarities between two systems. The level of simplification is decided according to the student model.

3. Inside of the Intelligent Advisor

3.1 Outline of the Learning Environment

Fig. 2 shows the structure of the intelligent learning environment. Parts that are available for students to build a physical system are prepared in the parts library. As shown in table 1, parts are accompanied with rules that defines their functions and buggy rules to identify students' error origins. A model of the physical system is represented by a network called causal network. The causal network generator generates the causal network from a given system structure that the student built on GUI and parts definitions. The table manager interprets student's input in the table. In order to measure progress of learning by using the table, the table manager labels each entry of the table correct/incorrect and experimented/predicted.

3.2 Causal Network

The causal network represents functional relations among system parameters. Fig. 3 shows an example of the causal network. It is generated by connecting functional definitions of parts according to the system structure. Values of constants like mass of weights and natural length of springs are given in the network. Values of unknown variables are worked out by propagating known values. Causes of student's incorrect answer about a value of a system parameter are identified by replacing correct functional definitions with buggy rules.

The causal network is used for the following purposes.

(1) To calculate correct values of system parameters.
(2) To identify student's error origins in order to infer the student model.
(3) To decide educational objectives.
(4) To explain causalities of system parameters.

3.3 Student Model

Even if students know fundamental rules of physics, they may fail to apply them to complex systems. One of the purpose of the learning environment is to develop their abilities to apply these rules. The student model, therefore, should represent not only the understanding state of each rule but also generality of applicability.

Our student model is represented by a n-dimensional coordinate system. Each coordinate corresponds with a measure of generality of a domain. For example, the student model for the domain of springs is represented by a 3-dimensional coordinate system as shown in Fig. 4. Measures of generality are a number of springs connected in series, a number of springs connected in parallel and a number of weights inserted between springs. Understanding level of each physics rule, which is equivalent to a functional definition in table 1, is recorded at the point that corresponds to the generality of a physical system where the rule is used. The extent of generality that the student can apply rules is represented by a surface in the coordinate system that covers points of good understanding levels.

4. Evaluation

We evaluated effectiveness of the intelligent learning environment by a pre-test and a post-test in a junior high school. Problems of both tests were the same. Students in three classes participated the evaluation. After the pre-test, students in two classes used the learning environment. They learned at least four physics systems, which appeared in the pre- and post-tests. Students in another class used a real equipment for experiments, and they conducted experiments on the same four systems. A teacher instructed what to do before starting experiment in all three classes. Students carried out experiments freely after teacher’s instruction.

Fig. 5 shows the result of the evaluation. These graphs show percentages of students in four categories; "o->o", "o->x", "x->o" and "x->x". The left of the arrow "->" is the result of the pre-test and the right is the result of the post-test. "o" means correct and "x" means incorrect. Students who answered correctly in both pre and post tests are categorized into "o->o", and students who answered correctly only in the pre-test are categorized into "o->x". Four graphs show the following.

(1) Most of students in all three classes answered problem 1 correctly in both pre- and post-tests. They therefore know Fick’s law before the pre-test. But about a half of students had not been able to apply the law to systems in problem 2 and 3, and a few number of students could solve problem 4 in the pre-test.

(2) In case of problem 2,3 and 4, percentages of "x->o" in classes "A" and "B" are higher than the in class "C". Note that the percentage of "o->x" in class "A" is higher, because time of the post-test was shorter.

These facts indicate that the intelligent learning environment worked well for students to acquire application knowledge.

5. Discussions and Conclusions

This paper presented an intelligent advisor for a simulation based learning environment. The advisor helps students to learn fundamental physics rules and to acquire ability of applying these rules. In order to model the student’s ability, we proposed the n-dimensional generality space. It can represent student’s state that the student knows a rule but cannot use it for complex systems.

Learning environments for discovery learning have been investigated for long. [Reimann 1991] focused on hypothesis generation in his work. His learning environment was well-designed for students to make a hypothesis and to receive feedback by using a graphical interface. But it doesn’t have capability of diagnosing students, hence the feedback is not adaptable to states of students. [White 1990] proposed a method of progressive learning of
What expertise do teachers require to facilitate pupils' self-expression with multimedia?

Abstract: This paper describes the expertise that teachers need to acquire in order to facilitate pupils' self-expression with multimedia. The central idea behind the argument is that multimedia is a creative tool for children and that multimedia learning in the near future is expected to be "Learning by Producing". In such a context of creative learning, pupils need to be recognized as multimedia producers. In order to achieve this situation teachers need to know how to become learning supporters, curriculum developers and multimedia coordinators, not just instructors. The necessity for teachers to know the typology of multimedia expression, the features of multimedia expression and program evaluation is also discussed with some suggestions.

1. MULTIMEDIA PRODUCTION BY CHILDREN

Before addressing the aspects of expertise teachers need to acquire in order to facilitate pupils' multimedia expression it would be very important to describe a new image of children learning, namely, children as multimedia producers and also what literacy they are expected to obtain in the process of producing multimedia products.

1.1 Children as multimedia producers

In IT education there has been a slow but steady shift from CAI (computer assisted instruction) to MACP (multimedia assisted communication and production) (Jacobs, 1992; Tanaka, 1995). This means that multimedia is becoming not only a teachers' instructional tool but also a creative tool for children. With the help of many user friendly software packages children are now using multimedia to express their ideas and the information they obtain during their studies. Thus it has become possible for children to experience the role of multimedia producers (Turner and Dipinto, 1992; Kenneth et al., 1994; Tanaka, 1995).

In addition, the collaboration between children is very important because multimedia production requires students to take diverse roles, for example, a writer, a painter, a video editor, an audio mixer, computer programmer and so on (McMahon, 1990; Crook, 1994).

For these reasons teachers need to acquire expertise which is different from traditional methodologies of instruction. These are discussed in the following paragraphs.

1.2 Multi-mode expression

Multi-mode expression is a comprehensive way of self-expression which integrates sound, pictures, videos and text. A good example of this is a musical. A musical incorporates music, singing, scenario, choreography, dancing, stage lighting, stage set and so on. Thus it can be said that multi-mode expression as actualized in a musical or a drama has much similarity with multimedia expression (Trowsdale, 1995). When multi-mode expression is done with multimedia, it results in multimedia products in the form of an electric slide show or an animation.

The potentials of multi-mode expression are very difficult to develop because of the subject barriers in the current school curriculum. But these potentials seems to be important in terms of self-actualization and talent development in a society where a visually persuasive and entertaining presentation is more and more required.

When multimedia production (a typical way of multi-mode expression) is introduced into the classroom, students are expected to acquire multimedia literacy in the process of producing multimedia programs.

1.3 Multimedia literacy
Table 1 shows a tentative set of multimedia literacy items. These ten literacy items can also become educational objectives in the instructional planning.

Table 1 Ten items of multimedia literacy (Tanaka, 1995)

Multimedia literacy requires an ability in the following items:
1. To understand the characteristics of multimedia, the various modes of information and their combination patterns.
2. To have a basic command of multimedia
3. To select appropriate media and to collect various pieces of information and find the relations between this information using those media
4. To operate data input and information retrieval with a variety of computer peripherals
5. To acquire learning methods and computer literacy through simulated experience with Hypermedia
6. To give a multimedia presentation making good use of the features of each medium
7. To convey multimedia products made with various computer peripherals to others by computer telecommunication
8. To produce a handmade TV program using a video camera, a video editing system, a sound effecter, a sound mixer, a multimedia computer and so on
9. To make presentation materials with an interactive video system or Hypermedia
10. To create multimedia products which integrate knowledge, images and emotions

2. CROSS-CURRICULAR MODEL OF MULTIMEDIA LEARNING

In most in-service training courses for the IT use offered by the local boards of education the main topics would tend to focus technological aspects of IT education more than pedagogical considerations for it. However, considering that IT coordinators are now being recruited in several technologically advanced countries like the United States, the United Kingdom and Japan, the classroom teachers' role could be changed from that of a technician to that of a pedagogical facilitator in the process of developing the IT curriculum and learning projects (North, 1991; Owston, 1995).

2.1 Isomorphic structure and cross-curricular model

Recently several books advocating cross-curricular practice have been published responding to the National Curriculum, which suggests five cross-curricular topics in the school curriculum (Webb, 1996; Radnor, 1994; Morrison, 1994). Before this Anderson (1991) had pointed out the importance of IT education as a cross-curricular element in terms of the availability of IT to all pupils and the possibility of improving the quality of learning through enhancing common information skills. Similarly Fox (1996) discussed some effective ways to incorporate media education (one form of IT education) as cross-curricular catalyst into the school curriculum. Also analyzing twenty three case studies on innovative educational projects in science, mathematics and technology Black and Atkin (1996) reported that there had been some arguments for the curriculum connection in their discussion of summarizing their analysis. Thus the need to promote IT education as a cross-curricular theme has been gradually recognized.

However there has been little literature so far which discussed the potential similarity between multimedia learning and cross-curricular activities. In figure 1 such a similarity between the two is illustrated.

The similarity stems from the feature of educational multi-mode expression which is a common activity to both multimedia learning and cross-curricular activities because multi-mode expression needs both contents to include and means to produce with. Such a combination of the contents and means of multi-mode expression is a typical feature of cross-curricular activities. Thus when pupils perform multimedia production, a cross-curricular learning context could be helpful to them through providing pupils with both the aspects of expression which are integral elements of multimedia production.

This cross-curricular model illustrating the isomorphic structure of multi-mode expression would also be useful to teachers to develop an integrated learning unit for pupils' multimedia production through combining different subjects (Figure1).

2.2 Learning unit model

In order to foster the quality of learning activities and multimedia products, a guideline for the sequence of productive activities is necessary. After examining the learning unit models adopted in the two classroom
implementations (Tanaka, 1995), several common features were found and a cross-curricular unit model was constructed according to these features.

The five common features are as follows:

![Cross-curricular model for multi-mode expression (Tanaka, 1995).](image)

1. The model includes a comprehensive sequence of activities, i.e. an appreciation of various multimedia products, image construction of multimedia products, image enrichment by analysis of previous products and research outcomes, creation of scenario and design blueprint, production of parts, assembly of parts and a final stage, i.e. presentation, performance and appreciation.
2. At the fifth stage 'Production of parts' various expression modes, e.g. sounds, pictures, stories are integrated to produce moving images.
3. The first activity stage 'Appreciation of various multimedia products' simulates students' interest and the third stage 'Image enrichment' provides them with good examples of multi-mode expression.
4. The third stage is inserted to enrich the motif or theme with empirical data for students.
5. This model accommodates collaborative production and role assignment.

Figure 2 illustrates a cross-curricular learning unit model developed in this process. Naturally the model is based on the idea of combining the investigation phase which supports the contents of expression and also the production phase which supports the means of expression. This idea of combination is not original in the recent literature of multimedia learning, but it was already discussed by Innocenti and Ferraris (1988), who made a combination model of the instructional use of a database by showing the necessary linkage between the database creation phase and the investigation phase.

2.3 Typical multimedia learning projects

The provision of pedagogical ideas about typical multimedia projects would make it easier for class teachers to acquire expertise in developing an integrated learning unit with cross-curricular activities for multimedia expression. Here are some examples of project ideas which could function as scaffolding for the effective curriculum development.

*Let's produce a CD-ROM encyclopedia*

This project could include both investigation about the topics which pupils have in mind and multimedia expression with CD-ROM facilities. These topics might be related to one or some of the several subjects like language, social studies, science, music and art. Pupils' multimedia production would result in a variety of multimedia CD-ROM titles like a multimedia slide-show, a home town database, a botanical database and a computer art gallery respectively.

*Let's open our children's TV station*
As described earlier in this paper the production and delivery of TV programs are a typical cross-curricular multimedia work. When children select a drama program as a production task, the combination of a language class (in charge of producing scenario), a social studies class (ethics and related laws of broadcasting) and an art and design class (multimedia production) would be very useful. In contrast when they select a news program, the integration could be between language, social studies, art and design, science, etc.

**Let's produce an Internet newspaper on the WWW**

Nowadays multimedia production in this information society is rapidly expanding into an international telecommunication world. A tremendous amount of information is being exchanged through Internet. Therefore it could be considered as meaningful for pupils to experience cross-curricular activities related to multimedia newspaper production and to obtain communication skills which could be applied to their future career or everyday community services.

![Diagram](Figure 2 Learning unit model for multi-mode expression)

### 3. FACILITATING ROLES OF TEACHERS

Pedagogical considerations at the level of curriculum development and project construction have been discussed so far. Then focusing on these two points specifically from the aspect of teachers' roles will be another important task to clarify what expertise teaches require.

#### 3.1 Learning supporter
Considering that multimedia is not only a teacher's tool for efficient instruction but also a learner's tool for creative learning, it is important for teachers to note that their role is no longer that of an instructor but more that of a supporter for learners.

The objectives of a teacher as a supporter could be categorized into the following ten points.

1. To praise what pupils have done well in order to activate their motivation towards further learning
2. To provide them with good examples of products and research findings
3. To offer alternatives for the learning themes and the methodologies
4. To provide pupils with opportunities to utilize a variety of learning materials and multimedia
5. To prepare open space as a flexible learning environment in which to foster diverse activities
6. To prepare learning aids such as a guidebook, an activity sheet, an orientation leaflet or a promotion video
7. To care for pupils' learning difficulties and answer their questions
8. To make appointments with institutions and human resources outside the school to enrich pupils with as much direct experience as possible
9. To describe the sequence of learning activities
10. To give advice which fosters a collaborative atmosphere in the working group

3.2 Curriculum developer

Some teachers in practice might think that it would be a good idea to wait for new curriculum resources to be developed by researchers and publishers. But what is more valuable for professional development of teachers is that they experience a workshop to develop curriculum by themselves. It will inevitably profits their creativity and curriculum knowledge on IT education. The role of a curriculum developer facilitating pupils' multimedia expression would include the three aspects described below.

1. Curriculum development for basic training of media literacy
2. Development of a cross-curricular learning unit
3. Emergent curriculum development

3.3 Multimedia coordinator

In multimedia learning it is also important for teachers to equip pupils' learning environments with multimedia rather than just to use the media for the delivery of information to their pupils. The idea behind this is that pupils should be encouraged to take advantage of multimedia on their own. What is indispensable in relation to this idea is a 'media-mix' approach which encourages pupils to think of and put into practice meaningful combinations of different types of media. Typical factors which teachers would need to consider are as follows:

1. Preparing media-corners space
2. Setting up a multimedia studio
3. Offering opportunities to use an intelligent library
4. Providing cooperative keypals and human resources for networking

But it is always difficult for pupils to find people who cooperate on a regular basis. Thus teachers will have to play another important role in making connections with keypals on the net or local volunteers in the school district. After establishing the connections, it is again the role of the teachers to act as a learning supporter as described above in order to encourage collaborative learning.

4. SPECIFIC KNOWLEDGE ABOUT MULTIMEDIA PRODUCTION

Furthermore it is another requirement for teachers to have some specific knowledge about multimedia production. With this knowledge teachers could guide and evaluate pupils' multimedia products and presentations.

4.1 Educational typology of multimedia expression

At first teachers need to know what types of multimedia expression can be done by their pupils. Typical multimedia expressions by pupils would be categorized as follows:

1. Multimedia production
2. Multimedia presentation
3. Multimedia debate
4. Multimedia telecommunication
4.2 Features of multimedia expression

Teachers need to have an overall understanding of the features of multimedia expression to facilitate their pupils understanding. This understanding should cover the seven points described below.
1. Expressing how you have reflected your personality and the originality of your investigation on the program
2. Combining various modes of information, i.e. multimedia materials
3. Adding interactivity to the program
4. Designing an information structure which is easy for users to understand
5. Designing an interface which facilitates information retrieval
6. Combining logical expression and emotional expression
7. Reflecting the merits of different roles within a group to achieve collaborative production

4.3 Creativity and spontaneity necessary for multimedia production

In order for teachers to evaluate pupils' productive activities with multimedia several symptoms of creativity and spontaneity which pupils would show during their multimedia production will be helpful.
1. Sharing of different skills needed in multimedia production
2. Construction of a role structure and role assignment
3. Needs assessment aimed at the audience
4. Collaborative information gathering beyond the National Curriculum
5. Mutual teaching and learning

5. Conclusion

The forms of expertise identified above, to be included as a knowledge base in in-service training program, is necessary because pedagogical knowledge relating to the educational use of information technology is as necessary as technical knowledge and skills. The subsequent research tasks needed will be to develop effective training methodologies to make this knowledge available for practice. In training workshops it will be important that this knowledge base be utilized with a great deal of flexibility so that teachers can adjust the content to meet the needs of each classroom context. In order achieve this, a comparative study methods using several cases of implementation would be one effective way of identifying and producing possible means of teacher training.

Collaborative Internet Learning

Joanne Tate
Computers Across The Curriculum
Ararat Community College, Victoria, Australia
araratcc@netconnect.com.au

Abstract: My pioneering in the area of telecommunications and the use of the internet across the curriculum in Australian schools has been achieved through involvement with the I*EARN (International Education and Resource Network) network. I have initiated a number of very successful international collaborative projects. This is a very exciting time to be involved in education! For the first time as classroom teachers, we have the capacity to harness technology to curriculum creativity and on a global level. This type of learning experience cuts across the traditional borders and barriers of our educational systems. It links like-minded teachers globally and allows curriculum development to become a flexible, collaborative process that tackles a broad range of immediate issues and needs. Primary, secondary and tertiary institutions can mobilise combined teams of human resources that challenge our traditional employment bases and concepts. This type of curriculum design extends effectively into the general community and invites interest from business and corporate bodies keen to encourage a technology smart workforce.

Changes to the Traditional Learning Approach and School Structure

1. The Role of the Teacher

When embraced at the classroom level, collaborative learning will accelerate the changes in the role of the teacher that have been occurring over the last decade. These changes include the shift of role to facilitation for the teacher, rather than the teacher being the source of all knowledge. The teacher will be needed to guide the learning process and to assist with the location of information in the labyrinth that is the internet. In a collaborative project, teacher time is also spent for example on establishing working partnerships on the net, seeking links with outside organisations and resources in the community, looking for new ways of utilising the technology in the project, presenting students with information on protocols and design recommendations for WWW page writing and collaborating with other teachers involved in the project. Collaborative learning means that teachers must be prepared to really work across the curriculum in a spirit of cooperation. There is no room for single minded approaches to subject areas or the inability to be flexible in course design and planning. The linking together of subjects through collaborative projects provides students with a holistic educational pathway and can lead to the development of real problem solving skills. Using the technology, educationalists can develop powerful networks of contacts and resources to draw upon outside of the school boundaries. It is important to maintain suitable levels of communication and protocol within these networks. These partners can often become long standing colleagues, involved in future collaborative projects and providing links to other global resources.

2. Resource Equity

Heavy school financial commitments in the area of technology mean that the issue of equal access across the curriculum is paramount. It is to be expected that subject areas with a comparatively small budget would resent the vast amounts of money that are put into the school computer lab if they can see no real use for their subject area or if they cannot gain physical access due to traditional computing subjects blocking out the timetable. For collaborative learning experiences to occur schools need to be working towards a model where enhancing technology is inherent in each subject area and staff and students look to it appropriately as an accessible tool. Technology must not remain the property of the (traditionally) privileged few staff in an educational setting; disseminate the knowledge throughout your staff workforce. As networking in schools becomes more common, it is an individual and often financial decision as to where the technology platforms will be located. Given that most
school still find the traditional one or two room lab the most practical solution, I would like to suggest that schools at least trial the ACOT (Apple Classrooms of Tomorrow) model in one or two general purpose classrooms if possible. A cluster of 3 or 4 machines are stationed in the room to be used as required. Keep a log book of use and timetable a range of classes into the room a range of subject areas. See what happens, then move on from there.

**Positive Spin Offs From Collaborative Projects**

- Increased connectivity for real cross-curriculum based work amongst schools
- Experience in the use of new age technologies for communication with a purpose for staff and students
- An enhancement of the trust relationships between Australia and other countries
- The publication of student work in a booklet is concrete evidence of the bonds of friendship and understanding built during the project and continuing through telecommunications long after a project's successful completion
- Other schools take up the model for this method of communication
- Developed appreciations for the unique elements of our own culture and the culture of others
- Heightened awareness of Australia's identity in the global community
- Imparting of critical technological skills to participating teachers and students, providing valuable training for global competitiveness in the 21st century
- Potential for multimedia applications with real purpose for the students
- Involvement of traditionally technology resistant subjects

**Real Outcomes**

It is important that when we are using a medium as intangible as the internet that we plan to have outcomes for students that are real and tangible. The possibilities are endless, but some that I have found successful are:

- Global magazines that put into print a selection of writing and artwork collected during the course of the project. These magazines utilise other aspects of the technology through desktop publishing. It is important that all participating schools globally are represented in the publication, and that they receive copies. In many cases this will assist them in convincing their administration of the value of the students involvement and of course is a great thrill for the students to receive. We presented copies sent from New York for one project our students had been involved in at a general school assembly - it made a nice change to sporting awards! A magazine is a lasting document that can be read in more places that a computer monitor!

- Global art exhibitions that commit schools to producing a number of pieces of work on a central theme by a particular date. Samples are sent to all participating schools from each base school. Exhibitions are set up in the school and comments on the work are collected from art classes and emailed to the artists who have sent the pieces. We have always organised an opening with guest speakers on the theme, and had students read out related theme based written pieces from representative countries at the opening. A virtual gallery gives interested students a chance at designing a WWW page of immediate interest to participating schools.

- A composite quilt made up of appliqued squares that represented the project theme is a great tool for bringing in the materials technology subject area and for involving a large number of interested schools. The National Identity Quilt, toured Russia, Budapest and Canada.

- A video resource of suitable materials uncovered in the project for general school use. Students see feedback on processes such as interviewing that they have been directly involved with. This is a lasting resource for school use. A CDROM disk resource of suitable materials uncovered in the project for general school use. Once again a lasting resource.

**Associated Problems**
The problems encountered come back to basics; time, money and access to equipment and login facilities. With determination, despite your school's resource situation, you can overcome these and be involved in major collaborative learning experiences. At Lake Bolac Secondary College all the success stories mentioned in this article were achieved with one phone line and modem linked to a single machine. It may fall back on a few people to download student writing prepared on other machines, at convenient times, but don't let the promise of next year's technology budget deter you from launching into current projects now. Great opportunities arrive daily through your email and networks. My problem is how can I involve my school in all that is available with limited hours in the day!

Other problems encountered can be overcome with careful and flexible initial planning. These include for example, conflicting international school holiday calendars and receiving firm commitment from participating schools. Don't expect to get other schools immediate involvement, remember we all have our administrative, curriculum and teaching commitments to juggle and negotiate. Be prepared to plan a year ahead when launching a collaborative project of large proportions. Raising money is never easy. There are certain organisations interested in this type of project support, such as the Australian Foundation for Culture and the Humanities. By meeting their annual criteria with your project description you can gain access to the necessary funds to support projects. Be ready for some disappointments, but roll with the punches and look in other directions that may be suggested to you. Be sensitive to the fact that in many countries teachers are meeting the costs of telecommunications personally for their students. They will not appreciate being asked the same questions time and again if the information has been supplied and is available in say a virtual conference on the I*EARN network for all to read. In many countries the approach to computers is still very much traditional programming. We need to support our pioneer colleagues who will be fighting odds, curriculums and administrations less sympathetic than our own. Treat your international contacts with respect.

Industry And Organisation Involvement

My first experience in linking technology students with industry was when I approached the International Wool Secretariat about putting all their educational materials on the WWW. This project allowed students to gain a first hand understanding of the protocols of industry and the processes involved in developing a prototype and working with a professional digital designer. The wool industry was of course close to our hearts being from the Central District of Victoria. We were able to compare the end product with the professionally developed American version that was being developed simultaneously. At this stage the students and myself had little experience with the use of HTML and this was a positive introduction to what was to become a new multimedia inclusion to the curriculum. We are still receiving emails and enquiries about the page from a wide range of internet surfers. We went on to visit and prepare a simple Web page for the National Wool Museum. This meant the school needed to invest in a digital camera so we split the costs with the nearby Primary School. As the students' skills developed in HTML, they have written pages for organisations like, the Grampians National Park and the National Trust Property, 'Mooramong'. Our text based work in the I*EARN virtual conferences can now be complimented by Web page development on the project. At this point in time students at technology conscious schools are rapidly developing advanced skills in this area. In many cases industry is keen to have a Web presence, but uncertain how to obtain this, opening up a perfect partnership for real outcome curriculum work. The possibilities are endless for all key learning areas as many previously closed doors open for industry research prior to Web page development. Other organisations like the Asian Education Foundation are pleased to involve students in Web work in their efforts to improve the studies of Asia in our curriculums. Recently, one of my students launched her page detailing the International teaching fellowship to India at the Education Victoria Conference. The Melbourne Holocaust Museum has been a wonderful resource and partner for collaborative project work.

Equity And Access

The collaborative approach has proved a very attractive use of technology for female as well as male students. Female students enrolling in senior technology courses are electing to use HTML as one of their software types and looking to community based projects that interest them. The percentage of female students electing to take these courses has increased dramatically at our school. Working in a team to develop an appropriate, creative solution to a real life problem is an attractive way of utilising new technologies.
Three Success Stories

1. War and Peace 1995

With nuclear testing hot on the media, students were keen to use the internet to make a statement about the issue. This statement met with over 2000 supportive responses across the I*EARN network and was teased out to become a collaborative project that examined the issues of war and peace in general. This was my first experience in how technology based cross curriculum ventures could produce impact on the whole school in a number of ways:

* The issue of Peace was taken up through text studies and by addressing the question of whether the A-Bomb should have been used in WW2. Finished pieces were posted into the electronic conference. Needless to say, the Japanese students had a different view on the A-Bomb to some of our students!
* Studies related to senior texts on the Holocaust were conducted and resulting writing sent into the conference. A visit to the Holocaust museum resulted. Student worked in a second I*EARN conference here, specifically on Holocaust issues. They were able to contact survivors personally over the internet. Some heated discussion was generated with New York students over one controversial essay!
* In history students were examining WW2 and propaganda and wrote up some interesting pieces on Hitler
* The Art department recognised the power of the technology and the first global art exhibition was organised, with school from 7 countries participating and a real and virtual exhibition resulting.
* The Regional Rotary Public Speaking Competition saw a student representative win with a speech on World Peace that she had prepared for her Year 12 Writing Folio and the global audience.
* The launch of the art exhibition occurred in a whole school Peace Week. Guest speakers from the Holocaust Museum addressed the whole school. Live phone calls from the US and Israel were put over the speaker system. The broader school community was invited to attend and much media attention was attracted due to the death of Prime minister Rabin the day before. Students elected to represent various countries and read out messages of peace that had been sent into the conference.
* A Peace Garden was created by the History students, and a commemorative plaque opened by a Holocaust survivor.

This project was interactive and cross-curriculum by nature. It relied on the use of technology to maximise global participation, access and input, and focused on The Arts, Culture and Humanities and the Sciences within its content. It examined the myths and realities of the National Identity and our emerging image globally. It allowed students to explore the impact of multiculturalism, the Arts, politics, economies, technology and history on the dynamic, evolving society we have today. Students participating came closer to knowing what it meant to be Australian. Particular emphasis was placed on symbols and events, and their implications and interpretations.

Written component

Global surveys, focusing on the range of subject areas mentioned above, collected data from I*EARN youth though the internet. The focus was on involving as many subject areas across the curriculum as possible. Interactive responses to clarify issues and discuss interpretations between students was achieved using email and the project conference topic. The key schools took on the responsibility of forming a joint editorial team, working across the internet to organise all editorial functions and decisions for a global magazine publication containing student writing collected throughout the project. Illustrations for this publication were taken from student entries in the project's global art exhibition based on the same theme.

Global Art Exhibition
The global art exhibition organised over the I*EARN network, established a number of global sites to display Australian students' work on the theme. The Australian sites received work from other participating schools in Australia and Internationally. An interactive feature of this exhibition was email discussion between the artists and student body, during the exhibition periods. A virtual gallery of the art work was constructed on the World Wide Web. This allowed all schools to access work on display at other sites internationally.

The Study Tour

An exchange of students with two schools in Moscow for a three week period, allowed representative global classroom students to experience another culture and lifestyle in contrast to their own. Intensive interaction using the I*EARN network's bulletin board conferences, before, during and after the trip, allowed this visit to have broad benefits to I*Earn students Australia wide. In other words, the number of students and teachers involved in and impacted by this component of the project was dramatically larger than the number of persons who actually participated in the exchange. Students prepared materials emerging from the project and draw upon conference entries from other students Australia wide, to present what they believe to be a realistic view of Australian society today to the students in Moscow. Comparisons between the identity of Russian and Australian Society formed a special section of writing by participating students were included in the Project's publication which was launched and distributed at the I*EARN international teachers' conference in Budapest in 1996.

This project opens up the possibilities for education to use new communications technologies effectively and creatively in the study of life experiences of ordinary people in traumatic and global circumstances. This project creates an opportunity to reconsider history and scale it to the dimensions of people rather than politics, ideologies or national movements. It binds generations and cultures through sharing. The project marks the first edition of an ongoing commitment by a team of schools to produce a globally distributed magazine. The 1997 edition of 'Faces of War', commemorates the victims of Wars since 1938 (veterans, P.O.W.'s, refugees, Holocaust survivors). In consultation with National Returned Soldiers Leagues (R.S.L.) and Holocaust Museums, Australian students are invited to join the project, conducting taped interviews with relevant individuals, which will then be presented as transcripts to be published on the internet, in a global magazine and in an oral history resource on video and CDROM. International students conduct similar interviews and transcripts and this serves to stimulate electronic exchanges with Australian students globally. Subsequent responses to the transcripts, and related theme writing sent into the internet conference from National and International schools were published in the global magazine which was sent to all participating schools and every Victorian school. A large vibrant web site was established in 1997 to supplement the original bulletin board conference (I*EARN network). However, the bulletin board continues to enable schools with low level technology to participate in the project. Selected Australian interviews were video taped professionally and edited to create an oral history CDROM resource made available to Victorian schools, and educational institutions. This was distributed by the Directorate of Education and sponsored by the University of Ballarat who involved some of their students in the design. This CDROM also published for the first time an original WW2 prisoner of war diary with teaching and learning materials developed across the curriculum and linked to each diary page.

A global art competition and exhibition was held. Australian and International Schools were asked to send in work on the theme for a central Metropolitan exhibition. Samples of this work were entered into a virtual gallery on the World Wide Web site and constructed by students. Visitors to the Melbourne exhibition were asked to make an entry into a virtual visitors' book on the WWW page. The work clearly shows the difference between the experiences of war for each cultural group of students. After the Australian exhibition, samples from the exhibition are mailed to participating schools for exhibition Internationally. The gallery can be accessed from the web site. Students undertook to construct the Victorian R.S.L. web site as part of the project. This major undertaking was launched in conjunction with the opening of the art exhibition at the headquarters of the Victorian RSL. Major educational leaders and veterans attended this gathering and it was held on one of Australia's commemorative days, the 11th of November. Mr Peter Copen (I*EARN U.S.) has worked on organising feedback from students involved in the project and the evaluation of these comments. In 1998 the project offers students globally a number of literary and art competitions and has attracted funding from the Department of Veteran Affairs. We will focus on setting up
teams of human resources in 1998 to answer student questions on the theme of 'War', thus utilising the grey workforce and their living experience. Problem solving using the technology takes on a new dimension when a student has to present memorabilia or original letters and diaries to capture the atmosphere of time and trauma. A large number of teaching and learning ideas are available for teachers on the web site and reach across the curriculum.

**In Conclusion**

The rewards available in teaching and learning through the collaborative approach will outweigh the extra effort that may be involved as you get deeper into working with networks outside the school boundaries. It is important that we all strive towards establishing a working environment and curriculum that allow us flexible access to the opportunities now open to education. The technology in our schools is only as good as the curriculum innovation and enhancement we achieve with it.

1. Introduction
When educators evaluate teaching materials and methods, they tend to measure the knowledge acquired by students from teaching material by using results of examinations. We propose that they should evaluate the courseware based both on the results of examinations and the log of student learning behaviour.

The methods that Sakamoto has reported only involve how to obtain data for evaluating courseware, describing in particular the actual questionnaire. The data gathered after a class may include uncertain as well as intentionally inaccurate information. Oda has reported that HyperClassroom records student learning behaviour, i.e. practice, references and communications, in order to build the student model, but he has not mentioned courseware evaluation. However, there are some research results on authoring tools. The focus of current authoring tools has been on supporting the teacher creating the courseware.

We propose a method for collecting data for courseware evaluation. That is, the data to evaluate the courseware is acquired by itself in parallel to the student learning process. When the student stops temporarily or finishes a learning session, the system sends data to a computer server. In order to put the idea into practice, authoring tools should support not only the creation and development of courseware but also the acquisition and analysis of data for evaluation.

In this paper, we describe how to gather data in order to evaluate courseware and give parameter for improving the courseware for educators based on the records of students' learning history. These functions should be included in the authoring system. We focus on how to obtain the data but do not mention statistical methods.

2. Courseware and its evaluation
In this section we describe the structure of our authoring system in order to realize the above mentioned idea. The system gathers information concerning interaction between the lessons and students as learning history. The data is transferred to the computer server and analyzed. Fig. 1 shows a model of our idea.

Fig. 1 Acquiring and analyzing learning history
2.1 Student behaviour in learning

Fig. 2 depicts a state transition diagram during student interaction with the courseware. In the learning mode, while the student works through the lesson, the LSLP (logger of students learning process) simultaneously records the interaction. For example, a student's referencing page, study time, keyboard typing and mouse clicking. In the quiz mode, the LSLP records right/wrong answers, unexpected answers and expected wrong answers for each question and each attempt. In reviewing pages, the LSLP records the students' referral to help or regular pages.

Fig. 2 State diagram in students learning

2.2 Assessment of courseware

The ALSLP (analyzer of students learning history) extracts two data sets from the data recorded by the LSLP. One is an assessment education. The other one is a assessment acquisition for mastering the use of knowledge. The instructor can evaluate each section of the courseware and ways of mastering the implementation of knowledge from each data set.

2.2.1 Mastering the use of knowledge

When we estimate mastering the use of knowledge of each student, we may define it as study time in obtaining the correct answer of each question, a ratio of the time to the number of referenced related pages, the number of referenced help or hint pages and the number of unexpected wrong answers. These items are extracted by the ALSLP.

2.2.2 Assessment education

Assessment education is closely linked to the evaluation of courseware. We use an expanded version of Sakamoto's methods. ALSLP extracts the following items from the data recorded by LSLP for the class and each student.

1. study time : maximum, minimum, average in class, actual study time of each student
2. the number of right answers, wrong answers
3. the total number of referenced pages
4. the number of unexpected answers
5. the ratio of the total number of referenced pages to the number of correct answers

3. Design and Implementation

The software system discussed in section 2 has been developed as expanded Tsumiki. Courseware created by Tsumiki consists of Tsumiki pages, pasted objects on a page with hyperlinks to each another. Tsumiki Executor interprets and executes the Tsumiki script in the courseware. The system that we have developed consists of clients for students and teachers, and a Tsumiki server as shown in Fig.3.

Fig. 3 System Configuration

3.1 Tsumiki server and communicator

The Tsumiki server has courseware files, SQL database files to keep each student's learning history and ALSLP.
Students can transfer specified courseware from the Tsumiki server to their own computer using the Tsumiki Communicator. At this time, the Tsumiki server sends the selected courseware, executor and LSLP. The data recorded by LSLP is transferred by the Tsumiki Communicator and stored into SQL database.

Fig. 4 shows the relationship between four schemes of the SQL database and their data structure. We call this database DHL (Data Learning History).

Definition of each table

3.2 Tsumiki executor

Tsumiki executor requires an ID and Password for users and queries the ID and Password on the Tsumiki server. After checking them, executor starts to transmit the courseware to the client. If he/she is a new user, the Tsumiki server creates a new database file. If he/she is a registered user, the Tsumiki server checks whether he/she has an interrupted or incomplete lesson.
3.3 Creating questions wizard & User interface

The Tsumiki editor provides a Creating Questions wizard for teachers to formulate questions. This enables LSLP to easily ascertain a student's current state. Furthermore, it facilitates the development of selection and descriptive questions by teachers. The creating questions wizard guides the teachers to initialize style questions, a number of question hyperlinked hint pages. The wizard automatically provides a standard question model for teachers.

![Image](image_url)

(a) Inputting a number of page and choosing mode    (b) Actualy making a question(type of descriptive)

![Image](image_url)

(c) Actualy making a question(type of selection)  (d) Seting reference pages

Fig. 5 User Interface of Creating Questions Wizard

Fig. 5 briefly shows the method of creating questions attached to courseware using the Creating Questions wizard. A number of page is typed in the box. Teacher can chose the way showing questions and answer by mouse clicking. Teachers inputs a number of queation page and choeses mode of question. Page No. is typed in the box. Teacher can chose a kind of question, descriptive or choices. Teacher set up text of question, answer and forecatsed right answers. References pages for reviewing to get right answer would be chosed from list of all pages.

4. Implementation

The various parts of this software system have been implemented using Visual C++ and Windows 95. The ALSLP and database files in the Tsumiki server have been implemented using MacPerl and Butlter on Macintosh. Users access the Tsumiki server via the Tsumiki Communicator which has been developed in Visual C++. The reason for not using a Webserver is that the target users are relatively naive with regard to computers, as many K-12 school teachers are computer novice users.

4.1 User interface for students

After checking a user's account file, the Tsumiki Communicator shows the list of courseware on the student's computer screen. The student can choose one lesson from a menu by mouse clicking. The Tsumiki communicator starts to download the courseware. After loading the couiseware, it is immediately ready for use.

Although the student can begin the learning, they don't need to know the mechanism of the system at this point.

4.2 User interface for teachers

The teacher also communicates the Tsumiki Server with Tsumiki communicator. The teacher can not only download any courseware lessons for editing, or obtain results of analysing the students learning history but also loadup the courseware. Of course the teacher can also use the ALSP for extracting various data from DHL.

5. Conclusion

In this paper we have described the design of a networked authoring tool which obtains a data set for the assessment of
courseware. Furthermore, the editor component of the authoring tool provides a creating question wizard mode for teachers.

The features of this system are to provide indexes of assessment for teachers and to allow teachers to easily include questions in courseware. Teachers can evaluate courseware developed by themselves using extracted indexes. The data for assessment is acquired by students' interaction with courseware.

Through developing the system and experience, we have identified two issues to be solved. One is that instead of using teachers to assess the courseware, we have to develop an expert system. The other is that the data set should be collected not only by recording and measuring interactions but information regarding student concentration on courseware should be also be gathered. About later issue, we have developed a measurement system using face image processing.

References
Abstract: Today's children can adapt and respond far more rapidly to the dynamics of the information age than their parents or tutors. Consequently educationalists aim to foster independent learning, where the child's own explorations are facilitated rather than constrained by the knowledge of the tutor. The Web assists this process, as it offers a vast learning arena for children to embark upon their search for knowledge.

A study was conducted using a Web browser involving what could be termed as a particularly representative computer literate child. By browsing the Web and email, the child independently augmented a task set in her class on the topic of the European Union and its member states. The child was thereby empowered, unlike the other children, to find out more about the task rather than being restricted to relying on the teacher's knowledge, one or two books, or on a CD-ROM.

Introduction

The 'Information Society' is visualised as being an essential requirement for a modern age, but its current drive is focused on information consumption rather than the quest for knowledge. If this notion is correct, then Aldous Huxley's statement that "life is short and information endless; nobody has time for everything" [Huxley] has considerable insight for a society ready to embark on what can be termed now as the "society of mass media and unlimited communication" [Tyrell & Tvedt 1998]. Similarly the Rt. Hon. Michael Heseltine, the then British Deputy Prime Minister in his speech "Communication in a Fast Changing World", declared that "the information revolution is about people, not machines", and that teachers "should face up to reality by acknowledging the inexorable advance of new technology" [Heseltine 1995].

Clearly then, along with many of the enlightenment and post-modern philosophers, we must remember that information itself is not synonymous with education or knowledge. Moreover, today's children can adapt and respond far more rapidly to the dynamics of the information age than their parents or tutors [Ultradab 1993]. Therefore, educationalists should encourage independent learning, where the child's flexible, creative and critical thinking is facilitated, rather than constrained by the knowledge of the tutor [Tyrell 1996].

From the network learning concepts of [Schon 1971] and the 'learning webs' of [Ilich 1973], it is reasonable to suggest that the Web will be a natural progression through which independent learning can take place. However, it should be noted that this concept remains to be fully evaluated. Therefore, the following study was conducted in order to gain an initial insight into the use of the Web as an educational tool for children.

Study Task

The research that this paper is based upon was conducted in 1996. A computer literate school child was facilitated in order to obtain information from data repositories, employing the Web. The task involved the child using the Web to augment a typical school project. The project, set for her entire class by the teacher, was about the European Union and its member states. The objective of the study was to observe the anticipated learning, intellectual and engagement issues of the child, prior to mass popularisation of the Web.
The School

The school is situated in a small village in suburban Kent, South East England, for children aged from four to eleven years. Two hundred children attend the school, with an average of thirty children per class. The school is highly sought after by parents and children alike, for its traditional educational values and teaching methods.

Access to computer equipment at the school has been limited to five low performance PCs. However, recently two new multimedia Pentium® based machines have been purchased by the Parents Teachers Association (PTA). At present, these new machines are not fully functional due to the teachers inexperience in the use and deployment of computer based activities. This typifies British primary schools, where teachers inexperience with information technology is commonplace [Heseltine 1995].

The Class

The class under discussion consisted of thirty mixed ability children aged ten to eleven. The children were set a project on the topic of the European Union and its member states as part of their normal schooling. They had already started work on their project using reference books and photocopied hand-outs, and so knew the boundaries of the project. The method of constructing their topic book to display their findings and other additional ideas for each country had also been covered by the teacher. Groups of children were assigned a particular country within the union and they then worked singly or collaboratively, to produce the research information to be displayed in their topic books.

Study Child - 'Amanda'

The study child, Amanda, a ten-year old girl in the class, was also subjected to study in previous work [Tyrell 1996]. There, Amanda demonstrated her skills in the genre of computer mediated communication (CMC) [Kress 1994] very effectively. Amanda's academic standing in the class was within the top twenty percent and, surprisingly, was one of the few children in her class who employed computers to support and supplement her learning. From the prior CMC study, it was considered that Amanda would rapidly be able to browse the Web and appreciate its potential. Although her computer literacy makes Amanda somewhat distinct at present, she could nonetheless be considered to be particularly representative of children in the near future who will be educated with an awareness of telematical concepts [EU 1994].

Experimental Design of the Study

In line with the technique adopted by [Tyrell 1996], Amanda was both observed and facilitated by the researcher. These functions were nevertheless kept separate, and Amanda was facilitated in her ventures through cyberspace.

Training Event Prior to Actual Study

One week before the study itself, the Web was demonstrated to Amanda. She visited the 'Walt Disney' site http://www.disney.com, and navigated the on-line pictures of 'Pocahontas'. These were then saved on local disk in a way still accessible by the Netscape browser. From these saved results Amanda subsequently demonstrated her findings to three class colleagues, and her five-year old sister, using her home computer during the week prior to the study.

The use of a training session was considered essential as it removed the possible novelty and potential fear factors of the Web. From this interaction it was hoped that Amanda would gain an insight into how the Web may serve both her current school project and future educational activities.

Actual Study
As explained earlier, the appropriate computer and associated technical resources were not yet available at Amanda's school. The study was instead conducted in the Library at Mid-Kent College, Horsted Campus, in Kent with a direct ethernet connection on a Windows® based 486 DXII-66 computer, running Netscape® 1.1. Amanda was given a previously recorded URL http://www.xxx.xx from which she accessed the Web for three hours. She had been instructed to access information that would aid her project and then to explore further avenues of interest to extend her knowledge of the subject area. The primary objective Amanda was given, was to search for a choice of selected member states and from there, to explore and retrieve facts for reference and inclusion into her own work.

This was achieved by clicking on links, images, the forward and back buttons, and the history and bookmark menus. Where necessary, guidance and direction was provided by the facilitator to help the child develop her skills, with helpful clues being administered to prompt for other avenues of research and why the data she had found was of relevance to the project.

The next stage of the task was the use of a search engine to locate information. This was prompted by the limited educational value of the information found using the above techniques. The standard Netscape search feature, 'Net Search' was used as the starting point, as this was the most likely place that users would first try given Netscape's popularity and that 'Net Search' is part of Netscape's main toolbar. Once the list of site matches were displayed, Amanda tried to interpret the associated short descriptions for relevance to her task. By clicking on the more promising sites, she investigated the subject and then returned to the search list for further investigations. Whilst engaged in the search and review mode, Amanda recorded bookmarks or saved the page as a HTML file, if she valued the information found. From this cyclic process, Amanda found some information of relevance to the class topic, although again she found the results were of limited educational value.

Summary Findings

The study demonstrated that Amanda's ability to interact with the Web browser was not an issue. She adapted to the environment, due to her prior knowledge from [Tyrell 1996] and the previously discussed demonstration at the Walt Disney site. She negotiated the hypertext links and valued the Web's dynamics, its breadth of information and, in her words, the Web's 'brilliant graphics'. The interface therefore presented no difficulties for Amanda, as it enabled the summary findings to be examined without the use of the Netscape browser, the Web's novelty, or fear of the computer task itself being considered as confounding variables.

Amanda did find many interesting graphical images, including detailed maps, country flags and vast quantities of untargeted information and statistical data. Other than this, Amanda quickly became frustrated with her inability to find good targeted information, which she could understand and retrieve at a speed which was acceptable to her.

The data and bookmarks she did find were collected on disk for transfer to her home computer. When she used the findings many of the graphical images and hypertext links would not work, unless she was re-connected to the Web. Given the expense of dial-up connections in the UK, and the Internet's retrieval speed limitations, it was felt that this method would be uneconomical in terms of both time and money. The loss of live hypertext and graphical links could be a further avenue of frustration that might undermine novice surfers interest in using the Web in the long term.

Even allowing for these difficulties, Amanda found the quality of the information she retrieved was complex. She was thus forced to assimilate material beyond her scope, and to extract the information relevant for her topic book. Under these circumstances this proved problematic, as the data was too far in advance of Amanda's current capabilities. However, this may not always be the case, and it is possible that the Web could be used for a Vygotskian method of learning, with the child striving "just beyond the psychological horizon" [Fortes 1976]. One of Amanda's most successful achievements was her ability to produce and reproduce graphical images of flags, country maps and other topical images. This enabled the project work to be a collection of multiple objects, gathered from a global environment and, therefore, met some of the objectives for a visual composition as described by [Kress 1994] and that of the underlying concepts from [Tyrell 1996].
The information retrieved, when presented in printed form, was welcomed by her teacher who, we later discovered, had asked Amanda if she 'could borrow the CD-ROM'. This remark typifies the general misconception of teachers about new media, and Web awareness.

Email Activity

An email task was omitted at the time of the study, due to the frustrations experienced by Amanda and the study's primary objective becoming too difficult to fulfil. An email was nonetheless written and sent by Amanda a week later, allowing for reflection of her findings, with a brief of her project and was directed towards the EUROPA European Commission, <Maruja.GUTIERREZ DIAZ@DG10.cec.be> the re-directed contact address on the European Union home page. It took approximately two weeks to gain a reply from the London office. The reply admitted that they could offer no further assistance, were themselves seeking help, and asked Amanda that should she be successful, they would be grateful to receive her findings.

Reflection and Concluding Remarks

Whilst engaged on the project, it became clear that the Web was not the enlightened vision for Amanda that it had at first seemed. Within a short space of time she complained incessantly about the access speed, the sources structure, complexity, relevance and commercial bias and the inability to find exactly what she really wanted. She was released from the study to complete her project just like the rest of her class, albeit with some additional facts and graphical images to add to her project, and a new insight into the power of global communications.

From Amanda's correctly understood views of the Web as a window to the World's information sources, she rapidly unearthed its restrictions and limitations. Amanda continues to be highly interested in global communication strategies and the Web and still requests access to the Web for extra materials for class topic work and discussions.

Discussion

The study did not progress beyond this trial stage. The passive and time consuming modes of engagement with the Web, and the overall educational value derived from the information located were considered to be of only limited use under the current circumstances.

A parallel can be seen elsewhere. Recent research within commercial organisations found that respondents admitted spending an average of four hours a week hunting for 'basic business information' [Computing 1995]. This in itself contributes to the described passivity, reinforced by a key businessman [Beales 1995], who believes that commercial users require a more structured approach to the Web rather than just search and filtering tools.

Returning to education, [Freire 1975] worried that learning would end up merely pouring untargeted information into the "empty vessel" of the learner's mind. Heppell's technology-based studies in education [UltraLab 1993] similarly demonstrate a concern for the 'passive victim'. Thus when popularising the Web as an independent learning resource amongst children, we should avoid turning them merely into 'couch potatoes' who browse the Web without intellectual motivation. This view may be considered marginal. However, problems of information anxiety stemming from the explosion of publications and e-media have recently come to the fore of contemporary thinking. The fact that there is so much information on any one subject or key word on the Web means that feelings of frustration and impotence similar to those experienced by Amanda in the study may be elicited. This reflects back to the point made in the introduction that information is endless, and as such we need to find a coherent and above all usable way to select only that which is of relevance to us. Future incantations of the Web may prove to be such a method.

Further research should be encouraged to investigate the educational use of the Web before it is incorporated into mainstream education as a principal research tool. If the reservations of this paper are to be overcome then the Web will be required to take on a more structured and coherent framework which removes the time-
consuming and passive tendencies discussed earlier. However, the view is taken that the Web will be a valuable tool for education if given the correct philosophical and structural underpinning. Should these suggestions be incorporated this will prevent the Web from becoming a 'highway to hell' [EU 1994] and a dividing entity in our society [Handy 1994].

Abstract: This paper presents a generalized solution to the problems associated with accessing the Internet by people with disabilities. Of particular interest is the way in which the authors' paradigm [1] allows for enhanced interaction with information resources, which we take to include distance learning and education in general. We provide here a basic overview of our approach to serving the WEB accessibility needs of the disabled community. In addition, we present as an example of the unique features of our disability resource web site, a customizable lightweight voice recognition / PC control module for speech impaired users.

Introduction

For many years people in the technology area, specifically engineering, have attempted in a variety of ways to make the lives of those with various disabilities easier and to give them access to the wider variety of activities and facilities that most of us take for granted [2-5]. Depending on the nature and severity of their disabilities, these people may have communication problems (hearing loss, lack of speech, blindness, et cetera.). In addition, they may have mobility problems that limit their access to telephones, light switches, computer keyboards, et cetera. Physical travel, entrances to shopping malls and libraries remain difficult, if not impossible for some of these individuals. Disabled students face an additional burden if their study materials are not in a form that they can easily work with. Students with sight limitations need tools that can read their books and notes to them and/or enlarge the text to a readable size. Science and math students with sight limitations currently have very few options when it comes to reading complex math equations. Individuals with speech and/or mobility problems experience a different set of challenges. But in each case, we believe enhanced access to a computer (and hence the vast resources available through the computer and the World Wide Web) is possible. When one attempts to do something in this realm one has to be intimately aware of the fact that the over all impact will be minor. Never the less, the endeavor is worthwhile, since the impact on the targeted subset of the disabled community may be quite significant especially where improving education is the goal.

Educators, family members and special assistants face their own set of challenges when working with disabled students. They need to prepare both a special environment and class material in a form accessible to each disabled student. In addition, they need to evaluate the performance of the student. Many times, the disabled student will have trouble taking tests in the standard time. Allowing extra time helps with part of the problem. But if an assistant is required to help the student with taking the test, it can be hard for the instructor to assay the difference between what the student understands and what the assistant inadvertently added. Most of these problems imply greatly increased effort and expense on the part of the facilitator. A properly configured WEB solution can alleviate many of these difficulties [6].

Basic Problem

The convergence of cheap miniaturized computers with the evolution of many other technical innovations has finally become focused to the point where a realizable impact can be made in the many areas just described. One might speculate that much of what is happening today in the United States is the result of recent U.S. legislation, in particular, the Americans with Disabilities Act of 1990 (ADA) [7]. Many of the products and capabilities now being developed may well
have occurred without this impetuous. But the publicity and media focus [8] on disability generated by this Act has enabled much of this effort to become public where as in the past, it might not have been.

A problem with many currently available assist devices is that they tend to be quite expensive and they only work with a very narrow range of disabilities. Many times, more than one special device or software package is required to meet the needs of the given individual. What will work for one will not work for another. It has also been found that separate packages/devices don't work well together. Thus educators and families face a difficult problem in selecting and configuring a PC to deal with their child's/student's problems. These solutions also become obsolete in a few years as the child grows up and their needs change and as technology advances. Lastly, these solutions deal with only a portion of the problem; namely the human to computer interface (HCI). They do not address human to world interface issues at all.

Consider for a moment the individual who has very poor eyesight and can only read large letters. This might include the inability to focus on a single letter or worse yet, to see multiple overlapping images. Consider further an individual with cerebral palsy in conjunction with a vision problem. Thus, there is a very limited ability to input information into a computer in the same way or with the same dexterity that a non-disabled person would have. How does one go about helping this person?

**A Solution**

Clearly what is needed is an inexpensive, yet comprehensive system that works on the wider range of computing platforms and which can adapt both to changes in the student's needs and to advances in the underlying hardware and software. The Internet provides an excellent starting point for such efforts. It works seamlessly over a wider range of platforms, gives access to the World Wide Web (WEB) and is essentially free. Through the Internet and the WEB in particular, a wealth of documents, search tools, news, special interest sites, shopping opportunities, travel information and booking services as well as resources for education can be made available. Teachers are now beginning to put full-blown courses on the network along with live sound video, problem solutions and interactive sessions. In a sense, the Internet can serve as the human to world interface. It can be easily extended via a local web site to allow access to scan textbooks etc. Many educators deem this interaction, which may be limited for disabled students, essential.

Because users with special needs do not fit standard interfaces, there needs to be an intermediate interface or adaptation that acts as a "prostheses" to make the original interface accessible to users with disabilities. If the adaptation is well suited to the user's requirements, it provides a better interface to the application. Much thought has gone into the development and implementation of these adaptations and intermediate interfaces [1-6]. For the past two years, the above investigators have been working to develop a general solution to the many problems that students with disabilities experience as they try to obtain an education at the University/College level. We have developed a paradigm that should prove effective for this class of students and which can provide a framework for solving many of the difficulties that presently are encountered. We believe that the solution that we have put forward will resolve one of the most serious problems in this area. Namely that each student with a disability is unique, and requires a unique solution to his/her specific set of disabilities.

The thrust of the project consisted of developing an Internet site that functions as a central location for computer resources targeted at the disabled. The site acts as an easy way to distribute new software that has been developed, as an online collection of documentation related to disabilities, as a pointer to other Internet sites containing relevant information and as an interactive tool for distance learning. Most importantly, since the people with disabilities will presumably be the primary users, the web site was built with them in mind and it is customizable to accommodate their disabilities.

When a user first accesses the site, he or she will be offered a chance to work with an online configuration wizard. The answers that they provide to the wizard will allow the site to dynamically alter its appearance and will pre-select the subset of software modules that will most likely be of interest to this user. The user can play with and pre-configure many of these modules prior to adding them to their local system. The ability to track users and maintain a profile of their unique preferences is built into the site through the use of a database. The idea of centering the site around the needs of the disabled is continued by allowing users to add links to external Internet sites as well as to receive updates by e-mail of when the site has been updated. The included built-in search engine facilitates finding specific software modules and information.

From a site administrators view point, incorporating additional software components is as simple as filling out a form and
copying the necessary files to the server. The framework for future growth of the site has been established. Because the site is simple to use and interact with the user, the likelihood of a user returning is greatly improved. As a general solution, it is an inexpensive, comprehensive system which works on a wide range of computing platforms and can adapt both to changes in the disabled individual needs and to advances in the underlying hardware and software technologies. This system functions to more fully integrate the person with the rest of the world without the addition of extensive additional human assistance. This concept is shown more clearly in Figure 1.

![Diagram of World Wide Web access](image)

Figure 1: Using the World Wide Web to provide access to the world.

In addition to the web site, a number of specific interface modules have been developed. These include several virtual keyboards, a voice controlled mouse, an acoustic output mouse, a joystick based mouse, and a variety of other acoustic PC navigation tools.

**Example: Speech Control of the Computer**

One module currently under development is a lightweight non-verbal recognition engine that can map reproducible utterances to specific PC control functions. Our initial application was the implementation of a voice-activated mouse (VAM). The VAM is a complex module, which requires training before it can be used. A setup wizard walks the user through a series of steps which gives the user vocal control the mouse on the screen.

Such a system is implemented through an Automated Sound Recognition System (ASR). There are a variety of techniques available that do voice-to-text fairly well. These are incorporated in many of the commercial products available, such as IBM's "Via Voice Gold" and Dragon System Inc.'s "Naturally Speaking" both of which allows for continuous speech recognition and conversion into text. Thus, it is possible to take some individual words and convert them into symbols, which ultimately can control the movement of the mouse. Coupled with this idea, is the possibility that some individuals might not be able to speak clearly and distinctly. The commercial packages listed above can not deal with this scenario. However, if the user can reproduce a small set of distinct sounds with some fidelity then these sounds can be mapped to control functions. Clearly, the larger the set of distinct utterances, the easier it will be to control the multitude of PC / browser functions. However, this technique can work with as few as one reproducible utterance.
Our example is very simple in as much as we chose to use the four letters L (left), R (right), U (up) and D (down), respectively to develop the concept. Any substitute for a clearly spoken articulation of these letters would be equally acceptable. Required are the use of an FFT algorithm and the development of a simple template for each letter (word). The process is simple in concept. A flow chart is given in Figure 2.

In our example, the articulation of each sound is first frozen in a window. Then the Fast Fourier Transform (FFT) of the sound is taken to create a template for the four letters. Then when the letters are articulated in a random fashion, the template of the incoming sound is compared to the templates in the system and identified properly in order to move the mouse.

The template was designed by taking the power spectrum of each of the signals and dividing it up into sixteen bins. A single number is produced for each of the sixteen bins by taking the average of the components in each bin. When the sound was articulated, it is processed and its template compared to those already stored. When a good match is found, that particular letter is identified and the appropriate movement of the cursor is initiated. A picture of a typical sound is shown in Figure 3 and its spectrum in Figure 4. For both the calculations of the templates, and the "unknown" test sounds, the average value of each bin is scaled to one hundred. The result of the template-matching procedure for one test sample is shown in Table 1. Several people trained the system and had their templates stored for use when they were active. The miss-identification rate was less than five percent in most cases.

There are certainly a number of issues associated with this particular technique. If a mistake is made, the user will hopefully, if not terribly visually impaired, see that an error has occurred and command the mouse to stop. In addition, the precise motion and control features can be configured on a user by user basis. This is similar to what we do with our other mouse controller modules [1].

Software

The question of software appropriate to such a project is always important, particularly in view of the fact that software is constantly changing and what might be appropriate today, might not be appropriate in another year. We have tried our best to avoid this problem by using software that has proven its worth over an extended period of time. Much of the software is available through Microsoft. The site itself makes extensive use of Microsoft's Active Server Page technologies. Many of
the end user modules have been written in Visual Basic as ActiveX controls. In the future, we plan to move portions of code base over to Dynamic HTML (DHTML). This will provide improved platform independence as well as performance enhancements.

Conclusions

The exercise reported here has demonstrated clearly that the development of the web site for the disabled is both possible and necessary. While only the voice activated mouse is reported here, there are a number of other modules, which we have developed to handle other kinds of disabilities. These can be simply adapted to individual needs, but more to the point, a variety of these can be developed, a subset of which will be applicable to most individuals whose disabilities are severe. Each case is unique and will have to be examined individually. At this particular time, the web site provides access to all other webs in the system and also provides a very simple search engine. In addition, the web site also stores information for various users once they register and keep track of the modules, which they desire to use and save. This information can individualize the module when certain things must be learned for specific individuals. In the voice activated mouse system, templates would be customized for each individual user, so when they return at a later date, development will not have to be repeated. Readers are encouraged to look at the web site that has been created at http://www.nd.edu/~vx.

Abstract: The decentralization process of medical information is the major motivation for the construction and use of computer based systems for patient education. However, in order to reach their objectives it is necessary that these systems have a set of quality characteristics related to the information they provide and the way they are. This paper describes a public access system for patient education, on the field of Nuclear Medicine, specially about the Myocardial Scintigraphy. It also defines a set of quality requirements to be considered on their development and evaluation.

1. Introduction

It is well known nowadays that patients should know and understand the problems that are related to their health and to medical treatments. Also, they should share decisions about these treatments and possible surgery they should undergo. The lack of this knowledge brings about several consequences related to improper use of food and medicines, and also psychological disturbances started on not having the needed information [Kalm 93, Kim & Watson 95].

Patient education, from this point of view, is based upon not only the information collected orally among health professionals, but also in printed material, audio-visual and more recently on computers. Several benefits are reached with this change. First of all we have the decentralization and democratization of access to information, since patients are able to have medical information without the physical presence of the health professionals. This information can be provided outside medical centers, sometimes even at home, and having the possibility of consulting the information how many times they want. Another benefit coming from this change is the possibility of cost reduction involved in treatments. Various studies pointed out that patients who use this kind of material supporting education are released from the hospital earlier. And, as a consequence, they show less problems at the phases before and after surgery. They also reduce the amount of medicines used against pain. Some studies have even shown a reduction of diseases and anxiety of the patients that used this material [Kahn 93, Abramson 95].

There are lots of ways of promoting the use of computers for patient education. Among them are the use of expert systems, interviews supported by the computer and hypermedia. Hypermedia use sound and special effects and should be used to inform patients with physical limitations, reducing and, sometimes, eliminating the need of reading text in the conventional media of spreading medical information. At the specific case of elderly patients, the user/patient repeat, explore or study a topic of interest, with the help of the computer, allowing freedom and comfort that some patients do not enjoy with physicians or nurses, mainly due to the lack of time of them. Computers can help on the process of democratization and dissemination of information about health topics and allow that through this individual educational proposal. Families and communities may hold a more active role concerning care
of their own health, minimizing the psychological charge due to treatments, exams and surgeries and also reducing the use of costly and unnecessary services.

In order to reach the goal of having knowledge and patients participating actively in their treatments, through the use of computers as a tool, it is necessary to produce educational solutions adequate to individuals and to their social context as well as systems easy to use and based on user friendly interfaces.

2. Public Access Systems

Public Access Systems based on computers, or simply kiosk, are used to help the spread of information of the more diverse categories. Some examples of this use could be to find the spatial localization of some shop inside a shopping center, another example are banking information, timetable of public transportation inside railroad stations and listing of events inside cultural centers or information centers. This kind of system have as a main characteristic the fact that they are located in public areas, can be used by anybody, no training is required to its use, the access is unlimited and unsupervised, and usage is typically quite brief and irregular [Kearsley 95].

The development of these systems could resemble simple at a first analysis. But two fundamental aspects should be considered, the user interface and the time needed to use the system.

There is a great worry from the side of software engineering with the human-computer-interaction. In the public access systems this aspect becomes more evident, as it is not previewed any training to use the system. It is expected that these systems become self-explained and this aspect is only achieved in the way the interface is developed with this objective.

However, this worry should not have been excessively focused on graphical aspects of the media used. There should have be considered aspects as presentation and content correction, that should be clear and ease of understanding, not requiring a high cognitive charge and transmitting correct and adequate information.

Finally, the screen presentation as the content presentation should have been adequate to the user reality regarding his/her social-economical level, age, and system expectation of use. Even being the system projected to a certain user profile, we cannot forget that, by its own nature, anyone could in principle use the system.

Also the aspect time of use should be considered and planned according to the goal of the system. Some systems need quick use, like banking systems. Others need the attention of the user, for example, systems used for marketing and sales.

Specifically in the medical area the use of public access systems is still very little expressive. However, there are several possibilities of application in this area. The use of multimedia systems, in this case is adequate and could be of great value to the transmission of medical information. In the next section we report the experience of building the public access system in the area of cardiology.

3. Public Access system for the patient education about myocardial scintigraphy

Myocardial Scintigraphy is an exam that evaluates the circulation of blood inside the heart of patients. It is performed in two consecutive stages: the effort test, and the rest exam. At the first stage, the patient do some physical effort test. After this the patient receive the specific medicine for contrasting and goes to the gamma camera where are done images of the heart. In the rest stage there is a new inject of medicine and again the patient goes to the gamma camera to a new section of images.

The execution of this exam need some care with the patients. There are restrictions concerning prohibited or not indicated food in the days before the exam, clothes that are unsuitable and observation concerning medicines. No observation to food restriction, for example, do not allow the patient to perform the exam. Furthermore, the fact that this is a Nuclear Medicine exam causes a series of fear that need to be clarified and eliminated.
At the Cardiology and Cardiovascular Surgery Unit at Fundação Bahiana de Cardiologia - UCCV/FBC - Brasil, the usual way to provide information about the Myocardial Scintigraphy exam was a folder and oral explanation by a receptionist. When the exam was scheduled by phone, the information were given to the patient through the attendant of the nuclear medicine sector. After years using this procedures it was observed that still a lot of patients do not follow the procedures and keep doubts and fear about the exam. As a result of this, they come to the exam without the necessary conditions or even do not undergo the exam, bringing about the exam cancellation, financial loss, and leaving a blank in the schedule, having a lot of patients in the queue to perform the exam.

This situation causes the medical team of the nuclear medicine sector to search for an alternative solution. It was then that appeared the motivation to build up a public access system. The system concerning myocardial scintigraphy exam, aims helping patients on their preparation to the exam, reduce their psychological charge, normally associated with the realization associated with exams that involve nuclear medicine.

The first critical point at the development of medical application concerning patient education is to define the content to be transmitted and its presentation form. To solve the problem the content specification was done mainly through interviews with the responsible physician of the nuclear medicine sector.

The target user group to which the development of the system was directed is formed by the patients of the UCCV/FBC that were indicated to do the exam of myocardial scintigraphy. The taxonomy of patients scholar level is the following: illiterate 10%, primary school 40%, high-school 30%, university level 20%. This taxonomy was very important on the definition of the content used in the system.

As it is a system based on the use of computers to a group of people where the great majority do not know how to do it we had a lot of care with the vocabulary and the medical jargon used and a great importance was given to the aspects of the user interface. The latest version (3.0) was installed in February 1997. The system is working at a multimedia kiosk with touch screen at the reception of the nuclear medicine sector [Figure 1].

![Multimedia kiosk about myocardial scintigraphy](image1)

**Figure 1: Multimedia kiosk about myocardial scintigraphy**

The presentation screen of the system start the process of adaptation/learning to the use of the touch screen. The system supplies a pointing message, *Touch here to start*, on how to begin the navigation [Figure 2].
On the second screen is presented a brief explanation about the indication of the exam and the user should then make a choice between the two main options offered: "What you should know to perform the exam" and "Additional Information" [Figure 3]. This division was suggested by the physicians of the Nuclear Medicine sector and aims to show up the main information needed to the exam and also some other additional information. We had then in the system the first part more emphasized on information and the other one with emphasis on education.

In the context of the option: "What you should know to perform the exam?", the user finds the following screens: Alimentation restrictions, Medicine, Extension of the exam, What you should do on the day of the exam, Results, and If you could not come. In all screens there is a bar on the lower part of the screen with the following message: Touch on the desired option, and with two buttons to navigate, the button of Begin again and the button of Follow to the next. Figure 4 shows, as an example, one of these screens.

In the context of the option "Additional Information", the user finds the following screen of information Why prohibited food?, Should I come alone?, Radioactivity is risky?, Accord Exam, Scintigraphy versus Cateterism, Alcohol and Smoking, How is the exam?. Figures 5 exemplifies one screen of this option.
4. Quality Evaluation of Public Access System

Public Access systems, or simply kiosk, are systems that should be used by people with any degree of computer literacy. This characteristic imposes that these systems should have a high level of quality. In the public access systems, the quality control should be done to evaluate different aspects of the system, for example readability, the existence of audible sounds, the interface used, the clearness of graphics and videos, the integration of software and hardware, among others. However, the proposals on how to evaluate these systems are rare and incomplete. In this work we departed from the model proposed in [Rocha, 83] and defined a set of quality attributes to be considered in the evaluation of public access systems for patient education. The defined set includes attributes that support the quality attributes, considering the point of view of the developers, of the physicians and the users of these systems.

The attributes defined should serve as a basis to the elaboration of the evaluation questionnaires of the kiosk.

From the point of view of the final user (patients) the quality attributes refers to the characteristic selected to the easy of use of the system and the satisfaction of the user with its use. Some examples of these attributes defined refer to apprehension (characteristics of the system that enable easy learning of its operation), localization easiness of information (characteristics that enable the localization of different subjects), memorization easiness (characteristics that facilitates the memorization of important information), uniformity (characteristics that make the system behaves always of the same form, keeping comprehensible and familiar to the users), interactivity (characteristics of the system have an interactive interface, where the control is, on the majority of the cases, with the user), motivation (characteristics of the system that enable his use motivating), help in the case of errors (characteristics of the system supports users in errors situations), initialization evidence (characteristics of the system that makes its initialization or re-initialization easy), comfort of the workstation (characteristics of the system regarding its installation in a comfortable equipment, that has adequate dimensions to different types of users), privacy (characteristic of the system be installed in a place that guarantees the privacy of the final users), localization (characteristic of the system be installed in a visible place and of easy access) among the whole set of attributes [Valle 97].

4.1 Evaluation of the Multimedia Kiosk about Myocardial Scintigraphy

The evaluation of the kiosk 3.0 version considered these attributes and three points of view: the physicians’ of the sector, the patients’ and attendants’. To perform the evaluation three questionnaires were build up where each question evaluates one of the identified attributes.

The result of the evaluation with the medical team showed up 100% of satisfaction with the system. The evaluation with the patients was done, initially, during a week with the patients from the UCCV/FBC, who used the system as they scheduled their exam. After the use they received a questionnaire. In a first evaluation were filled up 19 questionnaires by patients with ages ranging from 42 and 81 years old, with 8 females and 11 males. It was possible to observe, from the answers given by the patients, a very positive evaluation. The observation of the attendant, in most of the cases confirmed the opinion of the patients. However, sometimes, the patients were too optimistic in relation to their use of the
system. For example, concerning the relative easiness of use, the attendant evaluated that 5 patients showed up some kind of problem. The same occurred related to the easiness to find information. On the evaluation of the attendants 6 patients showed difficulties in these items while on the evaluation of the patients, only 2 pointed some difficulty.

There were also some extra comments concerning the questionnaires. This is a resume of the opinions given to the open questions in the questionnaire.

- lack of perception concerning the touch screen
- lack of perception related to the use of navigating buttons (some patients found that the system would change the screens automatically without any help of the user)
- desire for more information or more detailed information
- satisfaction concerning the fact of finding information about radioactivity
- satisfaction of having information available in an objective format and of easy comprehension

5. Conclusion

This article presented an experience of construction and evaluation of a public access system for patients education. The use of the system by the patients that are going to do the exam is being continuous and the results from this first evaluation are being used to the new versions of the system. The results stimulated us to follow up the project and a new system concerning other exams is being developed.

Abstract: A Computer-Based Learning Environment (CBLE) needs to be adapted to several teaching styles, since this is a condition for acceptance and effective use in school. In this paper we propose to provide teachers with an opportunity for describing the learning sequences they plan to perform within the environment. Then, from these descriptions, a specific instance of the environment could be built and made available to the learners and teachers. To allow such learning sequences descriptions we need a common agreement on data, concepts and basic reasoning criteria that could be used. We describe such a process and the results we have obtained in the framework of a spatial geometry learning environment.

1. Introduction

Despite an increasing availability of technology, there are still many signs of dissatisfaction with existing educational software. It remains difficult to build complete and adequate requirements for a piece of educational software because many teachers are not yet aware of what is easily feasible and what is still difficult with the available technology. However, the participation of teachers in the design of these tools seems to be a key factor of acceptance and of effective use in schools. We have learned from many years of working with teachers involved in introducing technologies in their schools that they will not use a piece of software in which they cannot include their own know-how and that they cannot reshape according to their local needs.

Starting from those observations, we came to the conclusion that many pieces of educational software should include adaptation functionalities. Moreover, the adaptation process should remain as simple and as close to teachers' ways of working as possible. To fulfil such requirements we propose a framework for learning sequences descriptions; from such descriptions we aim at deducing the accurate configuration of the educational software according to the learning sequence needs. To allow such descriptions we propose a model for knowledge classification and a set of "teaching" primitives.

The aim of this paper is twofold. First we describe an example of building such a set of definitions in a project for teaching spatial geometry. At the same time we focus on the methodology used in the project that could appear as another suitably balanced marriage between the "technology push" and the "learning pull" as suggested in [Conlon et al. 1996].

2. A Four-Level Knowledge Model

The collaborative work we have done with geometry teachers in order to design a learning environment underlined the difficulty for obtaining a consensus about the definition of the domain concepts and the functions that operate on them. These difficulties come mainly from the multiplicity of the teachers' points of view about the objectives of such an environment. We consider that these problems, that stretch from theory to implementation, can be easily overcome by using the 4-level knowledge model proposed in [Bernat et al. 1995].

By manipulating objects at the interface level of a CBLE, the user indirectly acts on an external representation of the objects of the learning domain, whereas the system reacts on an internal representation, which is not necessarily isomorphic. Then it is necessary to clearly separate domain specification mechanisms from interface specification mechanisms.
The domain level is a theoretical level that represents the domain knowledge to teach, independently from any symbolic-level representation. The representation level defines a unified realisation of domain concepts. This realisation is based on design choices concerning concept representation and underlines the relations between them. The represented knowledge is reified at the presentation level, which provides external points of view on domain concepts, as they are perceived by students and proposed by teachers. Finally, the visual level is the graphical interface level defined by the designer. It depends on the development environment for the implementation of direct manipulation.

2.1 The Domain: Teaching of Spatial Geometry

The taught geometry is a transposition of the geometrical theory, varying with respect to the progression needed for knowledge acquisition. A given concept may have different interpretations and its taught could be led according to different pedagogical activities. For example, the cube concept varies according to its use: it may be a composite object (i.e. composed of 8 points, 12 edges and 6 faces) or a solid object (i.e. taken as a whole object).

2.2 The Unified Representation

The representation level implements a unified representation of the different concepts to teach, i.e. the geometrical objects, the relations between them and the functions that apply to them. It underlines a unique conceptual facet that defines and represents the properties of an object. For example, the cube can be defined from 4 points and particular properties: the two first points define the initial edge of the cube; the third point belongs to a circle perpendicular to this edge and defines the first face of the cube; the last point is one of the two intersections between the circle and a perpendicular line to the first face, thus giving the cube volume.

2.3 The Presentation Points of View

The presentation level is an interface level that contains multiple views of the same concepts. This level allows the teachers to express most of their didactical choices: from the choice of one concept presentation depends the learning situation induced by the utilisation of the environment. In the context of a spatial geometry environment, the different presentation choices can be divided into three groups: the visual units for comprehension, the geometrical objects and the interaction modes.

2.3.1 The Visual Units for Comprehension

In spatial geometry, the interpretation of the plane projection of a spatial construction is a major difficulty. In order to make a scene easier to read, we introduce some visual units for comprehension. They are independent from domain concepts and thus could exist in fields other than geometry. For example, reference axes could be useful for understanding the position of an object in space [Fig. 1] but their precise kind may vary: traditional axes, grids, walls (i.e. a space delimitation by three perpendicular planes), ...
The choice of a particular visual unit for comprehension depends on the learning context and on the user's knowledge. For example, reference axes are useless in solid geometry learning (i.e., constructions based on a solid like a cube or a sphere) because the existence of strong cultural connotation objects could indeed be enough to provide good space reading. Some visual units like the walls, useful at the beginning of the spatial geometry learning for scaffolding, should be progressively removed.

### 2.3.2 The Presentation of Geometrical Objects

The choice of the presentation of geometrical objects also depends on the didactical situation that the teacher wants to realize. The cube, for example, may be presented as a 'wireframe' cube (all the edges are visible) or a 'hidden faces removal' cube (the edges behind the cube are hidden). The 'hidden faces removal' cube is suitable for solid geometry (presented as a physical object, with a volume) although the 'wireframe' cube would more underline its induced properties (e.g., opposite edges parallelism). The same problem happens for the choice of planes presentation [Fig. 2]. Shall we reify a plane by presenting it as a rectangle included in this plane (but which plane; what about the risk of misconception induced by limiting its visual dimension)? Wouldn't it be better to adapt each presentation of the plane to the global presentation context (for example, presented by its intersection with the walls, if any)? There is no unique solution to this question: the final presentation choice depends on the teacher, who is able to appreciate the relevance of a given solution.

### 2.3.3 The Interaction Modes

An interaction is a user's action, immediately followed by visual feedback and by a system's reaction. For example, direct manipulation of a point is one of the essential actions in a dynamic geometry environment. Moving a point according to the three dimensions of space cannot be performed by a simple mouse move. In order to reconstitute the third dimension, it is necessary to define a more complex task (e.g., combining mouse move with pressing a given key). Feedback has to clearly underline what kind of action is involved. Then the point could move according to user's expectations: a mouse move should involve a similar cursor move and the point move should follow the cursor's movement onto the screen. In the CABRI 3D environment [Qaseem 1997], the solution consists in decomposing the move of a point in a horizontal plane then along a vertical line (modification of the point elevation). Another method, based on the walls as a visual unit for comprehension, consists in directly dragging the projection of a point in the different walls. Whatever the chosen method is, it is necessary to decompose any movement in space in a set of movements in the plane, in order to avoid ergonomic ambiguities. Moreover, such a decomposition could offer a pedagogical interest.

### 2.4 The Objects Visualisation
At the Visual level, the different objects presentation attributes are translated at the interface, according to the properties defined in these presentations: the points shape (round, square, ...) and size, the lines thickness, the object colour, ... This level also allows to define the communication vocabulary: geometrical notations, support messages, menus and items names, dialog boxes, ...

3. Learning Sequences Description

Specifying a CBLE necessarily requires a collaboration between people from different backgrounds (didacticians, psychologists, designers and, above all, teachers) [Guin 1994] and thus needs a common language, understandable by everyone. Consequently, this specification has to be based on the Knowledge-level perspective [Newell 1982], [Nicaud 1994], a level of knowledge description that is independent of any symbol-level representation. For the teachers, it has to ease the expression of their know-how and pedagogical purposes, i.e. their choices concerning the knowledge presentation and the activities they want to manage around this knowledge. In particular, this specification mechanism has to allow the author-teachers (the teachers who directly collaborate in the design process) to define the teaching domain and to propose both geometrical objects presentations and their visual properties, and the user-teachers (the teachers who need CBLE adaptation) to select, among the available choices, those which will create the didactical situation.

Our method was to provide author-teachers with a frame, called utilisation context, for learning sequences description based on the activities they want to set using the CBLE. In a mid-term perspective, we hope to be able to specify information stemming from these descriptions using ontologies.

3.1 Utilisation Context

The presentations of a given object and the actions that could be applied to it are dependent on the context in which this object is used. Here we are closely akin to one of the principles of the KACTUS project [Laresgoiti et al. 1996]: "the context can be seen as a 'viewpoint' taken on the object. It is usually impossible to enumerate in advance all the possible useful viewpoints on (a class of) objects".

We define a utilisation context as the information frame needed for performing activities that share the same pedagogical objectives. From these objectives and reference activities, it is possible to define the representative object classes of this context, their presentations and the user-available functions. In order to illustrate the utilisation context, let us consider the following example [Fig. 3].

**Table: Utilisation Context**

| Context : "Cube section - Exercises" |
| Objective : intersection of a cube by a plane. |
| Reference activities : exercises 1, 2, 3 |
| Including contexts : |
| Cube section - Tutorial |
| Polyhedrons section - Exercises |
| Characteristics : |
| Object class: |
| Cube wireframe, hidden line |
| Plane all |
| Functions : |
| Construction of a parallel line |
| Construction of a midpoint |
| Construction of an intersection |
| Environment parameters : |
| Perspective: cavalier |
| Difficulties and supports : |
| { specify the available supports, that are used by teachers } |

**Figure 3:** Definition of the utilisation context "Cube section - Exercise".
The author-teachers wanted to manage a particular activity and thus decided to describe a context named "Cube section - Exercises". They specified the objective of this context and defined its characteristics that in their view will allow the student to satisfy this objective.

In this context, some particular presentations of plane and cube object classes stand out: the cube could be presented either as 'wireframe', or as a 'hidden line'. On the contrary, the 'hidden face removal' presentation is not suitable in this context: it does not allow the user to visualise the required intersections. These various required presentations of an object class are defined as facets. The functions, that allow the student to perform construction tasks, are specified: the parallel line, midpoint and intersection between two lines construction tasks. From their experiences in providing such activities in the classroom, teachers have identified several types of difficulties and have built several supports to allow the learners to overcome them. In particular, they proposed some software-based supports, like the visual units for comprehension [see § 2.3.11 or the perspective type, that are specified in the Environment parameters field.

3.2 Toward Teaching Ontologies

According to [Gruber 1995], an ontology is an explicit specification of a conceptualisation, i.e. an explicit specification of a simplified representation of a world for a given purpose. An ontology is composed of different entities of the domain (e.g. object classes, relations, functions, ... depending on the domain to abstract), the definition of which associates a human-readable description with formal axioms that constrain their interpretation. The main purpose of an ontology is to allow people to commit to it, i.e. to come to an agreement to use the given shared vocabulary in a coherent and consistent manner. Ontologies are mainly used for expert knowledge sharing and reuse but, more recently, for also managing pedagogical knowledge [Murray 1996].

3.2.1 Construction of the Ontology

Only the author-teachers are able to improve the ontology. The ontology is incrementally built from each utilisation context by specifying every new entity, or by enriching existing ones, that appear in the context: functions, objects, facets, ... Each new entity is then added to the ontology. In the previous utilisation context for example, author-teachers used a cube and the midpoint construction function, that had to be defined respectively as object class and function entities and included in the ontology [Fig. 4].

<table>
<thead>
<tr>
<th>Object Class &quot;Cube&quot;</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Description</strong> :</td>
</tr>
<tr>
<td>A cube is a polyhedron made up of 8 vertices, 12 edges and 6 faces. Edges are [...]</td>
</tr>
<tr>
<td><strong>Composed of</strong> :</td>
</tr>
</tbody>
</table>
| \{A, B, C, D, A', B', C', D'\} set of Points 
 [...]
| **Constraints** : |
| (perpendicular, (AB),(AC))  (relation) 
 [...]
| **Facets** : |
| wireframe  [...] |
| hidden line  [...]  (points of view) |
| Hidden faces removal  [...] |

<table>
<thead>
<tr>
<th>Function &quot;Midpoint construction&quot;</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Description</strong> :</td>
</tr>
</tbody>
</table>
| Construct the equidistant point from 2 points. 
 [...]
| **Facets** : |
| Midpoint of a segment : |
| function : Segment → Point 
 [...]
| Midpoint of two points : |
| function : (Point, Point) → Point 
 [...]

**Figure 4: Extracting the ontology entities**

They described the cube object class by giving a short description and a formal definition (composition, geometrical constraints, ...). In particular, they specified the different cube facets. The definition of the midpoint construction function required arity and arguments kind specification. It also refers to the 'Point' and
'Segment' entities that also need to be specified as object classes of the ontology.

3.2.2 Use Of Ontologies For Educational Software Adaptation

Until now, adaptation of an educational software to each user's specific expectation is only provided at the interface level. The CABRI environment [Laborde et al. 1994], for example, allows a user to configure all available functions by directly manipulating menu items. In CALQUES 2 [Bernat 1994], it is possible to select different interaction modes in a dialog box.

Such a parametrisation cannot be extended to too complex systems: the concepts points of view (and, consequently the parameters) are often too numerous and cross-dependent. Our utilisation contexts allow us to overcome this complexity. Indeed, they define a set of coherent parameters with respect to the context objective. Choosing a context can be done by a unique operation that automatically implies a parameters set.

Moreover, the context descriptions can be organised in a context library and made available to other teachers. Thus, the user-teachers could consult the library and choose a well-adapted context to the activity he would like to propose, avoiding to always begin from scratch.

4. Conclusion

In this paper, we have presented an attempt to provide teachers with a framework for describing their teaching needs with respect to educational software adaptation. The proposal includes a four level model for knowledge categorisation as well as utilisation contexts. The four level model has been successfully used to describe several teaching requirements at the appropriate level. The utilisation contexts have been used on the one hand to describe learning sequences and on the other hand to build step by step a type of teaching ontology for spatial geometry. Such an ontology will then be available for further context designs. Moreover, we expect that it will be part of larger pedagogical libraries available to teachers through networks in the schools of tomorrow.

5. Références

Acknowledgements

We gratefully acknowledge all the teachers and colleagues who cooperate with us in the "GEORGES" group. We have a special thought for our colleague Philippe Bernat who launched this project before dying very suddenly. We wish to express our gratitude to Professor Robert M. Aiken for his comments on the final version of this paper. The dynamic geometry software design was supported by a grant from the "Region Lorraine".
User Interface Design for WWW-Based Courses: Building upon Student Evaluations

Abstract: The user interface of a WWW-based (World Wide Web) course environment influences the user's mental characterization of his/her goals with the system. Although research has accumulated with respect to the user interface of computer-related products, little direct focus has developed for the new type of product: a WWW-based course environment. At the University of Twente we have been designing and using WWW-based course environments since 1994 and we systematically collect student reactions to the interfaces of those environments. In this report we describe how the student reactions shape our design of a WWW-based environment through the example of a first-year course. Most of the user interface redesign choices to the 1997-98 course were well received by the students. The major problem of site structure and how this is presented to the students via the user interface remains.

1. The Importance of User Interface (Re)Design for WWW-Based Courses

The user interface, the point of interaction between a user and a tool [Cox & Walker 1993], of a computer system has long been studied. Long lists of guidelines for user interface design have appeared, particularly within HCI (Human-Computer Interaction) research [Shneiderman 1987]. The user interface for educational software, including multimedia products, has also received regular attention in literature [Boyle 1997].

The term 'user interface' does not seem to be much used with WWW environments yet, although many sets of guidelines have appeared for WWW systems that relate to the classic focuses in user interface design. The function of the user interface is helping the user to have an internal mental characterization of his or her goals with a system, helping the user select an action, helping the user execute the action, and helping the user evaluate the results of his or her interaction [Norman 1984].

WWW-based course environments have begun to receive attention in terms of design issues, but mostly in terms of 'presentation design' and 'navigation support' instead of user interface design. Eekma and Collis [Eekma & Collis 1996] have made a summary of 20 of those design guidelines for WWW-based course environments. Guidelines, when used, are often developed by theory and put into practice in a WWW-based course under development. Little evidence is found in literature about student evaluations regarding the interface design of WWW-based course environments. There are few evaluations present in which they are using the interface themselves and even less evidence of how such student evaluations have been systematically used as feedback for the redesign of WWW-based course environments over several cycles of a course. Undoubtedly this is mostly a result of the newness of the medium. At the Faculty of Educational Science and Technology at the University of Twente, WWW-based course environments have been in use since 1994.
[Collis 1997]. Enough time has passed and experience has developed so that a number of cycles of student evaluations of WWW-based course environments have occurred, each resulting in a substantial redesign of the environments based on these student evaluations. In this paper we report on one such recent cycle.

In this report we describe how the student reactions shaped our design of a WWW-based environment through the example of a first-year course, and the redesign of its user interface between the 1996-97 and 1997-98 versions, as well as our first student reactions to the 1997-98 redesign.

2. Student Evaluations of the User Interface of WWW-Based Courses at the University of Twente

The Faculty of Educational Science and Technology has a pioneering history of WWW-based course environments. This has facilitated the steady collection of student-evaluation data about these courses. Also important is the nature of the courses themselves that are offered through WWW-based environments. Primarily these are courses in which students are studying instructional design, the design of educational media or user interface design as content areas, which means that the students are particularly sensitive to the direct impact of design and have specific criteria and vocabulary for articulating their evaluative comments. Even first-year students, in the ISM-1 (Instrumentation Technology 1) course, not only evaluate the user interface design of WWW environments made by others, but also learn to evaluate the user interfaces of sites they design and make themselves. It is natural that regular opportunities for the students to evaluate the user interface of their own course-site are built into the course activities as the course makes extensive use of a WWW-based environment [Collis, Verhagen & Gervedink Nijhuis 1997a, b].

2.1 Student Evaluations of the User Interface of the 1996-97 ISM-1 Course

An example of such evaluation by the first-year students occurred during the 1996-97 cycle of the ISM-1 course [Collis, Verhagen & Gervedink Nijhuis 1996a], a course that runs for an entire academic year. Approximately 85 students in the course were asked on four separate occasions to respond to a course-site evaluation form, offered via a CGI (Common Gateway Interface) form. The 27 questions had to be answered on a scale of 1 to 5 (lowest to highest). After each of these cycles, the students' responses were summarized and graphically displayed within the site [Collis, Verhagen & Gervedink Nijhuis 1996b]. In the following paragraph some main results are mentioned from these on-going student evaluations of the 1996-97 cycle of the course. It is also indicated how the 1997-98 version of the course was redesigned, based on these main results.

With regard to the results, the students were consistently pleased with the possibilities of the WWW-based course environment. Students expressed they liked working on the course through the ISM-1 site very much. They also liked the specialist tasks assigned to each person in the group-project part of the course, and were able to work on their tasks without help. The way lecture notes were available on-line before and after the classes was considered a good idea compared to other courses, where the notes were not available or only after class.

Students also stated specific suggestions concerning future improvement of the course and the course site:
- It is difficult to read from the screen, especially after some time.
- Hyperlinked study texts take up too much time, especially when studied at home through a modem.
- It is very easy to get lost because the information wanted is stored very deeply in the site.
- The exercises are time-consuming, just doing projects is preferred.
- The communication between group members has to be improved.

While these points relate to the organization of the course and the course-site as a whole, points such as the following relate specifically to the user interface:
- The navigation could be clearer.
- The text is difficult to read.
- It is not immediately clear where new things in the site are put.
• Consistency on the pages is required for better clarity.
• It has to be immediately clear whether the current page is an internal or external page.
• Italics are very difficult to read from a screen.
• Tables sometimes do not fit on the screen.
  Specific design-related conclusions are inferred from these suggestions and also by use of traces of student usage of the course-site and other student comments made during the course:
1. Students do not like to study by reading from the screen. They prefer printed, portable, linear study materials instead of hyperlinked interactive study materials so they can study them away from the computer.
2. Students do not want to go further than three clicks (or levels) to find what they need.
3. Students appreciate a navigation frame that is always present. They need a clear understanding of what is meant by each option in the frame.
4. Students are sensitive to the readability of text on the screen, to its layout, and to a consistent screen design, based on the way that text is formatted and spaced, with a restful contrast between background color and the colors chosen for text and links. Highlighting features such as italics are not appreciated because of their impact on readability. Consistent and restful are key attributes.
5. Students are not particularly interested in images and logos on the pages of the course-site, but they do appreciate being able to visually distinguish the course pages from external pages that are called up; thus all course pages have to possess a common look.
6. Students prefer to scroll through a page, rather than to use internal links to move around within the page, but they do appreciate a consistent link from the bottom of the page to the top of the page.
7. Students want a direct indication of what is new in a site, and where to find it, as soon as they enter the course environment.

3. Redesign of the User Interface for the 1997-98 Course Environment

The course was redesigned for the 1997-98 year based on these and other student reactions to the user interface. In the next paragraph the main way the evaluative comments of the students influenced the course redesign are described.

Navigation. In 1996-97 students said that the navigation frame appearing on the left of every screen had to be clearer. Thus the navigation frame has been changed from icon based to word based, because the students indicated that it was not quite clear what the icons represented. As it is difficult to find suitable icons for the different centres, the option of word-based navigation for the navigation frame has been chosen. Students also said that one of the results of using a frame was that it sometimes was not possible to go back or forward using the buttons in the browser. Therefore backward and forward arrows are now provided on the pages. A home button is also provided at the bottom of each page.

Layout. Consistency in the pages was required for better clarity. Thus all pages are now built using the same template. The template contains the background color, text color, title color, menu, ISM-1 logo, table format, bullets and horizontal bars. It was indicated that it has to be immediately clear whether the current page is an internal or an external page. Therefore different colors and the new (smaller) logo are used. The logo represents the KOPIE model [Collis & Verhagen 1997] which is the leading conceptual thread for the course-site. The Educational Science and Technology house-style colors inspired the choice of the colors blue, red and yellow.

Icons. In last year's course students said that the icons were not clear. Now the icons are renewed. As it was very difficult to find representative icons, headers are placed next to icons smaller than those of the previous year, to clarify their meaning; consequently an icon's function is reduced from a navigation item to a decorative recognition item.

Tables. The tables had to be clearer, thus a new template for the tables was designed, including no fixed table widths. Instead table width is indicated by a percentage of the screen, so that in this way the tables always adapt to the screen size.

Text clarity. Last year it was indicated that the black text on the white background was difficult to read,
and not pleasing to the eyes when larger portions of text were read. The improvement made is that the text color has been changed to dark purple, and the background color to light yellow. The choice of these colors was directed by comments such as: the background was too light, and the text was too dark.

*Text readability.* In the 1996-97 course students said that the texts were presented in paragraphs that were too long. Paragraphs are now shorter, and subdivided by horizontal bars. The main items are stated at the top of each centre in a menu. By clicking on these items the text immediately scrolls down to the requested part of the text. At each break an arrow to the top is presented that allows the user to easily return to the menu.

As an example of those adaptations, the user interface from the 1996-97 course [Collis, Verhagen & Gervedink Nijhuis 1996a] is shown in Figure 1, while the revised user interface from the 1997-98 course [Collis, Verhagen & Gervedink Nijhuis 1997a] based on the student comments is shown in Figure 2.

4. Student Evaluation of the Redesign

Continuing our process of on-going student evaluations of the user interface of the course-site, students in the 1997-98 cycle were surveyed during the fifth week of the course (October, 1997) with regard to the user interface of the course-site. This survey occurred with selected students via interviews and an evaluative CGI-form available within the course [Collis, Verhagen & Gervedink Nijhuis 1997b]. Students were not forced to respond, but 38 out of the 60 students did within a one-week period. The results were directly summarized after this one-week period and made available to the students via the course-site [Collis, Verhagen & Gervedink Nijhuis 1997c]. Table 1 gives some of the survey questions and a summary of the student responses.

5. Conclusion

From the survey results and student interviews, as well as other sources of data such as traces of student usage of the course-site, it is shown that most of the user interface redesign choices are well received by the students. The major problem of site structure and how this is presented to the students via the user interface remains. The conceptual decision to present the course-site based on the metaphor of 'centres' (Information Centre, Study Centre, Production Centre, Specialist Centre, Communication Centre and Search Centre) was
taken as a basis for navigation, to organize the types of materials and interactions supported in each of these parts of the course-site. This decision is conceptually logical, and fits the instructors' mental models of the course-site. Students however, live and work in sequential time: finding what they need for a given week in as efficient a manner as possible may be a more appropriate approach for the organization of the site as expressed in its user interface. This is a serious point of consideration for further cycles of the course, and for the design of WWW-based course environments in general.

6. Discussion

Designing the user interface of a WWW-based course environment is a complex task, involving the combination of form, function, style and practicality. It is important that student evaluations of the user interface of these environments occur whenever they are used. Some of the design decisions that the course-site designers may feel are most appropriate may not be perceived by the students as most helpful. Examples of this are: organizing the course-site conceptually rather than by a week-to-week basis, offering the students hyperlinked study materials, and offering frequent internal navigation options within pages. Other aspects, such as the way text is laid out on the page and an overall peaceful feeling resulting from the colors and style of the site, may be more important than previously considered. Asking the students systematically and regularly about their opinions should become part of our standard practice when WWW-based course environments are used. This can be realized through a combination of CGI-form surveys, informal interviews, and examination of the logs of their movements within the site.

Abstract. This paper describes a computer-supported environment to facilitate distance learning through collaborative problem-solving. Our goal is to encourage distance learning students to work together, in order to promote both learning of collaboration and learning through collaboration. Collaboration means working together on a common problem, communicating and coordinating activities towards a shared goal. We propose a system embedding three models: an activity model, a domain model and a conversational model. The system can support asynchronous collaboration in a number of dimensions: giving structure to activities and communication to articulate the problem solving-task, supplying a share space to build jointly common knowledge, providing relevant know-how by case and techniques libraries and facilitating further reflection on the whole learning process. Preliminary results have convinced us that this approach offers promises to establish collaborative distance frameworks to enhance students learning processes.

1. Introduction

Teaching and learning require a range of approaches to suit diverse domains and students. At the root of science courses, including computer science and engineering, is the acquisition of problem-solving skills, usually through practical activities performed individually or in group work. In the case of distance learning situations, communication technology opens for the first time, the possibility of deploying problem-driven and collaboration learning strategies, so that students could acquire and practice a variety of interpersonal and reasoning skills. Recently, several research teams work on developing tools to support the performance of (learning) tasks to be carried out together by students located at different places. As many authors point out, two key ideas are (1) learning activities should be structured to focus students on the issues to learn, and (2) educational software systems should exploit their interactive potential and the capacity to include and manipulate explicit models, in order to stimulate students' knowledge construction processes. Distance collaborative learning can be shaped in many ways [Collis 94], [CACM 96], [Verdejo 96], joint projects is appealing for a range of scientific and engineering subjects. To mention just a few of the current educational projects exploring this area, [Edelson et al. 94] offer a shared Notebook with a set of page types corresponding to a task model of scientific inquiry to be used for collaborative science learning. The page types include questions, conjectures, evidence for and against, information, commentary as well as plans and their steps. Students can create instances of these pages and link them as their work progresses. A learner interface built upon their scientific inquiry model, suggest students next steps to pursue. [Wan & Johnson 94] report on CLARE, an environment supporting the task of learning to understand scientific literature. They define an explicit process model: summarization, evaluation, comparison, argumentation and integration and provide representations and structure for each of these individual and group activities. Learning as collaborative knowledge construction can be difficult to achieve, among other reasons because often students have to learn at the same time the abilities to collaborate. However, group competencies are basic skills to be acquired not only for the purpose of the learning process at hand, but for future professional proficiency. This paper describes our approach to build a computer-supported environment to facilitate distance learning through collaborative problem-solving. The paper is organized as follows: Section 2 sketches the distance learning scenario. Section 3 gives a description of our modeling approach. An application is presented in section 4, and finally some conclusions are given in section 5.
2. Scenario

A scenario, described as a summary of situations, including information about its setting, participants, their tasks, roles and interactions, is often used to develop a practical understanding of how an end-user will perceive and use a technology-supported environment. For designers, it is a means to perform a joint visualization of candidates ideas in order to explore, refine, and test them for further implementation. In our case, the scenes concern learners-related actions and interactions, embedded however in a broader context. Main features are the following:

- Institutional framework: The institution is a distance learning university, offering diplomas, in a regulated course time frame, with formal examinations. The prevalent model is independent self-study with appropriate learning materials. The use of a collaborative environment should be on a volunteer base (both from academic and student side). Groups using the environment should follow the same calendar (for deadlines, assignments,...) and academic requirements as the rest of students.

- Kind of scenario: Collaborative learning, focusing on group project development. Groups of distance learning students, each group has to carry out a project using a system to support their personal and group work. This support should include, in an integrated way: (1) private and shared workspaces with notations for expressing alternative partial solutions at an adequate level of abstraction, (2) facilities to use domain-specific tools, (3) facilities to access information sources in a way relevant to the task at hand, (4) group communication facilities helping to manage the complexity of the interaction.

- Learners, organized in small groups, in each group there are a number of roles: moderator, contributor, and secretary. For the moderator role, two kind of functions are expected: organizational facilitation (such as conduct and end discussions), and social facilitation (motivate and promote cooperation). The role of secretary is to focus on intellectual facilitation, such as summarize contributions or highlight conflicting opinions.

- Settings, described by spatial and time dimensions: Students, Tutors, and Professors are in separate, distant and disperse locations, usually with different schedules, so that interaction and collaboration should be in deferred (no real) time.

- Facilities, comprising conventional and technological material and devices. We assume each participant has access to a standard multimedia computer connected to a central server, using low-cost communication technology (mainly asynchronous electronic mail, computer conferencing, or asynchronous access to file systems).

3. Modeling the system

Our system architecture to support learners for collaborative project development consists of three independent but interrelated components, which are based on the following models: (1) an explicit model of the problem-solving activities or activity model. This includes a description of each activity, to specify whether is a personal one or in group, main goal to attain, kind of information available and possible restrictions. Relationships between activities are also expressed. The group organization (participants and roles) is also provided; (2) a model of the participants interaction, both human-machine and human-human communication. Communication is performed through semi-structured messages using a conferencing system, each message belongs to a larger discourse unit, and depending on its type and purpose is related either to events of the activity model or to objects of the domain model; These two models are inspired on proposals from the CSCW stream, [De Cindio et. al. 88], [Malone & Fry 92] implemented for teamwork in professional environments; (3) a model of the domain comprising two sources of case-based structured knowledge, and a workspace offering a notation to express students' constructions for a solution.

In our system these three components are integrated and related one to each other. For instance, the activity to be performed can constrain the type of dialogue that is used; an activity is developed linked to a type of problem-solving task in a particular knowledge domain. In this way actions and interactions in the learning process are properly recorded. Thus, not only the whole process is also an inspectable object to reflect upon, but its explicit representation allows, as well, to include supportive actions from the system. The activity model is generic, that is, its elements are valid for any type of activity not necessary educational. The proposed model of dialogue for a moderated debate (structured in terms of sessions, rounds, and messages) is valid for any discussion that has as an objective to build an agreed solution. In the same vein, the notation for expressing domain problem's description, is also generic (objects and relationships to which the user can associate the
desired semantic behavior). To combine domain, activity and group modeling in a learning environment aims at least at two purposes, one to facilitate reflection so that students could have the opportunity to consider not only their outcomes but also the process they are following and, the other one, to provide students with support for building and exploiting cumulative understanding, giving them a further motivation: the opportunity to contribute to the extension of the domain memory for the use of future learners. Grounded on these models, different applications can be built following an user-centered design methodology as initially proposed by [Norman & Draper 86] and further developed by [Gould & Lewis 87]. An iterative, formative, and situated design process. Initial analysis leads to a preliminary specification to build a prototype, the evaluation of that release is used as a formative (information gathering) step, providing feed-back for further re-specification and re-implementation. Final testing should be situated with real users on a realistic task.

4. Developing an Application

We started focusing on the learning of a class of problem-solving methods, in particular related to software design. Taking into account our teaching experience on programming projects development for undergraduate students, a first set of scenes were defined, and experiments with small groups of students were conducted. Each scene was characterized in terms of participants and task at hand, focused on a main issue to test a range of support tools. Taken all together, had lead to gain insights for an integrated environment. Through observation and discussion of students' performance and results, the notation used to describe domain objects, including the description of problems, requirements for a solution, and the expression of partial designs was revised. Some changes affected the groupwork process model, and so the definition of the private and shared workspaces and their support tools. After this phase, appropriate features for an integrated learner interface have been established, and a prototype built.

4.1. Activity Model

This section sketches the main objects provided by the activity model. An Activity has a name, a description, a mode (either individual or collaborative), participants, a characterization of the information required as data or generated in each activity, as well as a description of the tools needed to carry it out. A part of this information, but properly distinguished, is the result or product. A Complex Activity is a set of activities with a partial order defined, it can be visualized as a labeled directed graph in which the nodes are activities. Attached to the nodes and/or edges, a control descriptor represents requests that the system will perform automatically during the development of an activity. For example, when the third step would be finished the teacher could establish that he wants to receive a report. Then the system will generate a message to the students requesting the report. A special case of complex activity is when the set of activities is ordered i.e. a sequence of activities. For each activity there is a descriptor pointing to the set of electronic messages that students have interchanged while carrying on the activity. This descriptor establishes a link between the activity model and the dialogue model. For our scenario, we have written the description of a main activity related to computer programming design. Students have to learn to characterize a problem and then select an approach to solve it using a set of known techniques. As a final result of this activity students have to build a piece of software and a documentation. The design methodology they have to acquire includes the following sub-tasks: Specification, Instantiation, Structured Design, Implementation/ Test, and Generation of the Documentation. Each one is in turn, a complex activity with its own input and output, its time schedule and participants. An outline of the definition for the Specification is showed in table 1.

| Specification is a complex-activity consists of (CA1, CA2) |
| ACTIVITY | TYPE | P ORDER | SUBACTIVIES |

The individual phase for making a Specification consists of three activities, namely, problem description, selection of an algorithmic technique and making a justification. The description and the selection can be done at the same time; but the justification has to be done once the other two are finished (these restrictions are expressed in a graph, see figure 1). A tool allows creating and editing an activity model. Along the learning process, the system works with the model, linking dynamically references to the event instances been created. A visualization of the current state of the activity model is available from the learner interface, so that always students can inspect the structure of the whole process, accessing to the information in a structured way, and being aware of the active sub-task in which they are involved.
CA1 is a complex activity

| Individual graph1 | Build Problem description, Decide which algorithm techniques are candidates to solve the problem, Justification of the proposed techniques depending on the chosen description |

CA2 is a complex activity

| Collaborative moderated debate | Mutual understanding of the work, Collaborative construction |

Table 1. Definition of Specification as a Complex Activity

4.2 Dialogue model

We had focused our study on the debate mode. Moderated debates are carried out through different stages related to a phase of the task model. There are two aspects, which become relevant: The structure and form of a debate and its relationship with the activity and domain model. For the specification task, the debate starts after a personal work phase, and consists of a set of sessions: the initial session is usually bounded to introduce personal solutions. This session just consists of one round. A round is accomplished when every member of the group has participated once at least. A session can be a set of rounds. A message from the moderator opens the discussion starting a new session, then students try to understand the others’ solution proposals. A number of comments are made and new solutions are proposed out of the old ones. This is called a diversification session, because new themes can appear in the debate. The debate is eventually focused by a message from one of the participants, opening a consolidation session, and can be followed by a new diversification session, and so on, until an agreement session is caused by the moderator. As mentioned before, the debate is established by means of electronic messages produced by the students using a conferencing system. Messages related to a collaborative phase for constructing a solution can be roughly classified in two groups as follows:

1. Those referring to domain contents (IS, IRS, CS). Introduce solution (IS): this type of message is only sent at the beginning of the debate. Its goal is to share solutions with the other members of the group. Introduce reviewed solution (IRS): Normally, during a debate, one has to review its last introduced solution due to others students comments. The goal of this message is to propose a reviewed solution. Comments about solution (CS): comments can be of any type (suggestions, criticisms, questions, misunderstandings) and can refer to any of the solutions introduced by the members of the group.

2. Those concerned with the task and debate evolution (CTM, CC, R). Comments on task management (CTM) for instance to summarize the situation up to the moment. Comments on coordination (CC): They are mainly done by the moderator, they can refer to time scheduling, handling of participation. Reflection (R): a variety of written thoughts, expressing personal/interpersonal dispositions.

Messages of the first group create new objects or links on the shared domain workspace, so that everyone can view for a proposal, new contributions as well as all the participants' comments on it. Providing a semi-structured way to perform interactions allows to create automatically links between the domain, activity and conversational models. This structured and interrelated information can be used in different ways, for instance by a teacher or the students to know the work progress, to focus on the current state of affairs, to analyze contributions to a particular proposal, or to further evaluate whether and how collaboration occurs. Furthermore, the system can have information, to some extent, about how the debate is going on. This, eventually, provides a potential source to be exploited for pedagogical support, as for example, to design and include a coaching facility to stimulate group interaction.

4.3 Domain Model

To support problem-solving in a domain, a variety of knowledge sources and tools can be foreseen. Sources may include declarative knowledge, for example the criteria to use a particular technique, and procedural knowledge i.e. how to proceed to solve a type of problem, with available examples from a case-based library. Tools like compilers and debuggers provide dynamic models to be used in some stages of the learning process.
Central to our application is a shared tool: a common workspace where students can write their solutions for a given problem using a graphic editor. Based on the entity-relationship model, the notation is precise enough as to be interpreted unambiguously, and powerful enough to describe the solution at different levels of abstraction. A semi-graphical representation has the advantage of being easy to use so that students can concentrate in the problem itself and not to bother about the features of a new formal language. An advantage of this type of representation is, that to some extent, an object can be automatically analyzed, and then the system can help in the comparison of the variety of solutions worked out, providing operations to answer questions such as the number of different techniques proposed by the group to solve a problem or check whether the restrictions for the input in a set of proposal are the same. The workspace model includes a set of predefined objects, built up from primitive elements, so that students can either built their objects from scratch (using the primitive operations) or by means of selecting and filling operations. The level of abstraction and grain size of the objects and the operations provided to manipulate them, is a tool design issue of great importance. Combining a graphical and textual representation for operations such as to visualize, edit, search and compare seems intuitively a sensible approach.

4.4 The learner interface

The learner interface aims to make easy creating and discussing a solution for a given problem. Figure 1 shows a screen shot from a mutual understanding activity.

The main window is divided in three areas: problem solving on the left, activity and conversational spaces on the right. The problem solving area includes a shared workspace were contributions can be written, either by selecting and/or editing a previous proposal, or by importing a new one. A set of buttons gives access to the case-based and technique libraries, where navigation is facilitated to find easily the information required. The discussion tool offers a set of typed messages. Students can discuss by posing comments to proposals, questions,... and responding to them. All the messages for the session can be visualized on the session window and the filter option provide a variety of views to see only kinds of interconnected messages. This semi-structured support facilitate learners to focus on the content of their discussion The activity button give access to the activity plan, to visualize the requirements of the current step, or to know about the next/past activities. This tool facilitates to students involved in the task, and also to teachers, to monitor their progress.
5. Conclusions

A number of experiences, involving students, have been undertaken with a previous version of the system prototype. The application described above, include all the changes derived from observation, analysis and discussion of the students activities. For the case study, we have used as domain subject a course on Algorithmics, run on the second year of a Technical University. Students following this course were involved in the design and implementation of an information system for the management of a library. They have previously done some groupwork and have positive feelings towards the use of electronic communication. The specification step was defined as the main focus of attention for analysis and assessing purposes. Scenes have been selected to study particular modeling aspects. The experiment was conducted with different groups, each one involving three students. The activity included an individual work phase followed by a collective debate to produce the collaborative solution. The concatenation of several phases covering the whole process has not been tested yet. Every group has been provided with the same problem. As these experiments went on, guidelines to incorporate pedagogical support on the models were established. As well, the mapping of learners activities on interface actions was clarified. Roles, particularly the moderator, were clearly seen as useful.

Our goal is to encourage distance learning students to work together, in order to promote both learning of collaboration and learning through collaboration. Collaboration means working together on a common problem, communicating and coordinating activities towards a shared goal. We propose a system embedding three models: an activity model, a domain model and a conversational model. Based on these models, a computer system can support asynchronous collaboration in a number of dimensions: giving structure to activities and communication to articulate the problem solving-task, supplying a share space to build jointly common knowledge, providing relevant know-how by case and techniques libraries and facilitating further reflection on the whole learning process. Experiences and preliminary results have convinced us that this approach offers promises to establish collaborative distance frameworks to enhance students learning processes.

Abstract: To illustrate the potential of spatial hypermedia for education, we present HyperMap. HyperMap is a concept implementation of a spatial hypermedia browser. Information is presented in a scrollable 2D space, based on a map metaphor. Where the unrestricted navigation style of WWW hypermedia is undesirable, HyperMap provides extra navigation and guidance. Educational hypermedia content displayed on a map allows various limitations of WWW information display and linking to be lifted. The 2D view of information in HyperMap provides ubiquitous navigation and allows communication of implicit structure through the positioning of information. With the conditional hypermedia links in HyperMap, a student can be given knowledge-based guidance support. Other innovations in HyperMap are persistent objects that can be annotated, interactive multimedia content, and straightforward hypermedia authoring.

1 WWW hypermedia for tertiary education

platform for hypermedia development. WWW hypermedia, originally designed for straightforward textual information retrieval, is more and more applied in educational settings, either in the classroom or outside for distance learning over the Internet, as described in [Marshall and students, the role of distance education and by future. Currently, most educational hypermedia applications are based on WWW browsers and HTML v3.2. Because of users and authors. Although HTML and WWW browsers have undergone numerous extensions over the years, there is as yet no fundamental approach towards guidance and navigational support. This is a definite problem when using WWW hypermedia for tertiary education. Students often become disoriented when browsing a large information space. When there is insufficient information to select a particular link out of many alternatives, users tend to feel lost and browse at random hypermedia links are still direct links, and thus prevent unrestricted navigation where users know where to go and how to get there. In contrast, in educational applications of hypermedia,.

From our previous research into tertiary hypermedia based computer science laboratory support [Verhoeven and Warendorf 1997], we consider navigational support to be essential for the success of educational hypermedia applications. Other researchers into hypermedia in education agree; [Jones and Berger 1995] suggest that hypermedia cognitive style influence a compatible with that particular design. These find content is desirable. The potential of education been explored before [Trentin and though no user interface design specifications were included.

for an innovative hypermedia browser. We illustrate our design with a concept implementation named HyperMap. metaphor.
2 Shortcoming of the WWW for education

Hypermedia developers have in various ways addressed guidance and navigation. One is to generate on-line adaptive HTML documents. Individualized hypermedia content allows links to be omitted, ordered, and colored in order to guide a user [Schwarz et al. 1996]. Schwartz and Brusilovsky preferred icons and text-based adaptive annotation to only coloring, but were restricted by the current HTML standard.

In the area of user interface improvement for browsers, some HTML limitations have been addressed with Java applets. Applets run as small programs inside HTML documents and provide interaction in their separate graphical user interface. With applets, HTML can include highly graphical user environments. Recent HTML hypermedia applications increasingly include both applets and scripts integrated in HTML for adaptive user interaction. Applets and browser scripts are able to achieve localized user interaction in a graphical user interface, but do not scale up well for integrated navigation support, as reported in [Verhoeven and Warendorf 1998]. Size and communication limitations of applets, caused by restrictive WWW browsers, make them unsuitable as integrated guidance and navigation tools. In addition, the 'next generation' WWW research such as the Hyper-G project [Mauer 1996], have made few improvements of the standard hypermedia user interface and its maximum guidance level.

We propose an alternative educational hypermedia design based on Spatial Hypermedia. A concept implementation named HyperMap has been implemented in Java. A major feature of HyperMap is that it is not restricted by HTML for its hypermedia document size and format.

3 Spatial Hypermedia and education

Spatial hypermedia [Marshall and Shipman III 1995] is based on a user interface with a central canvas where media objects (text pages, notepads, pictures, interactive visualizations, and questionnaires) are displayed and manipulated. Implicit relationships between media objects are visually present in the size and proximity of objects. The spatial layout helps authors to express relationships between objects and helps readers to interpret the information. The notion of a central canvas has been applied in development of collaborative hypermedia applications [Marshall and Shipman III 1995], geographic information systems [Lokuge and Ishizaki 1995], and applications for the communication of concept maps [Gaines and Shaw 1995].

Spatial hypermedia applications have been largely regarded as a tool for computer supported co-operative work. The usefulness of spatial hypermedia for education has not been fully explored yet. To investigate the potential of spatial hypermedia for education, HyperMap has been designed as a domain independent hypermedia browser for educational content. HyperMap allows knowledge-based connection between media objects, and thus the creation of adaptive hypermedia links. Its graphical user interface is based on a scrollable central canvas. A navigation tool, consisting of a scaled map of the canvas, is always visible. Interactive multimedia objects on the canvas form a media rich environment with a high level of interaction through guidance in link selection, questionnaires, visualization, animation, and audio support. This promotes a motivating multimedia experience that goes beyond passive reading of textual content. Where in HTML text is the central medium that links content together, in HyperMap the visualization and layout of objects is central. For educators, it aims to provide a tool in which a curriculum can be expressed visually.

4 HyperMap as an educational tool

HyperMap is intended for educational assignments in which information retrieval is a part of students’ activities. Both courseware and traditional intelligent tutoring approaches would be overly restrictive. In the spectrum of guidance in educational systems (figure 1), HyperMap aims at the middle area, with unguided WWW hypermedia on the extreme left and classical intelligent tutoring systems on the right. Here, guidance is interpreted as more than merely reducing the set of links from which to select. When restricting the available link set to one, navigation problems disappear, but also the opportunity to select the information that answers a student’s specific information needs. Thus, guidance should also explain and point out alternative links. For some educational domains, tutoring in HyperMap will be similar to guided discovery tutoring style [Elsom-Cook 1988]. Guidance is offered in a mixed-initiative dialogue, where the student usually will decide where to go in the information space. For some educational assignments, unrestricted browsing of information may be sufficient. Even then, HyperMap browsing will still differ from WWW browsing in that it takes full advantage of students’ map reading skills for orientation and navigation.
When an assignment involves information retrieval tasks, guidance is essential. Spatial hypermedia can provide the direct navigation support lacking in most WWW hypermedia. Unlike tutoring systems, it leaves the student the ability to browse.

In HyperMap, all hypermedia links are indirect to allow intervention in the browsing process by a knowledge base (figure 2). For basic applications, simple conditional links may be sufficient. They restrict a user’s path through an information space by becoming active only after a set of links has been first visited. The user is thus forced to follow a path defined by the hypermedia author. This potential resembles ‘hypermedia sequences’ in Hyper-G [Mauer 1996], except that HyperMap gives more flexibility. Not the number of links is restricted, but their state will change between either enabled or disabled.

Spatial Hypermedia, as implemented in HyperMap gives the user access to a large scrollable canvas, which may be up to several square meters in size. Free navigation takes place with the aid of a scaleable map, displayed next to it (Figure 3). When navigation is unrestricted, one mouse click on the map causes the large canvas to scroll to the requested position. When a valid link is selected, the view scrolls to the canvas position where the information is displayed. Guidance takes place when the application initiates scrolling to give the user a ‘tour’ around the canvas.
5 Accessing a 2D information space

Due to the virtually unrestricted size of the central canvas, even large information bases can be organized and placed on a single view area. This single-window approach avoids space contention, which occurs frequently in applications based on multiple windows, investigated in [Henderson and Card 1986]. Space contention can be regarded as user disorientation in window space. A navigational support facility, which relies on large numbers of simultaneously accessible windows, is likely to create more disorientation than it resolves. Therefore, HyperMap uses scrolling in a single window to access parts of the canvas currently not visible. Fast scrolling is initiated by a mouse click or mouse drag on the map in the right upper corner (figure 4). The map, which can be enlarged when necessary, displays the object on the canvas and the currently visible canvas area properly to scale. A map grid helps to visualize the current canvas - according to the map size ratio. Even when the map scrolling is disabled, the map still provides information to the student about the current position in the full curriculum, as all objects are displayed on the map.

One advantage of a large information canvas is that information objects can be displayed completely, as opposed to only displaying symbolic icons as in [Marshall and Shipman III 1995]. Further, HyperMap provides unlimited space for help texts and graphical guidance near hypermedia links. Thus, the user will generally have valid expectations when selecting a link. A third advantage is the space provided for users to leave annotations in empty slots scattered on the canvas. Whenever the need arises to add an observation, reminder, or memo, the user can do so and thus personalize the information space. The annotations are stored after the session has ended, and the personal information remains intact for future sessions. No separate and potentially distracting paper-based note taking activity is required.

Results in the literature on empirical experiments with hypermedia maps as navigational tools have shown mixed results. A negative effect from spatial navigation maps on information searching has been reported in [Sousa and Dias
1996] where it is argued that the presence of a spatial map of the content interferes with the development of a cognitive map. Although not empirically tested yet, a similar negative effect of the navigation map in HyperMap is not expected for two reasons. First, the map in HyperMap is not a separate node that has to be revisited repeatedly; instead, it is integrated in the browsing process and continuously visible. Second, the layout of the hypermedia objects visualizes their semantic relations, and is identical to the map layout. Thus, there is continuous and consistent semantic information available to help students in the development of a cognitive map.

6 Hypermedia link differentiation

In spatial hypermedia, the role of links is different than in conventional hypermedia. Information about the relevancy of a link is implied in the geometric organization. For educational purposes however, explicit links are also necessary. In HyperMap, explicit links provide guidance and restrict navigation, both by providing textual information and by scrolling the central canvas to the position where the link is anchored. Below five types of links are listed which are applicable in HyperMap. They can be combined on a single canvas to create a curriculum with an appropriate level of navigational freedom (figure 5):

- **Sequenced links**: In a sequence of single links, the student is forced to take one path. This may be desirable from didactic considerations, although it restricts free information search.
- **Multi-links**: When a link has multiple valid destinations, a multi-link offers a choice to the student which path to follow. Textual descriptive link information may be offered to guide the selection.
- **Conditional Links**: A basic condition for a conditional link to be a valid choice is whether a pre-read set of links has been visited before. This was proposed in [Lai et al. 1996] as a restrictive navigation control method. A knowledge base in conjunction with conditional links can provide a level of adaptation into hypermedia links, as in [Trentin and Midoro 1996].
- **Proximity links**: This type is specific for spatial hypermedia. When a proximity link is reached, it restricts navigation by disabling scrolling beyond a radial distance from the link location. This combats random browsing, while local information retrieval remains unrestricted.
- **Implicit links**: When laying out hypermedia content on the canvas, information is implicitly stored in the proximity of objects. For purely information retrieval, implicit links allow free but unguided browsing.

![Figure 5 Five types of hypermedia links are displayed. Sequenced links (1), multiple destination links (2), conditional links (3), proximity links (4), and implicit links. A curriculum can be laid out on the canvas from start S to the end E, with an educational optimal degree of browsing freedom.](image)

7 Interaction and Multimedia

Multimedia in educational hypermedia provides extra motivation for students. However, when non-interactive media are applied, the benefits are small. HyperMap is intended to provide both passive and interactive multimedia. Currently a component library, consisting of multimedia HyperMap objects, is under development. As an alternative, the inclusion of existing Java applets, with only minor modifications, is possible as shown in figure 4, allowing the inclusion of existing HTML applets in HyperMap. Future HyperMap components will be based on a more robust and versatile component model.

8 Support for object-oriented hypermedia development and authoring

The hypermedia authoring process is often a bottleneck in the realization of a real world hypermedia application [Nanard and Nanard 1995]. Various map-based authoring tools, such as [Zizi 1995], aim to support authoring with
graphical entity-relationship diagrams and other mapping techniques. In contrast, when authoring hypermedia content for HyperMap, the browser itself is the central authoring tool to display the information relationships.

Another supportive factor is that implementation in Java, an object oriented language, complements high-level hypermedia design. Object-oriented programming encourages the definition of classes of persistent multimedia objects, in accordance with existing object-oriented hypermedia development methodologies such as the Object-oriented Hypermedia Development Method [Rossi et al. 1995] and the Extended Object-Relations Model [Lange 1994]. We mention these advantages in [Verhoeven and Warendorf 1998]. An advantage for distance education applications is that Java applications easily support deployment over the Internet, while retaining platform independence. This makes Java an ideal foundation for educational applications. HyperMap has been designed with Internet features, either executed from the desktop or from inside a WWW browser.

9 Conclusion

The spatial hypermedia paradigm holds promises for tertiary educational hypermedia applications. The HyperMap browser under development is intended to provide a fundamentally education-oriented environment for hypermedia applications in which a student curriculum is integrated. The combination of a map-based user interface with knowledge-based hypermedia links offers guidance and navigation beyond WWW standards. Hypermedia authors benefit from the overall object-oriented design of HyperMap.

RESCUER: Intelligent Help for Plausible User Errors

MARIA VIRVOU

mvirvou@unipi.gr

Abstract: This paper deals with the problems that arise when a human user interacts with a computer via a command language (such as the UNIX shell) and makes mistakes. It investigates how to add reasoning to the computer so that it behaves like a helpful expert who watches over the user's shoulder and offers spontaneous help on problematic situations involving user's errors. A prototype, called RESCUER, implements such additional reasoning by tracing the user's thinking that may have led him/her to issue a command that s/he did not really mean. The main focus has been on the adaptation and incorporation in RESCUER of a cognitive theory called Human Plausible Reasoning Theory which is used for the generation and evaluation of hypotheses about possible user's beliefs underlying the observed user's actions. The success of RESCUER has been evaluated on sample scripts of real UNIX user interactions showing that RESCUER does follow the user's correct and/or incorrect reasoning to a satisfactory extent.

Key words: user modelling, intelligent help systems, human plausible reasoning, error diagnosis.

Overview

It is often the case that users make mistakes because they type other than what they mean. For example, they may accidentally delete files that they did not mean to lose. This may happen if they have issued the wrong command with respect to their intentions. Situations like this may occur even in user-friendlier interfaces than command language interfaces. For example, in a Graphical User Interface of an operating system, like Windows 95, there are still some actions that the user has to do in order to carry out a plan which s/he thinks serves her/his intentions well. In this case, the actions may be different from actions in a command-language interface, such as selecting some files and then clicking on a certain icon for them to be deleted or placed in the clipboard. However, a novice user still needs to conform with the user interface's formalities and may end up initiating the wrong actions with respect to her/his intentions.

We strongly believe that an important cause for the problems that people face when interacting with a computer, is the reasoning that they use as people. This reasoning often proves inadequate or even misleading when applied to solving problems which are based on formal methods, such as giving a command in a command language. This belief has been formulated by analysing the results of an extensive empirical study in the domain of UNIX [Virvou 1992] and has been reinforced by other empirical studies such as that described in [Fung et al. 1993] where the authors report that students talked of an introduction to formal reasoning methods as a "culture shock" or "surprise". People use approximate reasoning based on analogies, generalisations and specialisations which is very good as a heuristic method for understanding, discovering, making guesses and learning, but is error prone. In addition, as Lopez points out in [Lopez 1997], analogy-making is a natural human process which often shows that not everyone thinks about a situation in the same way.

Returning to the problem of the interaction of a human user with a computer, it seems that the computer lacks a human reasoning interface that could reason about the user's beliefs and the user's possibly incorrect thinking that may have led the user to a plausible error. What accounts for the incorrect thinking could be the same generative procedure that in some occasions may lead to correct guesses. Self in [Self 1989; 1991], also
This view reveals a role for a cognitive theory, such as the Human Plausible Reasoning theory [Collins & Michalski 1989] that provides a formal model of the approximate reasoning that people use to reach some conclusions about questions for which they do not have an immediate answer. The Human Plausible Reasoning theory (from now on referred to as HPR) tries to model the reasoning that a person uses, to find an answer to a question asked, given the facts s/he knows and considers relevant, provided they do not give an immediate answer to the particular question. The reasoning that this theory has formalised concerns the inferences made, based on similarities, dissimilarities, generalisations and specialisations that people often use to make plausible guesses. These guesses may be correct as well as incorrect. The theory is not concerned directly about the correctness of the guesses as long as these are plausible.

Here we exploit the fact that plausible guesses can be incorrect and thus turned into plausible errors. In this sense the theory is used in the reverse order. Starting from a user's possibly incorrect action (rather than the question) an intelligent help system tries to find out what reasoning s/he used to reach that action. The more human-like interface takes the form of an active help system, called RESCUER, which stands for REasoning System about Commands of UNIX using Evidence Reasonably. The reasoning underlying RESCUER could be extended to be used in domains other than command languages as well.

The UNIX shell, with particular focus on the filestore commands, has been used as an example domain for the construction of RESCUER. The UNIX user interface has often been criticised for not being particularly user-friendly for reasons such as its terseness or the names of commands not conveying the meaning of these commands [Norman 1988]. Therefore there have been in the past quite a lot of research projects which aimed at constructing Intelligent Help Systems, such as UC [Wilensky et al. 1988]. There have been various approaches in the aims of these help systems and the kind of response they generate. One of them is the trouble-shooting approach [Jones & Virvou 1991] which aims at providing help on user's errors and misconceptions which have occurred in UNIX-user interactions. This is exactly the kind of response that RESCUER aims at providing.

Design of RESCUER

A help system has to solve three main problems in order to achieve the behaviour of a helpful advisor in a situation involving user's errors.

1. Recognition of a problematic situation.

   The main difficulty is to find out when a situation may be problematic especially when the user appears to be giving commands that UNIX does not complain about. It may be the case that a user has typed a perfectly acceptable UNIX command that s/he did not quite mean. For example, a user has been observed removing a directory which she probably thought she had already copied elsewhere although she had not.

2. Diagnosis of the cause of the problem, if there has been one.

   Even if a problem has been recognised by the help system with a high degree of certainty, this does not mean that the cause of the problem has also been known. As Hollnagel [Hollnagel 1991; 1993] points out, it may be wrong to mix the classification of observable phenotypes of errors with the interpretation of the underlying causes of these errors. What has been identified as a problem, or the UNIX error message may just be scratching the surface of a user's problem. There may exist deeper misconceptions which are to blame for what appears to be a peculiar behaviour of a user, in terms of the commands s/he issues.

3. Decision upon the kind of advice and generation of response.

   In view of the hypotheses the system entertains, it has to decide whether to intervene or not, and if so what to say to the user in order to help resolve a problematic situation. The answers that we have given to these problems are summarised in the remainder of this section which describes RESCUER's design.

   RESCUER's architecture follows the main line of Intelligent Tutoring Systems (ITS) architectures. Researchers in the area of ITSs [Hartley & Sleeman 1973; Burton & Brown 1976; Wenger 1987] largely agree on the major functional components constituting an ITS architecture, namely a Domain Representation, a User Modeler and an Advice Generator. The three components will be briefly discussed separately in later sections in this paper.

   The overall performance of RESCUER is outlined as follows:
Its input is the command typed by the user. Then RESCUER uses its *domain knowledge* to record what change has been made to the filestore by the command typed and thereby generate the UNIX's interpretation of the command typed. The UNIX shell is an interface between a user and the operating system. The actual compilation and execution of a user's command can be viewed as UNIX's "interpretation" of this command. This interpretation does not necessarily account for what the user believes about the command s/he typed and does not necessarily account for what RESCUER believes about the user's beliefs.

Control is then passed to the *Advice Generator* which evaluates this interpretation using several criteria of belief or disbelief. These criteria include the questions whether the command was acceptable to UNIX or not, whether it was expected by RESCUER, in terms of the hypothesised users' intentions, whether it was a command frequently used by most users, whether it was typical of its class and so on and are only used as unconfirmed symptoms of a possible problem.

According to these criteria, each command is assigned one of four different labels: *expected*, *neutral*, *suspect*, or *erroneous*. Each of these labels represents a degree of belief or disbelief as to whether the command typed was intended. The label *expected* means that RESCUER expected the command typed with respect to the hypothesised user's intentions, therefore it has a high degree of certainty that the command typed was well intended by the user. The label *neutral* means that RESCUER has not found any reason for believing or disbelieving the UNIX interpretation, therefore in this case it adopts the default hypothesis that the command typed was intended by the user. The labels *suspect* and *erroneous* mean that RESCUER's criteria for belief have not been satisfied, therefore the User Modeler is asked to generate a "better" interpretation of the user's beliefs. For example, if the command typed has failed to do anything except producing an error message (*erroneous* command) or if it has partly succeeded but has also produced an error message (*suspect* command), or if it contradicts the expectations of RESCUER in terms of the plan recognition scheme (*suspect* command), then the User Model Generator will generate hypotheses about possible interpretations of what may have happened. The hypotheses will be generated using HPR transforms.

First RESCUER tries to generate an alternative command which is similar to the one typed and which would fit better in the context. RESCUER starts generating hypotheses about possible user's misconceptions. The order in which hypotheses are generated is by the degree of depth of the misconception. The deeper the misconception, the later it is generated. The depth of the misconception is measured by the place where the HPR transform has occurred as will be explained in a later section.

Each hypothesis generated is evaluated by the User Model Evaluator which takes into account information about the filestore and the hypothesised user's intentions. If a hypothesis about an error is considered viable by the User Model Evaluator then the Advice Generator will respond with a suggestion of an alternative command that would have worked in accordance with what RESCUER believes the user wanted to do.

However, RESCUER's response to the user depends on the significance of the error. This is a similar approach to other systems offering explanations such as Trauma-TIQ [Abigail 1997] that classifies errors into 3 categories, namely tolerable, non-critical but potentially harmful and critical (potentially fatal).

The response of RESCUER consists of a suggestion of an alternative command which would fit better in the context and an explanation of what happened. The explanation consists of a description of the problem observed in terms of what alerted RESCUER in the first place (criteria of belief or disbelief) and the cause of the problem (which misconception at which conceptual level was to blame.)

The Human Plausible Reasoning Theory in RESCUER

The Human Plausible Reasoning Theory

HPR is a descriptive theory of human plausible inference which categorises plausible inferences in terms of a set of frequently recurring *inference patterns* and a set of transformations on those patterns which is mainly described in [Collins & Michalski 1989] and also in [Burstein & Collins 1988] and [Burstein et al. 1991]. The theory consists of a set of *primitives* and a set of *inference rules*. The primitives specify the way knowledge is represented so that the inference rules can be applied to this knowledge in order to draw plausible inferences. A collection of a person's beliefs are called *statements*. An example of a statement is:
precipitation(Egypt) = very-light, which means that the precipitation of Egypt is very light. Precipitation is
called a descriptor, Egypt is called an argument and very-light is called a referent. A descriptor is said to apply
to an argument and together they form a term. For example, precipitation applies to Egypt and they form the
term precipitation(Egypt). A term constitutes the left hand side of a statement and a referent the right hand
side of a statement. A term is related to a referent by an operator which is usually the equality sign although
this is not necessary.

The simplest class of inference are called statement transforms. If a person believes some statement such
as that the flowers growing in England include daffodils and roses which translates to flower-type(England)=
daffodils, roses,... there are eight statement transforms which allow plausible conclusions to be drawn. These
statement transforms consist of four argument transforms and four referent transforms. Argument transforms
move up, down, or sideways in an argument hierarchy using generalisation (GEN), specialisation (SPEC),
similarity (SIM) or dissimilarity (DIS) transforms respectively. Referent transforms do the same in a referent
hierarchy.

For example, the person knowing the above statement can draw conclusions such as that the flowers
growing in Surrey include daffodils and roses because Surrey is a part of England where these flowers are
known to grow.

**Argument transforms**
1. GEN flower-type(Europe)=daffodils, roses,...
2. SPEC flower-type(Surrey)=daffodils, roses,...
3. SIM flower-type(Holland)=daffodils, roses,...
4. DIS flower-type(Brazil) ≠ daffodils, roses,...

**Referent transforms**
1. GEN flower-type(England)=temperate flowers,...
2. SPEC flower-type(England)=yellow roses,...
3. SIM flower-type(England)=peonies,...
4. DIS flower-type(England) ≠ bougainvillea,...

There are certain assumptions about the knowledge representation underlying the theory. It is assumed
that all descriptors, arguments and referents belong to some kind of type (isa) or part hierarchy. It is also
assumed that the potential referent of a term consists of the descendants of the descriptor of the term in some
kind of hierarchy. There are four kinds of relations among objects in hierarchies. These relations are
generalisations, specialisations, similarities and dissimilarities. Generalisations (GEN) and specialisations
(SPEC) relate any two nodes belonging to two different levels of some hierarchy.

**HPR in Generating Hypotheses about Users' Misconceptions**

The problems of applying HPR to an active help system arise immediately from the fact that there is no
explicit question asked to the user about the UNIX domain. Therefore the application of the theory is made on
the assumption that users ask themselves certain questions about UNIX in their effort to form a command that
would be accepted by UNIX and meet their goals. The chain of such questions constitutes a path of reasoning
that is assumed to have led the user into concluding what command to type.

For example, the user is assumed to have assessed the command typed before typing it in terms of whether
UNIX would accept it and must have come to the conclusion that the command was acceptable. This
assessment is expressed in HPR statements and is called the basic principle. There are two HPR statements
taking part in the formation of the basic principle and each of them represents a question that the user is
assumed to have asked her/himself in her/his effort to check that the command s/he has selected to type, is
correct:
1. What is the semantic and syntactic structure of the command?
2. Is this semantic and syntactic structure acceptable to UNIX?
The user is assumed to have given the answer "yes" to the second question if s/he has typed the command. Using HPR’s representation language we have expressed the two statements as a multiple descriptor statement, as follows:

\[
\text{UNIX-acceptable (internal-pattern(action))}=\text{yes}
\]

In the above multiple descriptor statement, we have two descriptors, namely “UNIX-acceptable” and “internal-pattern”. Each descriptor has an argument. The argument of “UNIX-acceptable” is “internal-pattern (action)” and the argument of “internal-pattern” is “action”. The term “action” means the command line typed by the user. The term “internal-pattern” is used to mean a simplified form of the preconditions of a command. For example, if a user has issued the command: \text{rm fred} then “\text{rm fred}” is the action and the internal pattern of it is “\text{rm file}” which means that “\text{rm}” takes a file for an argument.

Hence, we should have:

\[
\text{internal-pattern(rm fred)=rm file}
\]

“\text{rm file}” in the above statement plays the role of a referent.

The second statement is formed by replacing the “internal-pattern (rm fred)” with the referent “\text{rm file}”.

\[
\text{UNIX-acceptable (internal-pattern(rm fred))=UNIX-acceptable (rm file)}
\]

The statement UNIX-acceptable(rm file) refers to the second question that the user is assumed to have asked himself or herself:

Is this semantic and syntactic structure acceptable to UNIX?

The answer that the user is assumed to have given to this question is “yes” unless s/he is not sure about the correctness of the command that s/he issues.

The set of HPR transformations are applied to statements constituting the basic principle and generate different possible interpretations of how a user may have come to the conclusion that the command s/he typed was acceptable to UNIX. These interpretations reveal the possible misconceptions involved. Depending on where the transformation takes place, we have the conceptual level of the error and depending on the kind of the transform we have the cause of the misconception.

For the purposes of the illustration of some examples of hypotheses generation we will assume that a user has typed the incorrect command: % \text{rm tf}, where \text{tf} is an empty directory. This means that the \text{typed internal pattern} is \text{rm empty-dir}. We will also assume that the user has a file called \text{tff} in her filestore.

Examples of interpretations of the user’s error are the following:

1. \text{Another action was intended.}
   
   This case is characterised by an argument transform in the first statement. For example, the user who typed \%
   \text{rm tf} may have meant to type \%
   \text{rm tff} which is a different action.

2. \text{A unix-acceptable internal pattern was intended.}
   
   This case is characterised by a referent transform in the first statement. It is assumed that the user intended a similar pattern to the one typed. In this case, the action intended was the action issued but the user thought that a different internal pattern corresponded to this action. However, the pattern that the user had in mind was unix-acceptable. The misconception involved here would have to do with the types of the arguments\(^1\) of the action typed. The user must have believed that the arguments had different types from what they actually had. For example, the user may have typed \%
   \text{rm tf} only because she thought \text{tf} was a file.

3. \text{The typed action and its internal pattern were intended.}
   
   This case is characterised by an argument transform in the second statement. This would mean that the action intended was the action issued and the internal pattern intended was the typed pattern which the user falsely concluded to have been unix-acceptable. In terms of the misconception involved, this case reveals a problem with the semantics of the command. The misconception is deeper in this case than in the previous ones.

\(^{1}\) “Arguments” here, mean the Unix arguments and not the “arguments” used in the HPR terminology.
For example, the user may have typed `%% rm tf` because she thought that `rm` could be used for removing directories as well as files.

From the above examples of the use of statement transforms in generating hypotheses about possible misconceptions, it is clear that transforms taking place in the second statement imply deeper misconceptions of the user than those generated through transforms in the first statement.

Abstract

Computer-mediated communication offers the opportunity to teach outside the conventional settings of the classroom, the tutorial or the faculty office. But we know little about the social, linguistic, educational or emotional forms of relationship that are a consequence of virtual teaching. In this paper I will look at the use of First Class conferencing used to create a virtual culture among research students and as a vehicle for supervision/advising.

CMC and research

When personal computers first became available most of us tended to use them as them as superior typewriters. The printer in the room across the corridor never stopped, but now it remains quiet for long periods while we conjure up all kinds of things on our screens; catalogue searches, the directories of distant universities, on-line journals, specialist discussion groups, conferences and discussions, databases, transcripts and multiple conversations.

Perhaps paradoxically, as the marketing arms of universities put their efforts into making each university appear distinctive, for most academic staff the invisible college is becoming increasingly the day-to-day working environment. Much funded research is now inter-institutional and many of us find that we spend more and more of our working lives talking with our research colleagues (wherever they happen to be), and less and less time talking with people down the corridor. The nature of research work, and of the research community, has changed.

As the locus of research and the nature of research work has changed, so too have our working relationships with others. The cell-like nature of research groups, with often intense inside-relationships but only loose connections to wider networks, which characterised the social organisation of research until ten years ago, is increasingly being replaced by virtual communities. The table tennis table, once the centrepiece of most working research units, has almost disappeared. One of our conference areas now has a folder called 'The Gym'.

Entry to cyberculture

It is generally assumed that the training of research students is not just a technical matter but a form of induction, even initiation, into research communities. As the nature of these communities changes, it is obvious that the nature of the training that we provide must change too. Of course these changes are not just driven by the technology but by the need to manage research degree programs in conditions of change. Everywhere numbers are up, students are older, increasingly part-time and are often working in areas with little in the way of an established higher degree tradition (nursing, education, law, studio art, dance, business), not least in the 'new' universities.

Elliott Eisner [Eisner 1979] has talked about a 'null curriculum' (as an addition to the more familiar notions of the 'explicit' and 'hidden' curriculum). He explains the null curriculum as that which is not taught, for in any curriculum selections must be made, and once made this leaves gaps and silences that are usually left invisible to the student. I always found this a difficult concept to grasp, but perhaps the conventional supervisory relationship is an example, for in supervision the curriculum is not obvious. The student is required to make
sense of the research field by paying attention to some of what is said formally and some of what is said informally, but not all of either. This can be very confusing but progress is only possible when the student is able to see the research field as a gestalt. In practical terms the project may be concerned with investigating a small fragment of the field, but the meaning of the project must be located in a wider understanding of the field as a whole. The significance of much of what is said lies between the lines.

Supervision and the internet

Despite the abstracted nature of research at the level of meaning, for many students and supervisors, supervisory practice is essentially defined by face-to-face contact. (I am using the terms 'supervisor' and 'supervision' as they are the terms most often used in Australia and in Europe, but they carry overtones of authority that are inappropriate. The American term 'adviser' is perhaps better, or the term 'consultant' used in some programs.) Whatever term we choose, 'supervision' is a conversational form, or at least a form of teaching, conceived as dialogue. Putting computers between people seems, at first sight to destroy the very thing that is valued in supervision, the direct contact between people who interact as whole individuals dealing in multiple levels of meaning.

Our experience has been that computer conferencing has some clear advantages:

- at least for the moment it requires us to shift from talk to writing as the main medium of communication. This means that, from the start, students are working in the medium in which they are ultimately tested.
- The written word slows down interaction. Writing is more time consuming than talk, but it can be studied more closely. There is a record of what is said that can be re-read, questioned, referenced, quoted and developed.
- Though time-consuming, the medium frees us from schedules. We do not need to arrange times and places for meeting, worry about being late, disrupt other activities, travel to other sites.
- It is easy to move in and out of conversation - to include references to sources, to point to web pages, to attach documents and tables, even to discuss experiments.
- There is both an intimacy and a distance inherent in the medium. Some of the ambiguities of face to face conversation are ruled out (what to wear, where to sit, when to smile, when to interrupt) and this frees us from those constraints (and opportunities) inherent in social proximity.
- At the same time we need to be aware that it removes some of the checks in conversation that protect areas of intimacy.

Currently we seem to be at an interesting point of conjunction, where the nature of research is changing and where we need to adapt supervision as universal mass education reaches undergraduate education and begins to touch postgraduate programs. The use of computer-based communications appears to offer a rational solution, for it makes expertise more widely available in a situation where the one-to-one, craft-based, apprenticeship notion of supervision has become difficult to sustain. But at the same time, the new communications media are still poorly understood and whether they can sustain the demands of the supervisory relationship is open to question. They may be less an answer to a problem and more in the nature of a new set of problems. My view is that we need to treat them, not as solutions to the problem of how to teach people how to become researchers, but see them as providing a new set of opportunities for research. Applied to supervision they have the effect of making supervision itself problematic, a suitable topic for research, rather than a merely instrumental means to other ends.

The emergence of professional doctorates

In the early nineties a number of Australian universities began professional doctoral programs in response to a view expressed by the Commonwealth government that the PhD was perhaps not the appropriate qualification for the growing numbers of people enrolling in it. For some universities and for some faculties, especially those lacking a strong research tradition but with strong links into the professions, this was seen as an opportunity to extend the coursework masters degrees that they had recently developed. For others it was a way of building up numbers in the higher degree area by offering extended opportunities for study for the growing numbers who had completed masters degrees but who either did not want to, or were deemed unlikely to succeed in the PhD. [Trigwell, Shannon & Maurizi 1997] For a minority of universities (in Education; Deakin, UTS and Central Queensland University; in Business, the Swinburne Organisational
In the past ten years the strains within the Education PhD have become increasingly acute for those working in areas like action research, evaluation and curriculum, to the point where many research projects have been distorted to fit the instrumental needs and requirements of the degree. While many people (students, supervisors and examiners) have becoming adept at threading their way through the complexities, the emergence of the professional doctorate provides a new starting point; a means of setting an agenda that puts the needs of new forms of research to the fore rather than finding loopholes through which it could be threaded.

In our creating our EdD program we saw an opportunity to establish the following priorities:

- research projects in and for education (rather than projects that are studies of or about education),
- opportunities for collaborative research work,
- recognition of writing as a central research process (not just the medium of reporting research),
- recognition of audiences for research beyond the academy (the professions, client groups, the press and other media),
- recognition of the problematic role of the researcher within the research project (the demise of conventional notions of objectivity),
- responding to the changing nature of communications and its impact on the nature and practice of research.

None of these shifts are novel and all to some degree touch the work of all research students and their supervisors, but it seemed to us that the cumulative effects of these different shifts was enough to precipitate a structural change. We have responded in a number of ways -- constantly re-writing our courses and revising our procedures and practices, experimenting with new forms of supervision, progress review and assessment and examination. Central to these changes, however, has been our attempts to seize the opportunity created by Deakin's establishment of computer-based communications as a key resource for distance students.

**Computer-based supervision**

Since 1995 we have been using First Class conferencing as the basis for establishing a 'virtual campus' within which students and advisers can interact. The First Class conference provides access to a series of discussion areas.
We have tried setting up these folders in different ways. Some contain the discussions for particular tasks and assignments within the EdD program (for instance the folders called, 'Research Practice 1 & 2' and 'Workplace Research'). Other folders allow for discussions around phases of the program (the folders called 'Pre- and Post Colloquium'). Some are topic based and follow topics and ideas that have arisen within other discussions ('Case Study' and 'Hathaway'). Some are intended to be informal ('The corridor') and others formal, ('Staff'). Some are interest based (the folder 'KCU' has been established by a group of EdD students who are based at Khon Khaen University in Thailand).

These conference areas are intended to be 'classroom spaces', at least while we orient ourselves to this space and begin to stretch its pedagogical characteristics, but being a research oriented programme we soon found it was important to have a 'corridor'. This was intended not so much as a social space - we wanted to use our entrance 'foyer' for this - but to provide a space where conversation could free-wheel around work topics. Most of what happens in the corridor is serious and productive!

Some might find this all too task focussed and leaving little room for more immediate and social conversation. Perhaps so, but there is an on-line chat function within First Class which some users find meets this need. Though it is sometimes said that e-communications are good for people who already know one another, they can also be a way of getting to know others, and for some are less intimidating than a research seminar or even the cafe.

**Conferencing as supervision**

My intention here is not to provide a comprehensive description of this software and its functions and capabilities but to indicate the kinds of shifts this implies for supervision. From the start we have tried to make this conference the centre of our program, not simply an adjunct to it. This is the marketplace, the common room, the seminar and the lab. We expect students and supervisors to use it on a regular basis and to treat it as equivalent to walking into the building, indeed we sometimes call the folders 'rooms' (it would be nice if we could do this graphically too instead of being trapped in the iconography of commerce and administration!). So to go into a discussion like the ones on Research Practice we think of as 'going to class'. Here one staff member and a group of students discuss research issues, share papers, submit work for assessment and relate their experiences in attempting to do research in the workplace. There are other
resources available, students are sent a collection of papers for each 'course', we make extensive use of audio
tape and each discussion also has a web page which defines the topic and sets expectations and deadlines.

The differences are that we rarely meet face to face, that discussion is asynchronous, that it is written and
semi-public. This may sound straightforward - but it isn't! Just as the word 'classroom' seems at first sight
simply to denote a space where teachers talk to students, but where we know that the practice that develops
has its own complex dynamic of text and sub-text, explicit curriculum and hidden curriculum, so too there is
more happening here than is immediately obvious. First, for all users, finding a voice is problematic. Making
an entry is daunting for some people (students and supervisors) since they feel exposed and under scrutiny.
Having found a voice, losing it can be difficult. At some time or other most of us have found ourselves
becoming 'typecast'; shut in a role that is limiting and finding it difficult to move out of it.

As with email, discussion here is written (and so has a degree of permanency) but is also responsive, so
having some of the character of oral interaction. We are all of us still finding our way with this. Some are
cautious and considered, others spontaneous and immediate. Every so often it 'works' and we get extended
discussions, directly to the point that move our ideas and our thinking along. At other times we circle around
one another, missing connections, talking over the ideas of others and missing opportunities. Just like any
other classroom.

But, unlike a conventional classroom, what is said here is open to scrutiny and to challenge. Anyone in the
program can 'walk-in' to a discussion at any time, they can monitor performance, even see who has been
working late at night or early in the morning! Those of us who like working in this space have learnt to be
thick skinned about some of these things, we have learnt too to be forgiving of others, especially those just
finding their way. 'Flaming', often identified as a feature of listservs, has not been a feature of our discussions
to date. Friendships have formed and we have felt our way to a new set of intimacies inherent in the medium
(just as we did earlier with the telephone, and before that with letters).

This is hard for those of us with a degree of fluency in writing in our first language. In a second language it is
harder, especially given the somewhat telegraphic tendencies inherent in these media, the temptation to in-
group joking and plain showing-off. Managing this demands a level of communicative and cultural
competence that causes even some native speakers/writers to struggle. For others it may be doubly confusing,
and having only the written text to read/write exacerbates the demands for there can be no sudden recourse to
laughter to resolve a communicative impasse or a smile to encourage, gender can be invisible or even
ambiguous, it may be hard to tell who is a supervisor and who is a student. As with all new media there are
potentials here for liberation and for tyranny, for isolation and despair, and particularly confusing is the
dissolving of the conventional distinctions between speech and writing.

But, we argue, research itself is primarily an oral culture and, despite many texts assuming that research exists
only in the literature, anyone who has participated in a research conference, worked in an active research
centre or simply sat around among researchers knows that the process and the products are different. In
relation to methods and process most of what the literature has to say is in the nature of fiction, intended to
position the researcher as hero, to reconstruct the irrational and implausible in terms of convention. In order to
learn to be a researcher one must become a competent member of this virtual village, yet in most research
training programs this is left to chance, mediated only through supervisors or a part of the hidden curriculum.
What e-conferencing of the kind we have described does is make some of this explicit. So while this may
seem daunting to the student (and supervisor), it is in fact making a significant aspect of research culture more
accessible than it would be otherwise.

The virtual research community

The problem remains of how to create bridges between the kind of local culture we are attempting to create
and the wider research community. One obvious way is through the other resources available to students; the
library and the internet, but we have also introduced guest seminars into the conference desktop. During last
year we had three outside visitors contribute to discussions on narrative inquiry, on technology issues and on
qualitative research. Out of the last of these has developed an experiment in conducting a collaborative
memory work project on-line, which we think has not been attempted before.
From the start we have made extensive use of audio taped conversations with researchers, and these have been very successful, being especially popular with students and supervisors who spend a large part of their working day in the car. These do, however, create some problems for those without fluent English for colloquial spoken English can be hard to follow on tape. The ideal solution is to transcribe the tapes and put them on CDROM, so that students can see what is said as well as hearing it and so we can build in links and additional material and provide word search capabilities that make the taped discussion much more useful as a resource. But transcripts are expensive to produce, the CD format a little less accessible and the time that would be needed to produce such resources difficult to justify for small numbers of students. 'Guest appearances' on the conference may be a possible solution.

These ideas for development also point to other possibilities for collaboration. Producing a set of CDROM based discussions would be expensive for us to do for no more than a hundred students. But if we shared the task around other institutions and we each produced a CD for perhaps 500 students, then the economics of development might begin to add up. The current climate of competition between universities (or at least between their vice-chancellors and presidents) puts some barriers in the way, but not ones that are impossible to squeeze past.

New headings

We are all well aware that universities are headed in new directions and that the nature of academic work is changing in ways over which we appear to have little control. For some time we have tried to manage increasing demands within conventional frames, but it is clear now that these frames can no longer contain the demands that we make on them. As academics we are daily forced to rethink the nature and purpose of the research that we do, the forms in which we publish and the ways in which we construct our careers in terms of the changing functions and purposes of the university.

The supervisory relationship is perhaps the last structure to break, for it has been hedged around with myth and privilege and kept largely hidden from the change process. We now see this changing as the pressures for change become too hard to resist and as the new communications opportunities appear to be offering alternatives to the one-to-one, face-to-face armchair/laboratory bench notion of supervision.

We have sketched out some of the ways we have been trying to make these changes in the context of a professional degree. We are still at the beginning in doing this, but we see potentials in it. Being involved in it gives us some grip on the process, rather than just responding to economic and other pressures we are able to see that some things work better than others and work to steer the process in those directions.

Students who are not native speakers of English may encounter special problems, problems we have scarcely addressed because at the moment everything is new to us, but centrally these are problems of language, culture and communication. We have argued that the world of research is changing, and changing not just in what it does, but how. Computer mediated communication, not long ago an obscure enthusiasm among a group of nuclear physicists, is transforming research in the humanities, social sciences and professions. In supervising research students we have to take them into this world because this is where the action will be in the future. This shift is not just a technical shift but requires people to relate and communicate in new ways. Language issues lie at the centre of this change.

Abstract: We report about technical and didactical experiences obtained in the teleteaching experiment Telepoly, which has been set up between the two Swiss Federal Institutes of Technology in Zürich and Lausanne, and the Swiss Centre for Scientific Computation near Lugano. Using a high-speed network with Asynchronous Transfer Mode (ATM), Telepoly offers high quality audio and video transmission with full interaction possibilities to all participants at all sites, which is very similar to a real presence teaching situation. The Telepoly scenario is being extended beyond the classroom to any desktop computer connected to a high-speed network which can provide a guaranteed quality-of-service. This scenario, if successful, will offer a new perspective to distance education, bringing fully interactive synchronous teleteaching right to the place where people use to work and live.

1 Introduction

The advanced developments in digital and multimedia-oriented information and communication systems are increasingly influencing the education sector. They enable not only a multimedia support and extension of the traditional teaching and learning, but offer new and attractive methods especially for Distance Education (DE), which may be defined as a teaching and learning environment where lecturers and students are separated in space or in time. Space and/or time independent teaching and learning becomes increasingly important due to the fact, that the lifetime of specific knowledge in many fields becomes shorter and shorter. Thus, the need for Life-long Learning, Just-in-time learning and learning "any time, anywhere and any subject" is rapidly growing.

With respect to the time dimension, DE methods can be categorised as asynchronous and synchronous; see [Günter 96] for a general overview of projects and systems. In the first category, lecturer and students are separated in space and time, whereas in the second a separation exists only in space. A number of projects have been launched which support either of these two DE environments or a mixture of it. To mention only a few, [Schneider & Block 95, Apostolopoulos et al. 96, McLoughlin 96, Barnett & Burton 96] describe approaches in asynchronous distance education which use networked workstations with tutorial programs where students access lecture material over a network, e.g. through the world-wide web. Interactions with the lecturers occur only indirectly by e-mail or bulletin boards. Some of these systems support a direct interaction e.g. via telephone or ISDN-based videoconferencing, and thus get a synchronous component.

Since the potential of human communication with all its features is unreached by purely computerised learning environments, face-to-face teaching will always remain an essential component of the teaching and learning process, in particular in the sector of advanced, non-standard knowledge. To enable a more adequate synchronous teaching and learning environment, the networked systems mentioned above have been refined to solutions where lecturers and students can communicate and fully interact via real-time audio and video [Effelsberg 95, Hogrefe 95, Bodendorf et al. 96, Zny 96, Peder 96, Neuman 97]. We call such an environment teleteaching.

We present a solution for synchronous, fully interactive face-to-face teleteaching using high quality audio and video transmission based on Asynchronous Transfer Mode (ATM) networks, and supported by networked desktop computers with application sharing capabilities. Telepoly is a teleteaching project between the Swiss Federal Institutes of Technology in Zürich (ETHZ) and Lausanne (EPFL), and the Swiss Centre for Scientific Computing (CSCS), in order to obtain experiences in application-oriented multimedia communication as well as in didactic research [Stiller et al. 96].
2 Telepoly Scenario

At all sites involved in a Telepoly session, a classroom is equipped with audio and video recording and display devices [cf. Fig. 1]. For digitising analog audio and video streams, coder/decoder devices (CODECs) are used which are connected to a high-speed network and which prepare the digital data for transmission using the ATM protocol [cf. Technical Approach]. In addition, networked workstations are employed for the exchange of electronic teaching aids, such as slides, graphics, or tables which are locally and remotely displayed by a beamer.

Let us assume that only two sites, ETH Zürich and EPF Lausanne are involved, and that the lecturer is located at ETHZ (local site). Then the following audio and video streams of the classroom at Zürich are transmitted to the remote site at Lausanne: Firstly, a mixed audio of the lecturer's voice and the sound from the local audience; secondly, separate videos of the lecturer, the local classroom, and occasionally also of a visualizer used by the lecturer. From the remote classroom at EPFL, an audio and a video stream are received at Zürich, where the remote audio is directed to loudspeakers and the remote classroom view is displayed on two different TV screens: One TV screen is turned towards the lecturer to allow her or him to always be aware of the situation at the remote site (in particular, if a remote student wants to ask a question or make a comment), and the second monitor is directed towards the local audience to create the feeling of one single learning community.

The one-to-one teleteaching scenario described above can be extended in principle to a many-to-many scenario. As in the one-to-one case, from the local site a mixed audio and two separate videos (lecturer and local classroom) are sent to all connected sites, using the multicast features of the ATM. In order to present the audio and video streams from all remote sites involved, the local classroom is equipped with as many sets of loudspeakers and TV screens as correspond to the number of remote sites. Each remote site in turn receives a mixed audio of the lecturer and the local classroom's audience as well as an audio from each of the remaining remote sites. Furthermore it gets two separate videos from the local site (lecturer and local audience), and a video from each of the other remote classrooms.

3 Technical approach

Apart from the didactical and pedagogical requirements, various technical criteria need to be fulfilled for a successful teleteaching. Among these are the following: video of sufficient quality; very good audio quality (close to CD quality); perfect synchronisation of audio and video; well integrated facilities for electronic presentation of teaching aids; support for ad-hoc annotations; interactivity for audio, video and annotations; and last but not least sufficient reliability and stability throughout a session which may last up to several hours.

In order to fulfil these criteria, ATM [de Pryker 95] is chosen as network infrastructure for Telepoly, together with advanced video and audio coder-decoder devices (CODECs). The ATM network provides Telepoly with the required data rates at high bandwidth and low delays with guaranteed quality-of-service, in order to carry the video and audio streams and perform a perfect synchronisation between audio and video at each remote site.
Electronic teaching aids are distributed between sites using an application sharing tool which runs on workstations on top of a TCP/IP protocol.

3.1 ATM Network

Considering the ATM network configuration in use [cf. Fig. 2], the ATM switch at Zürich receives cells from the local end-system, which in the Telepoly setting comprises the CODEC. The switch is connected by a bi-directional 155 MBit/s STM-1 link (Synchronous Transfer Module Level 1) to the ATM network KOMBV 3 of the Swiss Federal Administration. At any participating remote site an ATM switch is connected by a 155 MBit/s STM-1 link to the ATM network as well. It receives the transmitted ATM cells and forwards them to the remote end-system which is again a CODEC.

As ATM inherently supports the multicast functionality during the connection set-up time, a many-to-many communication between \( n \) different sites is available. And this without any major adaptations of the one-to-one Telepoly scenario and the cabling of the utilised devices, except for adding a supplementary set of loudspeakers and TV screens per additional remote site. In this case, the generated audio and video streams respectively are multiplied \( n \) times transparently for the sender and all receivers inside the ATM switch or the ATM network. Every participating site receives multicast data streams likewise as unicast data streams.

3.2 Technical Set-up

For simplicity reasons we only consider the one-to-one scenario [cf. Fig. 1]. Analog audio and video signals are fed into the CODEC [cf. Fig. 2], transforming analog signals to digital ones and vice versa. The CODEC consists of three units, called CellStacks\(^{TM}\): one master and two slave units. A single CellStack hosts an analog to digital converter and is capable of processing incoming and outgoing streams, one audio and one video stream each. It performs full Motion JPEG (Joint Pictures Expert Group) [ISO 92a] compression on video. Each CellStack assembles this compressed video into ATM Adaptation Layer (AAL) 5 frames and segments them into ATM cells. Since only the master unit is connected to the ATM switch, all ATM cells from slave and the master units are transferred via the interconnected STM-1 link to the ATM switch. Simultaneously to sending the MJPEG compressed video, audio is transmitted in CD-quality: The remote CellStacks do the reverse transformation from ATM cells into AAL 5 frames, from compressed data into the uncompressed form, and from digital to analog audio and video.

3.3 Experiences with Telepoly

Telepoly has become operational in January 1996. For almost two years it has been used on a regular basis for transmissions of courses, conferences, seminars, and for examinations. The experiences are promising, although some improvements have been already identified.

Concerning the data rates required for the transmitted audio and video streams, the measured audio data transmission rates have reached an average value of 1.75 MBit/s (about 5% variance) due to packing audio samples into AAL 5 frames and ATM cells in turn. For MJPEG compressed video transmission an average rate of 8.5 MBit/s per video stream was measured, while variances (in average about 10%) are dependent on the transmitted video.

Within Telepoly the didactic quality of teleteaching and the quality of the technology used have been evaluated together by means of several questionnaires distributed to participants. The results obtained showed...
that in general the quality of the audio and video transmission has been judged positively as well as the main quality of the computerised teaching aids. Apart from the telecommunication aspects, important experiences have also been collected concerning ergonomic, didactic and pedagogical aspects of teleteaching:

1. Concerning the manner of preparing and organising teaching aids, the use of a professional presentation package has been beneficial, since it supports a clear structuring of teaching aids and provides a basic standardisation of the layout. On the other, it introduces the risk of choosing inappropriately small fonts, thin lines, and tiny graphic elements in order to concentrate as much information as possible onto one slide.

2. Most of the projection devices, such as beamers and TV monitors, are still immature in resolution to display small text and picture elements in a clearly recognisable manner. This problem can be reduced slightly by distributing paper copies of teaching aids to all students prior to every lecture.

3. The style of presenting teaching documents to students, given the restriction that, in order to enable electronic transmission, the used material either had to be stored electronically or to be presented appropriately (on a visualizer) in order to be visible and audible on the remote site.

4. The frequently observed weaknesses of conventional teaching became even more severe in the case of teleteaching: too little interaction, too brief animation, and inappropriate time management. Certain investigations revealed that during teleteaching sessions, students in general have to concentrate extensively compared to traditional teachings to follow the lecturer and her or his explanations. Therefore, frequent interactions are a necessity and a sufficient number of breaks has to be incorporated.

Referring to the requirements stated at the beginning of this section, Telepoly provides high quality audio and video transmission which is possible due to the guaranteed quality-of-service of the ATM connections. Drawbacks of Telepoly are the rather high investment costs due to the need of specialised equipment, and limited support for multi-point scenarios. Therefore, we are presently looking into an alternative to the current Telepoly scenario which combines the advantages of the Telepoly setting and resolves some of the drawbacks. In particular, our emphasis is on a better integration of components for audio, video and data communication and on extending the scope of possible participants in a Telepoly session.

4 Telepoly++ - Fully Distributed Teleteaching Scenario

Telepoly++ is aiming at providing teleteaching capabilities right to the desktop. As shown in [Fig. 3], the anticipated teleteaching scenario is similar to the Telepoly scenario except that remote sites are not necessarily classrooms but can be multimedia PCs or workstations on the desk even at home.

Following the approach taken in Telepoly, a mixed audio and two separate videos (lecturer and local audience) are sent from the local classroom to the remote sites. For pragmatic reasons only audio and video of a single remote site, i.e., the active site asking a question, is transmitted and received at the local site and all other remote sites. The local site sees the active remote site only, so that even in this restricted scenario, direct interaction between lecturer and student is possible.

4.1 Telepoly++ Research Issues

The challenges with the proposed teleteaching scenario are the following: Firstly, local and remote sites have to be connected by a network that provides the required quality-of-service guarantees and high data rates and which, at the same time, is cost effective and widely accessible. Secondly, transmission of audio and video has to follow agreed standards so that cost-saving off-the-shelf CODECs can be used. A solution to the latter problem is using MPEG 1 (Moving Picture Expert Group) [ISO 92b] and MPEG 2 [ISO 94] CODECs (hardware or software). In general, these CODECs support user-selectable bandwidth utilisation from some KBit/s up to several MBit/s. Since MPEG compression performs better than MJPEG, we get an audio and video quality similar to the one observed in Telepoly already at data rates of 2 MBit/s.

Our experiences up to now have shown that ATM is the technology that provides all the necessary features for supporting teleteaching sessions even if a large number of remote sites is involved (due to its quality-of-service guarantees and its multicast capabilities). However, providing ATM services - or broadband services in general - to those users we are aiming for requires either considerable investments into the communication infrastructure too expensive to be affordable by a non-commercial user, or a re-engineering of the existing infrastructure, so that existing cabling can be used to carry ATM traffic. During the past years such alternatives have been explored. One such an alternative is the ATHOC (ATM Applications over Hybrid Optical Fibre Coax) [Krijntjes et al. 96] project.

Its objective is the provision of broadband communication services with flexible bandwidth over existing cable infrastructure. PCs and workstations are connected to already existing coaxial cable TV networks (CATV...
network) which, in turn, are connected to the public ATM network. For the downstream direction, i.e., from the network to PCs or workstations, the provided bandwidth is about 34 MBit/s, while for the upstream direction, i.e., PCs or workstations to the network, a bandwidth in the range of 10 to 34 MBit/s is provided, starting initially with 2 MBit/s. In the overall network, ATM is applied as transfer mode and, thus, end-to-end ATM connectivity is provided with all the characteristics of ATM, such as multicast and guaranteed end-to-end delay.

4.2 Telepoly++ Prototype Implementation

For the prototype implementation of Telepoly++ three phases are planned. In phase 1, we install the infrastructure in the local classroom and at remote sites and set up the communication network. We use MPEG 1 CODECs for PCs and workstations in this phase. Because MPEG 1 can handle one audio and video stream only, this implies that we have to look for alternatives to transmit two videos from the local site, e.g., mixing two videos picture-in-picture. An audio and a video as well as computerised teaching aids are transmitted to all remote sites using the multicast features of ATM (over the ATHOC network). Video and audio of a single remote site is received at the local site only. To this end a connection from the remote site to the local site is established on demand. The local site relays all questions to all other remote sites. In phase 1 we start looking into the organisational and didactical details of having a large number of sites. On the technical side we have to deal with details of the ATHOC network, particularly a resource reservation protocol for bandwidth reservation in down- and upstream directions which are shared among all users.

For phase 2 a transition is planned using MPEG 2 instead of MPEG 1 CODECs. The advantage of MPEG 2 over MPEG 1 is that several multiplexed audio and video streams can be simultaneously transmitted. The receiving site can select which audio and video is being displayed. In this scenario, an audio and two or more videos are sent from the local site to all remote sites (the same mixed audio is sent with all videos). From a remote site to the local site an audio and a video are transmitted. As in phase 1, the local site relays audio and video to all other remote sites. In phase 2 we investigate how well the communication network scales with the additional bandwidth required by the transmission of several videos from the local site to all remote sites.

Finally, phase 3 transforms the scenario into a fully distributed teleteaching environment. The relaying of remote audio and video at the local is done by the network itself. This requires additional functions to be implemented in the CATV network due to its tree structure which is from the CATV provider towards the subscribers. Relaying audio and video of remote sites can only be done in the head-ends of the CATV network which requires additional investments into the CATV network. Additionally, signalling has to be implemented so that all remote sites are informed which audio and video to be received.
At ETH Zürich, the Computer Engineering and Networks Laboratory (TIK) and the Communication Technology Laboratory (NARI) have started the implementation of phase 1. A number of PCs have been equipped with MPEG 1 CODECs which are used in the local classroom and at remote sites. For the transmission of lecturers we initially use the in-house ATM and CATV networks.

5 Conclusions

Telepoly has been established as an experimental platform for synchronous, fully interactive exchange of courses between remote sites, as well as for application-oriented networking and didactic research. Although initially considered as a one-to-one vehicle for the transmission of courses between ETHZ and EPFL, Telepoly is used successfully for the transmission of workshops, presentations, and conferences even in a many-to-many scenario. In particular, the Telepoly set-up allows lecturing on every kind of topics.

Three of the main technologic prerequisites for Telepoly have to be considered explicitly. This includes the availability of electronic teaching aids paired with an application sharing tool, then a public ATM network, and finally CODEC devices for handling audio and video.

Since Telepoly only is a first step into a fully distributed teleteaching environment, we have started to explore alternatives to increase the number of participating remote sites and to reduce the initial costs of the equipment. With Telepoly++ we will provide a teleteaching infrastructure which will cover a large number of possible participants from academia (particularly students) and industry. Apart from the work done in networking, multicast, and audio and video communication, we have to further elaborate on a sophisticated integration of all components, CODECs and PC with application sharing software, in a single teleteaching platform.

Abstract: This paper considers the use of narrative within intelligent tutoring systems (ITS) and in particular the need for a narrative structure and the effects it can have on the learner. The use of narrative in ITS is reviewed and the application of narrative to a computer-based adventure game to teach computer architecture is considered.

1 Introduction

The design of hypermedia based tutoring systems often assume that the mere use of such systems by themselves will increase students motivation and desire to learn. This may be so for those learners who have not been exposed to such systems before but with increasing exposure, (and use of such systems), it is highly unlikely that the elements themselves (sound, graphics, video etc.) will be the prime motivators. The components of hypermedia systems themselves are not intrinsically motivating.

It is suggested that good teachers are able to adopt appropriate teaching strategies based on an assessment of the motivational state of learners and their understanding of the students' misconceptions or lack of understanding. Additionally the use of an appropriate narrative is both a useful method of communication as well as a way of connecting the complex social and cultural constructs that are part of any learning situation.

The use of a distinct narrative in educational hypermedia systems is useful for a number of reasons:

- narrative structure can affect a learners comprehension
- the use of narrative is a familiar and established method of structuring texts
- the structure of a narrative can be used by learners to assist in navigating a hypermedia environment
- the narrative itself can act as a motivating factor

(Plowman, 1996)

This paper reviews the use of narrative and other motivational strategies in intelligent tutoring systems and then describes the architecture of a game based simulation to teach tertiary level students about the domain of computer architecture.

Characteristics of good teachers often include the ability to tell good stories and to increase their students' desire to learn along with the domain knowledge they are trying to impart (Edelson 1993 and del Soldato 1992).

2 The use of narrative in Intelligent Tutoring Systems

Edelson (1993) has suggested that good teachers possess two qualities that make them "exceptional". They are the ability to "ask good questions" and "tell good stories". The development of the YELLO (Burke, 1993) and the CreANIMate (Edelson, 1993) systems are both based on a case-based teaching architecture. This technique uses storytelling and the context of a task as the basis of the teaching
strategy. Both systems also make use of video as the major method of conveying information to the learner, simple indexing schemes have been developed for the retrieval of the appropriate video.

YELLO is a system designed to teach the selling of Yellow Pages advertising. The underlying theme of the system is that the stories of experts capture the realities of a realm of knowledge from an experienced perspective, this type of knowledge can be very important to novices' learning. YELLO uses video based stories and indexed interpretations of them, to present situations to the student and provide instruction.

Traditionally Intelligent Tutoring Systems (ITSs) use modelling techniques to determine when to intervene in the learning process and what to say. The practical implication of this is that this type of system must deal with narrow domains where the knowledge is well-defined. One of the advantages of the YELLO system is that students can access a large body of expert knowledge that has been preserved as the stories of experienced practitioners. The system observes the students' responses and recalls those stories that are of interest using a failure based learning model (Burke, 1993).

CreANIMate is another case-based learning environment that teaches animal adaptation to (American) 4th-7th graders. The system is designed to teach the relationships among physical features of animals, the actions they can perform and their high-level survival strategies, by allowing students to design new animals. The system combines storytelling and the asking of relevant questions to teach students.

In common with YELLO this system uses experiences within a task environment and responses from stories in particular situations to teach the relevant concepts. The system uses a Socratic style of questioning as the main method of interaction in a free text environment. The architecture of this system has been developed to take advantage of the high information content of video based stories. Edelson (1993) identifies the key problem here as being knowledge representation as it is this that "enables a teaching system to identify appropriate questions to ask and present stories that follow through on the learning context established by the questions".

The CreANIMate system presents information in video form related to the context of the learning experience as opposed to the linear predetermined structure often seen in many systems. Edelson points out that students' motivation for learning appears to be enhanced with a wide range of emotions recorded.

3 Motivation and Learning

The relationship between the motivational state of students and their ability to learn has been investigated by a number of workers.

Lepper et al (1992) report the results of studies on educational activities with identical instructional content but differing motivational appeal. Computer-based learning activities with third to fifth grade school children where used as the basis of the investigation. These studies have shown that gains in learning occur when the learning activities occur in a motivationally embellished setting. The embellishments used were the provision of a number of fantasy contexts for the games - providing a simple narrative.

It is reported that students exposed to the motivationally enhanced programs showed significantly increased motivation for learning the domain knowledge, even when the motivational factors where removed. Lepper et al also distinguish between intrinsic and extrinsic rewards for learning. Intrinsic rewards are based on a high congruence between the material being taught and the motivational techniques used. Lepper notes that extrinsic rewards can have a detrimental effect on learning (Lepper et al 1992 and Lepper 1985).

Lepper and Malone (1987) have suggested that increasing the learners' sense of cognitive surprise and curiosity is important in motivation. They make a distinction here between perceptual surprise
(that which relates to changes in colour or sound for example) from the sense of puzzlement that could arise from an ambiguous statement or a result that is unexpected (cognitive surprise).

They suggest a number of tactics that could be used in a tutoring system to ensure that a learners cognitive curiosity is stimulated. These are summarised below:

- Cognitive curiosity is stimulated when unexpected facts arise from the subject domain. This encourages the student to explore the domain and determine an appropriate explanation of the facts.
- A similar effect is caused if the tutor asks questions of the student which are in related but "unknown" domains, or if incomplete information is presented. These tactics are designed to encourage exploration, generalisation and simplification.

Lepper and Malone (1987) point out that challenging situations can provide a high degree of motivation. They identify three factors that cause this:

1. A task that is too easy or too hard is not as attractive as a task that is of "moderate" difficulty whose successful completion is not easily predicted. Creating a sense of suspense regarding the outcome of any particular task is a useful motivational tactic.
2. The user must know what they have to achieve to complete the task. A clear goal for success of the task should be defined.
3. Informative feedback on the progress of the task is required to allow the student to assess and refine or restructure their approach to the task. When a task has been successfully completed some form of feedback should provide suitable acknowledgement and reward.

Lepper and Malone suggest that learners feelings' of control and competence are directly related to the level of control they have. Although acknowledging the need for feelings of control in the learner they consider that this control need only apply to those features which are not directly relevant to the teaching process (such as the colours of the interface).

Elsom-Cook (1990) considers the problems of providing the learner with hints and suggestions when they are required and trying to maintain the learners sense of control.

Feelings of control are obviously also related to the learners feelings of confidence. Those learners who do not feel confident require a more closely controlled teaching experience. Keller (1983) suggests that such students should be given some experience of success to build their confidence. For instance they could be presented with a series of similar problems which they are able to solve - these problems may or may not enhance their domain knowledge.

4 Making Learning Fun

It is well known that computer based games are able to hold the attention of the player - that is motivate them to continue to play. Malone (1981) has identified several reasons why this is so.

These are discussed as four factors which should be incorporated into a successful game:

- Goal. The activity should have a clearly articulated goal.
- Uncertain outcome. The system should have a variable difficulty level. Multiple goal levels and incorporate some randomness. Some information should be hidden and selectively revealed.
- Fantasy. The program should contain an emotionally appealing fantasy, and skills learned within the environment should be related to the program.
- Curiosity. Audio and visual effects should be used to decorate the system, enhance the fantasy and as a reward.

Malone also describes "cognitive curiosity", the system should provide some surprises and constructive feedback.
Provenzo (1991) points out the “universe” of commercial video games is strictly limited - often there are only a handful of possibilities available to the player but these are enough to allow them to immerse themselves completely in the illusion of an artificial world. The important point here is that the illusion does not have to be sophisticated to be entertaining as long as the user has rules to grasp about the environment and these rules are applied consistently. The opportunities available to act at any single point in a game is often very limited but the fact that users feel they have some control over the environment is enough to hold their attention.

The principles applied to the commercial games analysed by Provenzo also apply to educational computer-based games.

The adventure game genre is one that has been used in an educational context for some time (Sherwood, 1991).

Quinn (1996) has described the development of an educational adventure game designed to teach low-literacy youth about independent living skills. The system Quest for Independence, has been designed to run on low specification computers and to use a game format to motivate the intended user group to use the software. The game itself consists of a simulation of the tasks the learners would have to complete in the real world if they were to survive by themselves on a day to day basis. Such as getting a job and opening a bank account. The game does not attempt to simulate all the possibilities - just those that are considered most important by the games developers.

As the target audience have low literacy levels the use of a mainly graphical environment was considered an important design parameter. The entertainment value of the system was also emphasised as the users had “little tolerance for any material of a low entertainment value”. The game provides guidance for learning within the simplified environment, not all the actions available in the real world are available to users of the system - those discarded were the ones that either did not contribute to relevant knowledge acquisition or to game play.

The Quest for Independence does not however provide intelligent adjustment of the scenario based on the users interactions, this decision was made for because limited funds, time and hardware were available for such a system.

Quinn reports that pragmatic evaluation of the game by centres that are using it indicates that it has been favourably received.

5 The CAT System

Computer architecture courses involve a domain which contains abstract concepts and procedural knowledge. The problem faced by the tutor is devising suitable practical activities (Lees, 1987).

The author is involved in the teaching of such a course to students who may have little previous experience of the architecture of a personal computer or the components that comprise one. It is noted that such students often have a great deal of difficulty in visualising the inter-relationship between components and their inter-connections and functions. The use of real machines to allow the students to change, upgrade or repair components has been used but has two disadvantages. With repeated use machines used for this purpose frequently malfunction, also maintaining suitable machines and related equipment has a significant cost.

A simulation of a personal computer clearly has numerous advantages. The procedural skills the students must acquire as well as the conceptual ones can be taught at much reduced expense.

A game based simulation designed to teach the domain of computer architecture is currently under development as the Computer Architecture Tutor (CAT). The design incorporates a strong sense of narrative using a fantasy environment that allows direct manipulation of animated graphical objects.
6 Narrative Structure and Motivation

The narrative structure used has been based on the work of the Russian Structuralists, particularly the work of Propp (1968).

Narratives and the use of language are shared by all societies and the use of storytelling by effective teachers has already been discussed. A narrative allows us to make sense of the world by using common social and cultural experiences. The interaction between a teacher and her student occurs in this wider social context and therefore some analysis of the structure of narrative is important if it is to be usefully incorporated into a tutoring system.

The work of the Russian Structuralists on the structure of narrative has been particularly influential and is briefly considered here. The Structuralists argue that language and narrative share many properties and that, “they are structured along the twin axes of the paradigmatic and syntagmatic, that there may be a universal narrative structure” (Fiske, 1987).

The work of Vladimir Propp (1968) on one hundred Russian folk tales has been widely applied to film and television. Propp found a common narrative structure through all the folk tales he analysed. This structure was described through a series of thirty-two narrative functions which were subdivided into six sections.

The use of a strong narrative structure within an ITS is an area that has not been closely investigated. Several workers have commented on the relationship between good storytelling and good teaching. The aim of this project is to investigate the role of narrative in a game based ITS.

The advantage of the use of Propp’s “universal narrative structure” in an ITS is that is can be related to the motivational tactics described by Lepper and Malone (1987). For example a clear goal (or set of goals) can be created by a narrative. Achieving the goal provides satisfaction to the user and instant feedback. Tasks can include interaction with characters – the ease of the task can be varied easily in a narrative. Thus the use of a Proppian narrative structures provides a useful tool for implementation of the tactics.

The use of an adventure game based environment allows a number of interesting possibilities. The learner can be placed inside a personal computer as the microworld, where they must carry out a series of tasks and solve puzzles to build a working machine.

Firstly, the goals of the learner can be clearly articulated as a series of tasks, adventure games frequently incorporate puzzles, problems or tasks. In a fantasy environment these tasks must be related to the domain knowledge, however this can be further related to interactions with a series of characters that inhabit the fantasy world. A narrative can be used to help navigate the learner through the system and to motivate them to explore.

For example within the computer “world” the learner will encounter various tools, pieces of hardware and characters that may or may not assist them with the overall goal of building a working computer. The characters must have their own motivations and actions if the narrative is to work. If the learner is aimlessly wandering around exploring the environment, the system should present them with tasks to complete to increase their confidence level - this could involve an interaction with a character or the “discovery” of useful equipment or direct help.

Conversely, if they are presented with a task where they must carefully inspect and choose an object and they randomly pick one, the system should “ensure” the object chosen is not the correct one. The learner must then repeat the task using the correct procedure - after receiving appropriate feedback. The feedback itself can be provided by other characters rather than through direct instruction. Aimeur et al (1997) have described an analogous strategy of “learning by disturbing”.

1499
From these simple examples it is clear that the use of a strong narrative has many potential advantages for an intelligent tutoring system and that this area has received limited attention as yet.

7 Conclusion

This paper considers the role of narrative in ITS related research and relates this to the issue of motivating students to learn. The importance of narrative structure is considered and work on a computer-based adventure game in the domain of computer architecture is considered. The use of a strong narrative structure is important because all human interactions take place within a wider social context and this applies to learning as much as any other field. The use of narrative and an analysis of its importance within ITSs is an area that needs greater investigation.

ARMVLS - Atomic Reaction Model Visual Language System

Kai Warendorf, Wen-Jing Hsu and Poh Yeen Seah
School of Applied Science, Nanyang Technological University, Singapore 639798
wdorf@acm.org

Abstract: Visual language (VL) is a programming language without textual codes and algorithm animation (AA) is about visualizing a computer algorithm. Visual programming (VP) and AA are traditionally separate factions in software visualization (SV). With the Atomic Reaction Model (ARM), we have bridged these two major branches in SV. ARM Visual Language System (ARMVLS) is a visual language algorithm animator, modeling the fundamental cause-and-effect of a simple atomic reaction. ARMVLS is a system that allows the end-user to animate algorithms - to visually demonstrate or to assist in the description of how a computer algorithm works by means of drawing and moving images on screen.

1 Introduction

Since the early 1980's when researchers began building systems to visualize computer programs and algorithms, there have been many terms defined and used in the literature, such as VP and AA that we used in the previous section, and other phrases like program visualization. Yet after more than a decade of advances in interface technology, researchers have not fully agreed on these definitions.

The Oxford English Dictionary suggests visualization as "the power or process of forming a mental picture or vision of something not actually present to the sight", so a visualization can result from input of any combination of the human senses. The general consensus of program visualization is the use of various techniques to enhance the human understanding of computer programs, while visual programming is the use of visual techniques to specify a program in the first place. Algorithm visualization or animation is understood to be the visualization of a high-level description of a piece of software which is in contrast to code or data visualization (which are collectively a kind of program visualization) where actual implemented code is visualized. Price et al [1993] used the term software visualization (SV) to include all these definitions.

Although there were various attempts to bridge these two visualization branches from 1994 to 1996, we consider only Opsis [Michail 1996] to have achieved this task to a certain degree, based on our definition of a VL. Since there are no other currently existing systems that can integrate AA and VP, we put ARMVLS among the ranks of pioneer VL algorithm animators.

The objective of ARMVLS is the following:

a. Portability and extensibility. Portability concerns the amount of effort needed to deliver the new system across platforms; extensibility determines the extent of restructuring required when building new features on old ones.

b. Object orientation deals with assigning properties to graphical objects created using the graphical editor. Graphical objects are the basis for Object-Oriented Visual Programming (OOVP) [Kimura 1995].

c. Resource sharing, group-working and networking. Resource sharing pools graphical objects to share among users of the new system; group-working and networking distributes the responsibility of system development and maintenance between all participating members or users.

d. Incorporation of multimedia. This addresses the issue of integrating multimedia into animation. We defined visualization to be the result of combined input from all the human senses. Incorporation of multimedia pertains to the ease of specifying images, as well as sound for visualization.

e. Code-free programming. This is visual programming.

[1] We based our claims from the papers submitted to the annual International Symposium on VLs organized by the Computer Society of the Institute of Electrical and Electronics Engineers (IEEE), up to the year 1996.
2 The Traditional BALSA Approach

BALSA stands for Brown University Algorithm Simulator and Animator [Brown 1991]. It is one of the earliest AA systems to make use of the graphics and windowing capabilities of personal workstations in the 1980's. It was designed for two purposes: as a teaching tool for undergraduates and as an aid to algorithm design and analysis. As a teaching tool, it allows the teacher to give a running commentary on the prepared graphical animation running on each student's machine. This is the automated process of the traditional classroom teaching example that we gave in the previous chapter. Figure 1 shows BALSA with several view windows. A view is an animated picture portraying the events generated by an algorithm. Each view can exist as a separate window to show the various aspects of the algorithm being animated.

![Figure 1: BALSA showing the code view, input, status message, current view of the tree data structure, and a view of the tree history.](image)

We see from the still in Figure 1 that BALSA supports multiple simultaneous views of the running algorithm. The contents of each view window depend on what the teacher has provided and cannot be changed by the student. A code view (the window at the lower left quarter of the BALSA screen) is usually provided to show the listing of the current procedure in Pascal with the current line highlighted. Views of data structures can range from dots or sticks to complex graphs, trees or computational geometry abstractions. BALSA is able to display multiple views of the same data structure, and is also the first system that can show algorithms racing with each other on the same display (e.g. to compare the speeds of various sorting algorithms). This pioneering work made it the benchmark against which all subsequent AA systems have been measured.

To animate a computer algorithm in BALSA, the teacher starts with the standard Pascal implementation of the algorithm and annotates it with markers at points where the code changes interesting data structures or enters/exits a subroutine. These markers are called Interesting events and they make calls to BALSA's Interesting Event manager with parameters that typically identify program data [Brown 1991]. After annotating the source code, the teacher builds views. Each view controls some screen real estate and is notified by the Interesting Event manager when an interesting event is encountered in the algorithm. The notified view is then responsible
for updating its graphical display appropriately based on the event. This is done by either modifying the exist-
ing view from the BALSA library or by building a completely new view using the built-in graphics primitives.
With these overheads, the code can bloat to a considerable length. Animation code can even be longer than algo-
rithm code, resulting in a situation where the student spends more effort on constructing the animation than on
experimenting with the algorithm. Therefore, we re-state that BALSA systems are not particularly effective as
tools for active learning, i.e. to let students animate algorithm themselves.

3 ARMVLS: Design Issues

3.1 Features of ARMVLS

The features are manifold and only a few can be described it this paper. ARMVLS ...
a. belongs to the ranks of pioneer VL algorithm animators,
b. is the first VL algorithm animator to perform sorting, searching, tree and possibly graph al-
gorithms using the same engine,
c. enables very fast prototyping for both the novice and the expert animation programmer,
d. allows VP in the most natural manner so that algorithms can be programmed exactly as how
we would visualize them to be,
e. is Internet ready and capable of cross-platform interface since it is a Java applet2, and
f. employs dynamic state transitions to reduce programming efforts and to increase the detail
level and realism in animation.

ARM has an impact on the current SV technology as it injects fresh ideas into AA and VP. For AA, it is a
break from the traditional textual coding of algorithms; for VP, it gives a new lease of life to GRSs to handle
complex problems, and hence the ability to wrestle with the ever dominating dataflow VLs.

3.2 How to animate in ARMVLS

The snapshot in Figure 2 shows the Atomic Reaction Model Visual Language System (ARMVLS) after the
completion of a three-level binary search tree (BST) construction. The BST was programmed from scratch and
made ready to run in less than five minutes, demonstrating the rapid prototyping capability of our Atomic Re-
action Model (ARM). There are no functions or modes which specially cater for tree construction. All features
and constructs of ARM are generic and can apply to all algorithms that it can animate, where deemed fit. Cre-
ating animation in ARMVLS also does not require an expert user. In fact, the BST was animated by a pro-
gramming illiterate who was only briefed on the aspects of ARM pertaining to BST, and taught the BST inser-
tion algorithm itself just minutes before she created the animation.

ARM is designed as a general programming heterogeneous visual language (GPHVL) with the ultimate
aim of animating all algorithms achievable by textual coding. This is not to be confused with BALSA systems
[Price et al 1993]. Algorithm animation (AA) using BALSA’s approach are basically coded in text and there-
fore restricted only by the machine power, compiler capability and human creativity. ARMVLS is a visual pro-
gramming (VP) system to animate algorithms that are themselves programmed in ARM.

Of course, our goal is extremely ambitious and will take many more years of research to achieve, consid-
ering the level of VL technology today. Nevertheless, we felt that our contribution to the VL research community
is our approach adopted in ARM.

ARM introduces many new terms that may be unfamiliar in Computer Science. These terms are either
Physics or Chemistry jargon since ARM, as the name implies, is modeled after a simple atomic reaction.

[2] Architecture-Neutral is one of the greatest attributes of the Java language. A Java applet is designed to run on a variety
of hardware architectures and operating systems without the need for recompilation. Applets are truly portable and inher-
tently network ready.
3.3 The Atomic Reaction

In our simple atomic reaction, we assume only two types of atoms: the active and the inactive. Active atoms have kinetic energy. They are unstable particles and they move around. They are called reactors. Inactive atoms, or reactants, are stable and do not move. Because reactors move, they initiate interactions with reactants. In an interaction, there can be two possible outcomes: either nothing happens, or there can be excitation. We say the interaction is sparked when there is excitation. If the excitation involves only one reactor and one reactant, it is a reaction; if many reactants are involved, it is a compound reaction. ARM does not define the many-reactor-to-one-reactant and the many-reactor-to-many-reactant cases. In subsequent discussions, we use the term 'reaction' to include compound reaction as well, unless we explicitly specify that compound reaction is excluded.

In a reaction, there can be three resulting scenarios:

a. the reactor remains excited and the reactant remains stable,
b. the reactor remains excited and the reactant becomes excited, or
c. the reactor stabilizes and the reactant becomes excited.

When the reactor stabilizes, it becomes a reactant; the opposite is also true — when the reactant is excited, it becomes a reactor and fires an excitation response (potential energy to kinetic energy) that throws it into motion. The reactor also fires an excitation response in order to keep itself in motion if it is to remain excited. We use active responses to refer to the set of excitation responses that an atom fires as a reactor; and for those excitation responses that the atom fires as a reactant, we call them passive responses. Dual responses is the intersection set of these two response types, i.e. a dual response is both an active and a passive response. We say that an atom is triggered when it either becomes or remains active after a reaction.

Figure 2 ARMVLS constructing a binary search tree
To make clear the concept presented so far, we apply it to build a Binary Search Tree. Suppose we have the numbers 20, 12, 35, 28 and 43. We let these numbers be represented by an atom each. Each atom is specified with two active responses: 'move left down' and 'move right down'. The trigger conditions for these two responses are \( v_o < v_c \) and \( v_o \geq v_c \) respectively, where \( v_o \) is the value of the atom, and \( v_c \) is the value of the complement.

The complement refers to the other atom in an interaction, e.g. reactor A and reactant B interact, A is the complement of B and B is the complement of A. \( v_o \) and \( v_c \) are known as weights. Weights are like variables in textual languages; we do not call them variables because they are not memory cells that store only values — they are active structures. The meaning of the trigger conditions is that active response 'move left down' will only be fired if the atom's value is less than its complement's \( (v_o < v_c) \); otherwise 'move right down' will be fired \( (v_o \geq v_c) \) instead as illustrated in Figure 3.

In figure 3, circles represent atoms, and the arrows are the active responses. Observe that all the atoms are identical except for their values. This means that we only create one atom, then we duplicate them to the required number (in this case, five) and assign them their individual values.
Unlike previously for atoms 12 and 35, atom 28 does not settle this time; instead it starts another interaction with atom 35. $v_s < v_o$ so atom 28 remains excited and consequently executes the action for active response 'move left down'.

Reaching atom 35, atom 43 fires active response 'move right down', since $v_s \geq v_o$.

Atom 28 finally stabilizes after two consecutive reactions. It then allows atom 43 to enter. This frame now repeats the occurrences of frame 4.

 Atom 43 settles and the chain reaction initiated by atom 20 stops.

**Figure 4** Chain reaction sequence for binary search tree construction example

Before we animate, we have to introduce another term — *interaction arena*. This is the place where atoms interact. In implementation, we call this place the animation window or the animator board, which is actually the window that displays the atoms. Figure 2 shows an animator board with grid lines. Initially, this interaction arena is empty. Each atom will join the arena one after another and cause a series of reactions. This series of reactions is called a *chain reaction* as illustrated in Figure 4.

4 Conclusion

We have tried to achieve the following objectives with this new approach of Algorithm Animation:

a. **Portability and extensibility.** As ARMVLS is entirely written in Java the system can either be accessed via the Internet or as a standalone application on all platforms supporting JDK 1.1.

b. **Object orientation.** All animations are programmed using objects and interact by Atomic Reactions.

c. **Incorporation of multimedia.** This was not further explored in detail but all objects can be associated with images, and each reaction with sound.

d. **Code-free programming.** The BST was programmed without any line of code in comparison to the BALSA approach where the original PASCAL program had to be modified with animation sequences.

ARMVLS can be used as a supplement for Data Structure teaching since it allows students to understand the principles of an algorithm while using it. We think, that programming of algorithms is much easier when we can build a mental image of the algorithm execution sequence in our mind. Complicated procedures and recursive algorithms are more easily understood and therefore aid in the process of programming it in "real" programming code.

Abstract: In our research we are developing an interdependence model for collaborative telelearning. We envisage that such a model will inform the instructional design of learning scenarios, the technological design of the telelearning environment and the design of intelligent agents to mediate, or to support the mediation of collaborative telelearning. In this paper we present a model of a collaborative telelearning scenario and describe how coordination theory has provided a framework for the analysis of actor (inter)dependencies in this scenario.

1. Introduction

Collaborative telelearning emphasises the collaborative interaction between students in a telelearning environment. The fluid mediation of collaborative learning activity is a major challenge for telelearning. Mechanisms to support synchronisation, exchange and sharing of information or documents need to be as transparent as possible to avoid hindering learning. An environment capable of supporting collaborative telelearning needs to be knowledgeable about organising and supporting the collaboration.

The design of collaborative telelearning requires the instructional design of collaborative learning scenarios and the specification of the technological design comprising the learning environment configuration as well as the tools and services available. Furthermore, the specification of software agents to mediate the time, space and collaborative learning activity distance between students, is a means to including some needed knowledge about organising and supporting collaboration.

In our research [Bourdeau et al, 1997; Bourdeau & Wasson, 1997; Wasson 1997] within the Canadian Telelearning Programme (http://www.telelearn.ca), we are developing an interdependence model for collaborative telelearning. We envisage that such a model will inform the instructional design of learning scenarios, the technological design of the telelearning environment and the design of intelligent agents to mediate, or to support the mediation of collaborative telelearning. In this paper, our approach to building this model is described and an analysis of actor (inter)dependencies in a collaborative telelearning scenario is presented.

2. CSCL and Coordination theory

Computer supported collaborative learning (CSCL) gives an insight into what collaborative telelearning can be. Salomon’s work on CSCL [Salomon, 1992; 1993] provides the most complete approach to the study of CSCL in that it is built upon learning theories, relies on observations, raises strong design issues and gives methodological tools for educational research. Salomon’s focus is on the mediation in CSCL, which is a key issue in collaborative telelearning. In his view, collaboration means interdependencies, sharing, responsibility,
and involvement. Instructional design issues become, for example, to orchestrate these interdependencies and the shared activities, while maintaining personal responsibility and mutual involvement [Bourdeau 1996].

Genuine interdependence is characterised by [Salomon 1992] as: the necessity to share information, meanings, conceptions and conclusions; a division of labour where roles of team members complement one another in a joint endeavour and the end product requires this pooling of different roles; and, the need for joint thinking in explicit terms that can be examined, changed, and elaborated upon by peers. Salomon’s emphasis on genuine interdependence between team members raises our first challenge: How can such interdependencies be specified and supported in a collaborative telelearning situation?

[Malone & Crowston, 1994] describe coordination theory as an emerging research area focused on the interdisciplinary study of how coordination can occur in diverse kinds of systems. Coordination theory provides a means for specifying (inter)dependencies between, and among, actors, tasks, and resources by identifying a dependency type (e.g., shared resource) and a coordination process (e.g., group decision-making) for managing the dependency. In their work, coordination is defined as managing dependencies between activities [Malone & Crowston, 1994], hence they have focused on dependence between activities. Drawing on ideas about activity coordination in complex systems from disciplines as varied as computer science, linguistics, psychology, economics, operations research and organisation theory, they present a first version of an analysis that characterises the basic processes involved in coordination. [Tab. 1] gives examples of dependencies between activities and possible coordination processes for managing them.

Using ideas from coordination theory, an (inter)dependence model for collaborative telelearning is being built [Wasson 1997].

3. Modelling a Collaborative Learning Scenario

Adoption of Salomon’s definition of genuine interdependence has lead us to focus on the ponderation of interdependencies between actors such as individual students, teams/groups of students, instructors, tutorial assistants, or experts. Empirical studies have been carried out in order to document collaborative learning scenarios for various versions of a strategic management course given at HEC, École des Hautes Études
Commerciales in Montréal [Wasson 1997]. The part of the courses that the learning scenarios document are exercises utilizing Netstrat [Fig. 1] an Internet-based (http://cetai.hec.ca/netstrat/), strategic management simulation used to provide students with an opportunity to experience a realistic market. Participants form teams and compete for Market Shares. These documented learning scenarios have been modeled using a knowledge modelling tool, MOT, developed at the LICEF Research Centre at Télé-université. These MOT models form the basis of our analysis of inter-actor (inter)dependence.

Figure 1: Netstrat Simulation Game on the Web

The Netstrat simulation game is used in 4 different variations of the strategic management course at HEC. There is a 3rd year undergraduate BAA course, an MBA graduate course, a 3-day Executive course for managers, and a 1-week tailored course for a particular industry. In each variation, the Netstrat simulation game is central, but its role and implementation varies. For example in the 3rd year BAA course [Fig. 2], a month long Netstrat competition [Fig. 3] is held half way through the course and serves to give the students a chance to practice the strategic management skills they have been learning about over the past three years. The MBA students, on the other hand, are welcomed to their program with an intensive week long Netstrat session that serves as an orientation exercise to highlight just how much they have to learn.

**Strategic Management Course (BBA)**

- Course Objectives: to integrate concepts & develop skills in strategic management, including strategic thinking and collaborative decision-making (train based collaborative learning is central)
- Role of Netstrat simulation game: to develop skills in applying strategic management concepts learned through readings, case studies, and group discussions
- Evaluation: Netstrat is worth 30% of course grade (undergrad)
  - Netstrat Grading: 10 % strategic plan
  - 15 % stock value
  - 15 % written report & presentation

**Netstrat Simulation Game**

- strategic management simulation on the internet
- participants play the role of managers working in corporate conditions
- each team (5-6 students) is responsible for a firm that develops, manufactures and sells a range of products on various markets in realistic, competitive conditions.
- 5-6 teams compete against one another in a simulation game
- an Animator runs the game
The learning scenario for the 3rd year BAA documents student, instructor and a simulation animator's participation in the Netstrat competition. The major activities in which the actors are involved (although with varying roles) include: Briefing; Decision-making (7 rounds of team decision-making); Debriefing; Report writing; Team presentations; and Evaluation.

[Fig. 4] gives an overview of the model of the 3rd year BAA scenario emphasising the student view where collaborative team work plays a significant role (the complete model can be found in [Wasson 1997]). In this overview model, only the first three activities, briefing, decision making and debriefing are included. In the model actors are indicated as: an instructor (I); 200-250 students (S); an animator (A); teams of 5-6 students (Tx); and simulation groups (SG-x, i.e., a set of 5-6 teams). Goals are indicated by non-shadowed ovals, and activities by shadowed ovals. Concepts and resources are enclosed in rectangles and governing/regulating entities in diamonds. The shadowed elements indicate either a collaborative goal or activity, or a concept/resource that has been produced collaboratively. Links include: C - component; G-A - goal-activity; simultaneous, I/P - input/output; R - regulates; and P - precedence.
4. Reading the Model

The top node of the model indicates that the instructor (I), the students (S) and the animator (A) share an overall goal “A,I,S: to have all students experience a competitive market through a simulation game”. This goal is decomposed into three subgoals one for each of the actor roles. The instructor will meet the overall goal by “I: guiding and assessing the students in their learning objectives”; the students will meet the overall goal by meeting their learning objectives of which the overall objective is “S: learning to build a sustainable competitive advantage at the enterprise level” (three are 3 sub-learning objectives not shown here); and the animator will meet the overall goal by “A: supporting the students in meeting their learning objectives. Each of these subgoals is linked to a shared activity “A,I,S: participating in the Netstrat simulation” by a goal-activity link (G-A). Three simultaneous activities “I: guiding and assessing the students’ participation”, “S: competing in the Netstrat game”, and “A: supporting the Netstrat simulation game” illustrate both the task/subtask and simultaneity constraint interdependencies identified by [Malone & Crowston, 1994] and listed in [Tab. 1].

Following the students activity three sub-activities nodes, “S: participating in the briefing”, “SG-x: competing for Market Shares” and “S: participating in the debriefing” are met. There is a prerequisite constraint dependence [Tab. 1] between these activities indicated by the precedence (P) link. In the complete models [Wasson 1997] each of these nodes has a sub-model but for brevity only the highlights are shown. Notice here that in the second activity the students (S) have been divided into simulation groups (SG-x) and it is a SG-x that competes in one simulation game.

The simulation group activity “SG-x: competing for Market Shares” has two sub-activities “SG-x,Tx: team building” and “SG-x: inter-team dynamics building”. More will be said about these two activities in the next section, but note that the simulation group has been split into teams (Tx) for the team building activity. Under “SG-x,Tx: team building” there are three sub-activities “organising team”, “SG-x,Tx: developing global vision & strategy” and “SG-x,Tx: making decisions”. These activities (of which there is a precedence order) are the heart of the collaborative team activity. Output (indicated by the I/P link) from the “SG-x,Tx: developing global vision & strategy” activity is a “shared vision” and a “team strategy”. The shared vision is input into the team strategy which in turn governs (or regulates (R)) the “SG-x, Tx: making decisions” activity. This means that the team strategy has an influence over how team decisions are made. The final item to be highlighted is the “Market shares for decision x” concept. This concept represents the value of the Market Shares for which the teams within a simulation game are competing. The Market changes after each decision thus feeding new values into the next decision making round. The Market updates are released by the animator (not shown in [Fig. 4]) after a set criteria is met (e.g., all decisions have been entered by time x and no team will be out of the competition).

5. Discussion: Actor Interdependence

In analysing the dependencies between actors in the learning scenarios, the following observation has emerged. Actors in a collaborative telelearning situation have the obligation or necessity to:

- share Goals to complete Activities
- share Activities to achieve Goals
- share Resources to complete Activities
- share Activities to produce Resources

The first two are illustrated [Fig. 4] by the interconnection of the overall shared goal’s subgoals to the shared activity “A, I, S: participating in Netstrat simulation”. This illustrates a collaborative interdependence through a shared activity. The shared activity is sub-divided into three activities which have a simultaneous constraint dependency as identified by Malone and Crowston [1994]. By carrying out these three activities simultaneously, each actor carries out their part of the collaborative activity which in turn satisfies the shared goal. The third
obligation arises in this learning scenario by the sharing of the actual Netstrat software to compete for the Market Shares. This sharing of a resource to complete an activity is not illustrated in [Fig. 4]. The last obligation is illustrated in [Fig. 4] by the shared team activity “SG-x,Tx: develop global vision & strategy” production of the concepts/resources “shared vision” and “team strategy”.

Another aspect of this learning scenario that is worth noting is that there are both collaborative and competitive interdependencies and they are interlaced within each other. The collaborative shared goal “A,I,S: to have all students experience a competitive market though a simulation game” is achieved by a collaborative shared activity “A,I,S: participating in Netstrat simulation” which includes a competitive shared goal “SG-x: competing for Market Shares” which comprises collaborative shared activities “SG-x,Tx: team building” and “SG-x: inter-team dynamics building”.

6. Conclusions

Beyond the issues of reliability of computer communications and services, it critical for collaborative telelearning that environments possess the knowledge as well as the ability to orchestrate and support collaboration. The analysis of actor interdependence in collaborative telelearning scenarios has been the first step in the process of defining this knowledge. In the Norwegian project OCTA, we are proceeding to identify coordination processes to manage the interdependencies between actors and to determine how to mediate these within a collaborative telelearning environment. Fjuk’s analytic framework [Fjuk 1995] that has a foundation in activity theory [Leontiev 1975] and integrates elements from CSCW/CSCL, situated learning and problem-oriented project pedagogy, provides a basis for the design of our investigations and evaluations in OCTA. In an activity theory approach to human interaction the unit of analysis is extended to include a social dimension where individual interactions are analysed as part of a collective activity. Furthermore, activity theory is especially strong in emphasising the role a mediating tool (e.g. a computer system) plays in this web of human activities and stresses that it must be seen in the context of the entire learning environment within which it will be used [Wasson 1996].

Teaching and Learning with Flexible Hypermedia Learning Environments

Dr. Joachim Wedekind, Martin Lechner, Dr. Sigmar-Olaf Tergan
Deutsches Institut fuer Fernstudienforschung an der Universitaet Tuebingen, Konrad-Adenauer-Str. 40, D-72072 Tuebingen, Germany. E-mail: joachim.wedekind@uni-tuebingen.de

Abstract: Hypermedia systems may be used for different purposes. However, in order to be used for teaching and learning purposes they have to be designed in a comprehensive manner taking into consideration features considered as crucial for flexible HMLE. In outlining these features we will follow a conceptual model for describing computer-based systems. We then present our approach to apply this theoretical framework and to create a layered model of an hypermedia system, called HyperDisc, which served as a guideline for further conception and development activities.

1. Introduction

In information society lifelong learning is essential. People of all ages have to cope with an ever increasing complexity of subject matters as well as multiple formats of subject-matter representations. There is a need for just-in-time self-regulated, open and flexible access to world-wide distributed information as well as the need for flexible use of this information according to the individual's own study interests. Thus open and flexible teaching/learning environments as well as subject-matter representations which may support individual study interests effectively are becoming more and more important. Hypermedia Learning Environments (HMLE) are attributed to have a great potential in fulfilling the above mentioned requirements.

A review of empirical studies shows, that initial optimistic views on the efficacy of HMLE have to give way to a more realistic view [Rouet 1992]. Several other reviews revealed that existing hypermedia systems as well as empirical research often suffer from theoretical, conceptual and methodological shortcomings [Tergan 1997 a,b,c]. It is claimed that in many cases hypermedia environments have not been designed and used appropriately to foster learning. This is why Jacobsen [Jacobsen 1994] and Tergan [Tergan 1998] strongly argue for a closer link of theory to design, research and application in real instructional settings.

In the present paper some of the problems mentioned are addressed. In the first part the empirical background is discussed. Deficiencies of existing systems are outlined briefly. The second part deals with requirements for the design of HMLE. In the third part of the paper we present our program HyperDisc as an example of a HMLE which has been developed at the German Institute for Research on Distance Education as a prototype to cope with design requirements outlined for fostering open and flexible learning.

2. Empirical background

The first ten years of hypermedia use and research have been inspired by some basic expectations and theoretical assumptions concerning the global efficacy of these systems in promoting knowledge acquisition and information retrieval. For example, some researchers have argued that basic structural and functional features of hypertext/hypermedia-technology match very well with cognitive network theories of the human mind, constructivist principles of learning and multiple mental modes for representation of knowledge. The assumptions draw back on the potential of hypertext/hypermedia to represent subject-matter content in a non-linear fashion, to enable flexible information access and self-regulated learning, and to represent a subject matter from different views and in different symbol systems.

The suggested match has nourished expectations that hypertext-based technologies may overcome deficiencies inherent in the traditional reading comprehension and information processing approach of teaching and learning and may even revolutionize learning [Jonassen 1986, Landow 1990]. It has been claimed that
Hypermedia technology may overcome some of the limitations of the traditional database approach for information retrieval [Marchionini 1995].

Meanwhile the initial enthusiasm concerning the potential of hypermedia for promoting learning has given way to a more realistic view. Reviews concerning the empirical evidence of the suggested potential of hypermedia for fostering learning and information retrieval have revealed both disappointing and encouraging results [e.g. Rouet 1992]. The results indicate that learning based on hypertext and hypermedia on the one hand may lead to navigational and conceptual disorientation and is often less effective then learning with traditional media, as is shown in comparative studies [e.g. Gordon et al. 1988]. On the other hand the results indicate that learning with hypermedia may contribute to enhance learning and contribute to cognitive flexibility when the learning environment is designed taskappropriately and when it is used by learners with appropriate learning competencies in a flexible manner [Spiro et al. 1991, Rouet 1992].

Tergan [1997 a,b,c] has analysed the theoretical, instructional and methodological conditions which may be of relevance for explaining failures and successes in using (capitalizing on) the potentials of hypermedia for enhancing learning. His review on the validity of theoretical assumptions concerning the global efficiency of hypertext/hypermedia supports the suggestion that the theoretical rationale of most of the approaches has been primarily led by technology-based enthusiasm on the potential of hypertext/hypermedia to enable and support learning [see also Spiro et al. 1991]. From an instructional design point of view it is criticized that the rationales for hypertext/hypermedia design have not always been tailored taskadequately and have disregarded conditions of effective learning in instructional contexts [Tergan 1997 b]. It is claimed that because of the inadequate tailoring of hypertext/hypermedia design and an inappropriate match between the inherent potential of a system to support certain learning functions and the criteria used for assessing learning effectiveness, the potential of certain types of systems for supporting particular aspects of learning may have been underestimated.

Tergan [1997c] draws attention to empirical results and the central claim of cognitive psychology that effectivity of learning with the help of a technology is the result of a complex interaction of constraining conditions on the side of the learner (e.g. level of learning, study interests, motivation), instructional methods to support learners in task appropriate processing (e.g. modeling, coaching, scaffolding), attributes of the learning material (structure, complexity, formats of representation) and the media used (e.g. interactivity, accessibility of information elements, potential for multiple coding formats). It also depends on situational constraints like authenticity of the learning situation, embeddedness in an overall instructional approach, etc.

3. Design features

Hypermedia systems may be used for different purposes. However, in order to be used for teaching and learning purposes they have to be designed in a comprehensive manner taking into consideration features considered as crucial for flexible HMLE. In outlining these features we will follow a conceptual model for describing computer-based systems [Tergan, Mandl and Hron 1992]. Basic components of this model are the learner component, the subject matter component, the pedagogic-didactic component, and the information technology component.

3.1 Learner component

All learners do have their individual characteristics concerning motivation, cognitive abilities, and preknowledge, which have to be taken into consideration. Such an important factor is the learning strategy. Three main types of learning strategies in hypermedia-systems are postulated for improving learning [Astleitner and Leutner 1995], based on results in an exploratory study in which three component processes were identified (attaining a temporarily activated goal, ensuring spatial orientation, acquiring knowledge). The authors differentiate these further into eleven substrategies (i.e. use filtering, neighborhood exploration, and zooming as general methods for successful goal attainment; use nodes with landmark-quality for better orientation).

In spite of the lack of empirical data on the effect of these strategies on "learning" with hypermedia, it seems most important to offer a wide range of orientation and navigation features, in order to support most of the
conceivable strategies and to give the learners a real choice. Within the learning process the learners thus can be encouraged to change their strategies, according to task and training.

3.2 Subject matter component

Subject matters are not only increasingly complex but also change rapidly in many fields. HMLE, dealing with such complex subject matter and providing for flexibility in learning topics and extensive contents, have to be open for continuing completion and updating. This presupposes an open structure, allowing successive addition of new nodes and links. By now, this may be accomplished - at least to some extent - by directly accessing the WorldWideWeb, which has hypertextual elements itself. In the same manner application programs can be linked to the HMLE, thus enabling the learners to apply newly acquired (procedural) knowledge in real tasks with common tools.

Nonlinear use of the material should be stimulated by optional visits of nodes with additional information. They can be made available to the learners by filters or tours, thus highlighting different aspects and enabling different approaches. The relevance of the nodes within special filters or tours should be elucidated with annotations.

3.3 Pedagogic-didactic component

There are roughly three modes in which information technology resources can be used in teaching and learning:

*Expository learning activities* involve the learners in working through information presented at an appropriate level by a teacher.

*Exploratory learning activities* involve the learners in exploring ideas about a topic presented by someone else (teacher or expert), where the ideas may often be quite different from the learner’s ideas.

*Expressive learning activities* involve the learners in expressing their own ideas [Mellar et al. 1994].

In many situations these modes can overlap. As Mellar et al. point out in the case of simulation and modelling, it is possible to use the respective tools both in an exploratory and expressive mode of learning. With appropriate design features, we think HLMEs now can support all three modes, thus giving teachers and learners maximum flexibility. The different modes of using HMLE all depend on easy and successful orientation and navigation within the information base. It is therefore crucial that the structure of the material is made explicit, using textual or graphical browsers to visualize the individual learning path, the result of a query, the context of the present location etc.

3.4 Information technology component

As HMLE cannot be designed for a limited group with precisely described cognitive abilities - not least due to economic reasons - we need HMLE which are adaptable to various target groups and which allow the application of different learning strategies, thus optimizing the development efforts [Valcke and Vuist 1995]. These requirements have repercussion even on the architecture of such systems and must be taken into consideration in all phases of development.

Our prototypical HMLE HyperDisc demonstrates the close relationship between the results of an extensive analysis of the conceptual model components and our design decisions concerning the structuring the information base, representation, layout and screen design, the integration of additional materials, help functions and communication tools. In the following we can only exemplify this with the support functions for expository, exploratory and expressive learning activities.

4. HyperDisc - a prototypical flexible HMLE
4.1 Expository learning activities

The contents within HyperDisc can be structured to support the different prerequisites, preferences and goals of the users. A critical factor is the user with little prior knowledge and little HTML experience in general with the need for particular support. In this case expository adaptation of the content is a central approach which is implemented by arranging a subset of pages sequentially. HyperDisc covers three types of sequences:

Standard Tour: This tool is made for beginners and allows them a fast overview of the content. The most important pages are collected, annotated and presented as an item list.
Extra Tours: Authors may compile many annotated sequences to condense subjects or reorganise them in their sequences. Implicit connections can be made more explicit.
Sequenced hierarchy: Whereas standard tour and extra tours are excerpts of the content hierarchy here all pages can be read one after the other.

4.2 Exploratory learning activities

Of course users may deviate from the tours at any time and e.g. switch to a more explorative mode of learning. Four types of structure, respectively tools, are offered for this case:

Hierarchy: All available pages are arranged hierarchically and are represented in first-order fisheye view in the browser.
In order to support self-regulated flexible access to information, information seeking and the associated navigational strategies browsing and searching [Marchionini 1995] play an important role. Existing HMLE present both features without integrating them closely in the manner of Marchionini. However, this integration seems to be most relevant because these processes complement each other, altering permanently and unpredictably due to the changing knowledge and goals of the user during the localisation and learning activities.

As a consequence, corresponding tools and structure representations may be used parallel in HyperDisc on the one hand and on the other hand search results are integrated into all link anchors across the system by displaying different colors and little icons (small hooks and crosses). A particular status within this procedure is ascribed to the browser which allows the restriction of the search results using the hierarchical structure. On the other side, beginning with a single found item, its context may be re-established leading to a quick assessment of its relevance.

This principle of structural overlapping is applicable to all linear structures in HyperDisc, e.g. an extra tour may be used for filtering the hierarchy. This procedure is implemented consistently across the system and allows for drilling down information effectively.

4.3 Expressive learning activities

These learning activities - either performed in parallel or following explorative behaviors - will be supported by:

**Bookmark and annotation facilities:** According to the rationale of tours, the bookmark-function allows for gathering information and annotations according to definable categories.

**Restructuring facilities:** Advanced users may switch into the authoring mode in order to reorganize the hypermedia basis for individual needs, e.g. adding links, building up alternative hierarchies (multitrees) designing an individual tour.

**Creating and integrating new contents:** With the help of an extra editor new content nodes of ToolBook-pages may be generated and implemented into the database of the HyperDisc. In a similar way the links to the WWW may be supplemented.

4.4. Openness

The possibility to integrate and create new contents shows the openness of HyperDisc in terms of subject-matter content. This openness is realized technically by distinguishing three components: the content-nodes, the structure of content and the integrating shell itself. All components may be altered independently. Content-nodes in the authoring mode can be generated by providing the users with a standard Toolbook utility. Thus content nodes as well as multimedia components and external programs can be supplemented with contents of WWW-pages, which may be accessed on-line.

5. Perspectives

HyperDisc can be used to incorporate any topic for hypertextual and multimedia presentation. Our first application is training material for students, decision makers and developers in the field of new educational media. At present HyperDisc Version 1.0 is available, including parts on "Simulation and Modelling" and
"Hypertext/Hypermedia". Additional parts are planned. These versions will be available in 1998 as well as several tools to develop the HyperDisc-applications.

HyperDisc serves as material for our research. We will evaluate the use of Version 1.0 in a distance education course "New Educational Media", run by the Fachhochschule Furtwangen in 1997/98. Evaluative results will be available in mid 1998. In addition we are planning controlled experiments with variants of HyperDisc to investigate the use of different navigational tools in problem solving situations.

Additional information on concept, implementation and availability of HyperDisc can be found at: http://www.uni-tuebingen.de/uni/dii/A1/hyperdisc/beschs2.htm

Comments and critiques are welcome in our discussion forum at: news://news.diff.uni-tuebingen.de/hyperdisc.*

"Campus" - 
an Agent-based Platform for Distance Education

Dirk Westhoff, Claus Unger
University of Hagen, Department for Computer Science
58084 Hagen, Germany
dirk.westhoff@fernuni-hagen.de, claus.unger@fernuni-hagen.de

Abstract: Campus supports the communication and co-operation between a distance teaching university and its students in an Internet environment. While students usually connect quite rarely to the Internet, they can continuously be represented in the Internet by their individual autonomous agents which can fulfill a variety of tasks for their owners. Campus is being implemented with the help of the Agent Application Programming Interface (AAPI) package. AAPI is an extension of the Java Class Hierarchy and has been developed at the University of Hagen; it supports the design and implementation of systems of mobile, autonomous agents and is based upon decentralised control structures. Derived from the AAPI package, Campus offers a variety of Campus Intercommunication Agents.

1 Introduction

The University of Hagen is a distance teaching university with about 55,000 students, most of them spread all over Germany, some of them even over the whole world. Most of these students have access to the Internet, but because of connection costs are linked to the Internet just for short intervals. Campus provides an environment in which students are continuously represented by their own personalised, autonomous agents which can fulfill a variety of information, communication, planning and co-operation tasks on behalf of their owners. Each student runs on her computer a Campus environment, populated with several Campus Intercommunication Agents (CIAgents). The student charges her agent with a list of tasks, briefly connects to the Internet, releases the agent to the network, and disconnects again. According to their tasks, the agents migrate through the network, collect information for their owners, communicate and co-operate with other agents, until they are finally picked up again by their owners as soon as they reconnect to the network. Thus, while students are just rarely connected to the network, their agents can continuously represent them in the network. Beside minimising the student access times to the network, co-operation and communication between agents may stimulate co-operation and communication between students as well. Campus and its services are dealt with in more detail in chapter 4. Compared with the traditional server/client paradigm, mobile, autonomous agents in general show several essential advantages: transporting the algorithms to the data and substituting global network-wide communication and co-operation by local communication and co-operation may significantly reduce communication costs and the amount of network resources needed. On the other hand, security, authentication and accounting problems have to be solved for agent systems. Campus is being implemented as an agent application on top of the Agent Application Programming Interface (AAPI) package. In the following chapters, we briefly survey existing mobile agent systems, describe the basic concepts of the AAPI package, introduce Campus in some more detail, and conclude with some ideas on future work.

2 Survey of Mobile Agent-Systems

This chapter gives a brief survey of some existing mobile agent system environments. The java-based Aglet workbench of IBM [IBM 96] is an extension of mobile java applets. Similar to an applet, an aglet's binary code migrates through the network, but in contrast to an applet, the state of an aglet is transported together with the aglet. States are defined in terms of creation, migration, activation, deactivation and termination events. For each state, the aglet workbench offers the aglet programmer adequate sets of methods. Global and local communication between aglets is realised via the communication mechanisms Remote Procedure Call (RPC) and message passing. In both cases, aglets have to create so-called Aglet-Proxies. These are the aglets' communication stations which also protect aglets from unauthorised manipulation. Agent Tcl [Kotz et al. 96],[Gray et al. 96] is a mobile agent-system which was developed at the Dartmouth College.
Agents are realised in Agent Tcl, an extension of the scripting language Tool command language (Tcl). For communication between agents, Agent Tcl uses the Agent Remote Procedure Call (ARPC) or a paging mechanism. To work under non-permanent network connections, Agent Tcl contains the Laptop Docking System, which assigns every Laptop a permanent docking computer. When the Laptop is not connected to the network, the docking computer serves as target for the agent. Security services, based on Safe Tcl, protect a computer from malicious agents. Security services to protect agents against malicious environments have not been realised yet.

Mole [Straßer et al. 96],[Hohl 95] is the prototype of an agent system. Stationary System-Agents manage the resources and services of one place (set of computers). If mobile User Agents visit these places, the System Agent assigns special resources or services to these User Agents. Mole supports local and global communication [Röhrle et al. 96] with RPC and message passing mechanisms. If an agent wants to communicate globally, it sends its message to a central Mailbox Agent, which forwards the message to the other partner.

JAE (Java Agent Environment) [Park et al. 97] has been drafted at the technical University Aachen. JAE focuses on the integration of wireless (e.g. mobile phone) and Internet agent technologies. JAE introduces the concept for Personal Digital Assistants (PDA). JAE distinguishes between agent servers, mobile agents and stationary service agents. A computer based agent server provides an environment for incoming mobile agents, and is supported by service agents. Only mobile agents can leave a computer and travel to another computer. Additional approaches can be found in [Li et al. 96].

All the described agent systems are based upon a central architecture, i.e. one or more servers have to be permanently active and reachable. To avoid bottlenecks and problems with server failures, as well as to gain general experiences with decentralised architectures, the AAPI package is, following the basic Internet paradigm, uncompromisingly based upon a decentralised approach. [Tab.1] compares the described systems and the AAPI package approach:

3 The AAPI Package

The runtime environment for an agent is called an active context. Except when migrating between contexts, agents are always embedded in a context. A context can:

- start and ship its own agents;
- dock (i.e. receive, start and ship) foreign, travelling agents;
- synchronise several running agents;
- communicate with its own travelling agents;
- support communication with foreign agents in foreign contexts;
The agent's static profile is defined by a set of attributes, e.g. identifier, creation date, owner, task description, etc.

When the context starts one of its own agents, it defines an initial route for the agent's tour through the Internet. Such a route may be a simple list or, e.g., a complex path graph of Internet addresses. During its journey, the agent can extend its initial route.

If the agent wants to move from one context to another, the binary-code of the agent has to be sent together with its profile and route.

Agent, profile, route and binary code are represented as objects which are linked to each other. At the stage of migration, they change their representations into data-streams and, via its Internet address, move to the next site on the agent's route (Fig. 1).

Agents working in the same context are represented as parallel threads. They can communicate and co-operate with each other via ComObjects. When an agent wants to start a communication with a parallel agent, it creates a ComObject for this agent, which beside the message may contain algorithms in form of binary code to be executed by the other agent. It may also contain structured containers for results. Within its thread, each agent is continuously looking for ComObjects another agent has created for it. Communication between agents across different contexts in different computers works in a similar way. The agent creates a ComObject in its context and sends this object to the context of the target agent, which in turn executes the requested tasks and sends the results back.

The Internet address of its owning context always defines the last station in an agent's route. As mentioned before, our students' computers are quite rarely linked to the network and may get assigned different Internet addresses for different sessions. In such a case an agent cannot find home and present its results to its owner. The following algorithm solves this problem (Fig. 2): whenever the home context (HC) of an agent changes its Internet address from \( ip_i(\text{HC}) \) to \( ip_{i+1}(\text{HC}) \), it immediately informs all contexts \( c_i \) on the agent's reverse initial route until it finds the context where the agent is actually working in. This context changes the target station in the agent's route.
accordingly and confirms the successful change to the agent’s home context.
If the agent has extended its initial route and is actually working in a context $c^E$ that is part of the route extension, the home context cannot inform the agent about a changed internet address. In this case, after the agent has finished working on the extended contexts, the agent migrates to an active context of its initial route, to wait for information of its home context. Here the agent can be reached again, to change the target station in its agent’s route.

This reverse routing algorithm assumes that the home context can reach its agent. There are several reasons why a home context may not be able to reach its agent $A$:

- unavailability of $A$ during the migration;
- regular termination of $A$'s actual working context;
- irregular termination of $A$'s actual working context;
- interrupted connection to $A$'s actual working context;
- Agent $A$ is working in a context $c^E$.

While the first case can be solved by handling the migration of an agent as an atomic operation [Mira da Silva et al. 97], [Klar 96], [Westhoff 97], the second one can be handled by enforcing contexts not to close as long as they contain active agents. The last three cases can only be handled by restarting the reverse routing algorithm after a certain time-out.

The above algorithm assumes that only the home computer of an agent may get disconnected from the network and change its Internet address. We are presently working on an extension of the above algorithm which allows arbitrary computers to change their Internet addresses and to inform all interested computers in the network. To strictly follow the agent paradigm, even short messages between contexts are modelled as agents.

The classes and methods of the AAPI package realise a basic mobile agent, i.e. they support an agent's creation, travelling, working, self-copying and termination. More advanced agents can easily be defined within the AAPI environment by simply overwriting the corresponding methods. Details on the AAPI package and how to use it can be found in [Westhoff 97].

4 Campus

While lecturers as well as all university institutions are almost permanently connected to the Internet with constant Internet addresses, most of the students are quite rarely connected to the Internet; their Internet addresses may change between sessions. Thus within Campus we model a two-layered network [Fig.3], the outer layer containing all computers which are rarely connected to the network, the inner layer containing computers which are almost permanently connected to the network.

Address changes of computers in the outer layer are not reported to other computers; Address changes in the inner layer are immediately reported to all computers in the inner layer, as well as through their agents to computers in the outer layer as well. Computers in the outer layer send their agents to computers in the inner layer, let them perform their tasks and pick them up again, if necessary via reverse routing. The inner layer provides various service, information and chat ‘booths’, where agents on behalf of their owners can, e.g.:

- retrieve actual information from libraries, search machines, faculties’ and registrar’s blackboards;
- exchange information with other agents;
- search for individual agents;
- co-operate with other agents in setting up individual working groups;
- enrol their owners into existing working groups;
- arrange dates between their owners;

Each of these ‘booths’ contains one context where travelling agents can dock. We are presently developing a
variety of protocols for communication and co-operation between agents and booths. 

Campus contains several types of CIAgents. They are all derived from the basic agent type of the AAPI package. [Fig.4] depicts the CIAgents' docking- and its route window:

![Diagram of the two layered network of Campus](image)

**Figure 3: The two layered network of Campus**

The docking window is divided into the boxes *My-CIAgent* and *Docking*. The My-CIAgent box lists the student's personal CIAgents and the docking box gives a view of all the agents that are either working or resting on the student's context. In the Campus' route window the student can compose routes for her My-CIAgents, e.g. by selecting members of her learning groups.

**5 Conclusion and Future Work**

The AAPI package provides a comfortable and easy to use high level interface to implement systems of individual, mobile, autonomous agents in the Internet. It supports decentralised control architectures. With the help of the
AAPI package *Campus* is being realised, a platform that, through a variety of different types of agents supports communication and co-operation between a distance teaching university and its students. **Beside the definition of various protocols for inter agent communication and co-operation, security and authentication problems will be our major future concern: runtime environments have to be secured against malicious agents, agents have to be secured against their embedding environments; secure authentication methods have to be developed. Further more, appropriate accounting mechanisms are needed.**

Critical Practice in the Use of Listservs: A Case Study

M. Wild

School of Management Information Systems, Edith Cowan University
Churchlands, Perth Western Australia 6018. Email: m.wild@cowan.edu.au

Abstract: This study focuses upon the use made of two separate listservs for professional development—Oz-Teachers and UK-Schools. Both lists are used by teachers in Australia and the United Kingdom, as well as by teachers across the globe, to communicate electronically with each other. The practice of this communication is typically characterised by text messages that pose questions or offer answers; by 'threads' of discussion based around single or combined themes; and by statements of information. In this context, two windows are opened in this study: one shows a dynamic picture of teachers at work and play in the technology of listservs, developing skills and practices in asynchronous communications. The other looks into the content of many of the postings, demonstrating the practices, views, ideas and concerns teachers have with using technology in traditional school and classroom environments. This paper serves to provide an overview of the study, whilst a more detailed report can be found elsewhere (Lankshear, et al., 1997).

1. The net effect

As a global communications network, the Internet provides a range of possibilities for educational use. These are summarised in Table 1. Email is a technology based on the Internet, providing for the sending and receiving of text-based messages as personal communications. A listserv offers a facility for asynchronous email communications between members of a group connected by virtue of a common interest or affiliation, providing a means for public dialogue. The Web is a set of electronic protocols to access and publish information—in the form of hypermedia as well as text documents.

The Internet is, paradoxically, both a physical and virtual embodiment of computers and people. In particular, it is a social construction, where people live, play and work. A listserv is a commonly available Internet technology that provides a computer-mediated forum (a list) for written dialogue in the form of messages or 'posts'. To participate in a list you have to apply to become a member; instructions for both joining a list and managing your activity once a member are similar across most lists—in particular, there is a commonly shared but largely informal set of rules for participation (a 'netiquette').

These rules are generally learned by experience, observation and from direct advice; they can also be sighted, in some lists, by reference to an electronic archive set aside for such information by the list owner or originator. A list can function in either unmoderated or moderated forms—a moderated list is one where

1 This study was conducted as part of a larger research project investigating the interaction of literacy and technology in education, and was funded under the Australian Language and Literacy Policy (Children's Literacy National Projects) initiative, Department of Employment, Education, Training and Youth Affairs, (DEETYA), Federal government of Australia.
messages are subject to vetting by the list owner before being circulated on the list; whereas an unmoderated list allows all messages to be posted directly to the members of the list from someone other than the list owner.

2. Practice of communication

The act of posting messages to Oz-Teachers or UK-Schools falls largely into one of three major categories, corresponding to discussion or continuous dialogue between two or more list members (over at least four postings), the providing of information or the posing of a question. Within these categories, the content of messages may be either technical or educational in focus: technical content typically addresses the operation, function or application of various technologies; educational content is typically related to the practice, theory and administration of teaching and learning. Table 2 provides a guide to the application of this categorisation used in this investigation of Oz-Teachers and UK-Schools.

Of course, in a number of cases a posting can actually be classified across more than one category. In these instances, I categorised messages in terms of their main purpose, rather than subsidiary ones—although such an interpretation can never be entirely satisfactory, it does allow for building a reasonably robust framework for understanding the purpose, nature and content of messages posted to Oz-Teachers and UK-Schools.

</table>

3. Research methods

Investigation into both Oz-Teachers and UK-Schools has been conducted by the collection and content analysis of postings made to each of these lists. To undertake this work, I became a member of each list and collected postings made over a 12 month period, ending in July 1997. A purposeful selection of these postings were then analysed using a content analysis methodology, providing data on numbers of postings, their
authorship, and their 'thread'—that is, the discussion they may have initiated or contributed to. In addition, I conducted a small number of interviews, by email, with a selection of members who had made at least two meaningful postings to the list, to obtain data such as reasons for membership, how the list is used, and perceived value of the list. I also interviewed a smaller number of members who had not sent any messages to the lists. I interviewed 15 members of UK-Schools (2.6% of total current membership), and 12 members of Oz-Teachers (1.1% of total current membership)—this included 4 from UK-Schools and 4 from Oz-Teachers, who had not posted messages to their respective lists. I also collected documentation relevant to the lists, that reside on associated Web sites: http://owl.qutedu.au/oz-teachernet/; http://www.mailbase.ac.uk/lists/uk-schools/

These Web sites also provided access to archives of list postings.

4. Lists in context

UK-Schools and Oz-Teachers are localised approaches to the use of global communications networks for professional development of teachers. Both lists are examples of early attempts to bring teachers into a growing debate centred on the practice and to a lesser extent, the theory of using new technologies in school education. The lists are by their nature, dynamic—membership and topics of discussion change constantly, and their development reflects something of a maturation process. In particular, membership to Oz-Teachers seems currently to have reached something of a plateau (at about 1050 subscribers); whilst the number of postings made to both lists has fluctuated over the period of the investigation (see Table 3). Indeed, a maturation process in both UK-Schools and Oz-Teachers is probably the defining characteristic in the amount and type of postings carried, and this does not seem to be influenced by the numbers of members of these lists.

It would seem that the maturation process in these lists have certain identifiable aspects. For example, maturation includes a growth in the core of membership—those members who maintain an active interest in the list, by either making postings to the list on a regular basis, or who repeatedly use the list for professional activities, such as resourcing teaching, or for references to curriculum projects or for posing questions. At the same time, one sees a constantly changing peripheral membership—those who join for a short time and then leave, or those who join but make little ongoing use of the list. Some of the latter includes university students who are pursuing studies in education, who are evidently encouraged to join by their lecturers (who are presumably members of the relevant list) or perhaps by fellow students, but who make little or no use of the lists thereafter. This phenomenon seems to be especially true for Oz-Teachers.

Furthermore, maturation also includes developments in the so-called ‘lurker’ population. Lurkers are members who make use of the lists by reading postings but who do not make postings themselves. The act of lurking is really a passive use of the list, with lurking apparently being a preferred way of working with or using lists for large numbers of members. Whilst not all list members wish to post messages to the list, most of these still use the list for professional reasons—obtaining information, keeping abreast of issues and dialogue and using references to projects, ideas and literature given in postings. Lurking is not necessarily a mark of immature members (ie. those who don’t yet have the necessary confidence to make a posting) but rather a preferred approach to apprenticing oneself to the culture of a list; and whilst some members remain lurkers for prolonged even indefinite periods, others perhaps begin to make postings on a regular or occasional basis. Importantly, however, lurking is not to be seen simplistically as a behaviour of naive list members; and neither is the dichotomy between active and passive users of a list a static picture—it is dynamic, and movement between activity and non-activity for many individual list users is very fluid.

Interestingly, in both UK-Schools and Oz-Teachers but especially in the latter, members are actively encouraged to make postings. Active members appear to assume that passive use of a list is a sign of immaturity and that all list members should become active—in fact, the list owner in Oz-Teachers advises all new members that an introductory message is expected of all those joining the list. There is it seems, no justification for this: the passive members interviewed from both lists indicated, without exception, that they gained value from their membership of the list without feeling it necessary to make postings. Further, all admitted to feeling anxious about making a posting but said that they were likely to do so. Interestingly, a majority of interviewees felt there was some pressure from other list members to make a posting and that this heightened their anxiety about doing so.
Maturation in list activity can also be seen in the content of list postings, where messages of a trivial nature are tolerated less and occur less; and the form of messages increasingly follow the conventions dictated in general rules of ‘netiquette’, or those created by the list members or owner themselves, usually through practice but sometimes as part of a policy statement. Maturation might also be marked by the establishment of a list archive (which both Oz-Teachers and UK-Schools have) and/or a Frequently Asked Questions (FAQ) database, to which new members can be referred, to obtain information on subjects that have already been discussed or referenced on the list.

5. Lists as culture

Part of the conceptualisation in this study of Oz-Teachers and UK-Schools was that lists operate as communities or groups of people who have come together by virtue of an interest, affiliation or a more basic need or want. The notion of lists as communities is not new—indeed, it has been the basis for a range of studies of computer mediated communications (CMC) and is perhaps an obvious characterisation to infer (Lawley, 1994). Indeed, some of these studies have moved beyond the view of CMC as communities to describe them as cultures (Rheingold, 1993) but without a satisfactory exploration of what is meant by the use of the term, so that a culture can be seen to be different from a community.

What has clearly emerged from this study into Oz-Teachers and UK-Schools, is the notion that these lists do operate as cultures, where culture is something that is collectively created and resides, dynamically, in the constructed meanings of a particular community. In this sense, the culture of a list is generated by its membership through the meanings given to collective practices—the practices of a community. In another yet related sense, it has been possible to discern in both Oz-Teachers and UK-Schools, but particularly in the former, the operation of ‘cultural capital’, a term coined by Bourdieu (1988), where the capital of a culture is perceived to be that which is held to be of value, and which can be accumulated, earned and exchanged (Bourdieu, 1988). The capital within the cultures of Oz-Teachers and UK-Schools is that of expertise, experience and knowledge, and in the context of a variety of postings and dialogues on these lists, one witnesses the negotiation of cultural capital, and the clear divisions that occur between those with capital and those without it.

6. List activity

The activity of a list can be readily measured by accounting for the number of messages that it carries. The greater the volume of postings, the greater the activity of the list. More importantly, the more threads that occur in a list, the more opportunity there is for reflective and critical dialogue to occur—and it is in this type of dialogic activity that deeper involvement with knowledge can be found, where ‘apparent conversational immediacy’ is blended with ‘tempered thought’ (Haley-James, 1993 9), giving rise to what Haley-James has characterised as a ‘metacommunicative’ event (Haley-James, 1993 10). However, this is not to suggest that in all threads or dialogues, reflective and critical perspectives arise; indeed, an analysis of postings which constitute such threads on Oz-Teachers for example, would quickly demonstrate this is not the case. But there is an increased chance that these perspectives will be found, as part of a ‘conversation’ between two or more participants, and where there is an interaction between views, understandings and ideas on a single topic or theme. Indeed, this notion characterises previous findings from research into computer conferencing (Henri, 1992; Riel & Harasim, 1994), and underpins current assumptions about appropriate models of learning, especially for professional development (Schon, 1987), and teacher education (Hatton & Smith, 1995); and also for adult learners (Laurillard, 1993).

The relative activity in each of the lists, Oz-Teachers and UK-Schools for the period of this investigation is summarised in Table 3. The activity of Oz-Teachers is considerably and consistently greater than that of UK-Schools, a difference that is not adequately explained by the discrepancy in relative memberships (more members do not necessarily mean more postings). Even when we turn to an analysis of the relative proportions of total messages that occur on each of the lists as threads, or extended dialogue, the differences remain noticeable: dialogue occurs more frequently and in greater proportions on Oz-Teachers than on UK-Schools. It is possible then, although possibly dangerous, to suggest that Oz-Teachers works better as a community of
learners within a professional development context, as a result of its heightened activities, but more importantly, because of the greater number of threads or dialogues that occur therein.

7. Conclusion

Oz-Teachers and UK-Schools are computer-mediated communities in the making, being shaped by the members of those communities. These virtual communities operate at a number of different levels—at the level of professional development, social grouping, resource and advice centre, political movement—and overarchingly as a Discourse, in the sense that Gee (1990) writes about discourse:

A Discourse is a sort of identity kit which comes complete with the appropriate costume and instructions on how to act, talk, and often write, so as to take on a particular social role that others will recognise... Discourses are ways of being in the world, or forms of life which integrate words, acts, values, beliefs, attitudes, social identities, as well as gestures, glances, body positions and clothes. (Gee, 1990 142)

The lists are both ostensibly about professional development, about teachers learning about aspects of teaching centred on the use of new technologies. But of course, they are much more than this—they operate by virtue of their membership, as communities, both in a sociological and a situated sense. Both Oz-Teachers and UK-Schools have their owners, key members (the ones most visible and active, through frequent postings), moderating influences, power-plays, politics, rules (tacit and explicit), rule-keepers, core members, peripheral members and silent (passive) members. However, although these lists operate sociologically, they are more readily identifiable as communities of situated practice. For example, both lists have the indelible mark of practising teachers—they are used by teachers to talk and share with other teachers, issues fundamentally (but not always) concerned with using new technologies in classrooms. The culture created in these lists is the culture of teachers as professionals. But the two lists also have cultures of their own, each different to the other in small yet important ways, recognisable by the practices evident within each list. First time membership of either Oz-Teachers or UK-Schools clearly involves an apprenticeship, gradually acquiring the knowledge and skills of the particular practices within the list, using strategies such as observation, participation (interaction) and role playing, and finally becoming completely enculturated within the adopted practices. So, in this sense, we find in both lists the ‘communities of practice’ that Lave and Wenger (Lave & Wenger, 1990) describe in their conceptualisation of situated cognition.

By and large, discussion and information posted to both Oz-Teachers and UK-Schools has the effect of legitimising and informing, operationally, what occurs and what doesn’t occur, in the name of technology use, and especially Internet use, in schools. In this sense the lists work well, providing useful communities within which teachers can work and play. They also function to induct teachers into the practices of computer mediated communication. In addition there are a range of postings where questions are raised regarding applications of educational technologies, from perspectives outside the immediate ‘how-to’ or ‘what-to’
pedagogical culture established in the list. This is to suggest not only that the lists provide the means for reflection and reflexive practice—many of the teachers interviewed suggested this was a strength of the lists, particularly those who were part of Oz-Teachers. In addition, however, some postings, usually those belonging to a thread, serve to reorientate the operational dialectic in the list, and establish a more critical perspective. However, these types of postings are certainly in a minority and sit somewhat uneasily amongst the majority.

There is a possibility in the use of listervs, to create vital, energetic and occasional communities for professional development activities, building curriculum and information resource libraries and facilitating informal communicative networks, serving the social, professional and personal needs of teachers. The type of lists investigated here are unmoderated, self-serving and self-censoring, and they appear to work well for a majority of the membership. Topics of postings and the willingness to engage them are decided by the membership, and both these things appear to fluctuate as the list community matures. In particular, such lists appear to generate some limited dialogue which displays elements of a critical perspective—a necessary precursor to developing serious, reflective, engagement with practices, theory and research that should accompany any professional development process.

Oz-Teachers and UK-Schools work well, for the most part, in their current form. However, there are other list formats that have been used to engender dialogue more purposefully—for example, lists have, for some time, been used as 'institutionally sanctioned spaces' as a component of undergraduate and graduate level university courses (Bakardjieva & Harasim, 1997 1121). Similarly, IT–Forum is a list which periodically publishes formal papers, specially written by leading academics in the field of instructional technology, to create a forum for discussion between members of the list and the author of the paper, over a (usually) two week period (Reiber, et al., 1997). In these contexts, dialogue is more structured and arguably provides for greater critical dialogic engagement with the texts of postings (Bakardjieva & Harasim, 1997; Harris & Wambeam, 1996). In this sense, it is reasonable to suppose that as a supplement to Oz-Teachers, one or more lists could be created that provide for more structured discourse. Certainly, this presents a promising professional development model to develop purposeful, new and virtual communities, that bridge the professional gaps that exist between traditional communities of practice.

Multimedia and Hypermedia Publishing in Computer Science: Vision and Reality

Matthias Will
Institut für Informatik, Universität Freiburg
e-mail: {ottmann,will}@informatik.uni-freiburg.de

Abstract: Taking the example of an innovative textbook on algorithm design, we illustrate the problems to be faced in scientific electronic publishing within the context of open educational environments. The issues to be considered are in particular design considerations as well as what kind of media types and document formats should be incorporated. In the main section of this paper, the textbook's production process will be reviewed, which shows that the problems to be faced are due to a lack of author support.

1 Introduction

In the last few years, especially within the context of the popularization of the World Wide Web, numerous efforts have been undertaken to distribute electronically available publications via networks. For many technical areas, where documents are produced using text processing software, it seems reasonable to not only offer scientific publications as paperbound reports, but also to make them available as online texts for quick dissemination among the scientific community. A further step is to systematically offer online publications via digital libraries, including journals, reports, textbooks and others, and to make them searchable via the scientist's network browser. While it is important to provide an appropriate framework for distributed access to heterogeneous documents and databases, it is a challenge to produce high quality innovative multimedia textbooks for open environments, which can be easily used in varying contexts and for different purposes. We will discuss some of the considerations to take by reviewing the production process of a multimedia textbook on algorithm design. While some of the issues may be specific to this publications, we demonstrate that despite the technology available today, scientific multimedia publishing is still far from its possibilities.

2 Design considerations for knowledge-mediating courseware

In conventional educational scenarios, text has always been the main medium to transfer knowledge, whether written, as in the form of textbooks, or spoken, as in classroom teaching. Therefore, we decided to focus on both static and dynamic text-centered documents, namely scientific articles, involving graphics and diagrams, and lecture recordings, enhanced by animations, simulations and video clips. In the same way that pictures serve to illustrate certain concepts, the role of additional dynamic and interactive media may be described as a support to enhance comprehension. According to this, non-static media types were used only if they were able to illustrate certain principles in a more appropriate way than conventional media, namely printed text and diagrams.

It is well-known that the visualization of dynamic processes and the computer-based modeling of scientific experiments is a challenge, which makes it desirable to be able to re-use pre-existing modules, either self-developed or third-party, by integrating them into a piece of courseware. However, this is only possible in the context of open environments which minimize the constraints on combining heterogeneous media formats. By using a modular approach, individual components may also be re-used in other contexts.

While the logical structure of a printed publication, i.e. chapters, sections and paragraphs, is hierarchical and can be visualized as a tree, the relationship between the individual parts of a multimedia product may be arbitrarily complex, thus yielding a directed graph. The former is linearized by generating the hardcopy, where the table of contents illustrates the logical structure to the reader, whose orientation is thus guaranteed. In electronic publishing, the relation between individual modules is modelled by using hyperlinks, whose main role is, in analogy, to ensure the user's orientation. Structural references result from the publication's inherent structure, while logical...
references emerge from the logical interdependencies of the individual modules. While hyperlinks may be helpful to associate specific parts of a publication, they may lead to disorientation. Graph visualization techniques, ranging from context-sensitive menus to fish-eye views [5] and three-dimensional representations [10] help the user in constructing a mental model of the structural and logical interdependencies, but as these become more complex, the user's cognitive abilities are exceeded. Therefore, we focused mainly on modelling structural links (see also section 4.4).

3 Media types and document formats

The decision to use specific media types in an electronic publication constrains the set of usable document formats, but does not determine it. As an example, the use of video clips may be in the form of QuickTime or MPEG movie files, or simulations may be implemented in C or Java. A general advice is to use platform-independent software, or document types for which appropriate viewers exist for multiple operating systems. In this section, we first propose a general classification of document formats, which is helpful in the process of document conversions. As textual documents are essential for knowledge transfer (see section 3.1), the problems in transferring documents to a suitable format for electronic publishing are exemplified for the case of static text. In the last paragraph, we discuss the issue of recording telepresentations, since they form an integral part of the multimedia textbook whose production process is described in more detail in section 4.

3.1 Primary and secondary document formats

We call media types that are directly generated as output from a specific software or typed into an editor primary formats. All other media types can be assumed to be generated by processing primary formats, or by using export filters in standard tools, e.g. PostScript or image filters. These are called secondary formats and are characterized by not being directly generated. In many cases, primary document formats are proprietary, such as Word, Excel, or PageMaker, and therefore cannot directly be created using standard editors, but require special tools, e.g. word processing software or drawing tools. As opposed to this, secondary media formats result from a conversion process from a source format to a destination format, as in the case of a LaTeX document being transferred to PostScript for printing, or a Word document being exported as a HTML file. The source format may either be primary (Word, LaTeX, XFig), or, in case of repeated post-processing, secondary, such as a PostScript document, originating from a DVI file, which is being converted to PDF.

Since an automatic conversion of large documents without manual postprocessing is not feasible, it is crucial to supply the authors with concrete guidelines on document styles and additional mark-up which may be transferred to the publication format to automatically generate navigational support, such as typed hyperlinks. This would save the producer of having to manually adjust changed references in case of source document editing. Most importantly, the individual modules should be delivered to the producer as final documents to prevent repeated manual post-processing.

It is important to note that this classification is related to the process of how a file was generated, e.g. a HTML file may be in primary format if it was directly produced by using an editor, but it may also have been created via an export filter, and thus be a secondary format.

The advantage of primary formats lies in the fact that by editing and saving a document, a current version is directly available, whereas one or more conversion steps are necessary in order to generate other formats from the current version, which may involve a loss of quality. For example, this applies to the process of converting a HTML document with logical markup into a PostScript document, which results in the logical structure of the document being lost. Furthermore, manual post-processing may be necessary in order to generate an acceptable document version in a secondary format, such as in the case of a long PDF document which is enhanced by adding bookmarks in order to ensure the reader's orientation. Thus, in theory, primary formats are preferred when compiling multimedia courseware. However, experiences from library projects, such as MEDOC [2] or LIBERATION [3], show that the available primary formats, used by authors, are mostly not suitable for digital publishing. Therefore, a conversion of documents is mandatory, which proves to be tedious and time-consuming, followed by a post-processing to account for a potential loss of quality, or to optimize the converted document.

Since an automatic conversion of large documents without manual postprocessing is not feasible, it is crucial to supply the authors with concrete guidelines on document styles and additional mark-up which may be transferred to the publication format to automatically generate navigational support, such as typed hyperlinks. This would
save the producer of having to manually adjust changed references in case of source document editing. Most importantly, the individual modules should be delivered to the producer as final documents to prevent repeated manual post-processing.

3.2 Preparing text documents for digital publishing

As we have seen, the use of textual material is crucial for any knowledge transfer. In [2], criteria for hypertext formats were developed, the most important being availability for multiple platforms, typography, cross-referencing, document structure, and navigation. Additionally, the characteristics of HTML and PDF, currently being the only suitable alternatives for text formats in digital publishing, were sketched.

While HTML is widely known as the native language of the World Wide Web and is a primary format if directly produced (e.g., by using HTML editors) in order to generate information pages, most authors use word processing software that does not directly produce HTML output. Thus, in the context of scientific publishing, it is used as a secondary format. In particular, even if an export filter producing HTML code is available, the result does not suffice for direct incorporation into multimedia publications, e.g., if complex typography (as in mathematical formulae) is needed.

The Portable Document Format [9] is usually a secondary format and thus not directly generated. Also, software offering an export filter for PDF, such as some word processors, does not offer the editing features to produce a hyperlinked document for digital publishing. Therefore, even though tools are available to edit PDF documents, manual post-processing is required in most cases to achieve a satisfying presentation, e.g., by adding navigational aids. While it is theoretically possible to post-process PDF documents using a standard editor, difficulties arise in case of updating texts, such as the adjustment of hyperlinks, which are stored as geometric coordinates rather than associated with the underlying text or graphic.

In short, we note that the primary (authoring) format of a publication is generally different from its final (secondary) format and that crucial requirements, such as hyperlinking, are not met by the tools used by authors. Therefore, serious problems arise both when converting documents which were not intended for electronic publishing, and when the authoring format differs from the publishing format, which can be assumed to be the case except for authors writing in HTML.

3.3 Lecture recording

As mentioned in 2, our aim in producing the multimedia textbook was to enhance the printed documents by recording lectures, delivered by experts on the topic of the individual chapters. However, conventional recording of educational events by using analog media (video or film) do not match well with digital media. Additionally, the enormous bandwidth required for disseminating digital video makes it a questionable option for use within the context of Internet services. Even though streaming technologies (Real Audio, Real Video) may in theory seem to open new avenues, the quality of the data streams as received by the client is in general very low, and the load imposed on the networks is tremendous.

Alternatively, a recording of commands executed at the protocol level may be performed, as done by the MBone VCR [1], which records multicast video conferences, or by the Lotus ScreenCam software, which monitors and stores sequences of Windows commands. While this kind of approach saves storage space, the recording level, is generally too low to allow for extensions of pure playback, e.g., random access of data streams. Another disadvantage is its close relation to a specific protocol, i.e., the protocol of the underlying operating system.

A solution to this is the symbolic recording of a lecture, as it was done within the context of Authoring On The Fly [6]. More specifically, the actions generated by the lecturer annotating his slides on the whiteboard are stored into an object file, which contains not only the parameters of the graphical objects, such as polygons, circles and rectangles being drawn on the whiteboard, but also the file names of the slides and the external applications being used. At the same time, an event queue is written, which associates time stamps with indices of objects stored in the object file. The time stamps can be associated with specific fragments of the audio file, containing the lecturer's speech, such that it is possible to faithfully reproduce the lecture at almost any given moment. In this sense, random access to an online lecture is made feasible. Since the lecturer's video does not add much to

1The PDF2EP3ement project (formerly TEX2PDF) offers a solution to directly transfer documents in LaTeX into fully hyperlinked PDF format. This requires to include all hypertext-specific information as macros in the source files.

2By splitting large video documents, offline retrieval may be feasible, but browsing through large document repositories results in heavy network load.
the comprehension of the lecture, besides needing a large bandwidth, a factor which is relevant for data stream transmission, or teleteaching, it was not included into the final document, but instead, a picture of the lecturer is displayed during replay. The resulting multimedia document can be integrated in various contexts, namely CD-ROM products for offline use, and local networks. In the latter case, a Web interface can be provided, where an ordered list of subtopics is automatically generated with one entry per slide change, including access to externally launched applications. Thus, random access to AOF documents can be controlled both externally, e.g. from HTML documents, and internally, via the replaying software, a technique we call visible scrolling.

4 Producing a multimedia textbook

4.1 Authors as content providers

Each chapter of the multimedia textbook consists of a scientific article, whose topic was also expanded in a lecture. The primary format for the articles was \LaTeX, which is commonly used by computer scientists. These lectures were delivered by using the MBONE tool \textit{wb} [8], which can be thought of as the computer-based equivalent of a blackboard or an overhead projector. Before giving the talk, the slides of the lecturer, which had been edited using a variety of tools, such as SliTeX, PowerPoint or Showcase, were exported into PostScript format, and the external applications were installed on the local computer, which required writing appropriate shell scripts to launch them from the computer whiteboard. In our case, external applications were either XTango animations, which had been compiled to a program executable on the lecturer's platform, or MPEG movies, which had been generated from individual screenshots or the Maple mathematics package\(^9\). The articles and animations were available both in primary and in secondary format, the former because the authors supplied us with their source files, including required style files and extensions, the latter because the animations had been developed at this institute using the XTango package [11].

4.2 From lecture delivery to its multimedia reproduction

After having loaded all the slides and optional dynamic applications, the lecture was delivered by annotating the slides while commenting on them, while being recorded using our own software. At the same time, it was also transmitted to remote locations, since the MBONE tools allowed us to use teleteaching facilities. In order to be able to do this, the slides and external applications also needed to be installed at the remote locations. Thus, only the transmission of slide changes as well as start and stop commands for the external applications was required.

The recording yielded an audio file as well as an event queue and an object file, as described in section 3.3. The slides were automatically converted to GIF picture format and stored in the same directory as the other data, in particular the scripts to launch the applications and the applications themselves. In this way, instant replay of the lecture was made possible.

4.3 Post-processing

The main task to be done, besides developing and porting the AOF viewing software and post-editing the textual documents, which is addressed in section 4.4, was to post-process individual modules, in particular editing the lectures, revising the texts and converting the documents to appropriate viewing format.

In order to process the online lectures, a custom editor had been developed [7] which allows for cutting out unwanted portions of the individual data streams involved, namely slips of the tongue or pauses in the audio stream and whiteboard actions, such as scribbles, slide selections or launching of external applications mistakenly performed by the lecturer. In order not to erase any actions performed concurrently to an undesired event, such as in the case of a drawing on the whiteboard during a word repetition, whiteboard actions could be moved in time. In other words, the audio being the most important media stream was taken as a reference, as it is known that speech, being continuous, is much more vulnerable to errors than any other data stream, such as whiteboard actions, which only occur at discrete points in time.

Revising the textual components meant not only proofreading the articles contributed by the lecturers to remove typographic and other errors and adding the modifications to the source documents, which was mostly done by

\(^9\)Any readable or executable document constrained to be dynamic would have been a candidate for inclusion as an external application to a lecture, including Java programs.
one of the authors of this paper, but also adapting the layout to the publisher's specifications. Furthermore, index
terms had to be added to the source document, which only a few authors had thought of. Several additional textual
documents were added for didactical reasons and in order to ease navigation and orientation, namely

- a short introduction introducing the topic to be discussed
- a lecture overview revealing its structure
- an overview of the applications with reference to the chapters in which they had been used
- a description of the animated algorithms
- dead end pages

In particular, we mention that, since the lecturers did not provide any structuring information for their talks, it was
necessary to guess a structure by listening to each of the lectures separately.

Last, we mention the document conversion. In order to minimize the requirements for users, it was decided to use
uniform document formats, namely PDF for texts and slides, GIF for images, MPEG and QuickTime for movies.
We chose PostScript as the intermediate format, as it was necessary to generate it anyway to send the hardcopies to
the publisher master document for the printed version of the textbook. Since modifications on the source document
were numerous, this also required going through the document conversion process several times. In this context, in
was advantageous to have the sources spread across several documents so that local modifications could be made
without affecting the complete publication.

As the animations, developed using the XTANGO package, which requires X11 libraries for execution, we would
not have been able to include them as they were for the Windows version. We solved this problem by converting
the animations to QuickTime movies. In this way, simulations could not be transferred appropriately, but on the
other hand, the effort to re-implement the simulations would not have been justified.

4.4 Document integration

With all the individual documents available in their destination format, it was now possible to structure them
into a document tree, which would then be burnt onto CD-ROM after relating the documents to each other. In
particular, this involved adding structural navigation aids to the textual documents in PDF format, such as links and bookmarks, and ensuring correct launching of the document types involved, such as AOF documents, movies and animations, generating so-called thumbnails and, finally, generating a fulltext index.

While adding cross-document references was already a tedious process, since none of the source documents
contained suitable information to generate these references automatically, e.g. by embedding pdfmark [4] into PostScript output, a major problem was to reflect changes in the sources within the post-processed PDF docu-
ments, such as adjusting links and bookmarks.

For each slide change within a lecture, a file containing a timestamp (in milliseconds) had been generated. How-
ever, while associating the overview page entries with these starting points, it was necessary to adjust these timest-
mats so upon clicking a subtopic, the lecture would start at the correct time when that topic was about to be
discussed, and with modifications to the AOF document due to post-editing, as described previously, the times-
tamp also needed adjusting.

In order to prevent the user from getting lost within the electronic document, we focused on visualizing structural
relations, namely by using context-sensitive bookmarks to ease navigation between and within chapters, and, to a
lesser extent, links, the latter mainly from the overview pages (table of contents and lecture overview). We also

---

4 As the audio data for the lectures would exceed the storage available on a single CD-ROM, two disks were needed. The access of a lecture
was constrained to the respective overview page. The overview pages for lectures not present on the storage medium was then substituted by a
document giving instructions to the user on the necessary steps to view the lecture (i.e. how to exchange the CD-ROMs).

5 Note that this procedure is more or less applicable to all conversions from an authoring format (if not HTML) to a destination format suitable
for electronic publishing (PDF or HTML), since most text formats do not permit the inclusion of hypertext features, notably hyperlinks, which
then have to be added in a post-processing stage, as described in the next section.

6 More precisely, links can either be intramodular references, meaning that source and destination anchor belong to the same module, or
extramodular references, with source and destination anchor within different modules, or the destination anchor being an entire document

7 Bookmarks are either intramodular references, meaning that source and destination anchor are equivalent to an entire module, or intramod-
ular references, where the source anchor is equivalent to the whole document

8 Thumbnails are a small representation of document pages, which may appear simultaneously with a particular document.
decided to typify the links by using different colors, representing the document types which were accessed (red and black for texts, blue for animations, cyan for simulations, and magenta for video clips. In addition, we used the PDF Notes mechanism\(^8\) to provide literature references in order to prevent the user to move to a different page or document. Also, the images contained within the contributed articles were made available as GIF image documents and linked to appropriate references to figures within the text, because a reference is often located on a different page than the picture referred to (the destination anchor), but the user may want to continue reading on the same page while viewing the image. Thus, by clicking on a reference to a picture, it is displayed externally within an image viewer, which allows for arbitrary resizing of the image. Finally, intra-document references were also made available as (extramodular) links.

4.5 Considerations for multi-platform delivery

While the overwhelming majority of computer literates own or use a Windows-based PC, a large number of computers at scientific institutions are Unix-based. Our aim was to produce a multimedia publication which would be usable in various context, in particular as a CD-ROM product, but also within local networks, such as those found at universities. Thus, our own software, in particular the tools needed to replay the online lectures, was implemented for Solaris (SunOS), IRIX (SGI), Linux, as well as for Windows95/WindowsNT. Again, an implementation in Java was discarded because, in particular, the communication between the various modules replaying the individual data streams would not have been fast enough.

Our first approach was to deliver all necessary components, including required software, animations and movies, on CD-ROM. However, this would have raised considerable problems because of the following reasons:

- most software (shareware or freeware) is only allowed for personal use, but not for commercial distribution;
- updates of the software would have required to send a new CD to all customers for the most current version;
- the supplied software would have needed to be included for all supported operating systems, thus considerably augmenting the required storage space on the CD-ROM.

Therefore, it was decided to separate all platform-independent parts, i.e. all data, which were burned on two CD-ROM disks, from the platform-dependent modules, i.e. the software. More precisely, all textual files (including the fulltext index) and the video clips are found on the CD-ROM, while the software, all simulations and animations and miscellaneous scripts to activate the data and are found in a platform-dependent ftp archive. While the former is not likely to change, except if content-related errors are found, the software is likely to undergo changes and improvements. As an additional benefit for the customer, a direct hotline to the developers (via an e-mail address and a form-based Web interface) is provided. In particular, the following advantages are noted:

- it is always possible to retrieve and use the most current versions of the software from the archives;
- risks are reduced for the publishing house, since it is not liable for modules which are not distributed with the publication;
- software bugs encountered by the customers can quickly be eliminated and any other modifications or improvements result in a new version offered to the customer;
- other platforms may be supported in the future without affecting the CD-ROM shipped with the publication.

Although the required installation steps may seem unusual, we assume that most of the users will be computer science students who usually have easy access to Internet services via their respective institutions, and are thus able to retrieve the necessary archive and are knowledgeable enough to perform the necessary tasks to use the electronic version of the publication.

With a few simple modifications, it is also possible to configure the publication to be executable in local networks. In this case, the required software as well as the data for the online lectures resides in shared directories, while all textual documents and the destination anchors of the references to external applications are stored within a Web server. Thus, the transfer of the non-static media is executed via the local network protocol, e.g. NFS, while the static media are transferred via the hypertext transfer protocol.

\(^8\)Notes are visualized as small icons on top of a document page, which are opened as small windows containing arbitrary text by a mouse click
5 Conclusion and future work

We have shown in this paper that a carefully developed multimedia publication is more than just a combination of several media types. In particular, we see the role of new media in education as a complement to conventional educational scenarios, which are based on text and audio. These seem to be crucial for knowledge dissemination, and therefore any other media types are considered to be an optional supplement. On the other hand, considerations for electronic publishing have to be seen in the context of open environments: even if most end users are assumed to work on a PC, this is not the case at universities, where different platforms and operating systems are found. Another issue is re-usability of existing components and publicly available documents and applications in heterogeneous formats. Thus, the effort of integrating individual components should not be overlooked.

The experiences gained here show that powerful and easy-to-use authoring tools for the development of high-quality courseware to support university teaching are still missing when considering open environments. Therefore, we are investigating the possibilities of multimedia authoring with the goal to embed all information relevant to the publication into the source documents, in order to avoid tedious post-processing. Another issue is the possibility of active manipulation and customization of existing courseware, e.g. by providing suitable annotation mechanisms for generic document formats. These efforts are geared towards the development of widely acceptable tools, supporting authors, lecturers and students.

Abstract: Distance Learning programs tend to be thought of as alternatives or replacements for traditional classroom or laboratory-based instruction. We are exploring a third use of distance learning capabilities—to augment and amplify the learning opportunities for part-time graduate students. Many graduate students in George Mason's programs converge on one of the campuses for brief periodic interactions with the instructor and peer classmates. Between these synchronous interactions, the class Web site supports:

- ongoing asynchronous small group interactions with the professor, peer groups, and other scientists through online discussion groups, email and listserv facilities;
- hypermedia presentations on key concepts, developed for (and often by) the class, and available online for review or correlation to lecture notes;
- imaging and audio interactions offering advanced representations of molecular structures, using tools that provide a dynamic and easily updated capability beyond material available in the text.

Introduction

Students of modern biochemistry today find themselves in what is at once a very exciting and a very challenging situation. Our knowledge of biochemical systems is increasing exponentially, as the research tools applied in this area become more powerful and more laboratories address biochemical questions in an increasing number of areas. An important driving force for this rapid expansion of knowledge is the advent of an expanding biotechnology industry, in which detailed knowledge of biochemical processes allows the practical application of this information in ways literally unimaginable only a few years ago. That's the good news. The bad news is that students often find themselves overwhelmed with the volume of information with which they are confronted, and are often at a loss when trying to make sense of it all.

Objective

To provide students a means of visualizing the molecular aspects of Life's chemistries while pursuing and acquiring an intuitive understanding of the complex, interactive dynamic systems, upon which all life forms are based.

Background

Biotechnology, as an industry, requires a work force well trained in the cellular and molecular biosciences. Individuals seeking professional careers in the biosciences need to understand the molecular basis of their science and the tools employed in its pursuit. The impact of knowledge arising from completion of the "Human Genome
Project in a wide array of academic and commercial applications will increase the need for individuals to understand the “Chemistry of Life.” A fundamental understanding of Science is now a critical element in the education of all members of our Society. Advances in the molecular and cellular biosciences have and will produce knowledge, the use of which, will impact individuals in all walks of life. A means of capturing and presenting concepts from the molecular biosciences in a manner useful to students at various levels of preparedness is essential. As course work in Biochemistry is expected to provide the basis for an understanding of life at the molecular level, it serves as an ideal setting for developing enhancements to student acquisition of these concepts.

We are employing multimedia approaches in our one year graduate course in Biochemistry at George Mason University, with the end product sought being a fully web-based course. A major theme of the course is the relationship between molecular structure and biological function.

The Internet allows students to access biochemistry information soon after it is made available to the scientific public. This rapid access to new knowledge is unprecedented, and is rapidly changing the way biotechnologists do their work every day. The students receive training in ways to use tools and methods that will allow them to access and analyze this information in an efficient and effective manner. An essential feature of this course is the use of World Wide Web Browsers coupled to Molecular Modeling and Display software on assignments designed to illustrate practical problems and tasks that arise in applied biotechnology. Information describing these relationships were once located only in books and journals located in research libraries. Today much of this information resides on host computers connected to the Internet. Students use Web Browsers connected to Molecular Modeling and Display software to locate and analyze molecular structures of important biochemical systems currently under investigation worldwide. This permits us to design a system that provides "just-in-time", "just-in-case" and "just-for-you" solutions for the students.

While the fundamentals underlying any textual presentation in Biochemistry are relatively stable, advances in knowledge and technologies associated with this field are remarkably rapid. Establishing pointers to ongoing research through our web based instructional platform, allows students to fully appreciate this dynamic. It also serves to tie the materials learned in the class setting to real world activities of the moment. The capacity to "see" molecules in a variety of representations, enhances students' abilities to comprehend "structure/function" relationships, especially for the higher order macromolecular assemblages encountered in discussions of Proteins and Nucleic acids and their roles in biological systems.

Nature of the Students Served:

The class composition is made up largely of part time graduate students who are employed full time. These students are mature, and come to the course from a variety of disciplines. Graduate students from the Departments of Biology and Chemistry, and the Computational Sciences and Informatics Institute utilize this course as part of their formal course requirements. Thus, backgrounds are not uniform. This lack of uniformity is addressed through the web site by incorporating pointers to information resources that can both remediate and amplify a student's knowledge in a particular subject domain. Thus students with weak background in chemistry are given pointers to sites of information appropriate to their needs, while students seeking additional information or depth in a topic are pointed to sites of information that meet this opportunity. Given the enhanced role of Bioinformatics in modern biology and biochemistry, additional instruction in the applications of computer-based search, retrieval and computational tools are incorporated as well. This also provides a means of instruction through "doing" that increases the opportunities for students to explore structure function relationships across a wide range of biological and biochemical processes and highlights at the molecular level the concept of "Unity in Diversity" so fundamental to all of Life's forms.

Instructional Advantage:

The course Web site (http://www.america-tomorrow.com/gmu/biochem) is maintained on a commercial server that is available 24 hours a day, 365 days a year. The Web site contains objectives and syllabus for the course, presentations used to augment the text, and student-provided pages dealing with current event topics dealing with
Biochemistry, Molecular Biology, and Molecular Genetics. These pages contain links to news items, plus links to background information on research sites dealing with the news topic. For example, news reports on the Pfisteria attacks on fish in the Chesapeake tributaries are linked to the N.C. State University Research reports that identified Pfisteria piscicida and its unique capabilities to transform into 24 flagellated, amoeboid, and encysted stages or forms. (http://www2.ncsu.edu/unity/lockers/project/aquatic_botany/pfiest.html)

Use of the Internet in class for example, allows capture of detailed, high level information on a subject in response to a question, in a fashion impossible via other means. One can also, move to sites of information appropriate to remediation of background preparation on site and in real time as well. In all cases, having the capacity to present, especially the molecular concepts, in a manner that is easily perceived is a marked learning enhancement for the students. Now, one can see, in color, a molecular representation, that before these technological advances, required of students, a capacity to mentally construct their own “abstract 3D” representations...a skill not shared by many.

Asynchronous communication among groups of students and the instructor is supported with a “List Serve” and extensive use of e-mail for one-on-one communication, and a class discussion forum implemented on the George Mason University “Town Hall” bulletin board system (an application of the Lundeen Corporation “Web Crossing” software). Group student projects are facilitated by the use of private Chat rooms that allow synchronous communication. Given that most students do not reside on campus and work schedules do not permit extensive face-to-face time, the Chat sessions permit the students to “get together” at any time to discuss project direction and status. We have used private rooms in the Talk/Excite public facility as well as the more limited Chat capability of the University server. Capturing Chat sessions provides a built in documentation that is helpful to the instructional staff in following the development of the project. This facilitates tailoring of instruction, discussion and information retrieval and presentation to individual student’s needs.

Student projects are greatly improved through this approach, both due enhanced input and interaction between the student and the instructor during the project’s design, and also in terms of the multiple avenues now open to
the student for the project's presentation. Every effort is made to move the students toward use of a web based presentation. The electronic linkage of students allows collaborative projects among students whose free time is extremely limited and thus would otherwise be unable to perform projects in a team fashion.

The students also have the opportunity to develop mentor-mentee relationships with more experienced peers, full-time and adjunct professional staff, and expert guests who appear in the departmental seminar series.

Visualizing Metabolism:

One objective of the full year course is the acquisition by the students of an "intuitive" understanding of life processes at the molecular level. In effect, a "visualization" on the part of the student of metabolic processes both structural and informational. The multiplex of information and the hierarchy of linkages between information sets that comprise metabolism in all its forms is now accessible in a fashion that provides a marked enhancement to student learning. Database coupling and linkage produced as a result of the Human Genome Project, allows pursuit of integrative concepts in Biochemistry in a fashion never before possible. The course seeks to utilize these databases and the computational tools generated for their perusal in aiding the student's acquisition of an intuitive grasp of the molecular dynamics of cellular function. It is here that hypermedia presentations become most useful and appropriate. This feature of the course also provides the greatest opportunity for "learning by doing." It also lends itself to team approaches to projects involving complex higher level biological functions and attempts at understanding these phenomena at the molecular level.

The course has been designed to introduce students to the basic fundamentals of biochemistry. Emphasis is placed upon topics and approaches that are of most practical use to students working in various areas of biotechnology.

A major recurring theme of the course is the relationship between molecular structure and biological function. Many important examples of these relationships are given in the textbook for this course. Much more current information exists within databases and other files on host computers all over the world. The advent of the Internet allows biochemistry students to access this information soon after it is made available to the scientific public. This rapid access to new knowledge is unprecedented, and is rapidly changing the way biotechnologists do their work every day. The students receive training in ways to use tools and methods that will allow them to access and analyze this information in an efficient and effective manner. An essential feature of this course is the use of World Wide Web Browsers coupled to Molecular Modeling and Display software on assignments designed to illustrate practical problems and tasks that arise in applied biotechnology.

Information describing these relationships were once located only in books and journals located in research libraries. Today much of this information resides on host computers connected to the Internet. Students use WWW Browsers connected to Molecular Modeling and Display software to locate and analyze molecular structures of important biochemical systems currently under investigation worldwide.

Using viewing Tools

Software tools are available to allow biotechnologists to examine details of biomolecular structures. Some of these are commercial products that require very powerful graphics computer workstations. The current versions of Mac and PC computers however have sufficiently powerful hardware and operating systems so that public domain or shareware programs can provide every student with tools quite adequate for learning the important fundamentals of biomolecular structure. Several of these will be provided for students in this course. These include:

Molecular Imaging Software:

- RasMol a program for viewing structures whose coordinates have been presented in "PDB" format. Structures may be viewed at various levels of detail and abstraction.
- Chemscape Chime a "plugin" for Netscape and other Web browsers that allow you to view and manipulate Protein Data Bank and other molecular models directly from a Web page.
• **MAGE**, a program for viewing images and playing Kinemage Script files. This program and the script language which direct it was developed by David Richardson at Duke University. The journal *Protein Science* makes extensive use of this image analysis software.

![Image of the Tryptophan Amino Acid Molecule](image)

**Figure 2: Chime Image Views of the Tryptophan Amino Acid Molecule**

**Database Browsing and Querying Software:**

- **3DB Browser**, a program for convenient selection of Protein and Nucleic Acid structures deposited in the Protein Data Bank.
- **Klotho** is a useful Biochemical Compounds Declarative Database.
- The European Bioinformatics Institute is a source of both nucleotide and protein (SWISS-PROT, a protein sequence database) Databases and related software.

**Summary**

Multimedia technologies allow compilation and presentation of subject matters in biochemistry in a highly flexible and rapid fashion. This provides the instructor with a ready means of capturing both new and remedial materials on an as-needed or available basis. In combination, these capabilities provide a means of tailoring instruction to the individual needs of class members. It also provides a mechanism for capture and distribution of knowledge and insights of the class participants.

Given the importance of computer-based technologies in all aspects of modern biosciences, both theoretical and applied, a knowledge of these tools and the value of their application becomes basic to a student’s education in the cellular and molecular biosciences. Bioinformatics is now an integral element within these areas of study. Our course design and its formulation and presentation as a Web site is intended to both take advantage of and force the students use of, the concepts and tools associated with this evolving discipline.

Expressiveness and Multimedia Interface Design

David M. L. Williams, Vocalis Ltd, Cambridge, UK.
david.williams@vocalis.com

James L. Alty, LUTCH1 Research Centre, Dept. of Computer Studies, Loughborough University,
Loughborough, UK, j.alty@lboro.ac.uk

Abstract: Current issues in multimedia interface design are examined and a lack of a proper methodology for such design identified. The concept of media expressiveness is defined and an approach is developed which uses the task-user model-expressiveness triptych to inform on the design process.

1. Introduction

In order to communicate information effectively, the information must be intelligently organised so that the meaning of the stored information can be readily extracted, and the interface to the information must be effective and tailored to the needs and capabilities of the desired audience. Both are needed, because well organised information presented badly, is not likely to be understood, and the excellent presentation of poorly organised information will only emphasise the poor quality of the stored information. Modern data base organisation techniques preserve essential information relationships. Effective presentation, it is claimed, can be achieved through the use of multiple media. This paper will examine how multimedia techniques might actually achieve the latter.

2. Terminology

As soon as one begins to discuss multimedia issues, problems of terminology occur. What do the terms media, channel, and multimedia actually mean? This question is far from pedantic since inconsistent definitions can, and have, caused confusion. A number of authors have identified this as a major stumbling block in multimedia research [Arens 91], [Stenning 94] and there have been a number of attempts to define a consistent terminology set [Nigay & Coutaz 93], [Arens et al 93], [Frolich 91]. As yet there is no agreed terminology so in this paper we will adopt the following:

medium: representational system with a distinct syntax, semantics and pragmatics, (e.g. graph).
expressiveness: an emergent property of a medium - how much information it can carry;
multimedia: communicating simultaneously using a number of different media;
modality: a human sense, e.g. aural, visual;
multi-modal: stimulates more than one human sense, e.g. visual and aural.

3. Why might Multimedia Interfaces Improve Presentation?

There have been a wide variety of claims about what multimedia interfaces can offer to the interface designer. Some claims are:

- Increased information bandwidth: The variety of media which are available allow the allocation of information to multiple visual and auditory channels. This increase is described as increased information bandwidth.
- Improved 'attention getting': The new media provide unusual representations of information, useful in environments where obtaining a user’s attention is essential, e.g. control rooms.
- Increased realism: The use of realistic media such as still/moving video allows the interface designer to represent real-world situations directly and effectively.
Advances in technology have not been matched by parallel developments in a supporting design methodology, so the use of media in interface design is still problematic and uninformed. With more media choice, the risk of selecting an inappropriate medium has greatly increased.

Research in a variety of fields from social science to computer science has identified important ingredients for the development of a multimedia design methodology. Whilst some are not computer-based, in every case the goal of effective communication is paramount. There has been work concerned with goal and task descriptions for interactive and didactic systems [Casner 91], [Maybury 93], [Alty et al 93], data descriptions [Roth & Mattis 90], [Mackinlay 86], [Arens et al 93], automatic presentation design [Casner 91], [Mackinlay 86], perceptual characteristics of users [Casner 91], characteristics of media [Bertin 83], [Alty & Rijkaert 93], [Lohse 90], hardware constraints [Alty & McCartney 91], terminology [Frolich 92], [Arens & Hovy 93], [Nigay & Coutaz 92], demonstrates the multi-disciplinary nature of multimedia research, each group having its own motivations and goals. In [Fig 1] we suggest a three-dimensional framework for analysing multimedia research issues. The dimensions (together with their extremal values) are:

- Design (features --> benefits) What are the main motivations for design?
- Implementation (conceptual --> practical) How important is implementation?
- Interpretation (consumption --> cognition) How important is cognition in media selection?

4.1 Design: Features --> Benefits

So often, in highly technology driven application areas, the situation is characterised by solutions looking for problems. [Alty et al 92] stressed the need to separate technological features from user interface benefits pointing out that the latter should dominate interface design, and [Mayes 92] has commented, “Multimedia systems are not primarily defined by their data-structures, but by the nature of their communication”. An example of innovative technology not driven by user benefit analysis was the Bell Lab Video-phone. A lack of clear user need, probably caused the product to fail.

At the opposite end of the design dimension are investigations which add value to the interface design process. These approaches assume the existence of an adequate technology-base, and so focus on issues which would normally come later in the design process. It is only by addressing these issues, that the technologies can be integrated into a design rationale which considers both users cognitive characteristics and the nature of their tasks. The characterisation by [Alty et al 93] provides a useful basis for measuring this dimension (features to benefits).

4.2 Implementation: Conceptual --> Practical

This second dimension addresses the division between theoretical expositions and implementations, which may be prototypes or products. The conceptual work is related to issues of representation [Arens & Hovy 91], terminology [Frolich 92], [Nigay & Coutaz 95], and task
descriptions [Alty & Rijkaert 93], with no discussion of enabling technologies. What makes such discussions necessary is the lack of theoretical underpinning which accompanies the majority of multimedia interface design methodologies. In this case the central issues are the cognitive capabilities of users and the conceptual description of tasks. However, a higher percentage of research is carried out with a view to implementing systems. This covers automatic media allocation, automatic dialogue design and ‘widget’ selection, and modelling of multimedia interaction.

4.3 Interpretation : Consumption --> Cognition

This final dimension is based on a distinction made by [Stenning 95], who suggested the separation between work on information presentation research [Mackinlay 86], [Roth & Mathis 90] and that concerned with the cognitive effects of different representation methods. Stenning points out that in information presentation research, “All of these (authors above) are concerned with improving the consumption of information. However, there is very little theory which underlies the choice of design and spans a wide range of information expressions”. By ‘consumption’, Stenning means the transfer of deterministic domain data to the viewer or consumer.

The design of ‘Management Information Systems’ inspired early work in this consumption approach. Most of this research compares tabular to graphical methods which became readily available with the development of cheap displays. One basic question is how best to present the data to the decision maker. Most studies made the assumption that graphical methods such as functional graphs and bar charts were inherently better in the support of decision making. However, as [Pearce 83] pointed out, “Many extraordinary and unsubstantiated claims are made about the educational potential of computer generated Cartesian graphs.”. The assumption that mappings are independent of task and user have not been validated.

[Mackinlay 86] showed that a horizontal axis could be used to encode single variable values, and provided a notation to explain how. Such systems are concerned with representing information so as to aid managers in decision making. The emphasis is on quantitative measures of the use of standard media (e.g. charts and tables) in decision making, rather than investigating the cognitive explanations behind these performance differences. The focus is on consumption.

The other extreme of the dimension is a focus on cognition, and investigates the efficacy of representations in conveying information with respect to their congruence (or not) with cognitive processes such as human memory [Stenning & Levy 88]. A key issue is how knowledge of cognitive effects of media can be used to support media selection. This goes deeper than allocating media on the strengths of their form alone, as suggested by [Arens et al 93] and [Alty & Rijkaert 93]. Form is important, but only in the context of the cognitive and task landscape of the interaction.

4.4 Use of the Framework.

Generally speaking, approaches near the origin of the framework are less likely to succeed in the long term. For example, one might argue that the Bell Video Phone was Consumption rather than Cognition (Features rather than Benefits, Practical rather than Conceptual). Many interface design approaches are concentrated at the Features/Consumption end of the spectrum.

Much current research from the top end quadrant of the Framework approaches the problem of interface design using a top-down design approach. What distinguishes these approaches is their a priori analysis of many of the user/interface/domain tripartite issues of interaction. A number of authors see the main problem of providing multimedia representation as the adequate representation of domain data, which is achieved by providing a formal definition of domain data types. Database theory provides a rich basis for this classification and a number of data taxonomies have been suggested. [Arens & Hovy 93], [Arens, 91] provide a comprehensive taxonomy of data types from the perspective of single values and types. At this stage, the world knowledge is used to suggest that the data is required for the solution of some specific problem. Knowledge is classified in three ways at varying levels of abstraction, from individual values through to characteristics of types, and the density of these values in the world. An example of such a taxonomy is a photograph. Arens and Hovy view the photograph as a collection of points which have infinite dimensionally (intensity), are permanent, vary continuously, and are densely populated. This description is intended to help the interface designer match the photographic
medium to some interface world. Ideally this world would be populated by densely packed points which took on values which varied continuously. The method lacks a description of how data is to be used. Data has its own properties, e.g. density, which can affect which media should be chosen, and medium selection should allow for this.

[Roth & Hefley 93] make the traditional distinction between data types such as nominal, ordinal and quantitative and the meta-dimensions such as co-ordinate and amount. Unlike Arens and Hovy, Roth and Hefley describe relationships within their data framework, such as binary and complex ternary relations. They also suggest the use of intra-data element, meta-information, to allow aggregation and partitioning along some dimension. A third view of data characterisation is provided by [Alty 94]. His data types are nominal, ordinal and quantitative but the work offers a different perspective on building up complex data elements. Knowledge is treated in an object oriented way using data objects and inheritance. Three levels of data are defined, primitive elements e.g. temperature, derived e.g. density and complex elements e.g. co-ordinates \( \{x, y, z\} \). These are further described in terms of Name, Type, Cardinality, Range, etc. The description provides a robust description of data, but struggles with complex structures such as a photograph.

When a representation of the domain has been achieved, designers then need a rationale for mapping domain knowledge to particular output media. The APT system [Mackinlay 86] is based on the ability of media to present a given domain effectively and expressively. He defines Expressiveness as the ability of a graphical language to present a relational type with its associated source and target domains (in other words can the output medium represent the data or not?). Effectiveness, on the other hand, is the ability of a graphical language to encode all the members of the data set so that information processing can take place efficiently. Other techniques have tagged media with inherent qualities e.g. graphs and trending [Alty 94]. Some workers have tried to isolate variables such as user education, experience and personality, medium characteristics, and task dependent variables [Jarvenpaa 89, but the number of possible variables is large.

5. Multiple Media and Problem Solving

Most people use computers to solve problems. Indeed one might argue that Human Computer Interaction is mainly concerned with the “design of artefacts to provide new human problem solving strengths in computer mediated domains” [Williams 96]. The representation of the artefact through the interface presents the problem-solving space, and supports navigation through this space to allow the user to achieve tasks. The relationship between problem representation and the user’s cognitive apparatus is an important part of this process.

But how can appropriate media provide new problem solving strengths? To answer this question, human problem solving must be discussed with the emphasis on the effect representation has on the support of this activity. In fact there are two representations we have to be concerned about - the domain and the interface. The domain representation within the computer is important but we will concentrate upon the interface representation. The new application area of “scientific visualisation” is an implicit statement about the important role of media in an interface, and visualisation workers are coming to similar conclusions to our own. In a recent panel at ACM SIGCHI’96 [Gershon et al 96], experts in visualisation argued over the state of the art and visualisation of hyper-spaces in particular. They concluded - “There is a need for a definition of task semantics in order to inform the choice of visualisation. For example, in hyperspace visualisation, the focus should be on the meaning of information, rather than on the structure of the network representation, i.e. visualising nodes and links”. They also emphasised the need for a more systematic evaluation of different visualisations.

So, visualisation literature is reporting the same malady as the multimedia literature –a focus on new visualisation technologies and algorithms rather than justification for their use in terms of tasks. (Features rather than Benefits). The lack of formal descriptions of available representations is in evidence. Also, no consideration is given to the role cognitive structures play in the task solutions, and how these will be affected by different representations (Consumption rather than Cognition). A key issue in this higher-level matching process is the notion of abstraction. This describes the amount of encapsulation of domain information into some higher form capturing commonalities between constituents. As an example, consider understanding the executing of concurrent and distributed programs. They can only be understood by abstracting over different aspects of the program’s behaviour and structure. [Tab 1] below illustrates the abstraction range of which could be utilised. Each level points to a particular type of task which requires a specific
abstraction level. Efficient problem solving is achieved by matching abstraction level with task type.

Clearly, the dominant principle should be a matching of the abstraction level with the requirements of the task. In the right circumstances higher levels of abstraction reduce the operational state space and support effective task performance.

- **Direct Representation**: map program elements directly to an image
- **Structural Representation**: conceal/encapsulate program information
- **Synthesised Representation**: display derived information which is not actually in the program
- **Analytical Representation**: focus on correctness and completeness properties of the program
- **Explanatory Representation**: an "aesthetically pleasing" narrative description of program behaviour.

Table 1: Levels of Abstraction and Problem Solving

When solving problems, it is reasonable to assume that users hold some form of internal representation in their head. The correct choice of abstraction level (and hence medium) must match up with the user's internal model. Since user cognition internalises the external interface representation, so multimedia interface design should focus upon the cognitive effects of different media. As [Mayes 92], asks "will the user's mental model be improved by a more realistic or dynamic representation?". The design solution therefore lies in relating the interaction triptych of task—external representation—internal representation to media allocation. How do different media encode information? How are different mental models induced by different media?

6. So what is “Expressiveness”?

The process of abstraction is concerned with the coalescing of domain states into larger chunks, thereby reducing the complexity of the search problem [Williams et al 96]. Some media readily afford this process, others do not. The representation of button icons for activating features in WORD cannot be readily abstracted, whereas points displayed in a graph can be abstracted to higher levels such as clustering or trends. We therefore relate expressiveness to this higher level abstracting ability. A medium which supports many levels of abstraction is "highly expressive". However, the appropriate level of abstraction needed to support user problem solving will depend upon the experience and expertise of the user. Thus the trick, in allocating media effectively, is to match the expressive requirement of the user with the maximum expressiveness of the medium. We say “maximum expressiveness” because too expressive a medium could inhibit the problem solving process. People find graphs useful because they are at the right level of expressiveness for many problems. A more expressive medium would be natural language, but the description of a graph in natural language usually is less useful than the graphical form, which is less expressive.

In summary, the multimedia interface designer must take into account all three aspects task, user abstraction need, and media expressiveness, when allocating media, and the expressiveness level chosen should be that which best fits the user's current mental model. Media should then be chosen which can deliver that level of expressiveness but not more than needed. We are currently carrying out experiments to check the effect of media, using different levels of expressiveness, on users' mental models. Early results indicate that expressiveness does induce the expected user models and that in more complex situations the more expressive media, the better they support problem solving.

Abstract: A nagging problem concerning school-based learning is the difficulty many students experience in applying what they have learned to everyday situations. Problem-based learning (PBL) emphasizes solving authentic problems in authentic contexts and has been shown to be an effective instructional method. Though literature supports the efficacy of problem-based learning and the benefits of problem-based learning are obvious, little research exists which investigates the types of tools or features that are effective in supporting students working in PBL environments. This study examines how middle school students use and interact with a computer-supported PBL environment.

1. Research Framework

Historically, schools have attempted to teach the content and skills essential for individuals to function in society. Since the Industrial Revolution schools have emphasized the learning of basic skills. Yet today it is clear that this type learning is not enough. More jobs than ever require problem solving and critical thinking. Dewey [Dewey 1938] argued that intelligence is the ability to clarify a goal and develop a plan for its attainment. Authentic learning environments such as problem-based learning embody this in its problem definition and resolution.

With the shift from a behavioral to a cognitive perspective of learning, researchers have become increasingly interested in cognitive processes and their effect on the construction of knowledge [Driscoll 1994]. Many cognitive psychologists and constructivists believe that learning cannot be separated from the learning activity and context [Bednar, Cunningham, Duffy, & Perry 1992].

A nagging problem concerning school-based learning is the difficulty many students experience in applying what they have learned to everyday situations. Many schools are concerned with the transfer of abstract, decontextualized concepts where knowledge is viewed as a discrete object residing outside of the individual [Brown, Collins, & Duguid 1989]. Increasing amounts of research indicate that the inability of students to apply concepts learned in formal contexts is due to the abstraction and decontextualization of learning [Cognition and Technology Group at Vanderbilt 1992]. Spiro and Jehng [Spiro & Jehng 1990] argue that the decontextualization of knowledge creates inflexible understandings. But it is not the abstraction of knowledge as such that distracts learners, but that the abstractions are not illuminated with examples in context. Understanding is a product of the context and activity [McLellan 1993].

Context provides a framework which guides and supports the learner. The context naturally structures knowledge in a way that suggests its proper use. Traditional instructional design attempts to simplify learning by dividing the content into components and teaching them separately. Situated cognition argues that learning is simplified by embedding concepts in the context in which they will be used [Brown &
Duguid 1993]. The context provides the much needed support when working at the edge of one's ability. Yet authentic context alone is not enough to support student learning. Situated cognition argues that learners must engage in authentic tasks as well [Winn 1993]. Authentic activities are the ordinary practices of the experts in that domain [Brown et al. 1989]. The learning activity is an integral part of what is learned. An activity in which all domains engage is the solving of problems. Experts utilize tools to support problem-solving in context. Active use of a culture’s tools provide learners the opportunity to view knowledge from the experts’ perspective [Brown et al. 1989]. Active learning in the context of a domain’s culture allows the gradual “fleshing out” of concepts over time. Each use of a concept or tool will further develop the learners' understanding.

There has been a growing body of research on authentic and situated learning environments utilizing the problem-based approach to learning [Spiro & Jehng 1990]. Problem-based learning (PBL) emphasizes solving authentic problems in authentic contexts. It is an approach where students are given a problem, replete with all the complexities typically found in real world situations, and work collaboratively to develop a solution. Problem-based learning provides students an opportunity to develop skills in problem definition and problem solving, to reflect on their own learning, and develop a deep understanding of the content domain [Lajoie 1993] [Jacobson & Spiro 1995]. This approach was developed in the fifties for medical education, and has since been used in various subject areas such as business, law, education, architecture and engineering. Most recently, there is a growing interest among educators to use problem-based learning in the K-12 setting, and a growing need for problem-based educational software to facilitate the development of higher order thinking skills via technology.

Though literature supports the efficacy of problem-based learning and the benefits of problem-based learning are obvious, little research exists which investigates the types of tools or features that are effective in supporting students working in PBL environments. In order to design an effective computer-supported PBL learning environment, it is important to understand the tools and design features included in the software, and their impact on learning. It is, therefore, the purpose of this study to examine and understand how middle school students use and interact with a recently available computer-supported PBL environment developed by a major publishing company.

2. Research Questions

This study investigates the use of tools and design features as employed in a problem-based learning environment and their effectiveness on middle school students’ learning of science concepts. Specifically, the study asked the following questions: (1) What is the effect of the computer-supported problem-based learning environment on the achievement of middle school science students?, (2) What is the effect of the computer supported problem-based learning environment on the middle school students’ attitudes toward science?, (3) Is there a relationship between students’ math or reading ability and their achievement in the problem-based learning environment?

3. Design of Study

3.1 Sample

The participants of the study (N = 115) were students enrolled in seventh grade science at a middle school located in a medium-sized city in the southwestern United States. The school has a high percentage of minority students. The participants in the study consisted of 66% Hispanic Americans (N=76), 12% African Americans (N=14) and 22% white (N=25). The age of the students ranged from 12 - 14 years. Of the participants in the study, 50 were male and 65 female.

3.2 Treatment
The treatment consisted of three groups: computer-supported PBL environment, paper-based PBL, and a control group. Students from three intact classes were randomly assigned to each of the conditions described below. Because the treatment was included as a part of the regular science classes, complete random assignment was not possible in this case. There were 59 students in the computer-supported PBL environment, 38 in the paper-based PBL, and 18 in the control group.

3.2.1 Computer-Supported PBL

The computer-supported PBL group used problem-based learning software recently developed by Holt, Rinehart and Winston Publishing Company. The CD-ROM-based program contains eight activities on different topics developed to support the middle school science curriculum. Upon starting the PBL application the students find themselves in a virtual science laboratory. Immediately on entering the laboratory a short video segment plays in which a scientist provides important details about a scientific problem she is working on and solicits the students' help in developing a solution. The activity used in this study is concerned with the classification of a microorganism and was selected because it was related to the topic being studied in the classes participating.

The students are supported in finding a solution to the problem by the availability of tools in the virtual laboratory. An expert scientist built into the virtual laboratory provides information about the scenario and takes on the role of a mentor in which she provides hints and feedback during the activity. The inbox provides a printed version of the problem scenario thereby supporting students in defining the problem. A lab manual provides important information on the use and importance of the tools found in the lab. The lab also furnishes a computer database which contains information that is essential for solving the problem. A notepad is also provided to support students in note taking during the activity. Most students are able to complete the activity in approximately forty-five minutes.

3.2.2 Paper-based PBL

Other students worked through a problem-solving activity, equivalent in content and available resources to the computer-based software, except that the information given (including the information in the database and the pictures) was print-based. Though identical in the resources provided, the computer and the paper-based PBL are different in that (1) the computer-based version allows interactive access of information while the paper-based does not, and (2) the computer-based version provides information in multimedia format while the paper-based does not.

3.2.3 Control Group

A third class was included as a control group. Students in this class learned the same content on microorganisms using the traditional approach (mostly lecture-based).

3.3 Dependent Measures

There are three dependent measures in the study: (1) achievement, (2) degree and frequency of access to the tools/features, and (3) attitude toward learning science. Students' knowledge about microorganisms was assessed through a pretest and a posttest. Their use of the tools and various design features in the computer version was recorded. Their attitudes toward science were evaluated through a questionnaire entitled "Attitude Toward Science in School Assessment." This attitude questionnaire addresses students' feelings about science as a subject and consists of 14 Likert scale items, with a reported reliability of .95 [Germann 1988]. In addition, the students in both the computer and paper groups were asked to record
3.4 Procedures and Analyses

Each of the 5 classes involved in this study was assigned randomly to one of the treatment conditions. For students in the computer and paper PBL groups, the entire treatment consisted of two phases. First, the teacher modeled the problem-solving process using another activity from the computer software (for the paper group, the information was presented through paper and pencil). Then the students were divided into groups of four or five and asked to work through the activity on microorganisms collaboratively. Literature on PBL shows that providing necessary scaffolding is a critical step in making PBL successful. The purpose of this teacher modeling phase was to introduce students to the steps of problem solving and provide them with guided practice. This phase was included in both the computer-supported and paper-based environments because we felt that the modeling should be part of problem solving regardless of the media involved and our primary interest in this study was to find out if the hypermedia environment could provide additional support for the students. Therefore, the instruction of the two conditions were held to be same. The control group worked through the regular instruction on microorganisms with no intervention.

In order to answer the first research question, "What is the effect of the computer-supported problem-based learning environment on the achievement of middle school science students?" a two-factor mixed ANOVA was run with the grouping (computer, paper and control) as a between-subjects independent variable, and the data collection points (pre vs. post) as the repeated measure independent variable. The dependent variable was the pre and post achievement scores in the science content test.

In order to answer the second research question, "What is the effect of the computer supported problem-based learning environment on the middle school students' attitudes toward science?" a two-factor mixed ANOVA was run with the grouping (computer, paper and control) as a between-subjects independent variable, and the data collection points (pre vs. post) as the repeated measure independent variable. The dependent variable was the pre and post scores for the attitude questionnaire.

In order to answer the third research question, "Is there a relationship between students' math or reading ability to their achievement in the problem-based learning environment?" a multiple regression was run with students' math and reading ability, measured by their most recent Texas Assessment of Academic Skills (TAAS) as the independent variables and their achievement test as the dependent variable.

In addition, students' use of tools in the hypermedia environment and the problem solving steps students taken in the computer and paper groups were analyzed descriptively. Students were selected for the post interviews after they completed the study. The purpose of the interviews was to find out (1) what the students liked and disliked about the environment; (2) what they found most useful in the environment; (3) what they thought about the process in general. Interviews were included as part of the data sources in order to provide more information on the study and substantiate the quantitative analyses. The interview data will be analyzed according to Miles and Huberman's framework of qualitative data analysis [Miles & Huberman 1994]. Such descriptive analyses and the findings from the qualitative data are being conducted at this point and will be added to the conference presentation.

4. Results and Discussion

The results of the two-factor mixed ANOVA on achievement indicated that there was a significant two-way interaction between the grouping (computer, paper and control) and the data collection points (pre vs. post) for the achievement scores: \( F(2, 96) = 5.50, p < .01 \). All groups increased their achievement scores from pre to post. The gains from pre to post were significantly greater for the computer and paper groups than for the control group [Tab. 1] [Fig. 1]. The gain differences between the computer and the control groups, and the paper and the control groups were significant at \( p < .05 \) level based upon the Fisher’s PLSD post hoc tests. The gain difference between the paper and the control groups was also significant at \( p < .05 \)
level for the Scheffe post hoc test. This finding shows that both the computer and paper groups have significantly improved their achievement scores after they participated in the study while the increase for the control group was not significant. In other words, there was an effect of the problem-based learning environment on the achievement of middle school science students. Yet the difference between the computer-supported PBL and paper PBL was not significant.

The results of the two-factor mixed ANOVA on attitude indicated that there was not a significant two-way interaction between the grouping (computer, paper and control) and the data collection points (pre vs. post) for the achievement scores: $F(2, 95) = .26, p = .77$. Although there was a small increase in attitude from pre to post for all groups, there were no differences among the three groups [Tab. 1]. In other words, the treatment did not have an impact on the students’ attitudes toward learning science.

| Achievement | | | Attitude | |
|-------------|-----------------------------|-----------------------------|
| N* | Pre | Post | N | Pre | Post |
| Computer Group | 50 | 12.7 (12.52) | 31.58 (20.7)** | 48 | 28.23 (12.19) | 30.00 (14.10) |
| Paper Group | 32 | 8.22 (12.53) | 28.38 (18.43)** | 17 | 31.91 (9.98) | 34.76 (11.34) |
| Control Group | 17 | 27.35 (12.64) | 32.47 (13.35) | 33 | 25.82 (8.90) | 29.82 (14.33) |

* N indicates the number of students who turned in both the pre and post evaluation forms for each group.
** significantly different from the control group, $p < .05$

**Table 1**: Mean and Standard Deviation (in Parenthesis) on achievement and attitude for the Computer, the Paper and the Control Groups

![Figure 1](image-url)  
**Figure 1**: Achievement scores for the groups from pre to post

| R | .59 |
| R2 | .35 |
| F | 14.9, $p < .01$ |
| Intercept | 4.13 |

| t-values | |
| reading ability | 3.46, $p < .1$ |
| math ability | 1.26, $p = .21$ |

| Beta | Beta Weight |
| reading ability | .42 |
| math ability | .19 |
| reading ability | .47 |
| math ability | .17 |

**Table 2**: Results of the Multiple Regression Analysis

We were interested in finding out if there existed a relationship between students’ math and reading abilities and their achievement when working in PBL environments. Students’ scores in reading and math from a most recent TAAS test were used. TAAS is a state-wide testing system that assesses the overall
academic achievement of all students in Texas at different grade levels. It provides information on students' reading ability, math ability and writing ability. The results of the multiple regression analysis showed that the significance of the relationship was moderately high among reading ability, math ability and the achievement scores for students using PBL: $r = .59, p < .01$. This significant relationship was mainly attributed to students' reading ability $r(72) = 3.46, p < .01$ [Tab. 2]. That is, students' reading ability is a better predictor for students' achievement in a PBL environment than their math ability. A PBL environment relies much on problem identification, presentation, problem-solving and student reflection. Though mathematical ability is obviously very important in problem solving, being able to read and comprehend the problem is critical. This finding provides some evidence on this issue and suggests that in order for students to be successful in a PBL environment, we, as teachers, need to make greater efforts to increase students' reading levels.

The findings of this study suggest that problem-based learning can influence the middle school students in their learning of science. When students were exposed to the PBL environment, they increased their achievement scores more than those students who learned the same content in the traditional classroom. Consistent to the literature on PBL, the results of the study provide some evidence in supporting the use of PBL. The findings also suggest that both the computer-supported and paper based PBL are equally effective. An interest of this study was to find out the types of tools or design features that can support students when working in a computer supported PBL environment. Although there was no significant difference between the computer and the paper groups on achievement, initial examinations of the problem solving process by the computer and the paper groups show some differences in the steps and use of available resources/tools. The use of tools/resources are currently being analyzed. The findings of the analyses for tool use and the qualitative data will be added to the result and discussion section for the conference presentation. Together, the findings will provide more insights as to how the tools can or cannot support problem solving in computer-supported PBL environments.

No significant differences among the three groups were found on the middle school students' attitude toward learning science. That is, the middle school students' attitude toward learning science was not affected by the introduction of PBL, computer-supported or paper-based.

Abstract:
The key item of science and technology of our country—the development of the upgrading version of PCAI (v.2) is being undertaken. The key designing idea of the item is to make the software adapt the teaching mode facing the future. The software covers the main contents of college physics, including historical material, theoretical teaching, experimental demonstration, examples, exercises, tests and so on. It is based on WWW, makes use of the technology of Java and HTML etc. and takes advantage of hypermedia technology to endeavor to attain the international advanced level in technology. The software is open, expansinary and integrated. The development of it embodies that Chinese physics teaching is working for great teaching reform, trying to set up a completely new teaching mode and change the passive learning state of students. Education is walking towards democratization, lifetime, variety, personalization, efficiency and internationalization.

1. Preface

In March, 1995, [Physics Computer Assisted Instruction System (PCAI)], developed by twelve colleges and universities of our country, was completed and passed the appraisal by State Education Commission. It was authorized that the software chose a large scale of subjects and was powerfully systematic, so that it was the first set of complete physics CAI software of college of engineering and attained the domestic advanced level of CAI software.

The main characteristics of PCAI are:

1) PCAI lays stress on accuracy and vividness of its technique of expression. The use of PCAI will promote raising teaching efficiency. It is very difficult to express a lot of physics concepts, such as the shrink of length in the special theory of relativity, stationary wave, Doppler effect, magnetic focusing, polarization, and so on, clearly in words or in pictures on the blackboard. By means of animated drawing demonstrations, PCAI can cut down the lecture time in class and enable students to understand physics concepts more quickly.

The use of PCAI will enable students' left brains to be opened up together with the right ones, thus raising his study effect.

The use of PCAI will be good for making use of the students' unconscious attention and let them study with ease and joy.

PCAI software is welcome by vast numbers of lecturers. It is unquestionably the capable means of
engineering physics teaching at present.

(2). PCAI software takes notice of the influence of non-intelligence factors and does its best to inspire the students with enthusiasm for study from all sides, stimulate the students' interest for study and foster their tenacious, challenging spirit to study.

University students, who are distinct from middle school students, have greatly decreased the dependence on their lecturers. Since their personalities are progressively independent, they are eager to study gradually through their own efforts. PCAI fully respects this very character of university students in both the demonstration of physics concepts and the manufacture of examples. In the light of the requirements of subject, PCAI can fully make use of the function of heat key and lead the students to go deep into physics field step by step, so that they can independently learn to solve some practical problems by means of the theories of physics.

In the course of study university students have got a characteristic that they like to exchange opinions one another. A good many conversations between students and computers in the examples can be the match for discussion when the students study on their own.

University students pay attention to the appraisal from others. The appraisal of exercises and tests, which is made by the computer, including praise, encouragement, hint and criticism, enables the students to receive the feedback about their study in time and obtain an impetus for study.

University students, like ordinary young men, are apt to get excited and feel nervous. Sound, colours and good animated drawings can attract their attention and sharpen their ability of thinking. Reckon the time inversely in a test, marking the students' papers and giving an objective appraisal after the test, raising the atmosphere for examination, which are convenient for the students to look squarely at themselves, are indispensable links in the course of study.

After 2 years of the spread and use of PCAI, it proved that the software had played a good role in assisting the teaching of college physics. But the fast development of science and technology and the requirement of the education of the society make us obviously feel the urgency of upgrading PCAI. In the summer holidays of 1996, the work of upgrading PCAI spread in an all-round way. At the beginning of 1997, this item was among the key items of science and technology of our country, and it was planned to be completed at the end of 1997.

The upgrading version of PCAI, also called PCAI (V.2), covers the main contents of college physics, including historical material, theoretical teaching, experimental demonstration, examples, exercises, tests and so on. It is based on WWW, makes use of the technology of Java and HTML etc. and takes advantage of hypermedia technology. The key designing idea of PCAI is to make the software adapt the teaching mode facing the future.

Modern education is the product of modern production and should also adapt to the need of the development of production. So the teaching mode facing the future must impel education to realize democratization, lifetime, variety, personalization, efficiency and internationalization, and make education be the base of the development of social productivity. In the upgrade of PCAI, how do we try our best to have the choice of physics topic, computer software tool, script writing and interface designing etc. fit for the characters of modern education to design the teaching mode facing the future?

2. Reasons Based on WWW

WWW is abbreviation of World Wide Web. It's an inquiring and browsing system on Internet. With the guidance of its corresponding interactive software, users can easily inquire different kinds of information distributed to each node computer of different places, which can be shared by everyone. At present, there is no systematic Chinese teaching software on Internet. PCAI will fill the blank in 1997. Its page will enter some nodes of Internet in succession. People of the same occupation and people interested in it can all make inquiries, communicate with one another and create conditions for internationalizing education.

Because there are not only people of wealth but also people of poverty and regional difference in human society, the implementation of democratization of education is often rather difficult. The software based on WWW will help more students to get equal opportunity of receiving education at less cost.

In 1990, NCFC (The Nation Computing and Networking Facility of China) project was under construction. NCFC was divided into two layers. The lower layer was school net including the Academy of Sciences of China, Beijing University and Tsing Hua University; the higher one was the school net connected
with other domestic scientific research and educational units, and the backbone net of NCFC connected with international Internet. In 1992, the CASNET, TUNET and PUNET were completed. By the end of 1993, the backbone net of NCFC had been set up, and it connected three nets of the Academy and Universities by high-speed optical cable and router. The special line (64kbps) linked with Internet was opened regularly in April 1994. On May 21, 1995 the configuration of the CN main server which is of the highest domain name and the link of TCP/IP with Internet were realized, and the whole functional service of Internet to the members of NCFC could be provided.

In 1994, CERNET (China Education and Research Network), invested by State Planning Commission, presided over by State Education Commission, started, and the first period of project was completed in December 1995. Up to now over 100 colleges and universities have realized the connection with CERNET.

According to statistics, 11282 computers had been connected with Internet by July, 1996, which increased by 1003% in July, 1997, while the increasing ratio was 92% in the United States and 82% in Europe. The number of Internet users of China amounted to 50,000 in June, 1996.

In 1994, ChinaNet (China Public Computer Internet) invested by Ministry of Posts and Telecommunications of China started. As the first period of project, Beijing node and Shanghai node opened 256kbps and 64kbps separately.

The backbone net of China covers the large-scale data communication network of all the provinces throughout the country by TCP/IP Internetworking technology.

Today, with the continuous renewal of knowledge, lifelong study is an important means for anyone to learn how to exist. The basic construction of Chinese computer network develops very fast, and PCAI (v.2) will be the software that anyone who wants to study can study. In short, the reason PCAI chooses WWW as its network carrier is as following:

(1) WWW develops quickly with the popularity of Internet
(2) WWW browser provides direct picture interface for users.
(3) WWW has platform independence. HTTP and FTP etc. are application layer agreements that are of good transplantation.
(4) WWW supports transmission of multimedia.
(5) WWW also supports the integration with other service of Internet.

3. **The Basis For Choosing Technology**

Users who dial to Internet with the help of telephone line and Modem hope that the faster the speed of transmission is, the better it will be. AVI of data stream or MPEG shows the image at the speed of only 1-2 frames per second at most. But if you utilize "GIF Construction Set" to make animation, you can realize simple animation on WWW.

Java is used in the programs of physical pictures of the software which makes the software have good capabilities of trans-platform and interface. You can execute the program of Java so long as you have the WWW browser to support Java on the operating platform.

This software seamlessly links some relative contents into a systemic non-linear net-structured Hypertext by HTML.

In fact this is an interrelated net of multimedia materials. There are two patterns so far as linking pattern is concerned:

- According to playing sequence
  - Sequential link (Link according to the physics teaching sequence that is in common use at present.)
  - Link of detailing (Link the information of physics that is extended and deeply described.)
  - Link of jumping (Link with other knowledge.)
  - Link of side branch (Link with interrelated part of the same knowledge.)

- According to information type
  - Link of text
  - Link of sound and image
  - Link of programs

In order to realize integration of multimedia data such as pictures, writings, sounds and images, the software
utilizes some writing tools of HTML. For example, both FrontPage 97 of Microsoft and HotDog of Sausage support visual programs and a variety of multimedia information patterns like mov, avi, au, wav, jpg, gif and so on. Besides, you can control multimedia data simultaneously with the interface defined by CGI and ActiveX and description of VBScript and JavaScript.

The use of the latest computer technology guarantees the execution of the software on WWW without fault, and the incarnation of integrity, complexity and interrelation of knowledge, therefore the software will be guaranteed to realize the teaching function expected.

4. Significance of the Opening of Hypermedia

Many software developers notice that the development of teaching software should take consideration of the status of teachers and students. Most of software they have developed has good interface and is easy to use and coincide with the learning psychology of students. So the software has obvious teaching effect. For example, PCAI (v.2), taking full consideration of scientific teaching method, is welcomed by learners. But most software has a common shortcoming that the software is a system that is sealed off from teachers. Once the maker fixes the content of the software, the teacher who uses it can not add his (or her) content. This kind of software decreases the opportunity, making use of which one school, one course or one teacher can show its (his) teaching character; thereby it will affect the enthusiasm of the use of software.

The software of PCAI (v.2) can be expanded and integrated, and the software is made up of three layers: storage layer, logic layer and application layer.

- Application layer
  In this layer you can read hypertext information facing a dynamic and interactive interface.
- Logic layer
  In this layer you can link and organize multimedia materials.
- Storage layer
  The multimedia data such as texts, pictures, sounds and video in storage layer are content-relative elements that consist of software. But from the point of view of software structure, if a teacher is not content with some of these elements and wants to modify them, he (or she) can do it.

The freedom of information stream in opening system enables teachers to be satisfied with teaching, so as to accelerate teachers' breaking away from the tie of traditional habits and help them to form the idea of modern teaching.

5. Conclusion

PCAI (v.2) reflects the rules of physics vividly and accurately, which is welcomed by the teachers of physics and students throughout the country. The coming out of PCAI (v.2) will certainly make radical changes in physics teaching mode.

- On the pattern of information transmission, we should change the traditional method of expository teaching. The source of information no longer a teacher, nor is the linear transmission of pictures, sound recording or video recording, but the physical multimedia information world, in which action with stillness and sound with image take place, and both space and time can extend. The teacher giving lessons is a cooperator and organizer of physical information and guarantees the quality of information of teaching.
- On the pattern of acceptance, we create different conditions of software and hardware for the students, enable them to choose all kinds of modes, such as studying individually, studying cooperatively and having lessons collectively etc. It can exert the students' subjective capability, So that quality education can be infiltrated into physics teaching.
- On the pattern of the organization of information, teachers make use of network to store and search educational information, take advantage of computer technology of database and hypermedia to realize the structuralization and systematization of knowledge of information, embody the opening, relativity, complexity and dynamics of practical knowledge even better.

With the development of computer technology, there will be newer and better physical teaching software.
emerging in large numbers. Physics teaching activities will certainly coincide with human psychology of knowing and understanding matters more and more reasonably and adapt to the need of modern production better and better.
Lecture and Tutorial via the Internet - Experiences From a Pilot Project
Connecting Five Universities

Abstract: During the summer semester 1997 five German universities participated in a telelearning pilot project where a telelecture and -tutorial was held via the internet. Within this pilot project, we evaluated the m-bone based video conferencing tool as well as the applied didactic concept. The video conferencing tool provided insufficient quality of transmission and was deficient regarding its functionality as well as its interface. Concerning the telelecture we found reduced attention of the remote participants, and a lower level of interactivity between lecturers and students. Positive feedback regarding the tutorials which tried to encourage interactivity among the participant and regarding newly didactic elements within the lecture indicate that telelearning requires new teaching and learning approaches to compensate for its obvious constraints.

1. Introduction
Telelearning holds the premises of increased availability and reduced cost of education. Nevertheless the given technical constraints may reduce the efficiency of the learning processes. Each setting for telelearning faces this basic contradiction in a very specific manner. The basic challenge when arranging for any telelearning setting must be to gain the mentioned benefits without losing quality. Meeting this challenge requires an adequate technological infrastructure, an appropriate didactical concept, and a beneficial organizational embedment of the telelearning activities.

To analyze critical success factors in telelearning settings, case studies are required. In the following we will report about the experiences made in a pilot project connecting computer science departments of five German universities via the internet. The University of Freiburg is the only university in the south west German state of Baden-Württemberg where an institute is specialized in "Computers and Society". To allow students from the other locations to take a course in this subject, we offered to connect their universities by means of the internet. Thus, a lecture and a tutorial in "Computers and Society", normally just given in a face-to-face setting, were transmitted via an Mbone based video-conference application. Four universities (Constance, Mannheim, Stuttgart and Ulm) decided to join this pilot project.

There are already quite some case studies which report on telelearning projects in the German university environment based on the same technological infrastructure (e.g.: Stucky et al. 1995, Eckert, Geyer and Effelsberg 1997). Nevertheless our case is specific concerning the following focal points:

- the rather big number of universities involved and its technological, didactical, and organizational implications,
- the combination of a telelecture and a teletutorial,
- the distinct didactic concept of the tutorial.

2. Didactical Approach, Students and Technological Infrastructure
During summer semester 1997 the authors carried out twelve lectures and seven tutorials on a weekly basis. To benefit from the rather favourable traffic-load in the internet, we hold the sessions in the earlier morning (8.15 a.m.-9.45 a.m.).

Regarding the telelecture the didactic concept was to give a conventional lecture and provide additional material via the WWW. The tutorial was intended to ground selected aspects of the lecture. As the education of computer scientists typically does not stress the development of communicative competence and as we
assumed that this ability is nevertheless crucial for computer professionals, we tried to promote it by the way we set up the tutorials.

The tasks to work out in the tutorials asked the students to input statements which in some cases had to be prepared by carrying out interviews. These input statements were discussed in the following. We asked the students at the single locations to form groups to work out the tasks. Moreover, we established a mailing list in which all the participants were supposed to register for intergroup discussion. Finally the lecturers gave their telephone number and e-mail address to answer questions which could not be solved among the students. The students were supposed to deliver their solutions to the tasks via e-mail or by sending a h-tt-p-address.

The number of participants (students and local support) at the five different locations varied for the lecture between 22 and 8 with an average of about 15 and for the tutorial between 17 and 7 with an average of about 11. In the lectures as well as in the tutorials the highest number of participants joined the first session. The number declined gradually towards the end of the semester (cf. Wulf and Schinzel 1997).

The lecture and the tutorial were carried out based on a Mbone (Multicast Backbone) based videoconferencing toolset. Mbone protocols were running on top of the IP protocol of the Internet which had a bandwidth of 34 Mbps between the universities. Within the individual sites a typical configuration consisted of a university network (FDDI, 100 Mbps) and a local network (Ethernet, 10 Mbps). The video conference toolbox contained an audio tool (vat), a video tool (vic), a shared whiteboard (wb) and an additional tool to synchronise the display of the shared whiteboard (wbimport) (cf. Eriksson 1994). We favoured this freeware toolset compared to commercial ones because we could run it on different hardware platforms.

In Freiburg and Ulm the sessions were held in a lecture room. Thus, the screen of the connected workstations was - fully or partly - projected by a beamer. The audio was by loudspeakers, while microphones registered the local voices. The video was at each location caught by a single camera. In Constance, Stuttgart and Mannheim the participants followed the sessions in front of workstations which were placed in specific rooms. Thus, there was not any beamer display. While some of these workstations were equipped with a video camera (Mannheim and Stuttgart) and with headsets (Stuttgart), others were just equipped with microphones and loudspeakers.

3 Research Method

To evaluate the telelearning pilot project we have applied several qualitative methods. After each session the authors have written a report documenting the most important events. Moreover, we asked the local students in the end of each session to give us feedback. Following their feedback, we interviewed them individually or in small groups several times during the semester. In the second part of the semester, we used the video conference toolset, to get feedback in the end of the session from the remote participants.

One of the authors travelled once during the semester to each of the remote sites. After the corresponding session he had a group discussion with the students and the local support. In the last lecture we used the video conference toolset to discuss the experiences made with this type of telelearning. We used the shared whiteboard to ask the participants to type in anonymously positive and negative impressions on one slide. Based on this input we discussed advantages and disadvantages of the telelectures and -tutorials. In the second part of this lecture we discussed five thesis which the authors had distributed before via e-mail. The results of this discussion were documented and evaluated. Additionally we have achieved the e-mails exchanged and have written notes of the most important phone-calls concerning the lectures and the tutorials.

4 Experiences

4.1 Video Conference Toolset

The Mbone based toolset allowed us to hold the lecture as well as the tutorial during the whole semester, but nevertheless we experienced a lot of technical problems which challenged the patience and motivation of the participants. During the 19 sessions, we had four complete breakdowns of the Mbone-net which interrupted the connection to all external locations for 15 up to 45 minutes. The connection with Ulm was - especially due to frequent drop-outs of the voice channel - that bad that these students stopped participating after the first four weeks. The connection among the other locations were characterised by occasional problems of the voice channel especially in the second part of the section (after 9 a.m.) (cf. Wulf and Schinzel 1997). To reduce the netload, and thus to improve the quality of the audio channel, we often abandoned the video transmission in the second part of the session. It turned out that already short drop-outs of the voice channel can lead to serious
misunderstandings (cf. Wulf and Schinzel 1997). Based on the given infrastructure (bandwidth of the different networks and router capacity at the time of the study) there are severe problems in transmitting telelearning sessions by means of the Mbone-protocol. To allow for an undisturbed transmission between multiple locations bandwidth reservation seems to be indispensable (cf. Geyer, Eckert and Effelsberg 1997).

Moreover, running the Mbone protocol requires the cooperation of actors administrating the different subnets who do not necessarily value the success of telelecturing in a sufficient way. These incongruent interests can lead to considerable problems. For instance, lacking attention of one of the local network administrators caused one of the complete breakdowns of the transmission. A sixth university did not participate due to lacking cooperation among the different network administrators.

Looking at the video application toolset, we found severe deficiencies in the design of the surface interface as well as of the functionality. Looking at the surface interface the design violates almost every principle of the ISO 9241 part 10 standard. For instance, the surface design is inconsistent between the individual applications as well as within single ones, e.g. the meaning of the mouse buttons differs within the audio tool. This inconsistency led to problems in communication within the first sessions because one of the authors occasionally failed to activate the audio channel when speaking. Moreover, the functionality of the toolbox is badly documented. For instance, it took us several attempts of cooperative exploration to build up an appropriate mental model of the different transmission modes of the audio tool and their mutual interrelations at the different sites.

Beyond the surface interface there were severe deficiencies of the toolset's functionality, as well. The design of the audio tool's transmission modes inhibited the interactivity in the lectures and in the tutorials (cf. chapter 4.2). As the ambient noise resulting from the loudspeakers could not be suppressed automatically, formalised turn-taking protocols had to be applied which required to press a button before speaking. Neil (1997) reports about similar problems with videoconferencing tools when providing telelearning courses in a companies setting. Thus, research should be directed to allow for full duplex audio links.

The functionality of the shared whiteboard proved to be deficient, as well. The drawing functionality of the whiteboard is rather restricted. It mainly allows to annotate slides which have been imported. Its functionality is not sufficient to draw fully new slides. Nevertheless in the tutorial it turned out that there was a strong need to create slides spontaneously to visualise aspects of the discussion or to present multiple input on the screen (e.g.: technique described in chapter 3). Thus, the functionality of the shared whiteboard should be extended to the level of regular graphic editors. To collect multiple input, different turn taking protocols should be implemented in the whiteboard (cf. Greenberg 1991; Dommel and Garcia-Luna-Aceves 1997). This would allow to evaluate them in different learning scenarios.

Moreover, one should reconsider the given restriction to the keyboard as the sole input device. Electronic whiteboard with pen input devices would greatly encourage the simultaneous participation of different actors in creating graphics. Moreover, it turned out that typing on the keyboard and synchronously speaking is a difficult task. Here again a pen based input device would ease participation. Such an equipment would also encourage acceptance in scientific culture whose lecturing style is more based on blackboard than on slides (e.g. in mathematics).

The design of the shared whiteboard does not transmit the position of the pointer and movement of graphical elements to the remote locations. This design decision obviously limits the amount of data necessary to transmit. Nevertheless, it turned out during lectures and tutorials that the ability to spontaneously point to a graphical element or to encircle parts of a slide are very helpful in telecommunication. The implemented substitutes (creation and deletion of annotations) are not sufficient. Thus, in an new version movements of cursors and graphical elements should be transmitted at an appropriate level of granularity.

Moreover, the postscript based import-function of the whiteboard was not only badly documented but also badly implemented. It took us long lasting attempts involving various conversions and manipulations to import files created on Windows, Macintosh and Unix systems. Such problems are prohibitive for users who do not have a profound computer background.

Carrying out the lecture and tutorial it turned out that there is a need for additional tools for meta-communication. To compensate for the problems of the audio tool and to encourage interactivity, one should integrate a tool which allows remote participants to make the speaker aware of questions or remarks. Connecting just two locations Eckert, Geyer and Effelsberg (1997) have extended the video-conference toolset by implementing a "putting up of hands" tool. This tool should get extended to cover multiple locations. Meta-communication is needed furthermore to optimise technical aspects of the transmission among the different sites (e.g. position of the cameras, quality of the voice channel, transmission rate of the video channel). A
potential communication tool to use in these cases is the shared text editor which is included in the Mbone tool set.

4.2 Didactical Approach

As we have applied specific didactical approaches in the lecture and in the tutorial, we will look individually at the different experiences.

The first remarkable observation concerns the speed of lecturing. We were not able to present as many topics as in a face-to-face lecture. This fact is primarily caused by the many bigger and smaller technical breakdowns (cf. chapter 4.1). Beyond this we used additional time to collect verbal feedback from the remote locations (e.g. concerning: quality of transmission, attention and understanding). In a face-to-face situation this feedback is either not necessary or it can be implicitly collected by watching the audience. Feedbackwise, the video stream transmitted could not replace the physical presence of the auditorium.

Moreover, the participants at remote locations reported about a lower level of attention compared to face-to-face lectures. Those who followed the lecture from a terminal reported that they occasionally used their mail tool or their web browser during the lectures. Neil (1997b) hints to similar experiences when teaching in a multinational company. Obviously telelecturing implies the loss of social control which typically is imposed by the physical presence of the lecturer. Thus, the lecturer faces a stronger competition for the attention of the participants.

Like Geyer, Eckert and Effelsberg (1997), we experienced a low level of interaction between the lecturer and the participants. The first question of a student occurred after almost two months and was facilitated by a technical breakdown of the transmission. There are several reasons for this phenomenon. One of the local students in Freiburg stated that he did not want to disturb all the participants at the different locations by posing a question. A student from one of the remote universities explained that she hardly could recognise the appropriate moment for posing a question. In her eyes this problem is more severe if there is not any video of the lecturer. By contrary the lectures' failed in rising the interactivity when trying to pose questions to the remote participants. Due to a lack in context information, they were not able to detect the appropriate moment and the "right" partner. Moreover, the inappropriate transmission-modes of the audio tool and missing tools for metacommunication influenced the interactivity between lecturer and audience negatively (cf. chapter 4.1).

To increase the level of attention and interactivity, it turned out to be helpful to integrate additional slides into the lecture which asked the students questions about the content of the preceding chapter. These questions had to be answered immediately by textual input using the shared whiteboard. Based on the input we initiated a discussion especially when answers were wrong, incomplete or missing. This technique encouraged participation and gave us valuable feedback about the performance of the students.

The approach taken in the tutorial to encourage (tele-) communicative competence was appreciated by the students - especially in Constance and Ulm. Besides the considerable technical deficiencies of the video conference toolset, the students were able to give smaller talks which increased in quality during time. Moreover, they were able to participate in the occasionally controversial discussions. The participants especially appreciated the exchange of ideas with students from other universities which were often of rather different opinion. To start discussions it turned out to be helpful to ask the participants to express their point of view by typing text into the shared whiteboard (cf. chapter 3).

Due to the design of the audio tool, formal facilitation of the discussions was necessary (cf. chapter 4.1). Nevertheless there was a lack of context information which made it difficult for the facilitator to pass the right to speak among the participants. As not all of the sites were equipped with video cameras, it was impossible to see who puts up the hand to create a list of speakers. Furthermore it was difficult to predict which participant could contribute most appropriately to a current discussion. This led to problems in maintaining the focus of the discussion. Thus, to support tutorials which are strongly based on mutual interaction high quality video and tools for metacommunication seem to be indispensable.

Though we had asked the participants to introduce themselves within the first session of the tutorial, the students later reported about a feeling of anonymity towards each other. Occasionally they could not identify the speakers at the other sites or relate them to the introductive statements given in the first session. Thus, they reported about a feeling of emotional distance. Some of them suggest a face-to-face meeting of all the participants involved which should take place after the first month of lecturing. Nevertheless it was doubted whether there were sufficient resources of time and money for such a meeting. Thus, the students suggest to combine face-to-face and telelearning elements. Preece and Keller (1991) report about experiences with such a hybrid approach.
The perceived anonymity is contradictory to finding of Neil (1997 a and b) who used multiple technologies like videoconferencing, audioconferencing, and a variety of Internet-based conferencing to hold teleseminars in a multinational company. She found that students were surprisingly familiar with each other in the end of the class. However their seminar lasted only four weeks with sessions, typically scheduled three times a week for two hours. Thus, the contradictory findings may be explainable either by the shorter duration and higher density of Neil's teleseminar or by an in this respect more successful didactical approach. Anyhow, further research seems to be necessary in this point because the building of social networks is a crucial factor for the success of telelearning. In this respect the tutorial did not turn out to be successful. Neither within the different sites nor between the sites, the students built groups in solving the tasks of the tutorial. Moreover, the common mailing list was not used by the students to discuss between the sessions. It was merely used for announcements of the organisers.

Looking at the general attitude toward the telelearning pilot project, we found a significant difference in the attitude of the students in Freiburg compared to the remote sites - notably Constance and Ulm. From the beginning the students in Freiburg complaint about the disadvantages of telelearning:
- disturbance due to technical problems,
- interruption of the current lecture due to meta-communication with the remote sites,
- reduced attention of the lecturers towards the local students.

As they had regular courses in "Computers and Society" at their faculty, telelearning did not enlarge their curricula. Moreover, several of them had already experience with telelearning because this topic is a research focus of the Freiburg faculty (cf. Bacher and Ottmann 1996, Ottmann and Bacher 1995). Thus, we could not draw on their curiosity, either.

By contrary, the students at the remote sites appreciated the lecture and tutorial as an enrichment of their curriculum. They had a significantly more positive attitude toward the experiment though they suffered most from the technical breakdowns and deficiencies. Interestingly, Eckert, Geyer and Effelsberg (1997) also found that the students at the site where the lecture was held before in a face-to-face ensemble gave lower ratings than those at the remote sites. We believe that this attitude is rational because under the given circumstances the local students are losing quality of education without gaining an enrichment of their curriculum. To encourage their motivation one has to provide benefits to them like increased asynchronous availability of the lecturers or didactically elaborated material.

In carrying out both the lecture and the tutorial we experienced a significant higher workload for the lecturers compared to traditional courses. If one does not mention the overhead caused by the evaluation presented here, the following reasons have led to an increased workload:
- development of appropriate concepts for telelearning,
- higher standards for the layout of the material, e.g. slides,
- additional presentation of all relevant material by means of the web,
- higher efforts in asynchronous communication when supporting remote students,
- coordination with the local support at the remote sites,
- tests of the technical infrastructure,
- preparation of the organisational setting (contacting the remote faculties, arranging the time-table, booking lecture rooms etc.).

These additional tasks have to be kept in mind if one discusses the potential for cost reduction in education by means of telelecturing. Moreover, local support at all the remote sites is indispensable. As the preparation of didactic material is rather resource intense, there is the danger of an too extensive reuse of this material over time. This may lead to an outdated contend of telelearning courses.

From our experience it is crucial to plan and prepare courses in telelearning early in advance. We started to contact the remote faculties about four month before the first session was supposed to take place. In some cases this time span turned out to be insufficient. For instance, it was too late to get our course included in the printed programs of these faculties. As the faculties had planned their programs already, it was moreover difficult to get resources for the local support.

To develop new ideas for the use of the video conferencing tool in telelearning, the feedback of the students and of the local support proved to be very helpful. Quite some ideas presented here resulted form group discussions after the sessions. Moreover, it proved helpful for all of the participants to join a presentation of an experienced speaker. In our case a colleague providing local support in Mannheim had profound experience in telelecturing. His presentation in one of the tutorials was a source of inspiration for the following speeches. This experience hints to the fact that lecturers should be supported by specialists.
transferring telelearning experience. Especially in the beginning such a support seems to be crucial to develop appropriate didactical concepts for telelearning.

5. Conclusion

We have reported about experiences gained from a telelecture and teletutorial on „Computers and Society“ carried out in summer semester 1997 connecting five German universities. We evaluated the applied toolset as well as the didactical approach taken. It turned out that bandwidth reservation is indispensable to support our didactical approach. Moreover, the video-conferencing toolset proved deficiently designed concerning its surface interface as well as concerning its functionality. The telelecture turned out to lead to a lower level of attention and interactivity. To us it is an open question whether new didactical elements like the ones presented here will overcome these problems. The positive perception of the tutorials hints to the fact that telelearning requires new didactic concepts which involve the students more actively than lectures typically do.

Nevertheless our experiences are based on just one case. Our results are influenced by factors such as the topic of the courses, the personalies of the actors and the technology applied. Thus, these results have to get compared to further case studies. Tackling the problems presented, synchronous telelecturing has the potential to make education more easily available. Nevertheless, it is doubtful whether it will be more lecturer-time efficient than traditional face-to-face approaches. We believe that the quality of education requires the integration of interactive elements which restricts the maximal number of participants considerably.

Abstract: ATM is an emerging technology in computer networking. The technology provides potentiality for universities to build their networks based on the future vision of uniting voice, data, and video communications on ATM-technology-based equipment. A review of the literature revealed that minimal evidence exists to indicate whether the size, type, financial factors, and information processing maturity of a university affect a university's high-tech innovation adoptions. The purpose of this study was to determine the relationships between ATM adoption and four organizational variables: university size, type, finances, and information processing maturity. The results of the study provided evidence to show that ATM adoption in campus networking is significantly related to university size, type, finances, and information processing maturity.

Introduction

Today, information and telecommunication technologies have elevated human communication, information, and information resources exchange to the highest stages they have ever been. As requests for additional and the latest information in education increase, institutions of higher learning are striving to provide the latest information and information resources for university faculty members, researchers, and students. To meet the challenge of the need for information, higher education institutions are compelled to continue adopting state-of-the-art technologies to information and telecommunication systems to upgrade their information processing facilities.

ATM (asynchronous transfer mode) is an emerging technology in computer networking, which in turn is the physical media of information systems and networking/telecommunication (N/T) systems. The major benefit of ATM is of its potentiality for users to build networks based on the future vision of uniting voice, data, and video communications on ATM-technology-based equipment [McDysan & Spohn 1995]. Having realized the significant values of ATM on current campus networks and the potential of ATM to improve performance and lower overall network, equipment, and operating costs in the long term, some higher education institutions have adopted or are planning to adopt ATM in their campus networks. However, a review of the literature revealed that, in university settings, there is minimal evidence indicating whether the size, type, financial factors, and information processing maturity of a university would affect a university's high-tech innovation adoptions. No research of this nature has been found in any study of ATM adoption in any institutions of higher learning, nor has any research of this nature been undertaken by other organizations, either.

Purpose of the Study

The purpose of this study was to determine the relationships between ATM adoption and the following factors: university size, university type, university finances, and university information processing maturity. Another purpose of the study was to identify the current status of ATM adoption in campus networking.

Methodology

The research design for this study was correlational since this method permits one to analyze the relationships among a number of variables in a single study [Borg & Gall 1989]. The sample subjects were selected from the population of university domain LAN administrators in the United States. The list of the user address of these university domain LAN administrators in the United States was accessed electronically by using the InterNic.

The total student enrollment of a university was defined as university size and was obtained from National Center for Educational Statistics 1996 database. University type was specially defined as Research Universities and non-research universities for this study. The list of Research Universities was obtained from the technical report published by The Carnegie Foundation for the Advancement of Teaching: A Classification of Institutions of Higher Education: 1994 Edition [The Carnegie 1994]. The percentage of a university’s overall information technology expenditures that is expended for the university’s campus N/T budget is defined as university finances. It was obtained from two sources. One source was the Report on 1994 and 1995 Budget Information [CAUSE 1996] by CAUSE Institution Database Service. The other source was a researcher developed instrument, which contained questionnaire items designed for obtaining the data.

The questionnaire was posted on the World Wide Web. Internet e-mail was used to distribute the cover letter of the questionnaire to each university domain LAN administrator. A total of 554 user addresses were actually sent through via the Internet. From the 554 user addresses sent through, a total of 208 responses were received for a response rate of 37.55%. Out of the 208 responses, 9 were unusable, leaving 199 usable, yielding a usable response rate of 35.92%.

Logistic regression was used to study the relationship between the selected organizational variables and ATM adoption in a university’s campus networking. Nested Models were designed for analyzing the data in the study.

Of the 199 responses received, 58 universities stated that they had adopted ATM technology, which was almost 30% of the responses. Of these 58 universities which have adopted ATM, 51.7% were Research Universities, 22.4% were Doctorate-Granting Universities, and 25.9% are neither Research Universities, nor Doctorate-Granting Universities. The frequencies for ATM adoption are shown in [Tab. 1] and [Tab. 2].

Descriptive Statistics

Descriptive statistics (mean and standard deviation) for both the dependent and independent variables are reported in this section. Means for Overall IT Budget (m = 6.81) and Budget for Network/Telecom (m = 15.97) indicate that in universities an average of 15.97% of the overall Educational and General (E & G) budget that is expended for information technology is allocated to campus N/T. [Tab. 3] depicts the descriptive statistics for the predictor variables.

Variables CDATA, CUDMK, CDEPTDMK, CSTRUDMK, CUNSTRDM, and CLRNSCH are based on a scale of 1 to 6, with 1 = Strongly Disagree and 6 = Strongly Agree. High values represent high information processing maturity. Similarly, but in the opposite direction, CUDMK, CDEPTDMK, and CSTRUDMK are based on 1 (Strongly Disagree) to 6 (Strongly Agree), with low values representing high information processing maturity.

Table 4: Logistic Regression Coefficients and Goodness-of-Fit for the Nested Models

Nested Models were used to analyze model variables. The logistic regression coefficients for the Nested Models are listed in [Tab. 4]. According to Norusis (1994), the logistic coefficient can be interpreted as the change in the log odds associated with a one-unit change in the independent variable. The logit (the log of odds) is represented by the coefficient under (. Since it is easier to think of odds rather than log odds [Norusis 1994], the logistic model uses \( \exp (\text{exponential function of coefficient}) \) to represent odds, interpreted as by increasing the value of the independent variable's coefficient from 0 to 1 the odds are
increased by a factor of the value under \( \text{Exp} \). If the independent variable's coefficient value is positive, this factor will be greater than 1, which means that the odds are increased; if the value is negative, the factor will be less than 1, meaning that the odds are decreased. Based on this rule of thumb and the coefficient values revealed in [Tab. 4], the interpretation of these models is stated in each of the individual sections to follow.

**Model 1**

Variable ENROLLMT (university enrollment) was entered in Model 1 as the independent variable. The regression coefficient for ENROLLMT is .00008 and the exponential function of the coefficient (\( \text{Exp} \)) is 1.0001. The coefficient is positive and significant at the .001 level. Therefore, it can be concluded that there is a statistically significant relationship between dependent variable ATM Adoption and the independent variable ENROLLMT. The odds ratio = 1.0001 indicates that (without size classification) larger universities are 0.01% more likely than smaller universities to adopt ATM.

The model chi-square tests the null hypothesis that the coefficient in the current model, except the constant, is 0 (Norusis, 1994). This is comparable to the overall F test for regression. If Model \( \chi^2 \) is statistically significant beyond \( p = .05 \), it indicates that the predictor variable contributes no chance to the explanation of the dependent variable [Menard 1995]. In this model, a Model \( \chi^2 \) of 23.979 relative to one degree of freedom is obviously statistically significant beyond \( p = .05 \), which indicates that university size is significantly associated with ATM adoption.

**Model 2**

Model 2 included independent variables ENROLLMT and UTYPE. The coefficients for ENROLLMT and UTYPE are .00003 and 1.6733 respectively. The \( \text{Exp} \) value for ENROLLMT is 1.0000, for UTYPE is 5.3297. The p-value for ENROLLMT is \( p > .05 \), indicating that, controlling for variable UTYPE, there is a weak relationship between university size and ATM adoption.

The p-value for UTYPE is \( p < .001 \). Therefore, we can conclude that, irrespective of university size, there is a statistically significant relationship between ATM Adoption and UTYPE. To be more specific, the odds ratio 5.3297 shows that, net of university size, the odds of adopting ATM for Research Universities is 433% greater than for non-research universities.

Model 2 has a Model \( \chi^2 \) of 37.519 relative to two degrees of freedom, which is statistically significant beyond \( p = .05 \). Compared to Model 1, Model 2 improves the goodness-of-fit (37.519 - 23.979 = 13.540) \((2 - 1 = 1)\). As a result, Model 2 is better than Model 1 because variable university type further improves the fit by \( \chi^2 = 13.540 \) relative to one degree of freedom.

**Model 3**

Variable ENROLLMT, UTYPE, and NTBUDGET were involved in Model 3. The p-value for ENROLLMT is \( p > .05 \), indicating that, controlling for variables UTYPE and NTBUDGET, there is a weak relationship between university size and ATM adoption. The p-value for UTYPE and NTBUDGET is \( p < .001 \). A p-value less than .001 allows us to conclude that, regardless of ENROLLMT and NTBUDGET, there is a statistically significant relationship between ATM Adoption and UTYPE; that, regardless of ENROLLMT and UTYPE, there is a statistically significant relationship between ATM Adoption and NTBUDGET.

The odds ratio for UTYPE is 5.2095, which indicates that, net of university size and N/T budget, the odds of adopting ATM for Research Universities is 421% greater than for non-research universities. The odds ratio 1.0542 for NTBUDGET indicates that, net of university size and university type, the odds of adopting ATM for universities with higher networking/telecommunication budget are 5.42% greater than for universities with lower N/T budget. It is apparent that both university type and N/T budget are significant predictors of ATM adoption in campus networking, university type in particular.
Model 3 shows a Model $\chi^2$ of 53.953 relative to three degrees of freedom, which is statistically significant beyond $p = .05$. Compared to Model 2, Model 3 improves the goodness-of-fit ($53.953 - 37.519 = 16.434$) ($3 - 2 = 1$). As a result, Model 3 is better than Model 2 because variable N/T budget further improves the fit by ($\chi^2 = 16.434$ relative to one degree of freedom.

**Model 4**

Variable ENROLLMT, UTYPE, NTBUDGET, MT1, and MT2 were entered in Model 4. The p-value for ENROLLMT is $p > .05$, indicating that, controlling for variables UTYPE, NTBUDGET, MT1, and MT2, there is a weak relationship between university size and ATM adoption. The p-value for UTYPE and NTBUDGET is $p < .001$. A p-value less than .001 allows us to conclude that, regardless of ENROLLMT, NTBUDGET, MT1, and MT2, there is a statistically significant relationship between ATM Adoption and UTYPE; that, regardless of ENROLLMT, UTYPE, MT1, and MT2, there is a statistically significant relationship between ATM Adoption and NTBUDGET. The odds ratio for UTYPE is 4.5740, which indicates that, net of university size, N/T budget, MT1, and MT2, the odds of adopting ATM for Research Universities are 357% greater than for non-research universities. The odds ratio for NTBUDGET is 1.0540, which indicates that, net of university size, type, MT1, and MT2, the odds for universities with a higher N/T budget are 5.4% greater than for universities with a lower N/T budget. The p-value for MT1 is $p < .05$, which indicates that, irrespective of variable university size, university type, N/T budget, and the second index variable, there is a statistically significant relationship between ATM Adoption and the first index variable, namely the germane application of information system in university settings. This indicates that information processing maturity is statistically related to ATM adoption, which means that universities with germane application of information system are 101% more likely to adopt ATM than universities with immaterial applications of information system. The p-value for MT2 is $p > .05$. Therefore, it can be concluded that there is no statistically significant relationship between ATM Adoption and the second index variable, namely the immaterial application of information system in university settings. This conclusion supports the logic assumption that most universities have germane application of information system.

Model 4 submits a Model $\chi^2$ of 53.953 relative to two degrees of freedom, which is statistically significant beyond $p = .05$. Compared to Model 3, Model 4 improves the goodness-of-fit ($59.618 - 53.953 = 5.665$) ($5 - 3 = 2$). As a result, Model 4 is better than Model 3 because variable MT1 further improves the fit by ($\chi^2 = 5.665$ relative to two degrees of freedom.

**Enrollment Size Model**

A model separate from the nested models was performed for each independent variables in the nested models, namely, variables university type, finances, and information processing maturity (MT1 and MT2) using logistic regression. The results were very much similar to the results shown in the nested models, and they are not listed in tables for that particular reason. It was interesting to notice, however, that university size showed much less significant relationship to ATM adoption when compared with other variables. This is because variable ENROLLMT was used as a continuous variable. In reality, university size varies greatly from about 1,000 up to 50,000. Built on this fact, an additional model, Enrollment Size Model, was performed to analyze variable ENROLLMT based on the variable's enrollment classification of size: Small, Medium, Large, Very Large. The detailed analysis of variable ENROLLMT of Model 1 in [Tab. 5] revealed farther information about the relationship of university size and ATM adoption, and the results of this detailed analysis were far more informative and significant than Model 1 of [Tab. 4] in explaining the relationship of university size and ATM adoption. [Tab. 5] shows the logistic regression coefficients and Goodness-of-fit for the Enrollment Size Model.

<table>
<thead>
<tr>
<th>Variable</th>
<th>$\chi^2$</th>
<th>Exp ($\chi^2$)</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENROLLMT</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
As discussed above, variable ENROLLMT is significant in the nested models as shown in [Tab. 4], but its odds ratio is low, almost equal to 1 (Exp (0 = 1.0001). This is because ENROLLMT was used as one variable, disregarding the different size of each university. In the current model, however, enrollment size classification was involved and the odds ratio increased dramatically for Medium, Large, and Very Large categories, with reference to the Small size category. [Tab. 5] indicates that Medium size universities (Exp (0 = 2.0940) are 109% more likely to adopt ATM than Small size universities. Large size universities (Exp (0 = 5.8800) are 488% more likely to adopt ATM than Small size universities. Very Large size universities (Exp (0 = 16.3333) are 1533% more likely to adopt ATM than Small size universities. It is evident that university size does seem to be significantly related to ATM adoption. When classified, university size is a very good predictor of ATM adoption in campus networking.

**Conclusion**

Logistic regression statistical analysis shows that the variables university size, university type, university finances are all predictors of ATM adoption in campus networking. The MT1 index variable of information processing maturity is also a predictor of ATM adoption. Of these variables, university type is strongly associated with ATM adoption in campus networking. The statistics suggest that Research Universities are 357% more likely to adopt ATM than non-research universities, as shown in Model 4 of [Tab. 4]. University finances, namely Networking/Telecommunications budget, is also a good predictor of ATM adoption. The statistics indicate that universities with a higher N/T budget are 5.4% more likely to adopt ATM than universities with a lower N/T budget, as shown in Model 4 of [Tab. 4].

Statistics for MT1 shows that germane application of information systems is a significant predictor of ATM adoption, which indicates that universities with germane application of information systems tends to have higher information processing maturity. What this means is that universities with germane application of information systems, namely, germane application of information systems to support data and information handling, unstructured decision-making, and learning and research, are 101% greater to adopt ATM than universities without germane application of information systems. Thus, it is cognitive to conclude that information processing maturity is significantly related to ATM adoption.

In sum, the results of the statistical analysis support all the research questions of the study. Thus a conclusion is drawn: there is a statistically significant relationship between university size and ATM adoption; that there is a statistically significant relationship between university type and ATM adoption; that there is a statistically significant relationship between university finances and ATM adoption; that there is a statistically significant relationship between university information processing maturity and ATM adoption.

Abstract: The teaching/learning process does not occur in a vacuum. No instructor, support staff or administrator can single-handedly create an optimum learning environment for many students with different learning styles. When technology is added in the teaching/learning environment, a fundamental "team" commitment is required from the students, instructor, technology support staff and university administration. Music is a very accessible means to discuss many interdisciplinary teaching/technology applications. Thus, our presentation will demonstrate how the "team" commitment at UW-Stevens Point has enhanced the creative development of UWSP music students. Our panel presentation includes Daniel Goulet, Professor, Department of Mathematics and Computing and former Director of Academic Computing Services; Charles Rochester Young, Assistant Professor and Coordinator of Music Theory and Composition; and Patricia Ploetz, Multimedia/Instructional Technology Coordinator.

1. Setting the Stage:

The thesis for the session is:

For the use of technology to blossom in the teaching/learning environment, there must be a fundamental commitment by the campus to develop and support a technologically rich environment that fosters creative teaching/learning for students and faculty. This fundamental commitment must include a "teaching/learning team" of students, faculty, support staff and administration.

We will develop our thesis using the ideas of 'message' and 'medium.'

- In short, the faculty member should focus on the message and not have the medium that carries the message stand in his/her way.
- The administration should focus on the medium and create the technologically rich environment for the faculty member.
- The support staff should focus on bridging the gap between message and medium, that is, framing the teaching/learning message through a technology medium.

And these three foci are the content for our session.
2. Focus on the Message: Music Theory/Composition Demonstrating the Message

2.1 Teaching the Whole Person: Multiple Levels of Apprenticeship

"It is my belief that the purpose of teaching is to allow and guide students to becoming successful without the teacher. Another way of looking at this issue is 'if the student BECOMES the teacher, then they will not need a teacher.' Many successful and enduring teaching/learning models are based upon this ideal. Apprenticeships have served in this teaching/learning capacity in the arts and sciences since the dawn of time." [Charles Rochester Young].

For the students (apprentices) to become their own teacher, they must first have the same experiences as the master. In other words, they must manipulate the same tools and materials as the master, recreate the master's decision making processes, eventually learning to think like the master. Michelangelo expressed this idea, saying that "you cannot surpass that which you cannot equal." In other words, you cannot surpass your teacher/master until you can equal them.

The master/apprentice relationship ideally exists in many levels. An ideal example would be an environment where the students (apprentice) study with a faculty member (middle level master), but the faculty member (middle level master) may also be studying the work of a luminary in the profession (high level master) concurrently. This scenario allows both the student (apprentice) and faculty (middle level master) to learn and grow individually, while also establishing an important link between the luminary in the profession (high-level master) and the student (apprentice) through faculty/student interaction. Technology can enrich this interaction in ways that were previously not possible.

![Why Apprentice?](image)

Figure 1: Why Apprentice?

2.2 Apprenticeships using Technology

Composing music and performing music are each extremely complex processes where numerous choices must be made. The decisions that are made by a high level master composer and/or performer are critical for achieving a particular musical result. Using archived musical scores and performances on a computer, students can use the vast editing capabilities of the computer to redesign structures and re-create the decision making processes of the high level master composer or performer--literally dissecting the music and putting it back together again, not unlike what one might find done to a frog in a typical Biology course! The educational thesis for this exploration and discovery is: "You can't understand the creative process if you're always looking at the creative PRODUCTS! You must strive to re-create the PROCESS!"

Through these processes, students learn stylistic elements of a particular performer and/or composer and also learn from the "inside out" how the musical results are achieved. With thoughtful guidance by the faculty member (middle level master), the student ultimately learns how to think like that high level master.

While these types of activities were impractical before, the digital environment is perfect for these realizations, being much easier and faster than cutting and pasting the music with scissors and tape. The students can also hear the results of their inquiries immediately WITHOUT having to copy off the music, find willing musicians to rehearse it for weeks or years before performing it.
2.3 Sample Classroom Activities for the Musical Apprentice

2.3.1 Example One: Performing

The educational goal is for the students to learn how to make a performance more interesting through their interpretation of the printed music. The idea is to have the students realize that there is more to music than the realization of dots and lines on a printed page!

The students are given the printed music for George Gershwin's *Rhapsody in Blue*. They are then asked to listen to three different performances of the same excerpt while following the music. Before the recorded examples are played, the students are told that one of the performances is by George Gershwin (the composer), another performance is by a member of the UWSP faculty, and another performance is played by a computer. The students are told that the computer version has no human interpretation at all and is strictly a "technical" performance devoid of any human expression. The students are asked when they listen and follow the music to see if they can identify which of the three performances they are listening to.

Once we have listened and identified each of the performers, we use the computer to explore subtle nuances of each human performance such as pedaling, key velocity (touch), and variations of tempo. The computer is ideal for this because it can visually and aurally capture details and resolution that often escape human aural perception and musical notation systems. We then compare how the two human performances compare with one another and also how the computer performance compares to the two human performances. Since the computer performance is uninteresting, this gives students an idea of how subtle nuances of human interpretation are essential in achieving an interesting performance.

Additionally, students are asked to perform the same excerpt on their respective instruments so that they may apprentice with both of these master performers. When performing the students utilize a technology that we developed at UWSP, called a PORTABLE PRACTICE UNIT. This unit allows the student to record themselves playing alongside the master performer and gives them an objective vehicle for comparing their interpretation with those of the master performers. The final stage in this learning process is for the students to actually compose and perform their own pieces based on the principles of interpretation that they have discovered in their study of these masters.

2.3.2 Example Two: Studying the Science and Structure of Music

The educational goal is for the students to learn how composers vary and develop the themes in their pieces and organize those variations into a larger composite structure.

The students are presented with a digitized version of a theme from a piano piece. (NOTE: At this point, the students have NOT been issued the published music for the famous piece—they only have the digitized theme.) They are instructed to compose variations upon this theme and save each of their variations on the computer. During this time, the faculty member provides individualized instruction to each student as they write their variations.

Once the students have successfully composed a small number of variations, the faculty member takes ALL of the collective variations that were written by the students and posts them over the local access network, so that students can discuss and evaluate the work of their classmates. The next stage is to have the students take this collection of variations and put them into an order that they find suitable. Since these variations were not connected to each other before, the emphasis at this stage is having the students create "seams" between the variations that allow each variation to flow smoothly into the subsequent variations later in the work.

The next stage involves the students comparing their respective sets of variations with those of their colleagues. The students are encouraged to discuss the various solutions for the problems that they all faced. Next, the students are given the published music and a recording for the piano piece and asked to compare their solutions with the solutions of the master composer. At this point, students are encouraged to re-write sections to compare with the choices of the original composer. Sections or various structures are also removed by the students to see how integral they are to the overall design of the work at large. Finally, students are also encouraged to make changes in the score that their classmates must be able to identify as mistakes.

Having walked in the composer's footsteps and having re-created their various decision making processes, the students ultimately will have a illuminating and meaningful experience studying this masterpiece and its composer!
3. Focus on the Medium: UWSP’s Strategic Direction

The basic thesis here is that faculty and students should not be working at this level.

3.1 The Strategic Direction

As the graphic below depicts, and paraphrasing the UWSP Information Technology Strategic Plan Vision Statement1, we want all students, faculty and staff to have what they need, where they need and when they need Information Technology resources in a 24 x 7 environment.

![Figure 2: Graphical View of the UWSP Information Technology Strategic Plan Vision Statement](image)

3.2 What They Need

Faculty and students need access to software resources, both specialized for their discipline specific applications and general applications for productivity tools and communications. The latter are provided through a campus standard called the Comprehensive Software Environment which specifies a Windows 95 environment, Microsoft Office 97 as the standard productivity software, Microsoft Exchange as the single email system. The former are specified by the faculty and made available through a central campus service. All applications are launched via a campus common user interface.

Faculty and students need access to computing hardware. Each faculty member has a microcomputer in hers/his office, 90% are Intel based and 10% are Macintosh, both of recent models. A campus-funded replacement policy updates each faculty microcomputer every four years. Campus public computing labs located in the academic buildings, as well as in the residence halls, provide microcomputer access for students.

3.3 Where They Need

Access to information resources are needed everywhere. On-campus, a universal cabling plant connects every office, classroom and residence hall room to an optical fiber and copper campus network backbone. A single network operating system, Microsoft’s NT, connects all locations into a single, ubiquitous communications network.

3.4 When They Need: A 24 x 7 Environment

All hardware, network, and software systems are available in a 24 hours-a-day, 7 days-a-week environment, providing resources when they are needed, i.e., time and place independent.

---

1 The Vision of the UWSP Information Technology Environment is for all students, faculty and staff to be connected in an electronic environment that is one of the basic elements in UWSP’s educational fabric. From their normal working environment (including residence halls, laboratories, and offices), students, faculty and staff will have the computing power and voice/data/video communication links needed to accomplish their work. However, the technical aspects of the environment will be transparent to the non-technical user.
3.5 The Faculty We Focus On

At UWSP, we subscribe to the 80/20 rule. Thus, as can be seen in the following graphic, our energies and resources are targeted at a particular subset of faculty; those faculty who will have the greatest impact on the teaching/learning environment, but who will not drain the institution of all the financial and human technology resources.

![Figure 3: The 80/20 Rule for Faculty Technology Support](image)

4. Focus on Translating the Medium to the Message:

We take many approaches to support faculty using technology in instruction. For this discussion, we respond to the title theme, "It Takes More than Two to Tango: Translating The Medium To The Message," by exploring methods and ideas adopted when working with faculty new to the instructional technology environment.

4.1 Ground Zero

In order to entice anyone into doing something that is different, it is essential that the person -- in this case a faculty member-- be shown how a suggested change represents an evolutionary step along a path. This is related to how change can take place in an orderly fashion with small amounts of learning being spaced out over a long enough period of time to minimize the potential for negative impacts, like taking one away from family, favorite pastimes, and other important professional activities. Our way of encouraging this "evolutionary step" is to take a four-stage approach. However, in order to begin this process we need to first identify the working environment.

4.2 Creating an environment that supports change.

Whether we realize it or not, we are asking faculty to change the way they work. Therefore, any program dedicated to providing faculty support must be "customer service oriented". With that attitude in mind the first contact, whether a telephone call, a chance meeting in the hallway, or an email for information, becomes a critical point in establishing a supportive working relationship.

4.3 The First Stage

More often than not, a faculty member's first contact with the department is a request for help to scan an image or a slide. Once a request for support has been received, an appointment is made (generally within 24 hours) and they (the faculty member) learn how to scan. By meeting their immediate needs as quickly and efficiently as possible, we build a reputation for excellent customer service and are often able to identify some new technological activity that moves the relationship into the second stage of instructional development.
4.4 The Second Stage

While the scanning process itself is easy enough, taking that task to the next level through image editing, networking, and CD development leads to a whole new world of exciting educational technologies. When faculty can begin to see the possibilities technology has to offer the teaching/learning environment, they (faculty), become the force for change. It is at this point that learning can be promoted, demonstrating how change can take place in an orderly fashion. What was once an insurmountable task, becomes several functional and useful steps that ultimately lead to significant changes.

4.5 The Third Stage

By examining just a few of the activities that needed to take place in the scanning process above, we can see an increase in knowledge that supports the move to a new level of learning
- understanding file extensions
- manipulating large files,
- using networking, compression, and new storage mediums (CD's)
- working with image editing software,
These activities become a series of steps leading to the development of presentations and web pages, the preparatory steps to authoring technologically enhanced courseware.

4.6 The Fourth Stage

As faculty move into the fourth stage, they are learning the skills required to refine the context so that students can interact with the resources, that is, make up their own way through the resources, or take one of several faculty guided excursions. They (faculty) begin to critically examine the content through assessment. This assessment leads to refinement and refinement to new assessment asking the question: "Is technology enhancing the educational process, and thereby accomplishing its task?"

Eventually faculty, who were new to the instructional technology environment, become "the experts" and are invited to share their experiences with other faculty through workshops, conferences and in-house presentations. These new experts become a resource for both peers and students and the team adds a new member to the collaborative process.

5. In Summary, The Team:

The Team Building Model:
- Is achieved through faculty, staff and student collaboration.
- Supports efforts to enhance the teaching/learning environment through technology by building bridges where there are none, and enhancing those that already exist.

Team development begins when faculty, staff and students, working toward a common goal fill a need that the individual cannot. The product that results is more than the sum of the parts.

The Team:
- Moves from one place to the next, contracting and expanding as the need arises.
- Is created in need, and ends when that need no longer exists.
- Is an agreement, formal or informal, between its members, to collaborate on a specific project.

In this instance, the project is the meaningful and effective use of technology in the classroom.
A QUALITATIVE STUDY OF LEARNERS' USE OF AN INSTRUCTIONAL MULTI/HYPERMEDIA PROGRAM IN AN EDUCATIONAL TRAINING ENVIRONMENT

Shwu-ching Young
Center for General Education & Center for Teacher Education
National Tsing Hua University, Taiwan 30043
scy@cge.nthu.edu.tw

Abstract The purpose of this study was to investigate how AC members interacted with and perceived a CD-ROM-based instructional program integrated in their training context as a supplementary tool. The theory of constructivism was examined to frame the theoretical foundation of this study. A qualitative case-study approach was employed and data were collected through video/audio tapes, questionnaires, follow-up interviews, and field notes. Six female AC members of diverse background were recruited on a voluntary basis. Major findings of the study reveal that: (a) participants felt they situated themselves in an authentic learning environment that engaged them in a meaningful learning situation; (b) the CD-ROM was perceived to be a very interesting, appropriate, useful, helpful and good supplementary medium to adapt to heterogeneous learners' learning styles, needs, situations, expectations, and previous computer experiences. Discussions of findings concerning learning from constructivist viewpoints and human-machine interactions are presented.

1. INTRODUCTION

A combination of the state-of-the-art technology and the recently rising learning theory rooted in constructivism makes Vannevar Bush's dream early in 1940s become a reality nowadays [Smith 1988; Marsh & Kumar 1992]. Multi/hypermedia, a merger of text, graphic, animation, video and sound into a computer platform providing information in non-linear formats, is an attempt to provide a learning environment enriched with a wealth of information to allow learners to construct their own knowledge without requiring them to physically leave the environment in which they are working [Marsh & Kumar 1992]. This medium offers more learner control in the learning process than other traditional media presentations [Marchionini 1988]. Moreover, the beauty of interactive multimedia is that it can be designed to provide a variety of paths to learners, making it one of the best media available for dealing with heterogeneous groups of learners [Schwier & Misanchuk 1993].

2. THEORETICAL FRAMEWORK

Technologists' constructivism. Learning theory/psychology has undergone a major revolution during the past few decades [Cooper 1993]. Constructivism is not a completely new approach to learning theory. Most constructivists [Duffy & Jonassen 1992; Bednar, Cunningham, Duffy & Perry 1992; Ertmer & Newby 1993] hold that there is a real world that individuals experience uniquely. Therefore, they argue that meaning is imposed on the world by individuals, rather than existing in the world independently of human beings. Constructivists hold that there are many ways to structure the world and any event or concept should bear many meanings or perspectives. Generally speaking, constructivists do not deny the existence of the real world. The way we know the world is from individual's meaning making, interpretations of our experiences. Since there are many possible meanings to know based on individual experiences, we do not have to strive for a predetermined correct meaning [Duffy & Jonassen 1992; Ertmer & Newby 1993].
In the constructivist view, learning is an active and constructive process in which the learner builds an internal representation of knowledge from the individual experiences and interactions with the world. This representation of knowledge is constantly open to change [Bednar, Cunningham, Duffy & Perry 1992]. In terms of the constructivist learning approach, learners are encouraged to actively explore complex environments in which knowledge is linked to a context under study and to the experiences that the learners bring to the context. Cunningham points out [Cunningham 1992] that a major difference between objectivists and constructivists is that objectivists expect and require acceptance and closure of a world view, while the constructivist anticipate and encourage debate.

Constructivism and instructional design. The information-rich age and advanced technology capabilities, as identified by [Duffy and Jonassen 1992], have caused us to revisit constructivism, to reconceptualize the learning process and to design new instructional approaches. Cooper states that "changing the learning environment to incorporate a constructivist view adds complexity" [Cooper 1993, p17]. Because constructivists focus on the design of learning environments rather than instructional sequences, designing constructivist learning environments is much more challenging and difficult than designing objectivist instruction.

Jonassen points out that a constructivist design is more process-oriented than product-oriented and accordingly suggests that the design process should be concerned with designing environments which support the construction of knowledge and a meaningful, authentic context for learning and using the knowledge the learner constructs [Jonassen 1994]. Winn says that in order to accommodate instructional design to constructivist environments of learning we require a change in the assumptions about how people learn and about how instructional decisions are made [Winn 1992].

An emphasis on learning rather than on performance and instruction. Under constructivism, learners select their own learning strategies, and their own goals and objectives, unlike traditional instruction in which goals and objectives are set by curriculum developers and instructional designers and thus the learning content and strategy are imposed on the learners from the outside. Consequently, the learner has to assume much of the responsibility for selecting what to learn and how to learn it. The function of the instructional system is to support what the learner decides to do and the role of the teacher becomes a coach or a facilitator.

3. RESEARCH QUESTIONS

The foci of this study were to understand, describe and interpret how AC members interacted with and perceived a CD-ROM-based instructional program on interactive writing. Two sets of questions guided this study: Question set #1: How did AC members interact with this CD-ROM-based Instructional Program on Interactive Writing? What were the variations? What factors seemed to account for the variations? Question set #2: How did AC members perceive this CD-ROM-based Instructional Program on Interactive Writing? And how did this change over time? And did they perceive they learned about interactive writing?

4. METHODOLOGY

The methodology here includes background of the study project, research design, the participants, the study site, the procedures of data collection and data analysis.

Background of the research project. A CD-ROM (running on a Macintosh platform) entitled "Interactive Writing" is an interactive hypermedia instructional program developed as a cooperative project between the program of Instructional Design and Technology at a University in the mid-west of
the States and the AC Project [a national service project funded by the U. S. government since 1994] from autumn quarter 1994 through winter quarter 1995. The purpose of the project was to produce an instructional aide which supported the training of AC members who were to learn about interactive writing techniques in 1995–1996 training settings. The CD-ROM was composed of two major parts: "Let me learn about it" which was a slide presentation of detailed information about interactive writing and "Let me try it" which was a simulation of the interactive writing process, designed to allow learners to apply the factual knowledge they gained from the "Let me learn about it" to a real-world-like context with three virtual students.

Research Design. A qualitative case-study approach was employed to obtain a rich, in-depth and holistic account of the research events. Within the postpositivist paradigms [in Lather's term 1991], this study was described as interpretive and descriptive in nature, and utilize a case study method. As Patton points out, "cases illustrate the value of detailed, descriptive data in deepening our understanding of individual variation" [p. 17]. The design was flexible and emergent [Patton 1990].

Participants. Six AC female members were recruited on a voluntary basis and divided into three dyads/cases while they were interacting with the CD-ROM for three times. Their age range was 18 to 37 with a mean of 25 years old. Compared with the other two teams, team one was the oldest team with a mean of 35.5 years old. The age means of teams two and three were very close to each other at 20.5 and 19 years old respectively. Among the six participants, only one of them had already completed her Master's degree while the other five were working on baccalaureate degrees at a state University, four full time and one part time. Their majors were Business Management, ESL, Engineering, Psychology, Physical Therapy, and Management Information Systems.

Study site. The study site was the place where AC trainers conducted their training programs and where the members went to teach the young children. Once the intensive training workshop was completed, all of the members were assigned to three local urban elementary schools in Columbus, Ohio. Since the use of interactive writing program on the CD-ROM was intended to be part of their ongoing training process, there was a computer setup in each of the three elementary school's libraries.

Procedures of data collection and analysis. AC training schedule was divided into two phases: a three-week intensive training and an on-going regular training held on every Friday morning. Interactive writing session, given on the first day of AC on-going regular training, was the only session that provided AC members the necessary Interactive Writing techniques. A follow-up questionnaire was administered to the participants right after the session in order to collect the participants' starting experiences and knowledge about the Interactive Writing.

Shortly after the participants had received the interactive writing session in their training, each team started to use the CD-ROM for three times in the following three consecutive weeks. For the purpose of data triangulation, three sets of follow-up questionnaires were used to collect more information and to verify other data each time right after the participants used the CD-ROM. The questionnaires were mainly intended to help them gather their thoughts on the use of this technology and what content they learned from the CD-ROM program.

Several methods such as prolonged engagement, persistent observation, triangulation and thick description, peer debriefing, and member check were used to establish trustworthiness [Lather 1993; Merryfield 1990; Lincoln & Guba 1985] and to legitimate the research project. Reflexive subjectivity on the part of the researcher was continuing throughout the process of data collection and analysis. The data were gathered from the fall quarter of 1995 through winter quarter of 1996 and analyzed from winter through summer quarter of 1996.

The data analysis was guided by the research questions. The analysis evolved around the data reduction, organization, matching, generation of categories and coding as a result of the study of all
data sources. The categorized data eventually assisted the researcher in data interpretation and drawing conclusions.

5. RESULTS

5.1 Major findings related to the first set of questions

Participants felt they situated themselves in an authentic learning environment that engaged them in a meaningful learning situation. Evidence from observations revealed no general pattern in terms of behaviors was found across dyad’s interactions with the multi/hypermedia program but some phenomena were observed in their interactions with each section of the computer instructional program. Various factors were identified to account for the multiple variations in behaviors. They were: participants’ starting knowledge and experiences with interactive writing; personalities [active, passive, outgoing, or introverted; frustration tolerance levels]; personal learning styles [auditory or visual learners]; personal role [being a mother or a student]; intra-team interactions; comfort levels and familiarity with the computing technology; grade levels of their focus students; and curiosity about the innovative technology.

Additionally, in terms of seat arrangement and mouse manipulation, a pattern was discerned across three teams. The study showed that the participants were more likely to sit on the right side with the mouse if they were more active, comfortable with the operation of the mouse, preferred working individually, or liked to take the leading role in their learning or to control the advancement of the CD-ROM. Otherwise, the participants would like to sit in the left seat if they were shy, introverted, preferred working in pairs, or liked to be guided by their teammates.

Each team took different pathways and learned at its own pace. Each team took different pathways to get through this virtual world. Each participant felt that she learned at her own pace and most of the time she had control over the program except in the mode of “Let me try it” when she got stuck being unable to figure out some meanings of the language in the “Help” mode. It appeared that, most of the time, in the section of “Let me learn about it,” each team could make sense out of the meaning of each button and branched to different parts based on their own content knowledge, individual expectations, computer experience and team interactions and decisions.

5.2 Major findings related to the second set of questions

Overall, there was a unanimous agreement among the six participants about the multi/hypermedia program’s primary purpose. That is, all of the participants perceived the CD-ROM program to be a very interesting, appropriate, useful, and helpful medium to adapt to heterogeneous learners’ individual needs and their learning styles and, further, a good supplementary tool to be used in the AC training program.

The participants expressed that the program refreshed and reinforced their learning about the interactive writing techniques. In addition, the participants pointed out that they experienced some changes in their understanding of interactive writing after they used this CD-ROM several times. Participants constructed different knowledge, and gained in-depth information depending on the individual learning styles, needs, situations, expectations, and previous computer experiences.

6. DISCUSSION OF FINDINGS AND IMPLICATIONS

6.1 Discussion of learning from constructivist viewpoints

This study demonstrates that learning is a matter of individual knowledge construction and meaning making. It confirms the view [Bednar, Cunningham, Duffy, & Perry 1992] that learning is an
active and constructive process in which the learner builds an internal representation of knowledge from the individual experiences and interactions with the world. The way a learner knows the world is from individual meaning making and interpretation of personal experiences.

In addition, the study also supports Zucchermaglio's claim [Zucchermaglio 1993]. Learning with the CD-ROM, evidently, the participants were not merely empty vessels waiting to be filled up with the information from the computer. Instead, they had to actively interact with the screen and with their partners, to make sense out of the interface and language used in the program, then to make a shared decision before they moved forward to the next screens to explore further information.

This study correlates with other researchers' claim [Jonassen, Meyers, & McKillop 1996] that learning with hyper/multimedia requires learners' mindful engagement in the tasks provided by the technologies. Through the capabilities of the technologies and learners' intellectual partnership, the learners will enhance their thinking and learning. The participants showed evidence of being able to enhance their learning through the use of this CD-ROM program. They expressed that they learned more in-depth information which they did not gain from the AC training session and according to the data collected from the questionnaires the information each participant picked up from the technology was not the same. They also experienced changes in their understanding of interactive writing after they used this CD-ROM several times.

6.2 Discussion of human-machine interactions

The participants in this study demonstrated that their path taking was different and at the very beginning they did not use the directional arrow to advance their learning as the designers had intended. In addition, each team had various degrees of difficulty in interacting with the section, “Let me try it”, due to being unable to figure out some language employed in the “Help” mode and unable to recognize some button icons. This finding corresponds with a study conducted by [Suchman 1987] concerning how novices interacted with a Xerox machine. Suchman points out although the designer assumes that the preplanned information is clearly and adequately designed and, thus, would be used by the individuals while they are interacting with the system, the predictive model is insensitive to particular circumstances [Suchman 1987]. This is the fundamental problem in human-machine interaction.

As a matter of fact, the users, based on individual prior knowledge, need for exploration, and expectations, have both their own intent, which is not always following the procedural instructions assumed by the designer, and their own way to interpret the information which is made on a moment by moment basis in their particular situations. Suchman observed that "because instructions were sometimes read by the users differently from the way they were actually written on the displays, the reader will find some inconsistencies between sequences and the displays to which they refer" [Suchman 1987, p. 122]. Because language, common sense, and ongoing discussions, etc., will appear contextually related with the procedural information presented on the screen as part of the ongoing activity, Suchman explains that the users/learners, not the predictive model of instructions, will determine their actions through their own interpretation in particular situations. Significantly, the research finding corresponds with Suchman’s study. When the participants referred to the “Help” mode in the section of “Let me try it”, they interpreted the word “Student” as a “Student’s portfolio”, while the designers meant a “Student’s picture”. Their own interpretation suggested that they were to click on the icon of “Student’s portfolio” instead of that of the “Student’s picture”.

While interacting with a program, as Norman points out, usually the users cannot talk directly with the designers, and all communication takes place through the system image, which involves the use of language and symbolic representation [Norman 1990]. If the system image does not make the design model clear plus the user constructs his/her own meaning and knowledge based on his/her prior
experiences and knowledge, then the user's mental model does not match the designer's model. As a result, the user gets stuck. Norman's claim similarly corresponds to Suchman's finding. This study reveals that some participants did run into this type of problem. The participants' mental model, being not identical to the design model, resulted from the user's different meaning construction which, at times, hindered them from further advancement in the program.

Abstract: The Computer Clubhouse Esslingen was founded in 1996. After two years of operation the first experiences are compared with the early concept and the goals. Experiences with mentors and professional equipment in multimedia and communication areas are looked at. Further developments of the Computer Clubhouse idea are discussed.

1 Introduction

The Computer Clubhouse Esslingen was founded in autumn 1996 as a third party project (without government money) in the Softwarelabor of the Polytech of Esslingen (FHTE[1]) following an idea of the MIT-Media Laboratory [2]. It is the first application in Europe. Therefore, it is necessary to adapt the principles to the German framework of education, technology, sponsoring and bureaucracy.

The principle aims are: strengthening kids in a non-school environment, improving their ability to be successful members of the economy, enhancing their explorative activities in the world of new technology and researching the possibilities of applying „animative didactic“[3] in conjunction with new media and digital technology. This effort is based on cooperation between the FHTE and the College for Social Sciences (HFS[4]).

2 Background

Students of the MIT led the way in the late seventies in transferring computer technology from military applications to the people. Later emerging companies like Apple Inc. also began to push towards these aims. Cheap access to computer technology in the middle and late eighties led numerous people become nerds and geeks in computing. The majority studied the digital technology by themselves. They met in computer clubs, on bulletin boards and so on.

In the nineties computing started to enter more and more the areas of normal life. Nowadays knowing how to use computers has started to be widely accepted as a new „cultural-technology“. Therefore, technology has started to be used in schools [5] and other areas of education. In these environments the new technology has to subordinate itself to the traditional didactical forms. Project work, open environments and free access are not standards.

This contradiction between history and the present age gave birth to the idea of Computer Clubhouses. During the eighties most kid’s experience was either „a lot of time and no money to buy the tools“ – or other way round. The open didactic and drop-in character of a clubhouse, the absence of schedules and the availability of hi-tech professional tools overcome these problems and open a playground for interested kids, boys and girls. That’s why our kids think it’s grand to be here.

In the past few years the explorative character of learning has been recaptured in a lot of different fields. Learning in projects has started to become more and more attractive. Since multimedia emerged at the same time, it is just a small step to utilise the synergy of these fields to make learning in projects more successful. Since the multimedia and the digital technology fields are extremely versatile but still accessible through the same hardware, this opens a the possibility for any kind of mind to develop its own interests. The limits are set mainly by time and software, which is a good reason for using professional software with fewer limitations.
3 The Computer Clubhouse Esslingen

The aim of the Computer Clubhouse Esslingen (CCE) [6] is to link know-how from three different areas: industry, education and technical science represented by sponsors and the polytechnics of the fields of technology and social work.

The CCE provides an area which is open to kids between 10 – 16 years 5 days a week at afternoons. These young people are linked by a club, which is open to everybody, and mentored by students, trainees and volunteers of every age (14 – 104 years).

The room is equipped with 9 multimedia computers, instruments for robotics experiments (LEGO [7], Bricks [8], Crickets [9]), multimedia-professional programs (Photoshop, Pagemaker, Frontpage, Premiere, Office, Director, Navigator) and a professional communication connection (DFN, 34 MBit) and programs.

Opaschowski’s theses on animative didactics are the basis for the free and open learning environment provided by the CCE. The main principles include the encouraging our members through mentors, the voluntary participation of both members and mentors, the informal surroundings and the choice between alternatives.

The mentors support the members by providing a role model, including educational, social and technical know-how. They work animately and support the members in their motivation to create and to follow their own ideas.

3.1 Principles of the Computer Clubhouse Esslingen

3.1.1 Free access

In order to take advantage of the new prospectives offered by technology, communication and multimedia and to prevent the marginalisation of certain parts of society, the computer clubhouse was developed with the aim of addressing in particular children and youth from underserved communities. This means primarily that cost or know-how barriers should not determine access to new technologies.

Free access refers not only to the cost barriers but also to the pedagogical approach. In accordance with the principles of animative didactics, the Computer Clubhouse offers a many faceted program in which each individual can find his or her niche.

3.1.2 The building blocks of the animative didactics

- **freedom of choice**: means to act spontaneously according to one’s own personal inclinations without pressures or obligation. The children and youth are free to choose whether to come or not and whether to deal with a particular topic or not.
- **informality**: means to be able to act naturally, to be free from pressures to perform and succeed, and it means the absence of competition. An open situation without undue external regulation is offered as a field for activity.
- **free use of time**: The participants are allowed to divide their time as they choose and use it flexibly. They may determine for themselves the duration, tempo, intensity and interruptions of their activities. The only limits come from organisational parameters such as opening hours.

3.1.3 These three building blocks are supplemented by three principles

- **choice**: means the possibility to choose between alternatives.
- **decision**: means the ability to make one’s own decisions, to follow one’s vision, to know what one wants, to be able to use the freedom of choice. Nevertheless choice options must be structured so as to not overtax the participants.
- **initiative**: means that one develops initiative, either alone or with partners, that trust in one’s own potential is given room for growth, that one experience opportunities to practice self-organisation.

Thus free access also means the inner freedom to set one’s own goals.
3.1.4 Free access and Gender

It is well known that women and girls have a different approach to technology than men and boys do. An empirical study [10] has established that only a small percentage of girls actively use new technologies, such as the internet. In the light of our previous discussion of the fact that media competence is a prerequisite for active participation in today's society, we devote special attention to making these competences accessible to girls.

Through the institution of a "girl's day" we were able to double the participation of girls in the CCE (from 20 to 40%).

3.1.5 Rules

CCE offers children and youth the opportunity to develop in an atmosphere characterised by self-determination. Of course, there are some basic rules that all the members of the Computer Clubhouse must agree to abide by.

- Respect for other people.
- Respect other peoples' ideas (there are no stupid ideas, there are only stupid remarks).
- Handle the equipment with care.
- Team spirit is a matter of honor.

3.1.6 Mentoring

The members of our clubhouse are accompanied by our mentors, as they explore the new technologies. These mentors have the role of coaches, social catalyzers, advisors and sources of ideas for new projects. They work on their own projects and encourage club members to join them. At present there are 25 mentors working as volunteers at the CCE. In the past year and a half some of those currently working with us have grown up from the ranks of our members. Just as children and youth grow into the roles of mentors, in the CCE young and old, girls and boys, grammar school children, high school students and college students, volunteers and staff, Germans and non-Germans and professionals of both pedagogical and technical areas of competence work together and learn from one another. The approach is to integrate across gender, generations, school and class. And it is to a high degree interdisciplinary.

3.2 Subjects

3.2.1 Media Competence

Work in the CCE bases on the premise that media competence in the near future will be a necessary prerequisite for active participation in community processes.

The open framework CCE is the foundation that allows us to develop media competence. If we begin with the premise that media usage becomes increasingly productive, innovative, competent and critically reflective as the media get used in a supplementary fashion and as media use is tied into an intensive social and communicative context [11], then we must conclude that the mentoring system is a key factor in transmitting the basics of media competence. Our program offers not only the possibility of approaching the new media from the members own perspective but also offers an almost unlimited diversity in the person of the mentors. This generates a learning context that goes well beyond anything that is usually possible in normal daily encounters.

The interaction amongst a diversity of individuals provides insights and opportunities for exchanges amongst different perspectives and value systems. The experiences made with technology are embedded in a social context characterised by tolerance, respect and communication.

Through the fascination of the creative process, the strengthening of one's self by oneself and by the others participating in the process, through experiences in social learning and reflections on its conditions, the participants develop an ability to deal with media autonomously.

3.2.2 Communication

Media, both old and new, change not only working and leisure time, they also influence human communication habits. These include not only speech and interchange, but also the establishment of closeness
and distance, of strangerhood and trust, of security and insecurity, of solidarity toward the in-group and boundaries toward the out-group.

That is why this factor is given special attention at CCE. In the Computer Clubhouse we have the facilities for email, video-conferencing, chatting and access to news groups. Few studies have been done on the changes the use of these media induce in our habits of communication.

3.2.3 Creativity

We assume that creative potential slumbers in every human being. By creativity we mean the ability to develop something new, to leave old paths in order to grow and develop and to thus be prepared for the future. Creativity is closely linked to self confidence, to the recognition of one's own strengths and weaknesses and the ability to use these and to change whenever necessary.

Especially today when the dominant orientation towards consumption is impeding innovation and progress, the rudder must be turned about and this must be done in the early years. In order to ease the transition from consumption to creativity, we offer access to professional programs in all areas of multimedia. We do not offer access to computer games, though the children and youth are allowed to develop their own. It is quite interesting that they do not miss the games.

4 Experience

The original idea of the CCE was to provide children and youth between the ages of 10 and 16 with the opportunity for a playful interaction with new technologies in order to open new chances for their future. Mentors were brought in to accompany them in this process. In the course of the last six months, a remarkable development has been observed. It turned out that a high potential for the further development of the mentors lay dormant in our project (vis. What the project gets out of mentoring).

Currently CCE is frequented by about 50 children and youth per week. Each day 3-4 Mentors are available. As we mentioned above, these mentors come from diverse backgrounds and bring a variety of skills and talents to the CCE. Initially it was important that the mentors be equipped with considerable technical know-how, however that has changed in the past year. Young people who have attended the Computer Clubhouse over an extended period of time are often more skilled in the use of multi-media programs than the mentors. This has led to sharing and communal learning in projects. This mutual give and take promotes growth and development both in regard to the personal as well as the technical sphere.

4.1 Communication

At CCE communication takes place on many levels. Face-to-face communication with team members, mentors and other children plays an important role. It is essential for the further development of projects, for making arrangements, for telling one another jokes, for exchanging experiences, sharing, building relationships, for establishing different points of view, etc.

Shortly after we introduced "chatting" the kids enjoyed communicating with one another via the chat-channel, although they sat in plain view of each other. Sometimes these exchanges were open and sometimes they were disguised in order to tease the other person.

Since then the kids have begun to chat in public chat-channels with whoever is active there. They fib and lie, get annoyed over obscene overtures, and themselves write in vulgar language. They find a pleasant chat partner and make dates for future chats. They enjoy themselves, have fun and a good time. They learn to be selective in their chats, to defend themselves against unwelcome advances and to deal with both pleasant and unpleasant aspects. They struggle to understand and handle the anonymity of this medium and correlate that with their own desire to get to know people and to establish closeness. They try to relate this to their own environment and to integrate these experiences into their own view of the world.

Rejoicing over the abundance of superficial contacts opened by chatting does not last long. Increasingly we observe that stable contacts are being sought. The Computer Clubhouse members are delighted when nickname they recognise turns up and they can get on with constructing a relationship. Some chat contacts develop into pen pal relationships. That happens first through email and then, when the other has become sufficiently defined and is judged reliable, telephone and letter correspondence may follow. The latter are only permitted when the parents give their consent. At times the relationship culminates in a face-to-face encounter.
We want to build on these processes and are encouraging chats with the members of the Computer Clubhouses in Boston and with other youth centres. For this we are implementing a video conference system, because we have realised how much motivation is enhanced by seeing the "face" of the other.

We are only permitting access to video conferencing for this purpose, because we have unfortunately established that behind most video conference addresses lurk male individuals with sexist intentions. We are trying to encourage students to devote their diploma theses to the study of the changes in our communication habits and potentials which have been brought through communication technology.

4.2 What the project gets out of mentoring

As mentioned above under point 4, the potential for further development of mentors which lies dormant in this project is quite high. Through our contacts to industry, science, small and middle sized businesses, institutions and through their cooperation in CCE projects numerous opportunities for mentors to participate in projects have been generated.

Their membership at CCE also gives them access to international contacts via the Computer Clubhouse Network (CCN). One of our mentors is planning to write her diploma thesis at the Computer Clubhouse of the Computer Museum in Boston.

Furthermore, mentors are entering into cooperation with a regional business and schools to offer courses in digital photography and Internet basics. Following a period of intensive preparation at CCE, they will be developing their own courses. In the process, they will begin to learn to deal with a commercial situation: negotiating contracts, preparing presentation materials, organising conferences, speaking in public before a paying audience.

Other mentors are taking their first steps toward founding their own businesses, contracting out their know-how on the Internet to regional business partners. A mentor found a position as the direct result of the diploma thesis he wrote with us at CCE.

These results surpass our original goals of giving children and youth access to new technologies. People of different age groups are getting unexpected chances. These developmental opportunities are not limited to the technical sphere, they also include an extension of their own social competencies. People who otherwise would have concentrated on the technical area have had to develop extensive social skills in order to work at CCE. On the other hand, people who came to us with extensive social skills have had to expand their horizons and learn competencies in the technical area. We can see how this has enriched their lives but cannot yet fully estimate how this will enhance their professional potential.

5 Conclusions

Mentoring of socially underserved kids needs to be high quality which can only be achieved if mentors are involved in reflection processes which are professionally guided. This can only be done if the project is financially stable. This is one of our major goals for the immediate future.

In practice media competence is formed in the Computer Clubhouse Esslingen. Kids don’t explicitly mention what they learn by electronically manipulating pictures. Their parents do (when looking at a manipulated picture in 1997): "Oh, this is possible? So I can’t believe in any picture in newspapers nor in TV any more!". Well, he understood – just a little late. Let’s help our kids understand earlier.

After two years of operation, the advantages of a Computer Clubhouse environment have been firmly established. The first fruits have ripened. Kids have begun to take over interests from other kids. Mentors are beginning to start their own companies with the new know-how and self confidence they gained here.

As the members start to understand how the financing and sponsoring work, they want to support the CCE-Team in these fields. When sponsors realise the importance of CCE members as a "resource of ideas," they try to find ways to participate their development. Preliminary studies for prototypes of products have been realised at CCE, in cooperation between the sponsors, the Polytech Esslingen (FHTE) and the College for Social Science (HfS).

At this stage the project Computer Clubhouse Esslingen is emerging as far more than a project for children. It is a "Think Tank" and the kids are one of the resources and the motor.

SHORT PAPERS
A Multimedia Tool for Teaching Geometry at Schools

Nikos Alexandris, Maria Virvou, Maria Moundridou
Department of Computer Science,
University of Piraeus

Piraeus, Greece
E-mail: {alexandr | mvirvou | mariaml}@unipi.gr

This paper describes the work-in-progress of a collaboration project for the development of educational multimedia software. The project involves four partners both from academic and industrial sites and is funded by the Ministry of Education of Greece. The final product is going to be tested and evaluated in 60 state schools which are all going to be connected in a network. Among the development partners, there are two national Universities, the Greek Mathematical Society and a software house company. The content of this paper describes the design of the final product and focuses mainly on the work undertaken by the University partner where the authors belong (University of Piraeus) which is mainly the incorporation of intelligence into the system.

The main objective of this project is to create educational software that is going to be useful to teachers and students in high school classrooms and will be integrated in the school curriculum. The domain chosen has been geometry which has been admittedly considered difficult for students to understand [Senk 1983]. Therefore, we believe that software can provide a lot of help in improving the students' intuition and skills in the domain.

One very important feature of the tool to be developed will be an environment where teachers and students will have the facility to draw geometric figures which will be able to show motion like [Geometer's Sketchpad 1989]. The tool will also incorporate intelligence by using techniques from Intelligent Tutoring Systems [Wenger 1987] that have been proved successful. ITSs have not been used a lot in classrooms although there have been quite a lot of successful evaluations of ITSs [e.g. Mark & Greer 1991] and reports on the successful use in classrooms of ITSs such as ANGLE (A New Geometry Learning Environment) [Koedinger & Anderson 1993].

Teachers are going to be able to use this tool to prepare the presentation of the lesson that they plan to teach and exercises. Students are going to be able to use this tool to read lessons prepared by the teacher, answer questions, draw solutions to exercises and experiment with drawings. The various ways that a teacher and/or a student is going to be able to use the software will be represented as different modes of function:

- **Authoring mode**: In this mode the teacher will be able to prepare the presentation of a lesson and create new exercises in the context of the theory presented.
- **Lecturing mode**: All students in class are going to see in their screen the file that the teacher will have created in order to present a new lesson. In this case, the teacher will be in charge of the operation of the tool, which is going to work in the local network of the class.
- **Experimentation mode**: In this mode the students or the teacher will be able to experiment with drawings, motion and graphical representations. The teacher may need to do this in order to select the best way to present a lesson and the student may need to do this in order to gain better understanding and intuition of geometric proofs. The user interface in this mode will give the user two choices:
  a) Toolbar and menus, such as those used in the authoring mode.
  b) Communication in simple natural language sentences, such as “Draw a circle with centre O(x,y) and radius R”.

The facility of natural language processing will give the student the opportunity to practice and improve his/her skill of giving accurate and complete geometric descriptions.
• **Solving exercises mode:** Students are going to solve exercises using the facility of constructing geometry graphics. The educational software is also going to allow communication with a word processor.

• **Answering multiple choice questions:** Students are going to answer multiple choice questions which will help them consolidate their knowledge and assist the teacher in evaluating the students' performance. The students' performance in these questions is going to be saved in a file each time they are in this mode.

• **Recognition of geometric entities:** In this mode the student is going to answer questions concerning the recognition of geometric entities that will be shown on the screen. For example, if a "rectangle" figure is shown on the screen, the student will be asked the question: "What is this figure". The answer to the question will be in natural language. The system will recognize answers such as: "I think that it is a square", or "I don't know", or "It is probably a rectangle". In this mode, there is going to be a diagnostic component which will perform error diagnosis on the student’s answer. If the student’s answer is not correct the system will try to find out what the misconception of the student has been and give an explanation to the student.

The diagnostic component will be based on previous research [Virvou 1992] in error diagnosis which explored the utility of a formal theory of Human Plausible Reasoning [Collins & Michalski 1989] in the context of an Intelligent Help System for novice users of operating systems. This research showed that Human Plausible Reasoning could be a helpful tool when employed for error diagnosis. The Human Plausible Reasoning theory was originally constructed to provide a formal model of the reasoning that people use to reach some conclusions about questions for which they do not know the immediate answer. Starting from a question asked to a person, the theory tries to model the inferences made, based on similarities, dissimilarities, generalisations and specialisations that people often use to make plausible guesses. These guesses may be correct as well as incorrect. For the purposes of error diagnosis we exploit the fact that the human plausible reasoning that a student may have used may have led him/her to make an error. The diagnostic component will make use of domain knowledge represented in “isa” and “ispart” hierarchies. An example of an “isa” hierarchy is illustrated in [Fig. 1]. This “isa” hierarchy represents generalisation/specialisation relations among different quadrilaterals. For example, a parallelogram is a special case of a trapezoid, therefore it may inherit some properties from trapezoids. If a student gives an erroneous answer to the question asked then the system will try to locate the student’s answer in the hierarchy where the correct answer belongs.

![Figure 1: An isa-hierarchy concerning quadrilaterals](image)

Assuming that the figure shown in the screen is a rhombus, an example of interaction between the system and a student could be the following:

*System:* What is this figure, Chris?
*Student:* I am not sure.
*System:* Make an effort...
*Student:* It is not a trapezoid
*System:* You are right. Can you tell me what it is?
*Student:* It is a parallelogram
*System:* What you say is not wrong. The quadrilateral that you see is a special case of a parallelogram. Can you find what it is?
Student: Is it a rectangle?
System: No Chris, it is not a rectangle. It is a rhombus. I think you should study the definitions of quadrilaterals.

Improving the Learning Curve in Using an Intelligent Testing Environment during Practical Classes

Bollin Andreas, bollin@ist.tu-graz.ac.at
IICM Software Technology
Technical University Graz, Austria

1 Introduction

Because of today’s big amount of students in practical classes, teaching is, for tutors and students, hard effort. Beneath administrative details (accounts, teamwork) correcting the data needs a lot of time. Usually at the end of semester all data is collected and tested with a one or two weeks effort. This approach has two main disadvantages: too much time is needed for correcting the files and students have to wait weeks for important feedback. Possible problems are found too late, mostly after the end of semester. It turns out, that only a few points should be altered to improve the lecture: administration should be easy and mainly of students' responsibility, students should get immediate feedback and students should be able to learn from their mistakes. Finding solutions for that demands will lead to motivated students, better solutions and less work for the tutors.

2 Strategy for improvement

At the beginning of the project our students had to hand in their solutions via floppy disks. Teamwork was hard to manage, because our tutors had to organise the teams and were overwhelmed with group-internal problems. The first job of our environment was to simplify the way of handing in the solutions and to report problems with file formats. To intensify the contact with the students an electronically way of feedback, using the WWW, was established. The next milestone was the delegation of responsibility of teamwork to the students. The basic idea was to give students the right to create their own groups out of a pool of students. The administration of groups obeys following rules:

1. every student is able to found a group or to become a member of a group,
2. every student founding a group becomes the leader and takes responsibility. He gets back a name for his group and is able to set a password,
3. every student willing to join a group needs to know the name and the password of the group. Groups can be left at any time.

The rules are quite simple but effective. (So it is possible to exclude a lazy member out of the group by simply leaving the group and founding another one.) It is also possible to find partners for the team using our electronic discussion forum, which is based on Hyper-Wave (see [Kappe 93] for more information). The last milestone was the handing in with feedback. It was reached during the summer semester 1996/97. Our system now consists of a testing environment, a hand-in environment, an electronically feedback corner and a discussion board.

The question why students should use the environment, is still not answered. There are several reasons and benefits for students when using our working environment:

1. self-organising groups, so that teamwork (if allowed) is possible,
2. students can solve their exercise using more than one file. They can structurize their solution,
3. immediate feedback (whenever a test is possible), students have the chance to improve their work till a
deadline is reached,
4. students can send notes to the tutor and use the discussion board.

Beneath the fact, that tutors can also use the discussion board, there are the following important benefits:

1. the system is platform independent and works across the Internet,
2. the environment is easy to configure (simple to manage users and their data, lectures etc.),
3. the students' data (solutions) are already pre-tested. If no test routines are available at least correct formats
   are guaranteed and statistics are already generated.

Since 1994 we noticed, that the motivation grew and with it the quality of their work. Administrative work
decreased. Students used the feedback corner and our discussion forum to help improving the lessons, statistics
and test results helped fixing the marks and our tutors had more time for teaching. They also were able to
recognise students' problems much faster and were able to help them during the course. The drop-out rate
decreased from 20% (average mark 2.1) in 1995 to 11% (with an average mark of 1.6) in 1997.

3 Design and Implementation

In the year 1994 our institute began to improve its lessons and practical classes. In the winter term 1996 we
decided to redesign the whole system [see Bollin 95] and to improve our services. All interfaces were reviewed
and adapted to the Internet and heterogeneous systems (using Java JDK 1.1). The aim was platform
independence and comfort as well as meeting the demands listed above. The system consists of several
distributed objects (for a detailed description see [Bollin 97]), a test server including different testing
environments, a hand-in server, the administrative client and the hand-in client. All objects are implemented in
Java (which is leading to platform independence) and the working environment can be used together with
common Internet browsers.

4 Future Work

The system is designed to be modular and easy to extend. The next thing to do is to generate a student's profile
out of his or her last trials. The profile data should be used to find the optimal way in assisting students solving
the problem. Once a problem is recognised, an educational software should be activated automatically (to assist
students in finding a solution by their own). In winter semester 1998 we want to improve the feedback and in
the following summer semester we want to be ready to use educational systems in combination with our
working environment - to build a more intelligent working environment.

Dissolving the Barriers - Interactions Across Distance:  
The Creation of a “Virtual Faculty”

Trish Andrews  
Educational Services and Learning Support  
Central Queensland University  
Australia  
t.andrews@cqu.edu.au

Dr. Greg Klease  
School of Chemical and Biomedical Sciences  
Central Queensland University  
Australia  
g.klease@cqu.edu.au

Introduction

Using Chemistry as a test vehicle, several Australian Universities in mainly regional parts of Australia - central Queensland, Northern Territory, southern Victoria and Tasmania collaborated, through the assistance of a national teaching development grant to develop a virtual faculty using videoconferencing. By means of a “virtual faculty” senior Chemistry students in small science departments were able to access classes offered by experts in distant centres.

This project encompassed Universities in four Australian states - Northern Territory, Queensland, Victoria, and Tasmania - spanning an area approximately the size of Europe. Staff and students in Universities such as Northern Territory University (NTU), University of Tasmania (UTAS) and Central Queensland University (CQU) are geographically isolated from other Universities, limiting opportunities for cross institutional staff and student interaction.

It was recognised that students undertaking final year, honours or postgraduate courses in small Universities are frequently disadvantaged because of the limited specialist expertise that may be located within the institution. Chemistry is a discipline which is characterised by a remarkable diversity. Only very large departments, usually located in large city Universities can afford the staff to cover all the areas outside the mainstream. As is the case for most physical sciences, chemistry departments tread a thin line between capital investment in equipment and additional teaching staff. Both are essential for a wellrounded chemical education. Most regional institutions have foci of expertise, albeit though small, which if combined together represent a formidable range of teaching talents. The wide scale adoption of telecommunications technologies, such as videoconferencing, across Australian Universities offers a viable avenue for linking together clusters of expertise to form a “virtual faculty”.

Questions Asked in the Creation of a Virtual Faculty

The project sought information to gauge student and staff opinion on the following key issues.

- to what extent does a “virtual faculty” enhance the learning experience?
- what are the strengths and weaknesses of a “virtual faculty” as a learning environment?
- what are the most appropriate forms of learning best mediated via videoconferencing?
what features, from a student’s perspective, make the "virtual faculty" attractive as a mode of learning delivery?

What professional development for staff and students is required to effectively implement the "virtual faculty"?

Feedback to date suggests that the creation of a "virtual faculty" has been viewed as beneficial by participants in spite of some of the difficulties. Difficulties tend to focus around technical and administrative problems and the differences in content background of students at the different Universities.

**Challenges in Creating Virtual Faculties**

Technical difficulties accounted for a loss of approximately 10% of class time. Approximately 80% of this lost time can be attributed to bridge failures, (a bridge is the electronic device that connects multiple sites in a video or other kind of teleconference). While videoconferencing is generally stable in point to point conferences, multi-point conferences can experience difficulties. The remaining lost time can be explained through problems with other aspects of the technology such as incorrect video hook-ups and difficulties with the operation of the document camera.

Administrative difficulties tended to focus around timetabling issues and differences in semester organisation. Timetabling was a major issue as Universities tend to plan their courses around the timetabling needs of individual institutions well in advance. However, a willingness to work within an extended University day ie from 7.00 am to 10.00 pm can help to overcome this problem. Students surveyed indicated a willingness to operate within more flexible hours as long as they were given sufficient lead time to organise themselves. The students at remote Universities like NTU found that the opportunity to extend their understanding of chemistry and the exposure to totally different ideas and knowledge was a valuable experience.

While overall finding the experience positive, remote students commented on their feeling of being "poor country cousins". There was a strong feeling expressed that because they had different background knowledge to students from the delivering University that they weren’t as knowledgeable as their peers. This feeling inhibited the students in asking questions and even presenting ideas for fear of appearing inadequate in front of the larger (distributed) group. Students felt that the small group tutorials where individual University groups worked with the lecturer (from the geographically distant delivering University) was an excellent method in clarifying understanding and enabling interaction and sharing of ideas between lecturer and student.

To make “virtual faculties” effective, both staff and students need to develop skills in working in multi-site distributed teaching environments. Many staff require considerable professional development to acquire a thorough understanding of this unfamiliar teaching and learning environment. There is a need to master the operational aspects of the technology as well as develop the pedagogical understandings to create an interactive learning environment.

**Conclusions**

“Virtual faculties” have an important role to play in extending expertise in specialised subject areas to students and staff in geographically remote Universities. In spite of some technical and administrative problems, students strongly supported the concept of a “virtual faculty” and hoped to see such opportunities to extend their knowledge of chemistry continue.

The Education Communications Network (ECN) Project:
A Strategy to Integrate Educational Telecommunications into Schools in Georgia

George Antelava
Scientific Industrial Training Union (SITU) "INFORMATICS"
Georgia
E-mail: situ@access.sanet.ge

Integrating Educational Communications into Georgia's schools is crucial for giving youth in our country the opportunity to use IT for their activities in the information technology age and to benefit from the collective knowledge of the planet.

The role of IT in education is perhaps more prominent than it has ever been. IT is not only a subject in its own right, it emphasised right across the National Curriculum.

Activities in this direction in our country started in 1979. Scientific Industrial Training Union (SITU) "INFORMATICS" at present is a leading organisation in Georgia in the field. The Main Centre (located in Tbilisi) and the Regional Centres (situated in different cities throughout the country) constitutes its organisational structure.

To support Georgia's Education System Reforming Act, SITU "INFORMATICS" is accomplishing the Education Communications Network (ECN) project, funded by the "Open Society - Georgia" Foundation (member of the Soros Foundations network).

The goal of the project is to combine telecommunications and IT industry standards with specialist knowledge of the demanding requirements of Georgia's schools for providing them with the best of educational telecommunications.

The Project addresses the following major issues:
- Give youth and adults throughout the country an opportunity to use telecommunications and information technologies for the purpose of their educational and professional development;
- Using telecommunications services get access to diversity of educational and decision support information;
- Establish partnership with education partners world-wide.

The project's strategy naturally continues our fifteen year old experience of introducing IT into the education system:
- Personalising the learning process on the basis of educational information technologies;
- Organising groups of educators, instructors and software engineers for development and adaptation of modern educational IT applications;
- Providing intensive training for teachers for implementing teaching and learning with computers in schools.

According to the project's strategy we are planning the following:
- Establish the ECN Sites at the Regional Centres of Informatics and schools in all regions of Georgia, which will give all beneficiaries of the project to interface with each other, see, touch and use the ECN services;
- Develop and implement the Hypermedia Education System (HES) - the ECN-based non-profit state-wide information system;
- Design original multimedia educational applications, essential for the National Curriculum.

In the frame of the ECN project we are accomplishing the "Students are using e-mail" programme. Major objectives of the programme are:
- To develop creative and critical thinking skills;
- To allow students to accept leadership roles and establish areas of responsibility;
- To provide students with an opportunity to work in collaborative groups;
- To provide students with an opportunity to experience telecommunications firsthand;
- To improve self-esteem by successfully communicating and receiving responses via e-mail.

Students are involved in all aspects of computer-based production of electronic newspaper (e-paper) to be...
published on the ECN. They are obtaining stories for their e-paper from colleagues at the ECN participating schools and the Regional Centres across the country through e-mail connections. Students write articles for the e-paper, for example: current events from schools' life, advice from home economics, weather reports, statistics and graphs from maths, reports from business/economics, and sports. After examining sample resumes and identifying elements of a resume and cover letter, students from the ECN participating schools and the Regional Centres design and produce using word processing software their own resume and cover letter to apply for the e-paper staff. Prior to beginning work on the e-paper, students work as a research team to survey, interview and observe their target readership. The goal is how to determine what should be included in the e-paper and how to promote it. By this time several students have been "hired" as e-paper staff members (executive managers, advertising managers, public relations managers). The e-paper staff publishes issues monthly.

Accumulated experience will prospect good opportunities for the broadening of schools participating in the ECN project.

The ECN will provide for users from the educational institutions throughout the country the possibility to get access to diversity of educational and decision support information and work together for designing educational software, overlooking or newly creating text-books, curriculum programs, instructional materials. Bridging to external networks will be accomplished as a component of the ECN implementation.

The Project's implementation requires the interaction of technology, people, training and managerial procedures. We create in the frame of the project an organisational mechanism of "Change Management", parallel to IT advances.

The Project will radically change the classroom in three major ways. First off all it will change the way teachers teach in a positive and rewarding manner. In addition the ECN exponentially will increase the resources available for teaching and learning. Finally it will create opportunity for students to learn through meaningful, real-life activities and personal interchanges.

The ECN gives the educational telecommunications national visibility and at the same time demonstrate possibilities of IT-based methods for problem solving, particularly suitable for making transition to an open society.
Abstract: Web database tools are one of the hottest Internet technologies of the past year. While companies developing business systems are the prime target for these tools, there are a number of useful ways web databases can be used in educational environments, especially in higher education. This paper describes the general applications of web databases that are relevant for higher education. Two specific projects at the University of Virginia are discussed including an application that helps students use and add to unpublished Civil War research materials and a discussion forum system for student-student and student-faculty out-of-class interaction.

Why Use a Web Database?

One of the hottest topics in the Internet development community in the past year is web-enabled or web-based databases [Spitzer, 1997]. It is no accident that this rise in popularity coincides with the increase in industry and business use of the inter- and intranet. The largest single type of business and enterprise computing application is client-server database transactions — this need is driving the production of a wide variety of web tools for interfacing with and controlling databases. These tools range from add-ons to existing database packages or HTML editors to full-fledged web-based application servers. Though the majority of these tools are designed for traditional database tasks in the corporate environment such as data entry and retrieval, they also provide the opportunity to fundamentally change the way web sites are produced, managed, and delivered.

There are a number of advantages that result from using databases to generate dynamic web sites. One obvious advantage is that information currently in an existing database can be queried to produce web pages “on-the-fly”. Databases, however, can do far more than link legacy data to the Web! The content of entire web sites can be stored as data objects and generated as needed for the audience. This obviously saves time spent on brute force page design, but more importantly, it makes it easier to administer, modify, and customize the web site itself. In addition to these benefits, there are a number of novel ways to use web databases to address specific educational tasks, both in and out of the classroom.

Dynamic web content is clearly useful for drawing in new visitors for commercial web sites, but educational web sites have an inherent need for regular change and maintenance. Time and money both affect the regularity of content updating, so any time- or labor-saving techniques have a strong influence on the existence of new content [Helinski, 1996]. Web databases are well-suited for situations where new content fits into a common template, such as images of slides with explanatory notes in an architecture course. In this situation, after the instructor scans the slide and uploads it to the web server, the only remaining step is to add the image filename and the accompanying explanatory text to the course database which makes the new page instantly available to students. Several projects of this nature have been developed at the University of Virginia using commercial and locally-developed web database tools.

If the server load of generating dynamic web pages is too high, or if the appropriate server software is not available, another alternative is to generate static web pages based on templates filled by the database application itself. This case is just like the previous example, except at regular intervals the new entries in the database must be “published”. This solution requires more work, but is still much easier than creating web pages from scratch. This method is straightforward to implement for a single-user and can be used with desktop databases such as Filemaker and Access.

The design components of a web site are the perfect candidate for automatic management tools. Page headers and footer as well as navigation bars are common page elements that need frequent updating. A
number of HTML editors now provide the capability to interface with external databases to change, generate, and update these elements dynamically or as a regular batch job.

Databases are also an excellent way to manage the media components of a web site. Educational web sites are rich with a variety of media types, whether they are design components such as backgrounds and logos or the actual educational content, such as images, sounds, and text. Object-oriented databases are best-suited to this task [White, 1996], but even the simplest comma-delimited text file can serve as a useful data-management tool. In our experience, instructional web sites comprise huge numbers of media objects and multiple of content creators; databases make managing this information and longer-term maintenance issues easier to address. The database manages the file names and locations, as well as version information, which not only simplifies administrative tasks, but also begins to document the web development process. This approach is particularly useful when student help is employed in web design since it provides an archive of information about the media objects (original source, processing techniques used) that would otherwise leave with the graduating student.

**Educational Benefits of Web Databases**

Along with the various administrative tasks that databases simplify for web sites, they offer the educator completely new ways to involve students in learning [Smeaton & Neilson, 1997]. These so far fall into two basic categories: involving the student in a dialogue and involving the student in research. Both prospects are exciting and offer the instructor ways to fundamentally improve both the depth and dynamic of their courses. I’d like to conclude with several examples of each type of application.

Many academic research projects, especially in the humanities and social sciences, involve large amounts of information, which are typically stored in some sort of database structure. Web databases are useful for giving students access to these growing bodies of research information that are being developed by the course instructor or colleagues. Since this information is usually highly structured, using template-driven web pages to present the data as it is added allows the students to participate in research in real-time. One current research project at the University of Virginia is a catalog of the military records of over 17,000 Civil War soldiers, based on information previously only available at the National Archives in Washington, DC. Students in a Civil War history course taught by that instructor are not only using that data as it comes online (and being among the first people ever to use that data) but they are actually becoming part of the research process itself by adding their own research to this material.

Databases can also be used to fuel web-based applications that allow students to interact asynchronously. One great example is a form-based student response system that facilitates student-professor interaction [Carver, et. al., 1996]. Another example that we are using at the University of Virginia is a discussion forum package run by a web-database system. It is intended to be used as a bulletin board for interaction outside of class-time. This forum provides a place to have students answer each other questions and interact with the instructor. We have also modified the package to serve as a web-based private student journal where the student and instructor can both have instant access to the student’s weekly journal assignments.

There are a number of convincing reasons to use web-based databases in education. The advantages of databases as a site- and media-management tool are clear, particularly the reduced need for manual page design work. The applications of web-databases to improving instructional methods, however, is an even more exciting and little-studied area. The Teaching+Technology Initiative at the University of Virginia is starting to shed some light on their uses in education. Our web site, http://cti.itc.virginia.edu/iti/, has more information and links to our current projects.

Acknowledgements

Parts of this paper are based on research done by the author for his forthcoming book The Essential Guide to Web Site Databases. He would like to thank John Wiley & Sons, Inc. for permission to use extracts from that book.
1. Introduction

In general publishing multimedia data is a very time consuming task which requires skills not commonly available. To make the publishing process more effective we use a database to manage and arrange the parts of multimedia information.

2. Approach

Textual data is currently stored inside the database, multimedia data are stored outside the database in the filesystem. The structure of a document is defined inside the database. An author uses a special entry-form of the database to edit his information (text, image, audio, video). Pictures, audio and video-sequences are prepared with special picture/audio/video applications like Adobe Premiere or Adobe Photoshop. The database is used to arrange the information and to store the relationships between the elements.

The database is accessible via a WWW-Server. For the user, information is accessible via a normal WWW-browser. The final formatting of the information is carried out using format specifications which offer several layout alternatives depending on the kind of media and structure of information. It is important to state that the formatting rules are separated from the information and the structure of the document. So it is possible to deliver the same content in different layouts for different needs.

3. Advantages

Editing and storing information and meta-information inside a database offers various advantages:
1. several people can edit simultaneously inside the same structure
2. access rights for authors and readers are managed by the database
3. different views on the stored information
4. (e.g. through tables of content, indices, glossaries which are all generated automatically by the system)
5. the author just enters his content, the formatting is done by the system (no need to learn html or to use a html editor, however basic understanding of url’s is required for linking to information outside the database)
6. high quality user-interface; html-output is produced by the rules of the system, not the author

A demonstration of the system described above is accessible via WWW at the following URL: <http://lomi.e-technik.uni-ulm.de/lanpro>. The demonstration shows content related to a lesson about Local Area Networks.

4. Current Work

Course material like mentioned above is normally based on existing collections. To integrate these resources we started to build a database backed repository for this material. As a starting point we used a collection of the local physics department containing pictures, videos and descriptions of demonstration experiments and other physics related material.

Our current work will result in a version of LanPro (LanPro is the name of the demo-version at http://lomi.e-technik.uni-ulm.de/lanpro), which will be integrated with our multimedia repository: From the editor it will be possible to retrieve objects from the repository and integrate the results into a presentation.
5. Screenshots

In the last several years the use of the World Wide Web for multimedia/hypermedia delivery of education and training has increased substantially. As the amount of development with this medium increases, the need for sound instructional design principles beyond surface page element design also increases. Design prescriptions based upon theoretical principles related to learning are needed to guide this development. Currently, Web-based instruction lacks a strong theoretical base on which to draw instructional principles. Theoretical principles which have evolved surrounding related technologies such as distance education, hypertext and computer-mediated communications can be applied to instruction and training delivered via the World Wide Web. Principles borrowed from theoretical constructs associated with emerging technologies can perhaps provide a strong starting point for establishing a theoretical base which can assist designers and developers in creating instructionally powerful applications for the Web. Working toward an established theoretical base may permit Web-based instruction to become as Ritchie & Hoffman [1997] describe it "... a meaningful learning environment where learning is fostered and supported".

This paper will provide a review of applicable theoretical constructs which are associated with related Web-based technologies. Theory bases related to distance education, computer-mediated communications and hypertext technologies will be reviewed.

DISTANCE EDUCATION

Web-based instruction may be subsumed under the broader framework of distance education and therefore can assume a similar theoretical stance. Unfortunately, the field of distance education is also struggling to define a theoretical foundation [Mclsaac & Gunawardena, 1996]. Much of the research and discourse to date involving distance education has been focused primarily on the delivery technologies involved and less on developing a strong theoretical framework on which to base further instructional development. However, a few theoretical constructs related to adult learning and communication theory have emerged such as theories of autonomy [Wedemeyer, 1977] and independence of the learner [Moore, 1973]. More recently, Moore & Kearsley [1996] expanded these ideas into the theory of transactional distance which describes a pedagogical distance between learners and instructors. Through these evolving constructs, researchers and theorists in the distance education field have begun to focus more on the learning process and teaching strategies rather than the technologies involved. These constructs can also serve as a tool to help to view and describe interactions within Web-based instructional applications providing a much needed theoretical base. Designers and developers can then incorporate these useful principles into their sites therefore potentially improving the quality of instruction available with this medium.

COMPUTER-MEDIATED COMMUNICATIONS
A related technology often included in various distance education efforts and also incorporated into Web-based instruction is described as computer-mediated communications (CMC). CMC can include different types of electronic communication channels such as electronic mail, computer conferencing, discussion lists and bulletin boards. These technologies have been most notably associated with constructivist learning theory due to the "conversational" nature of the medium which can provide a vehicle for social negotiation of meaning [Romiszowski & Mason, 1996]. As a capability within many Web-based instructional courses, CMC represents a means for collaborative inquiry into a specific topic area. Researchers in this area are beginning to examine the nature of collaboration and communication applied to the Web-based environment [Collis, 1997]. Familiarity with the fundamental principles of constructivist learning theory as implemented by computer mediated communications, may provide needed insight into the design of instructional environments on the Web.

HYPERTEXT

The World Wide Web represents the quintessential hypertext environment. A theoretical notion which has evolved associated with the nature of hypertext is cognitive flexibility theory. This theory conceptualized by Rand Spiro and colleagues [Spiro & Jehng, 1988] addresses the complexity of higher level instructional content attempting to avoid the common perspective of oversimplifying concepts for instructional delivery. The theory provides a framework for addressing ill-structured content through providing the learner with multiple representations of content and multiple opportunities to assimilate complex information by viewing it through different themes. The attributes of hypertext provide a good match for this theoretical approach. Web-based instruction capitalizes primarily on hypertext delivery of information and can therefore benefit from implementing a theoretical construct such as cognitive flexibility theory.

CONCLUSION

As the World Wide Web may ultimately become the delivery mechanism for the majority of education and training worldwide, more emphasis is needed to ground further development in strong theoretical principles related to learning. Much can be gained from existing theoretical constructs which have been associated with related technologies providing a framework from which to expand our thinking related to the new technological delivery of instruction on the Web and sound learning principles.

Introduction

When discussing multimedia development and delivery we come across a heated debate between two different camps. Those promoting and defending CD ROM based technologies and others promoting exclusive Web based technologies. This paper explores some issues surrounding these debates and it looks at the Hybrid CD ROM/Web technology that takes the best from both.

When considering the use of multimedia technologies, issues concerning authoring, delivery and content updates are the most important. In particular, questions focus on whether the authoring tools are powerful and easy to use with both formats and whether there is a real benefit from using this technology. Macromedia Authorware® was selected as the best authoring software to test these criteria.

Why use hybrid CD-ROM/Web technology?

CD-ROM has been considered by many as a good and inexpensive vehicle for delivering interactive multimedia content. The major criticism of CD-ROM is that its content is static and quickly becomes out of date. On the other hand, Internet and in particular the World Wide Web, offers incredible flexibility, real time information and distributed collaboration. On the negative side, the bandwidth and authoring capabilities are very often criticized and are seen as the major obstacles in the creation and delivery of multimedia content.

It has been suggested (Ozer 1997) that improvement in the Internet bandwidth will eventually kill the CD-ROM. It is also widely agreed that wide adoption of the Web in the developers community will improve the authoring tools as well. If when this happens is open to speculation. Meanwhile, the advantages of utilizing both technologies to create hybrid CD-ROM/Web content should be considered as a bridged solution.

Different types of Hybrid CD ROM/Web Designs

It has been estimated (Cole 1997) that in the mid-1996 there were 350 or more hybrid titles and that by the end of 1997 there was around 3500 titles available. Many are from well
established companies such as Microsoft, Voyager, Grolier, Dorling Kindersley and others. Careful evaluation of these products will allow the separation of marketing hype from the useful tools that will improve the development and delivery of multimedia content.

The major types of hybrid CD-ROM/Web designs to consider are:

1. CD-ROM media content (video, audio, large graphics) accessed directly from web browsers (could be either local or remote mode).

2. Interactive multimedia titles with simple links to a web site by launching a web browser.

3. Interactive multimedia titles with links to the various media content update site or sites (e.g. Microsoft Baseball, Cinemania 97).

4. HTML-based CD-ROM with HTML structured content (e.g. Encyclopedia Britanica 2.0).

5. Shockwave based website with links to CD-ROM media content.

Each format has its own strengths and weaknesses and we can choose those elements that are particularly suitable to our application.

Creating hybrid CD-ROM/Web Content

There are several authoring tools available on the market today. Asymetrix ToolBook II, Allen Communication QuestNet+, MarketScape, WebCD, Macromedia Director 6.0 and Authorware 4.0 and others which embrace the Internet integration more effectively and with various ease-of-use. We have chosen Authorware 4.0 for our projects because of our familiarity with the software, its suitability to our particular content design and its cross-platform capability. Also noted should be its student administration and quiz creating capabilities. In particular, Authorware 4.0 offers good integration with Java, so that movies can be embedded as applets. Similarly, Java applets can be played within Shockwave movies. These capabilities offer a number of advantages over other authoring tools.

At the recent Macromedia conference an announcement was made that Shockwave titles will be saved as Java applets. Therefore, with Java you will not need a separate player with your browser. However, the question of delivering large files and the slow speed of Java processing will remain with us (Dinucci 1997).

Conclusion

With the advances in Internet-based technologies, such as VRLM 2.0, proposed HTML 4.0 and XML markup language, improved Java JDK and just in time (JIT) compilers, ActiveX and Java Beans the integration of CD-ROM
looks very promising (Gustayson 1997).

At the CITD, we have started to convert two course related titles "Invertebrate Phylogeny" and "Russian Heritage: Its Land, Peoples and Culture". One project includes small video clips, animation and voice-over with many images - media that CD ROM handles reasonably well. On the other hand, fast changing textual information mostly dealing with issues of course administration, is well implemented on the Web. Placing the media intensive part on the CD ROM (such as video and animation) and linking the changing textual information (such as course information, timetables and other information) presently available on the Web site seems to be the best solution for now. At the same time, we are also evaluating the possibilities of using this technology in several distance education projects. Similarly, many publishers today consider CD-ROM not as an exclusively standalone product, but rather along with the Internet, as a hybrid strategy in their publishing effort (Cole 1997).

Interactive Electronic Technical Manuals: New Opportunities For Learning And Instruction

Yvonne F. Barnard and Johan B.J. Riemersma
TNO Human Factors Research Institute, The Netherlands
E-mail: Y.Barnard@tm.tno.nl

Interactive Electronic Technical Manuals
More and more technical documentation on devices and systems is becoming available in electronic format. The question we address is how this information can be used in the training of engineers. The work presented stems from a research project for the Royal Netherlands Air Force (RNLAF) investigating the possibilities of using Interactive Electronic Technical Manuals (IETM's) in training [Barnard & Riemersma 1997]. The complexity and functionality of IETM's may vary a great deal. The least advanced manual is a page oriented, electronic document with a simple index. This can be upgraded by adding hyperlinks and search facilities. More advanced types of IETM's are database oriented systems. The most advanced types can be integrated with facilities such as fault-diagnosis systems. A basic characteristic of IETM's is that the data on the system they describe, are separate from the viewer which present the data on screen. This makes it possible to present the same data in different ways, allowing the possibility to use the data for other purposes than they were created for, such as educational purposes.

Scenarios For Training Maintenance Engineers
Maintenance engineers need to have technical skills in order to be able to perform necessary procedures, they need to have extensive knowledge about the system and they must be able to reason about the system in order to perform fault diagnosis. In the RNLAF helicopter maintenance trainees are given, after an initial basic training, a specialist course for a certain helicopter type. This course starts with several weeks of theoretical lessons about the helicopter components and their functioning. After this, they start to learn the maintenance tasks in practice on the job. At the moment, learning material in the form of a syllabus is constructed from both the paper-based technical manual and from the training course documents provided by the manufacturer. One of the big problems with paper-based learning materials is that if something is changed in the technical system, the learning materials are outdated. Especially in helicopters many changes are made during the system's lifetime. If the information available in IETM's is to be used in instruction, what kind of instructional scenarios will become possible? We are currently investigating four scenarios in relation to helicopter maintenance training. Although some research (e.g. US Navy) is beginning to emerge in which IETM's are linked to educational applications, there is as yet very little experience in realistic educational settings [Kribs et al. 1996]. Some of these scenarios are easy to realize, and are geared towards facilitating current educational practice. However, the future availability of more advanced IETM's, and the development of innovative educational software, will widely broaden the range of instructional forms but may also change training needs.

IETM as a presentation source: In classroom-based courses, IETM's can serve as a source for presentations by instructors. If the instructors could extract the information, such as a scheme of a part of the technical system, in digital format this will enable them to use it in different ways. The information may be annotated or parts may be highlighted and printed out for the learning materials. It is also possible to use the information to prepare a computer-based overhead presentation, for example in PowerPoint. Presentations may be improved by the possibility to zoom in and out on details of drawings and schemes. More didactic functionality may also be added. One of the problems in technical domains is that many processes in a system are dynamic ones. In manuals these processes are represented in a static way. It is often difficult to explain such processes to trainees. It would be a powerful facility for instructors if static information from an IETM could be animated. For example a spot could be placed in an electronic scheme, which moves along the scheme to demonstrate the propagation of impulses.

Case-based training: The use of IETM's may also facilitate training in which the trainees have to take a more active role, such as case-based training. The trainees may be presented with assignments to find information about components or to find the right procedure to diagnose a fault and to fix a certain component. In this way the trainees become acquainted with the system information as well as with using the IETM. When some parts of the manual are too difficult or too complex, the instructor may add annotations to help and to guide the trainee. The IETM can be used in a computer based learning environment in which cases are stored as well as solutions and solution paths. Such an environment guides the trainees throughout their search in the IETM, gives feedback and suggestions to the trainee and evaluates the solutions. This may be done by letting the instructor input the
correct searchpath and comments or by using intelligent agents, able to evaluate the path dynamically. If automatic fault diagnosis becomes available in IETM's, using Artificial Intelligence techniques, then even more opportunities will become available to compare solutions and solution paths between the AI system and the trainee. In this situation case-based reasoning techniques can be used to generate models of both the system and the trainee. Interesting ways of case-based training may be opened up by creating a training situation in which practical work is combined with theoretical learning about the system. This might also be done in groups of trainees learning collaboratively [Leroux et al. 1996].

**Computer based training programs:** Computer based training programs can be developed which use the IETM as a source of domain knowledge. For example XAIDA is a software tool which offers this possibility [Sorensen et al. 1995]. This means great savings in terms of development effort. The challenge is to make CBT such that it has dynamic links to the IETM. If the IETM is updated, the CBT takes in the new data. This might cause problems because, for example, the texts in the CBT which came from the courseware developer, might then no longer fit the data taken from the CBT. This problem may be solved by developing a facility which warns the instructors about parts of the IETM in which changes were made and allows them to adapt the CBT. In this case the remaining problem might be that many, maybe small, changes are made rather frequently in the IETM. Going a big step further is to develop CBT that uses virtual reality techniques for the presentation of information. Such a system would enable the trainee to ‘walk’ through the components of the systems or through schemes etc.

**Just-in-time and on-the-job learning:** The introduction of IETM’s offers a great opportunity for developing forms of instruction that integrate learning and working. Maintenance engineers will have the IETM at their disposal at their workplace and will have experience working with the IETM. These conditions make it easy to introduce learning-on-the-job. By using educational applications linked to the IETM, engineers can spend time at their workshop to learn in their own time and pace. By adding the possibility to seek contact with a training centre by different telematic facilities, help and guidance can be provided. Just-in-time learning can be introduced by training the maintenance personnel just before they have to perform a certain (complex) task. This training may take the form of rehearsing what the engineer already has learned before, but it may also concern new information. Learning may not just be restricted to individual engineers, but may take place in the organization as well. For example a large repair job may be simulated with the aid of the IETM by a repair team with different specialists, discussing the different options and learning about possible ways to proceed. More organizational learning will take place when a facility is added to the IETM in which experiences with repair jobs can be stored, both formal experiences, with links to the procedures in the IETM, as more personal notes of the various engineers.

**Future Developments**

The introduction of IETM’s provides the training developer with a large amount of digital information about the system. In the development of courseware (and other training materials such as syllabi), the gathering of domain knowledge forms a large part of the development process. Courseware developers usually spend a lot of time together with domain knowledge specialists in order to get sufficient insight into the domain. Then materials have to be either copied or constructed from the paper manuals. So there is much to be gained in terms of effort and time by having available all the system information in a digital form. Also, the development of more intelligent forms of courseware, such as intelligent tutoring systems (ITS), is always severely hampered by knowledge acquisition problems. Most ITS’s therefore are to be found in very small, artificial and/or formal domains. If, however, advanced forms of IETM’s become available, this domain knowledge problem might, at least for a part, be solved. The most promising development, in our opinion, is to be found in possibilities for bringing together work and training. IETM’s make it possible to have system information and training facilities available always and everywhere.

Introduction

This work briefly sets out the methodology used during the academic years of 94/95 and 95/96 for the evaluation of educational software destined for the teaching of Engineering Thermodynamics in Mechanical Engineering. This research has been being developed since 1991 in the Area of Thermic Machines and Engines in the University of Zaragoza.

The constant need for ratification of the design and performance mechanisms of educational software, as well as measurements of the level of attainment of the educational objectives reached by the students who use these programmes, make it necessary to use systematic evaluation processes which verify the quality and suitability of the software that has been developed. It is worth noting that even though there exists a certain consensus about the varied functions which educational software should perform and about the strategies that it can exhibit, there are no generalised mechanisms which allow us to check the level of efficiency in a determined instructional sequence.

The evaluation of educational software includes two different phases [van der Mast, 1995], one of which concerns the evaluation of the developed product based on its specifications, a formative evaluation. The other is one which evaluates the level of attainment of the educational objectives which is proposed with the usage of educational software in determined conditions, a summative evaluation.

Formative Evaluation

The objective is to adjust the design to the user's needs. We start from the assumption that the initial refinement, by means of periodic checks, guarantees that the programme is at least intelligible and robust. This evaluation should be on a small but intensive scale. Two subjects have been tested during this research:
- Interface: appearance, navigation, ease of use and functionality.
- Contents: extension, quality of organisation, resources and speed.

The session files which were generated by the system were used for the evaluation as well as the responses to the multiple choice questionnaires, on an evaluation scale, and the interviews carried out with the students who gave extreme responses. With these results we carried out a classical statistical study in order to compare the results of each programme with the rest.

Summative evaluation

This type of evaluation tries to obtain a measurement of the level of the attainment of the objectives posed in the educational design. The results should allow us to establish comparisons with other teaching methods with the aim of providing a measure of the suitability of the proposed teaching sequence. It is necessary to specify in what conditions the software will be evaluated in order to obtain significant results on its introduction and use in the educational ambit. One long term objective is to test the programme under different conditions of use, seeking those which provide the most favourable results.

Measuring the level of attainment in an educational sequence is usually associated with the value of the academic performance that is obtained when carrying out tests [Bisquerra, 1987]. Traditionally, in order to establish comparisons between different instruction sequences, the same instruments used for measuring performance are applied to two or more groups, one of which has followed the sequence which we wish to compare, and it is a question of seeing if there are statistically significant differences between the groups. This
type of description does not inform us about how the type of sequence followed influences the final results, it only informs us about whether or not there is any kind of influence.

Most of the cases which arise in the educational ambit, the strict causality between two variables, is an excessive hypothesis. It is more reasonable to consider a more complex system of relations in which a larger number of simultaneous explanatory variables are involved. Depending on the precise objectives of the analysis and on the type of data which is being worked with, we have a large variety of statistical techniques which are currently available, which are increasingly powerful and better adapted to the requirements of information processing in human and social sciences.

Within their large variety, the factor techniques developed by J. P. Benzécri [Benzécri, 1965, 1970, 1973, 1982], which use the properties of Euclides vector spaces to describe individuals as well as variables, stand out as instruments of great use for the study and interpretation of complex phenomena such as educational situations. The quantitative treatment of what is qualitative, and the simultaneous analysis of a collection of variables, define the substantial contributions of these statistical methods.

The basic idea is to consider each element, characterised by a sequence of relative values, with a determined number of descriptive variables. The whole can be represented in a multidimensional space, the different share density of which allows us to look for a smaller subspace which takes into account the arrangement of the whole of the data with the least possible loss of information. For this reason, multifarious techniques, that is the descriptive ones, are tools which facilitate the synthesis of multiple factors in their more significant tendencies.

In order to establish the level of attainment reached in the assimilation of the content, the results from two tests have been used throughout this research. One of the tests is of a theoretical nature, focused on the conceptual content and the other test is of a practical nature, focused on the procedural content. In the case of the group which uses information technology resources, we also took into account the work summaries from the sessions and the files that were automatically generated by the system in order to add precision to the qualifications. Once all the data corresponding to the two tests had been collected together, we proceeded to analyse it. The method followed is divided into three phases:

- Reduction of the data: This phase is about trying to obtain units of information which are at the same time comprehensible, relevant and significantly dense.
- Arrangement and transformation of the data: The final aim is to present the data in an operative way thus facilitating the examination and comprehension of the data, allowing us to reach conclusions. In this case, we used the SPAD N ® programme which allows us to obtain graphics which ease interpretation of the results.
- Interpretation and discussion of the results: In view of the graphics obtained, the factors which appear and their influence on the proposed sequence, of instruction are discussed.

Conclusions

The factorial methods are considered appropriate for a summative evaluation for the following reasons:

- The description of tables by observation is difficult when the dimension is big and this does not allow us to interpret them completely.
- The developments in information technology make them methods which are easily applicable and not very expensive.
- Multifarious methods consider all the relations between the elements in the table simultaneously. Educational phenomena are multifarious and it is necessary not only to realise a synthesis of the individual data, but also the relations have to be described and structures detected.
- In general, this type of analysis allows us to reduce the criteria and the factors, to select the most important ones, arrange them in order of importance, create groups and position them.
- They are descriptive or explanatory methods, they are not causal. They measure associations or interrelations, but they do not establish relations of causality, which have to be formulated by the analysts.
- In many cases, the results are graphical and this facilitates the work involved in a meticulous interpretation.

The Mime That Screams: Where Is the Teacher In the Multimedia(ted) Classroom?

Dr. Alfred Benney
Fairfield University
Fairfield, CT 06430-5195, USA
Benney@Fair1.Fairfield.edu

Thesis
What is the role of the teacher in a multimedia teaching environment? The "title-question" intends to suggest the seldom-examined idea that perhaps all classroom instruction is multimediated; that what we think of as multimedia lies primarily in the interactivity between persons rather than between persons and machines; and that the role of "equipment" in the "multimedia environment" is simply control and delivery. Given this definition, there is the strong possibility that the success of this interactivity could be determined in large measure by how invisible the technology is. It is certainly clear in the case of technology that doesn't work that it becomes a hindrance to learning. In the case of programming that is so "slick" it is unnoticeable or has been made so natural to the circumstance that its use is simply intuited, it becomes like clean glass in a window. This presentation will illustrate the premise that "invisible" technology becomes another intermediary between learning persons in a classroom environment.

Problem
The issue of media transparency is central to questions about the "appropriate use" of technology in support of classroom teaching. In the case of a student whose reading skills are inadequate, the text becomes a barrier to learning -- it gets in the way. As well, presenting an image or icon that has no relationship to the knowledge base of a student must likewise distract from learning. A teacher whose concern is that the projection system and presentation program work without flaw or whose entire preparation consists in the development of "pleasing visuals" may have allowed the machine to get in the way of teaching. What the teacher does is being controlled by the machine which by that fact becomes the focal point of instruction. It is impossible to see beyond the hardware because it is in the way.

Technique
Using CD-ROM packaged digital video, this experimental presentation demonstrates one way of making technology more transparent. The strategy is to present and discuss the questions below by having a conversation between a real individual -- the teacher, live -- and a virtual individual -- the teacher, digitized. The questions were deliberately chosen as illustrations of controversial topics, but they also raise the point at issue -- that humans are the key to successful multimedia use because only they can orchestrate the technology and keep it from getting in the way. The objective of this demonstration is to invite audience participation in the conversation without giving a direct solicitation.

Questions
1) Can machines motivate? Isn't interaction with a machine actually interaction with the programmer who is absent and is therefore not able to respond except in his/her imagination? Most success stories about learning with technology seem to assume that the student is already motivated to learn. Is it possible for a tuned-in teacher to queue the machine to create an interactive moment (like a conversation)? Is the stimulus of human interaction necessary for motivation?
2) Do I need only information or problem-solving models or must I learn to apply general knowledge to specific circumstances or to analyze complex interpersonal/interthing/interpersonthing puzzles? The goal of instruction is always discipline specific. Some areas of study are information intensive and some are more process oriented, some require analysis and some management skills. How does technology satisfy the needs of discipline-specific pedagogy unless directed by a person with a clear vision of the need?

3) Am I looking for “42”?  

5) How is it possible in the hypertext, non-linear environment of the computer to teach the linearity of logic and the discipline of analysis? Both of these skills are necessary in order to understand and create this technology. How is it possible for a person to contribute to the development of an intellectual project if he/she cannot present ideas in a disciplined and logical way?

6) Is technology “glitzy” and superficial? Books “require” a person to look at information on many different levels but the CRT seems to “require” passivity! Does it manage text in a way that is different from bound paper? Is it somewhere between the book and TV? What does that mean?

“I see a parallel between the goals of ‘Sesame Street’ and those of children’s computing. Both are pervasive, expensive, and encourage children to sit still. Both display animated cartoons, gaudy numbers, and weird, random noises. Both encourage passive acceptance of a medium that will follow them for the rest of their lives. Both give the sensation that by merely watching a screen, you can acquire information without work and without discipline. And both shout the magical mantra: ‘Here’s the no-effort, fun way to learn!’”

Consequences

There is clearly a middle place between the extremes of those who expect multimedia in the classroom to be the magic bullet and those who fear the glow of electronic display. While technology will never make a “bad” teacher into a “good” one it certainly has the potential to do the opposite. Good multimedia courseware will facilitate creative links between its parts; and the “parts” of any learning environment are always curious learners. If classroom technology is so opaque that it isolates students, it will not mediate learning.

In using multimedia in the classroom, the role of the modern teacher is like that of ancient mediums. They are the ones who read the spirits of their students and prescribe solutions for their curiosity. In this case -- sorry Marshal McLuhan -- the medium gives the message!

---

1 Teaching isn’t good because it is novel, but because it entices student involvement with ideas and interaction with other minds. Teaching is “good” when it makes critical thinking attractive and when it raises a creative or inventive curiosity about questions.

2 The characteristics of multimedia are the same as the characteristics of a good teacher: responsive, directed by needs, highlights content, versatile and adaptable, non-linear, interesting!

3 Almost too complicated to explain, this refers to the passage in Douglas Adams, The More Than Complete Hitchhiker’s Guide (Avenel, NJ: Prentice Hall, 1994), 118-120 where the world’s second greatest computer gives its answer “To the great Question of Life, the Universe and Everything?” Because the humans were upset that the answer is “42”, the computer points out that the question doesn’t make much sense either!

Introduction
With the advances in computers and instructional technology many new teaching methods are available, however, there is minimal data to support that new methods are superior to existing techniques. A lot of the research in educational multimedia and instructional technology has focused on the effects this media has on children’s education. The use of interactive multimedia has recent made its way into adult education, and is making a strong surge in the medical setting. Few studies have been performed and little analysis has determines the effects of multimedia in medical education, particularly in surgery education. This study helps bridge the gap and provides a foundation for the further use and development of interactive medical software.

Study Issues
This study is comprised of a two step process. The first stage involves the creation of a multimedia product appropriate for the education of medical students. Numerous design and development models were accessed as a means of creating the learning material which entails a student navigated, problem-based learning approach. The finished product will be used primarily as an aid in the instruction of third-year medical students whose focus is in the area of surgery. The second stage of the study involves using a post-test performance measure. The goal is to determine the extent to which the created problem-based learning software improves student performance.

Hypothesis
The hypothesis of the study is that the post-test performance of the students participating in a multimedia student-directed learning environment will be statistically significantly higher than the students in a faculty-directed group.

Brief Study Methodology
This study compares the post-test performance of two groups of medical students. Students will be assigned to one of two groups, either the experimental group or the control group. Each group will retain their current educational regiments as required by the medical school however one group has the additional aid of the multimedia software.

The experimental group has been defined as students who participate in the student-directed non-linear method of problem-based learning with a follow-up faculty review. This group will use a multimedia decision based learning product specifically designed and developed by the researchers for this purpose. The control group will be students who participate in only a faculty-directed linear problem-based learning method.

Product Design
The multimedia product allows students to pursue the course of patient management. Through the software students will provide care they believe most appropriate for their simulated patient(s). The software is designed to reflect the efficacy of students’ diagnostic and therapeutic interventions and records treatment(s) and invention(s) suggested by the student. The application will provide various routes of interventions with no true “right” or
“wrong” answer. Students will be free to choose among the given options without penalty, although patient outcomes will benefit or suffer accordingly.

**Analysis**

After completion of the program both the control group and the experimental group test scores will be quantitatively analyzed. Descriptive statistics are used to describe demographic information about the two groups. The student t-test is used to look at the differences between the two groups. A p-value < 0.05 is used to determine significance. Further information collected concerning the intervention or lack of intervention will be collected however is considered ancillary data and will not be used in addressing the study's hypothesis.
Visualization of Optimization Algorithms: The Downhill Simplex and Simulated Annealing Methods

Kathryn M. Boner and Jay Martin Anderson
Department of Mathematics
Franklin and Marshall College
Lancaster, Pennsylvania, USA
j_anderson@acad.fandm.edu

We present animated visualizations of algorithms for optimization. In particular, we show visualizations of the simplex algorithm [Press 1988a] and visualizations of the simulated annealing algorithm [Press 1988b] [McLaughlin 1989] [Carlson 1997] for a variety of optimization problems. These animations are useful in university courses in mathematics, applied mathematics, and computer science, especially wherever the topic of optimization is encountered.

The downhill simplex algorithm originated with [Nelder & Mead 1965]. Although it requires only evaluations of the function whose minimum is sought, and not derivatives of that function, it is not efficient in the number of function evaluations required. Nonetheless, it has a natural geometric treatment which makes it easy to describe and to learn, and it lends itself readily to visualization.

In the downhill simplex algorithm, a geometric figure, called the simplex, begins somewhere on a multidimensional surface, and, by a series of motions based on four rules, moves towards the minimum.

The animations we show begin with frame-by-frame sequences in two and three dimensions, showing the motion of the simplex down a surface which monotonically decreases.

The figure on the left shows the simplex in two dimensions; after nine steps it has come close to the bottom of the surface. The figure on the left shows the simplex in three dimensions. We progress towards QuickTime movies in three dimensions to show the motion of a simplex down surfaces with multiple local minima. The visualizations show the problem of becoming trapped in a local minimum and not escaping to reach a global minimum. The visualizations also show the utility of restarting the algorithm from a presumed minimum.

We show animations of simulated annealing algorithms applied to discrete and continuous problems, including the simplex method just discussed. The simulated annealing algorithm modifies greedy optimization algorithms by permitting an intermediate step which moves the system away from the minimum with a probability proportional to exp[(E_{old} - E_{new})/kT]. The probability function resembles the Boltzmann distribution from thermodynamics, where the E's are energies, T is the absolute temperature, and k the Boltzmann constant. For optimization, E represents a score, or value of the function to be optimized, and kT is systematically reduced.
according to a "cooling schedule." It is helpful to follow the progress of simulated annealing graphically in order to choose a suitable cooling schedule.

Interesting applications of simulated annealing include the "Traveling Salesman" problem [Carlson 1997] and the problem of optimal placement of labels on maps [Christianson et al. 1995].

![Figure 2: Itinerary of the "traveling salesman" before (left) and after (center) optimization; length of itinerary (right).](image)

The figure on the left shows the initial attempt at a traveling salesman itinerary, and the figure on the right shows the final solution after approximately 200 iterations of the simulated annealing algorithm. A plot of itinerary length vs. iteration shows that, for some trials, the length of the itinerary actually increases, because of the "annealing" algorithm.

Similarly, here we show the initial and final states of the simulated annealing algorithm applied to finding the optimum placement of labels (in this case, names of towns) on a map [Anderson 1998].

![Figure 3: Placement of names on map; before (left), after (right) using the simulated annealing algorithm.](image)

Using animation, a simple greedy method can be compared to the simulated annealing method instructively. In addition, various "cooling curves" can be designed and tested empirically.

RECEPTION AND EFFECTIVENESS OF AN EDUCATIONAL SOFTWARE PROGRAM OF LEARNING AND SELF-ASSESSMENT IN LAW HISTORY

** Faculté de Droit
UNIVERSITÉ DE LIÈGE
Boulevard du Rectorat, 7 (B31) - 4000 Liège

I. INTRODUCTION

What does the work of a lawyer consist of? It mainly comes down to finding solutions to legal problems by using three 'databases': first, the law; then, the jurisprudence which is also called case law, that is the way the law has already been applied; and finally, the doctrine which comments on the law as well as the jurisprudence. Students are expected to learn how to synthesize these three sources by making links between them. This is a particularly difficult task for first-year students whose most of their secondary courses is taught in linear mode. So as to take this into account, the course of Roman Law was right from the beginning split into three elements:

- the duplicated lecture notes which may be considered as the doctrine in actual law;
- the texts which include judicial precedents or jurisconsults' opinions over tricky cases;
- the vocabulary which contains basic notions in Roman Law and is similar to the law.

The computer could be used as a potentially very convenient tool to establish a network of links between numerous concepts as well as to ease students' initiation into the makings of their own conceptual network. During the design of this educational software, have been added some items of secondary importance. Finally, this educational software includes a stack of multiple choice questions (MCQs) on Roman Law, allowing students to assess their knowledge and improve it thanks to explanations given each time answers are wrong.

These four elements (lectures notes, texts, vocabulary, and MCQs) pursue two distinctive goals. On the one hand, the first three elements aim at knowledge to be taken in by linking them to each other. On the other hand, the 400 MCQs enable students to check the accuracy of their knowledge.

II. RECEPTION AND EFFECTIVENESS

In spring 1994, when it was decided to build up a software program which would serve as a new medium for the teaching of Roman Law, Hypercard software made it quickly possible to build up a prototype which integrated most of the functional elements peculiar to the educational software into a proper architecture whose design features remained mainly unchanged until the ultimate stage of the project. The CD-ROM was obtainable from September 1996.

It seemed judicious to check, if not its profitability, at least its effectiveness in terms of harmful, neutral or beneficial effects on exam results. Exam results of May 1996 were therefore a very long time coming to us. Exams took the usual form of MCQs and were computerized to be marked. Comparisons with previous exam results showed a higher simple arithmetic mean computed over 577 data as well as a new statistical distribution of results (see Table 1).

It seemed putting it a bit strongly to conclude from this simple comparative analysis that the availability of the new medium was the explanation. So as to verify this relation of cause and effect from a scientific viewpoint, a survey was carried out in May 1996 over more than 500 first-year students in Law.

Some results are specially striking. For instance, when preparing for the exam, students used the educational software more than studying Roman Law by way of the lecture notes. It shows that advanced technology can quickly become integrated into such an educational environment as the field of social sciences, not mentioning Roman Law! In most cases, using advanced technology does not constitute an alternative teaching method to more traditional ones. Students who state spending some time in using the CD-ROM do go on reading the textbooks.

Figure 1 compares results from students using the software to those from students still sticking to traditional educational methods. The availability of advanced technology is shown to have some important effects on pass rates as well as on arithmetic means.

<td>(n = 328)</td>
</tr>
</tbody>
</table>

Figure 1: Compared performances using or not the software

When relating these figures to those on time spent in using the software, a clear relation between the two sets of data is pointed out, providing some time is simultaneously spent in using traditional educational methods. An upper limit to the time spent in using advanced technology is also shown to exist: beyond it, students do not succeed to improve their results anymore.

Data collected during this survey have made it possible to study the relationship between students' marks and different variables, such as:

- does the student attend lectures?
- does the student attend practical exercises?
- how much time is spent in studying lecture notes?
- how much time is spent in using the educational software?

The statistical model which is based on a linear method of regression gives very significant coefficients for the relation between the dependant variable (students' marks) and independent variables including the new interactive teaching method. Results are given in Table 2.

Training Disabled People to Do Gardening Tasks: A Pilot Study on The Effectiveness of a Multimedia Software.

Xavier Bornas
Department of Psychology, University of the Balearic Islands, Spain, dpsxba0@ps.uib.es

Jordi Llabrés
Department of Psychology, University of the Balearic Islands, Spain, dpsjlb0@ps.uib.es

Mateu Servera
Department of Psychology, University of the Balearic Islands, Spain, dpsmsb4@ps.uib.es

One of the most important goals of the Education of people with disabilities is to get them included in regular job places or, at least, to prepare them to do regular jobs. Gardening is a job that many mildly disabled individuals can do in both public and private organizations and companies. Nevertheless, training people with disabilities to do gardening tasks has a very high cost. Learning depends too much on the weather and the season. Disabled people usually need to see several times how to do every task, but it may be impossible to repeat some tasks in real settings. Furthermore many disabled individuals can not read, so that they can not learn the names of the plants or their characteristics from conventional gardening books. New technologies may be very helpful to overcome these difficulties. Specifically, multimedia software can be used to model how to do any task as well as to present text free information about plants, tools, and tasks. However, the effectiveness of such software is usually assumed but rarely tested. In this paper we test the effectiveness of a multimedia software to increase the subjects' knowledge about plants. Since the study was conducted in a natural environment we had not the level of control that an experimental study usually requires. Therefore the results must be considered cautiously.

Method

Subjects

The subjects in this study were six mildly disabled males, with a mean age of 23.66 years (SD=4.13) and a disability level from 33 to 66 per cent. All subjects are enrolled in a sheltered workshop in the Mallorcan Association for the Psychologically Disabled People (AMADIP).

Design

The experimental design had to be adapted to the conditions of the AMADIP environment. No other subjects could be used as controls because there were not more people waiting to learn gardening tasks. We used a repeated measures design with only one group.

Variables and instruments

The variables were: the names of the plants, their size (big, normal, small), their leaves (deciduous or not), their light/sun needs (much light, normal, few), their water needs (much water, normal, few), and their growing speed. We prepared an assessment software to be used to collect data before the subjects began to use the training software, and after training. Pictures of 45 plants in the assessment software were the same than in the training software. Pictures appeared in the computer's screen one at each time. The size of each picture was 320 x 240 pixels.

Procedure

Before using the training software, subjects were evaluated individually. The evaluator and the subject were seated in front of the computer. Using the assessment software, while the picture of the plant was on the screen, the evaluator asked the subject the name of the plant, its size, etc., and marked one of two possible categories for each variable: The subject know it or the subject does not know it. The same process was repeated for each
one of the 45 plants. During the next months subjects worked with the training software with a gardener who knew the software and how to use it. The total amount of training time ranged from 4.5 hours (the subject who used the software the less) to 7.5 hours. The same procedure used to initially evaluate the subjects' knowledge was used to carry out the final assessment but the evaluator was not the same. In the last case, a Psychology student who did not know the subjects at all assessed them after being trained with the assessment software during a short period of time.

Results

Only the names of six plants were known by all 6 subjects during the initial assessment. These more well known plants were typically mediterranean plants (palms, pines, orange trees). During the final evaluation the number of names of plants that all of the subjects knew increased to 10. To compare the data from the pre-training to the post-training, the SPSS t-test for paired samples was used. Table 1 shows the mean values found for each variable as well as the t values and the significance levels. Improvements can be seen in all the variables. Statistically significant differences were found for names (t=4.57, p=.006) and leaves (t=4.19, p=.009). As only six subjects participated in the study, an analysis of the individual improvement for each subject was made through charts. Figure 1 shows the number of names of plants that each subject knew before and after using the training software. We wish to underline the fact that all of them increased the number of plants' names they knew. The same can be said for the variable leaves, as shown in figure 2.

Figure 1: Knowledge about the plants' names

Figure 2: Knowledge about the plants' leaves
Discussion

It is necessary to repeat that our study is just a pilot research study to test the effectiveness of a multimedia gardening software that we have been developing during the last year. We are aware of the limitations of the study: the lack of a control group, the short and unscheduled training period, the fact that the subjects were doing gardening tasks in real settings during the period between the first and the final evaluation, etc. Nevertheless, we think that our results give support to the usefulness of the multimedia software to increase the knowledge that the mildly disabled subjects who participated in the study had about the plants. Hopefully the software will show its usefulness to improve the gardening skills of this people, but we know that a more controlled study is required to support this hypothesis. On the other hand, we wish to point out that some results are very useful in order to change specific features of our software. For example, we found that the subjects' knowledge about the size of the plants did not increase after training. This result could mean that the pictures we used were not as clear as they should be or that the icons showing the three possible sizes were not the appropriate ones.
MACS: A Flexible and Scalable Collaboration Environment

O. Brand, W. Mahalek, D. Sturzebecher, M. Zitterbart
[brandlmahaleklsturzelzit@ibr.cs.tu-bs.de], http://www.ibr.cs.tu-bs.de/hm
Institute of Operating Systems and Computer Networks
Technical University of Braunschweig
Bültenweg 74/75
D-38106 Braunschweig
Germany

1. Introduction

The aim in the development of MACS (Multicast based Advanced Collaboration System) is to provide a powerful and flexible framework for CSCW (Computer Supported Collaborative Work) applications. Key features of MACS are the advanced session and floor control, the intuitive user interface (based on Virtual Reality) and its flexibility, scalability and portability (JAVA-based implementation). Due to the highly modular design new applications can be added.

2. MACS

Central components of MACS are the Control component and the Network glue. Each application is attached to these components (cf. [Fig. 1]). The Control component offers collaboration services, such as access to the user database, application database and token management. Attachment to the network services (e.g., LRIVIP) is through the Network glue. The Network glue provides an abstraction layer and, therefore, allows an easy incorporation of different protocols (currently LRMP, TCP/IP and CORBA are available).

Basic compatibility to the MBone [Kumar 96] is provided. Advanced features will be implemented using partially non-compatible formats to circumvent shortcomings in the MBone protocols. Some aspects of the advanced conference control are influenced by the ITU-T.124 standard. The aim is to provide the mechanism known in tightly-coupled conferences while maintaining scalability. This is achieved through a hierarchical setup, that corresponds closely to the hierarchies found in "real-world" conferences. Especially in large conferences only a small number of participants is actively involved, the majority listens passively. It is not necessary to couple passive and active participants tightly. Obviously all active participants have to be tightly-
coupled. With this model the overall count of tightly-coupled participants will remain manageable even for large conferences. The intuitive user interface is achieved by reducing the control elements to the essential ones. Advanced options are still accessible but will only be shown on request. Keeping the number of windows down by not using child/pop-up windows helps tremendously to improve the handling of the system. The visualization module VISCO (Visual Session and floor COntrol) presents the conference control and floor passing in an intuitive and easy to use way.

3. Visualization of session and floor control

In commonly used conferencing systems like the MBone-Tools [Kumar 96] or JVTOS [Gehring and Guther 95], user interfaces for session and floor control provide an immense set of buttons, sliders and the like. This easily embarrasses users. Human perception issues are not addressed properly which significantly reduces the widespread acceptance of conferencing tools. In MACS, session and floor control is performed by VISCO (Visual Session and Floor Control). It performs session and floor control in a virtual meeting room, in which the participants of a conference are represented either by simple graphical symbols or by small images. Various state information about the corresponding users are represented within the symbols or images. The temporarily absence of a user from the conference, for example, is indicated by closed eyes in the symbol. The audio and video capabilities of the user's conference equipment are also represented in a graphical manner. If a user isn't capable of sending audio data, his symbol lacks a mouth; if he is able to send a video stream, a small camera icon will be displayed on top of his image.

Floor control can be performed within the virtual meeting room. A conference participant usually indicates a floor request by raising the arm (symbol view) or a “speaking bubble” (image view). This is recognized by the other participants and especially by the floor holder. Hierarchical conference structures are supported by VISCO. If a user wants to conduct a private conversation, he can drag his symbol and move it through the meeting room to the symbol of the other user. This way, he can participate in both, the private as well as the public conversation.

4. Integrating applications into MACS

Due to the modular design of MACS, it is easy to integrate very different kinds of applications. An example is TelSEE (Tele Software Engineering Editor), a multi-user editor based on an enhancement of the MVC (Model View Controller) concept. TelSEE supports users distributed in time and/or space during cooperative project-work.

A JAVA-based Tele-Teaching Whiteboard is another example. It provides enhanced collaboration features, such as tele-pointer, highlighting as well as individual and independent handling of graphical objects.

5. Current status and ongoing work

Development of MACS is an ongoing process. A first demo release of the JAVA-based whiteboard is currently available. The whiteboard will be used in a lecture transmitted on the MBone between end of April and end of July. Other parts such as the virtual meeting room and TelSEE are available as prototypes. A first public release of MACS itself is scheduled for third quarter.

Distance Study Program „Multimedia in Education“:
Investigating The Internets’ Potential

Arndt G. Bubenzer, Dipl. Päd.
. Dr. Thomas Jechle
Prof. Dr. Michael Kerres

Tele-Akademie, Fachhochschule Furtwangen, University of Applied Sciences
D-78120 Furtwangen Germany
E-mail: tele-ak@fh-furtwangen.de

1. Introduction

The Tele-Akademie is the distance and continuing education unit of the University of Applied Sciences in Furtwangen, Germany. The location in the picturesque, but somewhat isolated Black Forest mountains, and the combination with a strong Computing Science and Media Department, provide an ideal background for distance education. One of the Tele-Akademies’ main functions is to test the potential of the internet in training and re-training of professionals. The Tele-Akademie has been offering internet and video conference based continuing education for almost three years. The didactics of two main scenarios are being investigated here: Tele-Teaching, a multimedia-based, synchronous form of training, and tutored Tele-Learning, mainly based on asynchronous forms of internet communication. Since the internet has become widely available in Germany, the Tele-Akademie is mainly utilizing this technology for both communication with participants and cooperation among the students. A staff of about ten, joined by expert authors and a group of tutors, prepares didactically sound multimedia courses and supports distance education students. The Tele-Akademie staff is comprised of psychologists, adult educators, didactics and multimedia specialists.

2. Distance Study Program "Multimedia in Education"

Since 1997, the Tele-Akademie offers a one-year distance study program on "Multimedia in Education", jointly granted by the Federal Government of Germany and the State of Baden-Wuerttemberg. The course program, geared towards adult educators, teachers and other education professionals is, in its complexity, form of distribution and communication unique to the German continuing education field. The 100 participants in the 1997/98 course program are mainly based in Germany, but also some international students (e.g. from Turkey, South Africa or Russia) take advantage of the worldwide accessibility of study materials prepared in the Black Forest town of Furtwangen. The Tele-Akademies’ concept of collaborative distance learning combines flexible and individualized learning with improved learner support and social involvement of the participants to fight low motivation and high drop-out rates often encountered in distance education scenarios.

2.1 Course Content, Schedule and Materials

The contents of this course program are derived from the practical needs of the target groups:
• educational hard- and software (media technology)
• learning theory and the design of learning environments (instructional design)
• the social impact of media use in education (media education)
• economic and management aspects of educational media (instructional management).
The course is organized in two semesters and based on five main elements:

1. **Study materials**: textual study materials, up-to-date supplemental information on the WWW, additional resources on CD-ROM
2. **Exercises**: independent study exercises, group work exercises
3. **On-site Seminars**: three 2-day sessions framing each course, designed to further enhance communication and allow networking among the participants. Discussions about technical problems, content related workshops, and participants’ presentation of project work results are also part of these sessions.
4. **Project Phase**: during the second semester of the course program, participants are required to carry out a project that introduces the theoretical course information into their work-life.
5. **Final Tests/Certification**: essay on participants’ projects or answering test items

### 2.2 Distribution of Study Materials

The written study materials are mailed out to participants bi-weekly as e-mail attachments in an Adobe Acrobat Reader format. Additional and up-to-date information, in-depth literature tips and interesting links are provided on the "Multimedia in Education" Web-Site (access restricted to participants, also updated bi-weekly). Resources, sample programs and software are provided to participants on several supplemental CD-ROMs, distributed to participants during the course of the program.

### 2.3 Communication and Cooperation

Participants of the Tele-Akademie’s study program "Multimedia in Education" work and study in a different environment than, for example, students in a regular university setting. Accordingly, possibilities and strategies for communication and cooperation are quite different:

**a) Communication**
- participant → Tele-Akademie: via e-mail, internet chat, phone, fax, traditional mail
- participant → participant: via e-mail, internet chat
- participant → tutors: via e-mail, internet chat

**b) Cooperation**
- study group of 6-8 participants → work-group newsgroup: designed for in depth discussion about exercises and questions arising from the written study material, supported by a tutor
- study group of 6-8 participants → internet chat: short discussions on specific topics, chats with ‘experts’
- work group for all participants → 'Plenary'-newsgroup: designed for posting results from the study groups visible to all participants, possibility for discussion of all program related questions

A group of 12 tutors assists the Tele-Akademie staff in supporting participants, answering questions and initiating discussion in the study groups and the plenary newsgroup.

### 2.4 Results

One objective of the distance study program is to instigate interpersonal communication and individual commitment through the use of internet technology. Several parameters indicate that it has been possible to reach this goal: the posting per person-ratio remained on a high level throughout the semester with a distribution typical for face-to-face seminars: 20% of the students initiate almost 80% of the communication, 60% participate moderately, 20% do not post any messages. The drop-out-rate after the first semester, typically high in distance education programs, was as low as 5%, indicating high participant commitment.

Providing students with electronic communication opportunities alone does not result in communication that can be classified as didactically meaningful. Study questions play an important role in initiating such a meaningful interpersonal communication in internet-based seminars. In the context of the internet, study questions must be even more to-the-point than in face-to-face situations. Furthermore the provision of "real" tutors is another factor that instigates interpersonal communication and the success of the program.
A Cognitive Model of Knowledge Exchange in Telematic Learning Groups

Jürgen A. Buder, Friedrich W. Hesse, Stephan Schwan
Abt. Angewandte Kognitionswissenschaft (Dept. of Applied Cognitive Science)
Deutsches Institut für Fernstudienforschung (DIFF), Tübingen, Germany
E-Mail: j.buder@diff.uni-tuebingen.de

Introduction

After two decades of research on computer-mediated communication the connection between cognitive science and media research is still rather unsatisfying. The general accounts of computer-mediated communication in organizational as well as educational contexts [McGrath & Hollingshead 1994], although being quite elaborate, do not deal with cognitive processes on a level where the manipulation, storage, and retrieval of knowledge structures come to bear. This neglect of cognitive processes can partly be attributed to the fact that until ten years ago cognitive science itself has neglected processes outside of the individual mind. During the last few years, and primarily advanced by research on human-computer interaction, this situation has changed rapidly. Several models and concepts now address cognitive processes within groups [Hinsz et al. 1997]. These approaches share the assumption that cognitive processes and mechanisms are not entirely localized within the individual mind, but are distributed over several representational spaces, thus forming a socio-technological single system which is comprised of several people and artifacts. The single system view claims that the internal representations of several individuals and the external representations being used by these individuals constitute both the frame of reference and the unit of analysis in related research. However, until now no account of cognitive processes in groups has explicitly referred to the use of computer-mediated communication.

Overview of the Model

This paper formulates a cognitive model of telematic learning that is inspired by the notions of distributed cognition [Hutchins 1995] and socially shared cognition [Resnick 1991]. I.e., it attempts to account for the rich interplay between the internal representations of several individuals and the external representations (media) in use. The model in its current form does not address the whole range of computer-mediated communication but is restricted to a prototypical instance of telematic settings, viz. the exchange of knowledge within peer groups via text-based, asynchronous computer conferencing technologies.

Using this model one should be able a) to generate hypotheses regarding the internal and externalized cognitive processes involved in the acquisition and conveyance of knowledge; and b) to test these hypotheses under laboratory experimental conditions. If the hypotheses derived by this model can be validated empirically future extensions will involve the group structure (e.g. by including moderators or instructors), and the media being used (e.g. synchronous video-conferencing).

One of the central assumptions of our model holds that the transition from a state of distributed cognition to a state of shared cognition is involved in knowledge exchange. In other words, knowledge exchange will only prove useful if the relevant knowledge is initially distributed over the group members. The goal state of the interaction would be achieved if all group members share the same knowledge (equalization).

The model regards knowledge exchange as a complex interplay between internal and external processes embedded within a socio-technological single system comprised of three parts. One part is the external representation of the information that is available within a computer conference at a given time. The other two parts model learners engaged in one of two basic activities, viz. acquisition of knowledge and conveyance of
knowledge. Note that during the course of interaction learners often switch their roles between acquisition and conveyance. Both acquisition and conveyance are characterized by activities that involve the reception of a given message in a computer conference and activities that involve the production of a message. The receptive process of knowledge acquisition can be divided into several subprocesses. To acquire knowledge learners have to select information from a given message. This internal process of selection is reflected by externally observable activities. Firstly, learners select (or don't select) a given message in a conference folder by judging the subjective relevance of the message. The relevance can be assessed by using message attributes like sender, date, the status of the message as being read or unread, and the subject line. Secondly, subjectively relevant messages will yield higher relative reading times than irrelevant ones. Both relevance assignments (reflected by the number of times a given message was opened, or by deleting a message) and reading times can be traced back by analyzing log-file protocols.

At the same time message contents must be internally organized by the learners. Internal organization is reflected by the order in which messages are being read. In asynchronous computer conferences topics are often discussed in parallel, thus raising the probability that chronologically subsequent messages are thematically incoherent. Experienced learners will use the subject lines of messages (especially if messages are connected via the reply function) to establish coherence between successively processed messages. In other words, meaningful organization processes are reflected by deviating from a strictly chronological processing order.

To emphasize the constructive nature of knowledge exchange the model includes a productive component of knowledge acquisition as well. While searching the internal knowledge structure and/or the external conference a learner might experience some kind of knowledge deficit. This will lead to the production of a new message containing a request for information.

Similar to the acquisition processes, conveyance of knowledge is characterized by receptive and productive components. The receptive part involves diagnosing a knowledge deficit of a peer learner, e.g. by reading a message that requests for further information. This will lead to internal search processes. If the requested information can be retrieved from the internal knowledge structures this might lead to the productive part of conveyance, viz, creating a new message that contains new knowledge elements.

To summarize, our model constitutes a cognitive cycle of knowledge exchange that is comprised of four parts. Learners acquire knowledge from a conference, formulate requests regarding their knowledge deficits which in turn are received by other peers who might provide an answer to the request. This cognitive cycle within the socio-technological system can be started or finished at any of these four steps.

Knowledge Distribution and Knowledge Exchange

According to our model the initial distribution of knowledge over the group members is crucial for knowledge exchange. We are currently conducting a series of experimental studies based on [Stasser et al. 1995]. They found that factors like the availability of meta-knowledge (knowing who knows what) and group heterogeneity may lead to the efficient transition from distributed to shared knowledge in face-to-face groups. Our model comes to similar conclusions. Meta-knowledge will support selection processes and lead to a better deficit diagnosis; group heterogeneity will decrease the number of parallel discussion threads, thus supporting organizational processes.

Developing and Using Interactive Software Templates for Learning Modern Languages

John Byrnes
Department of Modern Languages and Literatures
Wabash College, USA
byrnesj@wabash.edu

The impetus to develop interactive software templates came from the desire to move away from more traditional oral testing, which had typically consisted of questions read to a class which they answered in writing, to a more truly oral test that did not require putting the student in the often stressful situation of having a one-on-one interview with the instructor and did not involve the problems connected with scheduling such interviews. To solve this problem, our computer support specialist, Jacqueline Kaminski, and I developed a simple HyperCard template, which we call Listen and Respond, to allow students to hear a set of oral questions in the Macintosh laboratory and to record their responses to those questions on our server.

Before using the template for examination purposes, the students were, of course, required to use it at least twice for listening and speaking practice. These trials were very successful and encouraged us to continue using and refining the template, for when using the template the students became very interested in improving the quality of their oral responses. They also preferred testing done with the template to the traditional method.

When using Listen and Respond the student first signs in on the HyperCard stack and then works with a single card in the stack for each question and response. On each of these consecutively numbered cards, there are instructions on using the HyperCard Audio Palette to record and save responses and a button with the number of the question that allows the student to play the question as often as time allows. If desired a field can be added for the student to respond in writing as well as orally. This is particularly useful to determine with precision if students have mastered certain endings that are impossible or difficult to test only orally, for example the difference between je parle and te parles and the German article and adjective endings that are not always distinct when spoken since they do not fall in stressed syllables. Navigation through the cards is done with the standard arrow buttons. After completing and saving his responses, the student can, on the final card, hear each of the questions and each of his responses again and rerecord responses as desired. For the instructor there is a single card for recording questions. This card contains instructions on using the Audio Palette to record each question and a separate button to check each question. The evaluation card, which is accessed by pressing an invisible button, allows the instructor to hear each question and the student's response, which is particularly useful when the questions have been scrambled to avoid having all the students responding to the same question simultaneously. On the evaluation card the instructor can also assign a score to each response, total these by pressing the total button, and record comments orally and in writing. The evaluation card also has a print button that will print the card with the student's name and all scores and comments.

Having used the basic template for both oral practice and testing using only instructors' questions and students' responses, we wanted to extend the use of the templates to include external audio and eventually video sources. The first step in this direction was made in French instruction. Jacqueline Kaminski and I created a template from which the student could link to a newscast from Radio France Internationale, listen to the newscast, and then respond orally to the instructor's digitally recorded questions on the newscast. Shortly after that we followed an analogous process to have the students watch a video segment and respond to prerecorded questions on it. For this we used a segment from a video that accompanied one of our textbooks that we were allowed to digitize for educational purposes under the fair use guidelines.

Other members of my department have augmented the templates in other ways. For particularly difficult texts such as a formal speech, one can provide on the template the text of what the students hear to give them support they often need to cope with complicated material. One can add glossaries and links to web sites to the template to further assist the students in comprehending such material. In addition one can add a slower and more carefully articulated digitized recording of such material in order to bring the students to an understanding of the original.
Jacqueline Kaminski and I have begun to create various versions of the template in Authorware. We have done versions entirely in the target language and have created versions for faculty members with different levels of sophistication as computer users. In my department, faculty have also been working at integrating these templates, and other technology as well, into our teaching.

Conclusion

Both faculty and students can use *Listen and Respond* with ease. It has proven to be an effective approach for improving and testing listening comprehension and oral responses. Moreover, it is a template that can be modified and augmented to fit the needs of students at various levels and the particular pedagogical needs of various target languages.
But is it interactive and does it work? A review of some CALL English pronunciation CD-ROMs

Michael Carey
Speech, Hearing and Language Research Centre, Macquarie University, Sydney, Australia
michael.carey@macquarie.edu.au

1. Suggested Guidelines for the Research and Development of Pronunciation CD-ROMs

But is it interactive? Does it really work? Teachers who examine educational CD-ROM products usually ask these two elementary questions. How many product developers can honestly say yes to both questions? An impressionistic examination of 23 English pronunciation products has revealed that in a majority of the products, an obvious lack of research into content and/or pedagogy has led to the development of products that are at worst misleading or inaccurate in terms of content, and pedagogically naive. The fundamental flaw of the products is related to the breadth of the market that they have attempted to reach. Producers of all of the CD-ROMs reviewed have attempted to tailor a product that targets all nationalities of English language learners who are in need of pronunciation modification. This is untenable because each first language has its own unique phonological inventory that interferes in a different manner with the English phonological system. Because of this variation in the learners' needs it is critical that a thorough contrastive phonological analysis of the first (L1) and second language (L2) is carried out and a needs analysis approach is taken in the methodology. The contrastive phonological analysis should form the basis of the needs analysis. The products reviewed have overlooked this and instead have taken a didactic "this is how we say it in English" approach to pronunciation modification without regard for the L1 phonological inventories of individual nationalities. Therefore, a deductive, task based model should be implemented in the design of multi-media whenever possible. This is what gives the product interactivity. The limited interactivity in the reviewed products was a result of the tendency for developers to adopt an inductive model. An example of a model that is inductive (and didactic) is this visual display (figure 1) from the ELLIS pronunciation tutor. The learner is given a complicated phonological explanation of the place and manner of articulation of American English consonants. This may be a valid approach if the learner is an undergraduate linguistics student but can not help to develop the pronunciation skills of an L2 learner. The student can't possibly emulate the tongue position in the model just by looking at the diagram because they can't see inside their heads to compare. The articulatory adjustments required to imitate the model speaker are of such refinement that visual cues of this type can not possibly aid the process.

Figure 1: Ellis visual display of [l] articulation
Figure 2: Waveform display from Pro-Nunciation

Another visual cue used by many of the products is a waveform and/or spectra of the target phoneme, word or utterance (figure 2) which can also be generated from the learner's utterance and (supposedly) compared with...
the model. This display may look impressive to those untrained in acoustic phonology, but unless you are trained you will not realise that this series of wiggly lines can not even be matched exactly by the original model speaker. Spectra and waveforms are an individual's unique voiceprint, however unlike a fingerprint, the variables involved in replication result in a different waveform every time. Such a misguided application of technology is similar to the rain machines of the Wild West, it looks impressive but can have no more than a placebo effect on the student's pronunciation ability. The visual displays that were reviewed serve as both practise activities for skills development and as an assessment of the student's ability. The assessment component of the products must be able to accurately analyse and give comprehensive feedback to the learner. The products reviewed did not do this. Most products left the assessment of performance to the student to gauge by listening and comparing their production to the native model. The computer has untapped potential to assess production much more accurately than the student can because it can isolate the important L2 acoustic cues that the learner filters through their first language and deems insignificant. With further research, the computer may be able to substitute for the ears of the student and assess their production quantitatively.

An aspect of content which the author takes issue with is the inclusion of tongue twisters as a drill for minimal pairs. Minimal pair drills assume that the speaker cannot distinguish minimally distinctive sounds such as the vowels in ship and sheep because these distinctions do not occur in their L1. This may be true for some L1’s, but in certain languages such as Korean, there is a distinction, similar sounds exist in the L1, but at a phonetic level not a phonemic level. In a nutshell this means that they can’t see the point in making a distinction. So the method of instruction should not only be skill based (eg. minimal pair drills leading on to contextualised practise) but also knowledge based (explaining the phonetic/phonemic contrast) to rectify this error. Many of the worst pronunciation tutors featured minimal pairs and/or tongue twisters exclusively. Tongue twisters are pedagogically unsound because they drill sequences of discourse with frequencies of phonemes that do not occur in natural speech. Besides this the difficulty of the exercise is de-motivating. It is even too difficult for a native speaker to say red lorry, yellow lorry ad infinitum at a rapid pace.

Most of the products only dealt with the segmental level of speech (individual sounds) and isolated words. This is only one component of pronunciation. Supra-segmentals, otherwise known as prosody, the components of which are stress, rhythm and intonation, are recognised by some practitioners as more salient errors in L2 speech than segmentals. To say prosody is more salient is however a generalisation. While prosody is important, the interlanguage significance of prosody varies across L1’s depending on the extent to which they use prosody in the L1 and how the use of it contrasts with the L2. Prosody is the most complex aspect of pronunciation, causing many difficulties for linguists who have tried to develop a description of its structure and function. However, if a first language-specific approach to the development of a product is taken, it is possible to identify the needs of the L2 learner via a contrastive analysis and to then develop an interactive visual feedback model which can address some of the learner's needs. Pioneering work done in the past has shown that it is possible in theory to teach intonation by means of a fundamental frequency (F0) pitch trace. See [de Bot 1983] for an introduction to this idea and also [Molholt 1990] for visual feedback of segmentals. However, certain difficult system engineering refinements are necessary to make such a model workable.

This paper has raised criticisms that cut to the heart of educational multimedia development. If there is to be a future in developing multimedia products there needs to be the same amount of energy expended in the research of content and pedagogy for multimedia that has been spent on traditional pedagogy. Unfortunately, at least in the area of pronunciation software development, there is still a lot of room for improvement. The best way forward is for developers to ignore the economic imperative to get the product on the shelf, do the research required and make a product which is interactive and does work.

2. References

1 The measurable acoustic correlate of pitch is fundamental frequency (F0), which is the number of times per second that the vocal folds complete a cycle of vibration.
The Effectiveness of Interactive Computer Simulations on Teaching Circular Motion

Dr. Cheng-Chih Chien
Department of Educational Technology, Tamkang University, Taiwan, ROC

Department of Physics, The Ohio State University, USA
Email: avanhs@mps.ohio-state.edu

Abstract: A series of computer simulation activities were developed at The Ohio State University to support the introductory physics laboratory. Based on our development experience, an instructional design model is proposed to integrate instructional technology, content needs, and pedagogy for technology-based material development. In this paper, the circular motion is used to illustrate this model.

1. Introduction

At The Ohio State University, a series of computer simulations were developed as a supplement to support the existing introductory physics laboratory activities. After the designing and implementing experiences, a technology-based instructional design model, the general Chain Model, involving educational technology, pedagogy, and content domain is proposed for effective use of computers in learning. In this model, a pedagogy is selected based on the content domain needs for achieving the expected learning outcomes. Educational technologies are used to both facilitate the use of selected pedagogy and provide the content needs with special features which may not be available from other media. All three elements link with and support each other to effectively help students to learn.

2. CAL Design Model

In this study, computer simulations, constructivist and Vygotskian perspectives, and circular motion were the three elements of the specific Chain Model, see [Fig. 1]. Research on misconceptions shows that students usually have their own ideas about the world before taking science courses [Osborne & Freyberg, 1985]. Therefore, the goal of science courses is not just introducing new ideas to students, but also to help students remove the inconsistent ideas and rebuild new knowledge. To achieve this goal, the strategies of using conceptual conflicts suggested by constructivists [Jones, 1990] and using language to internalize specific tasks into mental functions suggested by [Vygotsky, 1978] were included to challenge student preconceptions and to help them internalize the physics principles. The instructional materials include computer simulations and accompanying worksheets that guide students to work through the entire learning activity. The animated images from computer simulations can also be used to describe the dynamic processes involved in the circular motion so to reduce the complexity and possible miscommunications resulted from verbal explanations.

  - Vygotsky
3. Learning Activity Development

Newton's second law, \( F = ma \), implies that the net force and the acceleration always have the same direction. In the preliminary study, it was found that after practicing the formula for weeks students still considered the force and acceleration as two independent factors when asked by qualitative questions about circular motion. A series of learning activities were then developed to help students learn circular motion by reconsidering the already learned equation \( F = ma \). In the circular motion module, students are to determine the directions of accelerations at various points and to compare the tension of the rope and the weight of the pendulum bob at the lowest point. With accompanying worksheets, students go through the following steps to study a pendulum:
1. **For each problem, students are asked to predict the answer first.**
   This step helps students examine their current understanding of the accelerations and forces in a pendulum motion before they go through the learning activity.
2. **Students explain the reasons of their predictions.**
   This procedure helps students reorganize their knowledge and facilitate translating these physics principle into meaningful language.
3. **Explicit instructions are given to suggest students use some simple techniques which help solve the problem.**
   The computer simulations provide a visualized dynamic process for each problem solving procedure.
   Questions in this step are usually very simple and straightforward. In circular motion, students are asked to use vector subtraction to determine the acceleration direction, and to draw a force diagram.
4. **Students use physics principles to analyze and synthesize the answers obtained from the previous questions to determine the answers of the problems asked at the very beginning.**
   In circular motion, students use Newton's second law, \( F = ma \), to analyze the acceleration direction and the force diagram obtained from the previous questions to determine whether the tension of the rope is greater than, equal to, or smaller than the weight of the pendulum bob.
5. **At last, students run the simulations to check the result and compare the answers predicted at the very beginning and after analyzing the motion with previously learned physics principles.**
   After analyzing different physics properties at various points (the highest and middle points), student see the entire swinging process with vectors which represent different physics quantities.

4. Result and Discussion

The effectiveness of the instructional material on student learning is evaluated. Student conceptual understanding was tested by problems which either do not require mathematical equations or provide very limited information that deters students from manipulating the numerical variables to obtain an answer. The problem solving ability was tested in the midterm examination which includes a process of abstracting the physics properties from a description of an event, identifying appropriate physics principles and formulas, and then finding the numerical unknowns. All the needed formulas were given in the test so students do not need to memorize the formulas. Two hundred and thirteen students science and engineering students took the introductory physics course in the winter quarter, 1997. Due to the fact that different data were collected at different times and places, the data were analyzed with preliminary and follow-up analyses by the analysis of variance (ANOVA). The results of problem solving activities show that students using computer simulations had significantly higher scores than students not using computer simulations. On the pretest of the conceptual understanding, students in the non-computer group scored significantly higher students in the computer group. On the posttest, there was no significant difference between the two groups.

Design, Development and Pilot Test of a Distributed Collaborative Science Learning Laboratory

Dr. Martine Chomienne, Centre collégial de formation à distance, Centre de Recherche LiCEF, Montréal Canada. mchom.ccfd @crosemont.qc.ca

Dr. Jesus Vazquez-Abad, Dept. de didactique, Faculty of Education, Université de Montréal, Montréal Canada. Vazquez@scedu.umontreal.ca

Introduction

One of the challenges facing distance education courses in science is the question of labs, considered an essential element in most science courses. However, science labs have proved difficult to integrate into a distance context, and most institutions either mail out lab kits or have students go to traditional sites for the lab component of a course. Another major challenge to all distance education activities is that of overcoming student isolation and low motivation. For these reasons, the decision was taken to explore the feasibility of creating a distributed collaborative science learning laboratory (DCSLL) using the Internet for delivery and communication. In a project of the Tele Learning Network of Centres of Excellence (Canadian government) and the Fonds de l’autoroute de l’information (Quebec government), researchers from the Centre Collégial de Formation à Distance (a post-secondary distance education institution) and the Université de Montréal have been working to develop a workable prototype of such a system.

Conceptual framework

The concept of DCSLL draws on four contributing areas: collaborative learning, science laboratories, information and communication technologies, and distance education. After reviewing the literature in cooperative/collaborative learning [Johnson & Johnson 76; Salomon 92; Slavin 86], we have adopted the approach of Salomon, who defines collaborative learning as requiring interdependencies among learners and with the learning environment on four levels: knowledge, competencies, resources, and infrastructure.

As a learning environment and an instructional strategy, the science laboratory [Collette & Chiappetta 94; Gallagher 87; Lazurwitz & Tamir 94; Soloway, Krajcik & Finkel 95] includes practical work within planned learning experiences taking place in a purposely assigned environment. The important aspect of a science learning lab is the controlled nature of the actions and the environment which permits generalization by the students beyond the specific instance under study. The term distributed is used to refer to different kinds of distribution: physical, temporal, and cognitive. Distribution across time and space are defining characteristics of the distance learning context [Bourdeau & Bates 96] we are addressing. Cognitive distribution, however, means that team cognition is distributed among its members, with team learning dependent on the characteristics of this distribution. The concept of distributed cognition has implications, therefore, not only for the way in which a group will work, but the results of that work. The role of information and communication technologies is defined as providing common space and communication channels for teamwork.

Design

The lab was developed in the context of a post-secondary course offering an Introduction to the Scientific Method for non-specialised students. The lab is a series of three experiments to be completed by a team of 3-4 individuals. The experiments were designed to be a progression along four continua: communication, from simple (voice only) to complex (whiteboard with screen capture, annotation tools, voice, chat, etc.); collaboration requiring less interdependence (joint data interpretation and conclusion-drawing only) to more interdependence (team planning, completion, analysis, interpretation and conclusion-drawing); concrete activities (manipulating real objects) to abstract, symbolic representations and manipulations; and data analysis beginning with qualitative and moving to quantitative data. The first experiment is a qualitative exploration of simple electric circuits. It involves the manipulation of real objects (batteries, bulbs, wires, etc.), qualitative observations, individual analysis of the data, and collaboration for the interpretation and conclusion phase. The second experiment deals with Ohm’s Law. Students conduct experiments and analyse
data individually using a computer simulation, and use the common work space to discuss the results and draw conclusions. The third experiment deals with Kirchhoff's Laws and requires collaboration from the beginning, with planning the work to be done the responsibility of the students. All phases of the experiment are done collaboratively.

The pilot test

The pilot test had several objectives. The first was to verify the feasibility of creating a DCSLL. The second was to collect data to suggest modifications to the prototype for the development of detailed design specifications. The third was to examine the results of merging the four contributing areas in one learning environment. It took place over two days with three "pseudo-students" participating. The participants worked in three rooms, each with a computer with Internet access and a telephone. They each had a copy of NetMeeting, and access via Internet to the simulation software. Data were gathered from group interviews, productions, and participant observation.

Results

The ideas taken from the four contributing areas combined in the Simulateur Electrique to produce a DCSLL that functioned largely as expected. Results of particular interest are presented briefly below.

It is extremely important to start with individual work, and provide the student with on-going access to personal workspace to respect individual cognitive and affective profiles.

The progression from qualitative observations to quantitative data to graphics to formal representations with equations allowed the students to integrate the different representational modes and develop a more complete understanding of the scientific principles under study. This progression must be designed into the activities. The need for individual and common work space must be balanced; in our case the simulation was limited to individual use while results could be shared in the common space.

Audio communication was used successfully to substitute face-to-face interaction and supported the creation of positive interdependence among team members.

Conclusion

The results demonstrated the feasibility of a DCSLL. The data gathered were used to create detailed design specifications; an improved version of the lab is currently under development. The new version will be used to explore certain questions that emerged from the pilot phase; the most salient are listed below.

Should productive errors be encouraged or introduced in order to provoke discussion of certain concepts?

How should the distant tutor act and interact with students to motivate and enable them to follow an approach based on cognitive conflict?

Under what conditions is asynchronous communication useful and what form should it take?

What is the impact on the tutor's role of the increased student-student interactions?

An Expanding View of Literacy: Hypermedia in the Middle School

Pat Clifford, Sharon Friesen, D. Michele Jacobsen

“So, what have you guys got your kids on anyway?”
It was an early morning meeting in the provincial capital. Teachers from across Alberta, brought together to work on technology integration, were talking about the software packages they used in their schools.
“Well, Office 97 as the basic suite.”
“No, you don’t understand my question. I don’t mean what do you guys use. I mean, what software do you give the kids?”
“Like I said, Office 97. That’s what we use for ourselves most of the time. That’s what the kids use, too.”
The group was incredulous. “I thought you said you were in elementary. What grades do you teach, then?”
“Well, we used it with Grade Two last year. This year we teach Grade Six. Same deal. It’s what we’ve got on our network.”
“But you haven’t got all kids on it, have you? Like, I can see how it might really stretch some of them for enrichment. But what about the rest? You must have something more suitable for them.”
“Nope. Everybody uses the same.”
“But it’s far too difficult for children. For heaven’s sake, teachers go nuts trying to figure out how to use all the applications. How could you ever get kids doing it? You’d have to spend too much time even getting them to understand how to use Word let alone the rest of the stuff. And what about the learning disabled guys? You can’t mean you just throw them to the wolves. I have to say I really disagree with you on this one.”
It was one of those conversations that has stayed with us for a long time—not because it was so unusual, and not because it’s about the particular merits or flaws in one commercial software package, but because it holds, in microcosm, so many of the issues of technology integration that we wrestle with daily. Kids, it is thought, cannot bear the full weight of adult technology tools. Students require, such teachers tell us, developmentally appropriate versions of software applications because the real thing is too difficult for them to master. Children, the story goes, require direct instruction in the simulated use of applications before they take on real tasks. Teachers, most are certain, must control and direct the scope and sequence of skill mastery if anything useful is to happen. Learning with computers, say the cautious, requires labs ‘with locked doors, strictly rationed access, and a designated technology teacher. Otherwise all hell can break loose.
These are the kinds of assumptions many educators accept without question as right and necessary for all students, let alone for children with identified learning problems, for whom such orthodoxy becomes true in spades. In school, these children’s encounter with computer technology most often involves carefully sequenced courseware, remedial applications and computer assisted instruction. Applications guide such students through carefully monitored, controlled and measured steps. Learning tasks proceed in small, incremental stages. Walk before you try to run, the thinking seems to go. Sometimes these applications are sold to the educational community on the promise of on-going reinforcement and immediate feedback. Mirroring teacher-directed lessons, they frequently provide as low a level of interactivity and as high a degree of control as traditional worksheets. Clever marketers now package them as edutainment: supposedly more palatable to children, books become “living” software packages; skill drills are tarted up with co-opted cartoon characters, and math facts get blasted with hyperactive graphics and manic sound bytes.

“We may not like who is is following us down the slopes, but they’re gaining on us” (Rushkoff p.38).

Douglas Rushkoff calls them Screenagers. They are children “born into a culture mediated by the television and the computer” (p. 3). They are deeply at home in exactly the environment that schools try to tame and control: the rapid-fire, non-linear, chaotic, multisensory world of the computer. It is a commonplace that children know more about computers than adults, that they are better and faster than their parents and teachers. It is commonplace because it is true. But that is not the main point of interest. What is even more interesting, harder to grasp, and ultimately more compelling is that Screenagers use computers in ways that adults do not anticipate and frequently misunderstand. What we assume they require of us—careful instruction, step-by-step activities, computer curricula developed with a close eye to scope-and-sequence—is often exactly what gets in their way.
It is helpful to think of the difference between teachers' images of computing and children's experiences by comparing skiers and snowboarders. Rushkoff describes what happens when Screenagers hit the slopes. Scoring carefully groomed runs, snowboarders seek out precisely the gaps and obstacles that frustrate skiers. "Unlike parallel skiing, snowboarding is a sport designed to give its participants the opportunity to test their reactions to gaps of many kinds" (p.38). The action in snowboarding happens in the spaces-in-between. "Getting air" means confronting discontinuity. It is improvisational and instuitiontal, an "intentional exercise of relaxing into chaos" (p.38) in which gaps, openings and obstacles define the sport. The precision and control required of skiers gets in the way. For snowboarders, more is better. It is "usually always better" (p.38) to overshoot a jump than fall short; better to push your limits than pull back; better to overestimate than chicken out. Usually always: an ambiguous phrase that frustrates the precise and exactly portrays the improvisational skill of the breed. When they grab a mouse, they already know that it's usually always better to jump right in, to explore, to test the waters, to see what happens when you paste this graphic, import that sound or create a link right

Whether students confront the conceptual gaps and opportunities that computers offer, or jump "the physical gaps between mounds of snow, the coping strategy is the same: usually always overshoot and definitely always relax and have a good time" (p.38).

It is hard for schools and teachers to accept that the culture of screenagers and the attitudes of snowboarders embody skills and strategies that almost always work better with technology than our own carefully groomed, carefully planned, carefully schooled approaches. Unable to see any recognizable, underlying order in their apparently chaotic behavior, we tend to see only random energy and danger. Well intentioned on behalf of what we understand learning to be, we want, somehow, to prepare them, to direct them, to shape and control their encounters with computers. Nervous in the face of their obvious comfort and skill in an area that unsettles many of us, our deepest instinct as unseated experts is often to rein them in.

The Question

Shortly after hypermedia tools became readily available to educators, Marchionini (1988) predicted that hypermedia authoring tools had the potential to alter teacher and student roles and the transactions between them by allowing students to construct their own interpretations of information as well as share their interpretations with their teachers and other learners in unique ways. Marchionni points our attention in an important direction: hypermedia authoring tools have the power to change, forever, the power structures of the classroom. Exploring snowboarding as a fundamental metaphor for children's use of emerging technologies, we have already suggested something of the nature of that change. What follows puts meat on those theoretical bones. It is an account of what happened in a Grade Six classroom when one student, academically marginalized by his unsuccessful struggles to read and write in conventional ways, grabbed some air when he and his teacher stumbled upon Power Point.

Act One

Bryce was mad. He had to write a report on bears as part of his science unit on Forest Ecosystems, and he had had it. Years of failure with pencil and paper welled up inside him, and he crawled under his desk, arms shielding his head and knees drawn up to protect his heart. Entries to come out and just try failed. Suggestions about where he could find help failed, too. Demands that he at least sit up and think about what to do next actually broke the log jam. He crawled out, shook himself and walked out of the room. At his locker, hands shaking, he pulled out his jacket and boots.

"I'm out of here," he said. "I'm going home. You can't make me. You can't stop me."

And he was right. We couldn't make him and we couldn't stop him. But we could help. Half an hour later, he had calmed down enough to accept an offer to sit with him and open up a word processing document so that he could get something started. We promised to go down to the library and search for books with him. We said we would read them with him and type out anything he wanted to say.

"Okay, I guess you can do that," he agreed, tears still close to the surface.

Bryce had never opened a Word document before, so one of us sat with him and talked him through the initial steps: click on Start, go to New Document, choose Blank Document. One, two, three easy steps. Hands still unsteady on the mouse, Bryce accidentally opened Power Point instead of Word.

"Oops," he said. "How do I get out?"

His teacher sat for a second. "Do you really want to get out, or can I show you something?"

"What?"

She pulled up a template. "Look at this. If you want to make a bunch of slides about bears, you could do something like this." Working as quickly as she could to keep his attention, she made four quick slides, importing graphics, playing with layouts, showing him how to use bullets for point form.

"Nothing says you can't do your report like this. What do you say?"

Bryce said nothing. He just grabbed the mouse and started to play.
Act Two

Two days later, Bryce (now working with his friend Mac, an equally reluctant writer) had finished six slides.

"Hey, guys, can we show the rest of the class what you’ve been up to?"
"Why?"
"Well, it’s really neat. And besides, they might get some ideas for their own stuff. What do you say?"
Unused to being cast as role models, Mac and Bryce shifted from foot to foot, looked at one another and agreed. "Well, okay, if you really want."

We grabbed the projector, hooked it up to the computer and called the class together for a quick meeting. Bryce and Mac stood beside the screen and walked us through their slide show. In the space of two days, all by themselves, they had figured out how to import graphics, create transitions with dissolves and sound effects, and design builds with bulleted text that flew in from left to right, right to left, top to bottom. A buzz ran through the class.

"Hey, cool you guys. How’d you do it? Where’d you get those pictures from? I want to do that. How do I do that?"

The teacher gave a quick demo so that everyone who was interested could open up the program. Singly and in pairs, students returned to their terminals. Some continued with their Word documents, but many went straight to Power Point. Clustered in pods of three and four machines, they compared notes, made suggestions, experimented. Bryce and Mac hung around for a bit making suggestions, then returned to their own work.

Act Three

A month later, the bear reports were all done. Some were handwritten, with cut-out pictures from National Geographic and pressed leaves and specimens from the forest floor. Others were word processed, pages neatly stapled and bound. But many of the reports were saved to disk as Power Point presentations, and we were ready to watch.

Students gathered together around the projector. They were all curious to see what others had accomplished, and they were in a celebratory mood. They were hot, and they knew it.
--critiqued their design: annoying sound effects, silly color choices,
--fought about spelling and how dorky it was to have a hugely projected slide with stupid spelling
--recognized that slide after slide of text didn’t work. Janeve asking for advice from the “worst” students
--ability to talk to the points that they had captured on their slide. Presentation both in terms of the slides and in terms of their human presence to explain the concepts that lie behind the glosses they had chosen to present in bulleted form.
--eagerness to go back and fix up the mistakes they could now see in their work, and refine their work, try other things, experiment. Work wasn’t over at all--it truly was theirs, and they wanted to keep going.

How do hypermedia authoring environments challenge conventional conceptions of literacy development?

Conventional approaches to teaching writing are built on pervasive assumptions about the nature of text and of literacy:

- Text organization is linear (i.e. beginning, middle and end)
- Text production proceeds in a linear fashion. (i.e. the “Monday to Friday” writing process sequence of pre-writing, draft, revise, proof-read, publish)
- Text means the written word and recorded symbols
- A report is one long stream of uninterrupted text
- Reading and writing are solitary endeavors

The present investigation examines the merger of a constructivist approach to writing that regards the student as knowledge creator and the use of hypermedia authoring as the publishing and presentation medium for student work.

Review of Literature

Shortly after hypermedia tools became readily available to educators, Marchionini (1988) predicted that hypermedia authoring tools had the potential to alter teacher and student roles and the transactions between them by allowing students to construct their own interpretations of information as well as share their interpretations with their teachers and other learners. Turner and Dipinto (1992) have recently demonstrated that the capability for students to create
their own interpretations includes the ability to author individual HyperCard documents that are shared with other students. Turner and Dipinto (1992) suggest that in order for students to become hypermedia authors, they must learn not only the content they will present in the hypermedia document but also the tool skills they need to use the hypermedia software. Carver, Lehrer, Connell, and Erickson (1992) emphasize the importance of master teachers who have a thorough understanding of design skills and can embed explicit discussion and practice of the whole process of design into daily classroom activity. Thus, hypermedia becomes an object of instruction as well as a medium for teaching and learning (Turner & Dipinto, 1992).

**Project Description**

In this study, sixth-grade students used PowerPoint to create multimedia research reports about bears as part of a cross-curricular investigation. Each student conducted research on bears using both physical and digital reference sources, such as books and encyclopedia, CD-ROM reference materials, and by searching for information about bears on the World Wide Web. Students digitized images of bears using optical scanners, created charts in Microsoft Excel, and downloaded images and sounds from the Internet. Students then determined what information to include in their research report, organized it into slide-by-slide chunks, re-organized these slides using the slidetray in a meaningful way, and presented their PowerPoint presentations, which were true hypermedia documents that incorporated text, links, graphics, charts, and sounds, to their classmates and teachers. During the presentation of the PowerPoint projects, students offered thoughtful and well-considered feedback to their peers on content, screen design, and media issues.

**Purpose**

Through an examination of the role of hypermedia technology as a medium for students to actively construct knowledge, our purpose is to explore alternatives to conventional conceptions of the development and nature of literacy.

**Methodology**

Our students are a heterogeneous, grade 6 classroom with 60 students in a rural community close to a major urban center. They range in ability from those who represent the “traditional” struggling writer to those who represent the traditional conception of the expert, or successful, writer.

Our data was collected over the course of a two-week study that was part of a larger, integrated study of the local environment. Students were, as a group, inexperienced in using the computer. A few were confident in their use of word processing, and fewer of those had also spent time using the World Wide Web. None of the students had previously authored a multimedia document. Instruction in the use of appropriate software applications was part of the regular classroom emphasis on the integration of technology into curriculum, following the requirements of Alberta Education.

The skill and ease with which students mastered the technology, and the surprising outcome that students at the “lower” end of literacy skills and abilities as measured by conventional means, has drawn our research interest to a number of compelling issues:

- Conventional understandings of “ability” are constrained by traditional assumptions about the nature of literacy. When teachers change the publishing environment, a whole new set of competencies appear to emerge.
- The conventional social structure and communication patterns of the classroom were transformed when students generally seen by their peers and by their families as “less able” produced the most interesting and exciting work.
- Conventional understandings of text as linear and uninterrupted gave way to an experience of knowledge construction that was multi-faceted, iterative, and malleable.

**Discussion**

--Interesting that the class did not become PowerPoint junkies, instead PowerPoint seemed to be a springboard into other applications and tools, ways to write, communicate.
Our discussion will focus on how hypermedia authoring provides and also demands alternatives to conventional conceptions of the development and nature of literacy. Results of the hypermedia authoring project will be discussed in light of the differential development and production of "lower" and "higher" ability students.

Development and Implementation of a CAL Package on Plant Anatomy: Rationale, Preliminary Analyses and Student Response.

Glynis Cron* & Gail McCallum+

Introduction

Context: Where and When Used
A hypermedia package entitled "Constructa Plant" is being developed for use in a course on "Plant Development, Structure and Function" in the second year of the Biological Sciences curriculum in the College of Science at the University of the Witwatersrand. The College of Science is a two-year foundation programme developed to address the educational imbalances of the past in South Africa, especially in science and engineering (Rutherford 1997). Students who pass the programme proceed into the second year mainstream. The students in the programme are admitted with lower than traditionally accepted school leaving qualifications, but have been selected on potential. The majority of our students are therefore educationally and often socially “disadvantaged”, but are highly motivated and talented, though lacking in many basic skills.

The Constructa Plant package aims to provide a foundation for the recognition of plant cell and tissue types, but also to enhance understanding of the 3D structure of cells and relate this to their functions and positions in organs, as well as to give students the opportunity of practising answering questions (Cron et al. 1997).

Rationale: Why Develop It?
The package has been and will be used to assist self-study of basic plant tissues in preparation for the introductory practical of the course, in which students examine plant cells as whole structures and in transverse and longitudinal sections. The students do not receive formal lectures on this section of the course, and prior to the development of the package, used their textbook to research and summarise the main features of these cell types during a tutorial session. In 1997, they were able to use a prototype of the 'Background Knowledge' section of the package in conjunction with the textbook for this purpose.

The package has also been designed in response to observations of difficulties experienced by students over a number of years of teaching plant anatomy. Most of the students come from schools which lack practical facilities and have little experience in microscopy or interpreting sections of tissue. At a more basic level, some students have difficulty in conceptualising cells in three dimensions, as functional entities connected to other cells. They then produce drawings of cells with thickened walls (e.g. epidermis, collenchyma and sclerenchyma) as disconnected entities, reflecting their lack of perception of the cell wall and middle lamella.

Rationale: Why CAL?
We chose to use a computer package as the medium of instruction and as the intervention mode because of the many advantages associated with CAL. These include the following: (i) It is, if so designed, highly interactive and thus promotes active learning (as opposed to the passive rote-learning at which these students are especially good); (ii) it allows for learning to be directed or guided by the way in which the information is presented, and specific problems can be addressed; (iii) the learner can learn at his or her own pace, which is very important for the very diverse group of students in our programme; and (iv) it is a very non-intimidatory medium in the sense that no one "sees" the mistakes and students feel free to attempt to answer questions without fear of peer or teacher criticism.

Computer Design Features
The package is being programmed using Visual Basic 5 to allow for maximum flexibility in design. The Windows environment is being used, but no previous computer experience is assumed for the users. Simple screen layout is used and instructions for each screen are given at the bottom. A "Help" menu also provides information regarding text colours and navigation. A concerted attempt has been made to use relatively simple language with E2 language learners in mind. A sans serif font has been adopted as research has shown that it is the most easily readable kind of font (Dekkers et al. 1993).
Instructional Design Features

The instructional design of the package is based on educationally sound principles as discussed by Alessi & Trollip (1991) and Peté (1997). Features worthy of note are the following:

Navigation: Students can select from the Main Menu which sections they wish to visit and a colour change indicates where they have been. There is maximum control available to the learner, who can move forward (Next button) or backwards (Back button) as desired, thereby repeating screens, and can quit at any time.

Leanness (or "chunking" information): "Leanness" embodies the principle of not giving the learner too much information at once. This is achieved in two ways: firstly, through time lapse in revealing information and/or activities, although this has disadvantages as reading speeds and computer speeds differ, and secondly, through hypertext, to provide more information or explanations (usually of terminology), or more illustrations.

Interactivity: This is achieved in a number of ways by involving the learner in activities such as clicking for labels, answering questions: multiple choice and open-ended types, matching and search activities.

Feedback: The students receive the correct answer after a maximum of three tries for any attempt at answering a question. The feedback includes confirming or correcting information as well as indicating the correctness of the answer. Open-ended questions allow for variety in answers by letting students check their own answers from a "model" answer or list of possibilities.

Self-testing: The QUIZ is designed to give students the opportunity to test themselves and gain practice in answering questions. Students may select specific sections on which to test themselves, and note their score afterwards. They are also offered the option to see the screens they answered incorrectly and then given direct feedback as to whether their second-attempt answers are correct or not.

Method of Preliminary Analysis

In evaluating the effectiveness of the package in its initial usage, we analysed the scores of two groups of students when answering an exam/test question. The question was given in the June 1996 examination to students who had not used the package, and then in a test in March 1997 to students who had used the 'Background Knowledge' section of the package. The question required the students to identify three different plant tissues and their constituent cells, to note their functions, identify structural features which enable them to perform their functions and where they occur (see Cron et al. 1997, Fig. 1). Differences between the scores of the two groups were then tested using a one-tailed two-sample t-test, assuming equal variance.

Correlation analyses of student performance in the test question with performance in practicals during the course and the practical exam were also carried out to see how effective a tool the test question was in assessing knowledge and understanding which could then be applied in these new situations. Pearson's coefficient of correlation was used.

In a more qualitative approach to assessing the impact of the package, students were asked to fill in a questionnaire at the end of the tutorial during which they had used the Constructa Plant package. They were asked for feedback on whether or not they had enjoyed using the package, what they had liked/disliked, whether they felt they had gained new information and understanding from using it, and questions regarding specific items such as quality of illustrations, clarity of explanations, etc. Students were also invited to make suggestions for improving the package, as it was made clear that they were the "prototype testers" and that their input was valued.

Results

Analysis of the scores of the two student groups for the exam/test question revealed that in 1996 (Figure 1a), 39.5 % of students failed the question overall, 25.5 % obtained between 50 - 62.5 % and 30.4 % between 63 - 79 %. Only 4.5 % of the students got 80 % or more for their answers. In comparison, in 1997 (Figure 1b), the number of students failing is markedly reduced to 25 % and a larger percentage (15.6 %) of students got more 80 % or more. Using a one-tailed t-test (two sample and assuming equal variance), the improvement is significant at the 2.5 % level: P (T A-t) one-tail = 0.024476; t (Critical) one-tail = 1.6669144 at 72 degrees of freedom.
In analysing the different parts of the exam/test question in (b) 1997 (N=32), it can be seen that the number of students failing the specific parts (b) and (c) in 1996, although not for part (a) of the question, there is a substantial increase in the number of students getting 100% for the all of the question relates to a different tissue type.
Figure 2. Comparison of performance of students in parts (a), (b), and (c) of the question in 1996 and 1997.

**Correlations of Performance in Test Question with Performance in Practicals and Practical Exam**

Pearson’s correlation coefficients for the test/exam question, assessment of performance during practicals in the plant structure, development and function course, and for the Practical component of the June exam in 1996 and in 1997 are presented in Table 1.

Although the correlation coefficients on the whole are low (Tab. 1), most of them indicate a significant correlation between the variables for the population from which they are sampled (as indicated by p). An exception is the very low correlation between the exam question and the practical assessment in 1996 (r=0.1976) and its lack of significance. Another exception is the high correlation value (r=0.6774) between the exam question and the Practical exam in 1996, and its high significance. It should be noted that the test/exam question did not form part of the practical component of the June examination, but was part of the so-called "theory" part of that exam. The exam is divided into two parts, involving the use of microscopes and experimental equipment in the "practical" part, although the work done throughout all components of course is integrated and tested in both parts of the exam.

Table 1. Pearson’s correlation coefficients and assessment of their significance for two rounds of students.

Student Response to the Questionnaire

The students were overwhelmingly positive in their response to the package and requested that more, similar packages be developed for other topics. The following are a selection of their responses from the questionnaires completed at the end of the tutorial:

Q. What did you like MOST about the package?
   "Every aspect is accompanied by a drawing."
   "The way information is being highlighted."
   "Being asked the question and then given the correct answer to compare with the one I gave."
   "Explanation of cells and tissues, especially their microscopic structures."
   "The whole of it, I was so impressed by the way the information was written, you know beautifully and most understandable."

Additional Comments:
   "I wish that there can be more of this kind of package for every topic as it is easy to understand, and you know what, it's most enjoyable."
   "It is easy to understand things 'cos everything is done at our own pace. It'll be useful if more programmes on other topics are developed."

Discussion and Conclusions

A major assumption in the underlying theory of the two-sample t-test is that both samples come at random from normal populations with equal variances (Zar 1984). Although this cannot be known, it is hoped that the influence of the selection procedure in establishing entry to the course may assist here. "The t-test is nevertheless robust enough to withstand considerable departures from its theoretical assumptions" (Zar 1984: 130), although the samples in this analysis were not equal in size, nor were they very large. Nevertheless, the difference between the groups tested is significant at the 2.5% level, which reflects a considerable level of improvement.

Although there are other factors which have possibly contributed to the significant improvement in the group of students who used the CAL package, the results indicate that it has been an effective mode of assisting learning in a foundation tutorial for plant anatomy. The most important of these contributing "other" factors is possibly the fact that the 1997 group were tested nearer to the time of learning the content. Another factor might be the different levels of anxiety associated with a test (in 1997) as opposed to an exam (in 1996). Different time pressures may exist in a test and an exam, although we propose that the test may be more pressurised in that there is an overall lesser time period and therefore less flexibility. This last factor would therefore not have enhanced the test scores in 1997.

Students also did not answer all aspects of some parts of the question, and this may reflect bad test technique, rather than lack of knowledge. It cannot be known whether the students would have supplied the correct answer if they had answered a question in its entirety. Similarly, poor exam performance could be a factor contributing to the poor correlation between practical assessment during the course and the practical exam (Tab. 1), as many students do not achieve as well during exams as they do during the term.

The lack of correlation of the scores for the exam question and the assessment for the practical component of the course in 1996 (Tab. 1) may be explained by the fact that a considerable proportion of the marks for practicals is awarded for drawings/diagrams. Although a good understanding of cell structure and the ability to recognise cells would assist in producing a good, well-labelled drawing, drawing ability is not directly being measured in the test question as it is in the practical mark. It should also be noted that the Practical component of the June exam (2½ of 5 hours) includes work and skills from the both the first and second blocks of the semester, thus including additional skills and topics not correlated with an understanding plant anatomy.

The enthusiastic response of our students to using a computer package to assist learning is similar to that of the
students in Blackmore & Britt’s (1993) study. Most of our students had had limited exposure to computers before using this package, and the only aspect with which they experienced difficulty was in "dragging and dropping" arrows in some of the on-screen activities, reflecting inexperience with use of a mouse.

In our opinion, the three main reasons why the computer package did significantly positively affect learning is due to (i) the more directed nature of the learning, (ii) the more simple and more visual presentation of information, and (iii) the fact that fundamental concepts are emphasised.

We wish to acknowledge the financial support of the Richard Ward Foundation and the Foundation for Research Development in South Africa. We also thank Professor Alan Critchley for his initiative in setting up a CAL group within the Department of Botany, for his encouragement and inspiration. Thanks also to Mrs. G. Carter and the BIOL 123 students for their evaluation of the package prototype, and to Vivienne Williams for assistance with the statistical analyses.
What is the program 'Neurology Interactive' about?

We are faced with the facts, that educational resources have become progressively scarcer, clinical teachers have less time for teaching and patients with classical presentations are not available, when the curriculum calls for them. As medical student, I received my information from lecture and books, then I converted the information to knowledge at the bedside and in the laboratory. It is this latter activity which is threatened most by the resource shortage.

With the computer-aided-instruction-tool ('CAI') 'Neurology Interactive', we intend to soften the adverse effect of this processes to the education of medical students in the field of clinical Neurology. While I do not propose that CAI can replace the actual clinical experience, I propose that appropriately designed programs can supplement reduced clinical exposure.

Our approach is a case based interactive computer simulation of the neurological examination of ten prototypical patients - including the essential clinical and paraclinical features. A concise theoretical framework of the different diseases and their investigation is provided.

---

**Figure 1:** User interaction is provided by an intuitive graphical interface.

---

**The Simulated Clinical Examination**

In analogy to normal clinical practice, students are first presented with a case history.

When the student proceeds to the clinical examination part, the patients face and history are already known to him - elements that are important to invoke empathy.

Then, the student is confronted with a pictoral representation of a patient. Each patient is representated by four pictures: the frontview, the rightsideview, the leftsideview and the backview. This allows the student to 'turn-around' the simulated patient and so to reach any point of interest.
The interactive graphic interface is based on a set of implicit maps of the body surface representing the trigger-areas for various neurological signs. The application of neurological tools (reflex hammer, ophthalmoscope etc) to the appropriate location causes the program to provide realistic verbal and visual responses.

![Image](image_url)

**Figure 2:** The application of the tool "hand" to the leg of this patient causes the program to provide the user with a digital video in which he can analyze the reaction of the patient to a specific examination.

**Indicating the Appropriate Locations for Each Examination Tool**

Each examination-tool is represented by two different cursors: One represents the active tool, the other one the inactive one. While moving the cursor over the simulated patient, the appropriate locations are indicated by switching the cursor into its active form.

**Providing a Help-System for Case-Based-Learning**

The case-based learning environment demands for a help-system that doesn't destroy the student's curiosity while protecting him against losing itself on a wrong track.

We provided a simulated tutor who advises the student the way he should handle things. A user can anytime demand for assistance. Then a little QuickTime®-Movie is presented to him in which an experienced tutor recommends an examination not yet performed but of importance for making the diagnosis.

Here's an example:

Examine the sensibility for touch on the legs - compare sides and regions of both legs. For this purpose, you take the tool "feather" and put it against the regions you intend to examine!

**Feed-Back**

For a computer-based program, it is possible to track the users' actions. This offers the opportunity to give either immediate or summative feed-back. In 'Neurology Interactive', three different summative feed-backs are provided.

There is first a tracking of the users actions for each case, then second a reminder of "what is to do" and third an assessment of the reactions caused by the users' actions.
1. Environmental Management Training: international issues with specific individual training needs

Taking environmental issues into consideration is an ever evolving endeavor—one in which Environment Managing Standards (EMS) appropriately step in to assist willing industrial and commercial enterprises of all sizes, at national and international levels, to harmonize their activities in view of respecting the environment. The challenge is to provide adequate personnel training for all the enterprises that want to apply these standards and wish to obtain accreditation [Boutin et al., 1996].

This type of training which targets a potentially large and diversified clientele, must be flexible, adaptable and transferable, context-wise, as well as with respect to the appropriate methodological approach and pedagogical activities. This is especially desirable when the learners are adults from different walks of life, each one of whom has objectives, some level of education and professional expertise. It is also well known that, in the same learning environment, each adult has his/her own cognitive style and could resort to different strategies to assess what is needed to construct knowledge and attain the required learning objectives.

With the stack of such needs, the World-Wide Web and Hypertext hold a lot of promise as teletraining media, to the extent that an adaptive Learning Environment (LE) can become a relevant solution. Put together, these technologies can help not only improve access to training but also come up with a constructivist approach for designing an individualized, user-centered, authentic-task and cognitively flexible model for adult learners.

A Web/Hypertext training project is more than just an information base or an electronic book. It must provide the type of LE in which elements of the content, the pedagogic approach, learning activities as well as help and support tools are expressly made available. With professional training in mind, such an LE must be flexible, adaptable and transferable, context-wise, as well as with respect to the methodological approach and pedagogical activities which are best suited to adult learning.

Within educational circles, the Hypertext has commonly been seen as a valuable, new constructivist tool—one usually associated with nonlinear properties which, by extension, give the learner more control in the LE and its content--; it allows for different levels of prior knowledge, encourages exploration, and allows the learner to adapt material to his/her own learning needs [Stanton and Stammers, 1990]. But in reality, we have to recognize that these virtues do not all come from the hypertext properties alone, but mostly from the decisions made by its author-designer such as his/her own view of the learner, his/her conception of learning and of what learners could or should do in an LE. The design of a hypertext for training should therefore be based on these considerations.

Hypertext can be defined simply in terms of text organized into chunks, units, or "nodes" linked together. So, a hypertext software can be linear or non-linear and access to the hypertext's contents is mainly defined by the organization of the links provided by the author/designer. The type of interaction permitted in a hypertext is essentially provided by its link structure type (e.g.: linear, hierarchical, associative, random linking, etc. and combinations of these types). Also, because of the implication of the content's organization over learning, decisions about the linking structure provided for hypertext searches should take into account the cognitive styles of use [Chi-Hui and Davidson-Shivers, 1996].

In fact, depending on knowledge levels (expert or novice), goals and learning styles, learners can have different strategies and choose different paths in a hypertext LE. Cognitive style has been demonstrated to be a significant component of individual behaviors and strategies within computer-based LEs and hypertext environments [Ellis et al., 1993]. Depending on their learning styles, for example, if they field independent/dependent or holistic/serialist, a learner can adopt a surface processing of symbols or a deep or strategic analysis of the meaning that underlies the symbols. They can also prefer certain teaching methods or
styles—behaviorism, mastery learning, apprenticeship, constructivism and free discovery [Mendelson, 1996]—
which can have a significant impact on their achievement [Conti and Welborn, 1986].

2. The Hypertext Learning Environment For Adult Training: Toward Adaptive Model

Many authors have thus suggested that an LE offering “cognitive flexibility” [Spiro et al. 1992], should be
designed to support a variety of teaching and learning styles [Collin, 1993; Powell and Okey, 1996] by
regulating the locus of control between student and system, and accommodating task-based methods and
providing feedback to help the learner control explorations, investigations and problem-solving, and by allowing
trainees more routing choices and access strategies to cater for their preferred learning styles and trainers more
flexibility in tailoring the design of the LE to organizational and trainee needs [Ellis et al., 1993].

This perspective corroborates the learner-centered conception of the constructivist movement which
acknowledges the importance of adult training outcomes such as problem-solving and applications by proposing
a transition to the problem-based or case approach from the traditional linear and content reproductive one.
From this point of view, an LE using hypertext as a delivery technology should: engage learners in authentic,
context-sensitive or case-based learning tasks; facilitate problem identification, definition and solving;
emphasize knowledge construction, rather than reproduction; present multiple perspectives, and provide
alternative means for reflecting on personally constructed meaning [Jonassen, 1993]. It should be designed to
allow the interactive manipulation of information based on the models of the “problem exploration systems” and
the “systems for structured reading/browsing/reference”.

Guided by a constructivist conception of learning and focusing on the characteristics and differences of the
clientele in the environmental teletraining context—by taking into consideration and combining different
variables such as: a) adult learning styles and strategies; b) teaching methods and styles; c) organizing and
linking hypertext structures—, we look forward to designing a cognitively adaptive teletraining model which,
with its diagnostic and prescriptive modules, will offer the user-learner alternative avenues, scenarios and
learning paths, based on the problem-solving and authentic-tasks approach. It will also provide a trace
mechanism, guidance tools and the necessary pedagogical support. In all, this polymorphic training model
should offer each student a customized learning environment tailored to his/her needs, and which equally allows
for transferability of training products and services to various contexts and countries. This model will be tested
and put in place as an ISO 14000 training prototype in industrial settings.

Hands-On Distance Education Opportunities in Science Education: Maintaining Excellence While Extending Frontiers

Dr. Donald R. Daugs, Utah State University, USA, drdron@coe.usu.edu

An award-winning elementary science program provided a foundation for this project. In the early 1980s, cooperative efforts between College of Education and College of Science faculty and administration resulted in program changes that met National Science Teachers Association (NSTA) standards for preparing elementary grade level teachers. The outcome was an Award of Excellence in 1985, as one of seven universities nationally meeting NSTA standards. A large part of this recognition was based on a hands-on approach to teaching elementary grade level science. In 1985, the author initiated science methods course offerings via distance education. In the time interval 1985-1996, these offerings have included audio conferencing, slow scan video, live video both directions, public television, and on-site facilitators. Student populations have ranged in size from a few persons at up to 10 sites to over 2,000 people enrolled for a single offering. These experiences have formed a foundation for the current project, which utilizes the World Wide Web, accompanying CDROMs, hands-on labs, and e-mail interactions. Utah State University offers courses and degree programs at sites throughout the state as part of Land Grant University extension role. Typically students at ten to twelve sites will enroll in the science methods course annually. To offer ten courses with a few students and a live instructor would be economically unsound and would be physically impossible with available faculty. The obstacles of distance, numbers of students, and faculty availability are alleviated by electronic delivery. One of the basic challenges for the project was how to best incorporate the very important hands-on lab experiences into a course delivered on the web. The issue was dealt with by designing instruction at three different levels. First, students are presented with text material which explains the nature of basic science process skills: e.g., observation, inference, classifying, hypothesis testing. Students are then provided with materials and instructions for doing these types of activities. In some instances, their results are self-evaluated using website information. In other cases, their results are e-mailed for instructor analysis and response. At the second level, students are required to view video files in which children perform tasks similar to those experiences in first level student hands-on labs. Students analyze the children's activities using provided analysis strategies. They then report their analyses to the instructor or to colleges for comment. These interactions are in the form of linear discussions, thread discussions, or group discussions (see website for examples). At the third level, students are provided content and procedures in the form of a CDROM and are then required to plan, carry out, evaluate, and report on an electronic-based practicum experience with children. Another challenge was the issue of how to maintain a feeling of instructor presence. This was also done at three levels. First, text materials were tied to the instructor's philosophy early in the course, with the student admonition to view all text as the instructor's perspectives, which could be different from student perspectives and should be viewed as one way to look at course content and procedures. Student reflections were built-in to encourage a feeling of interaction with the instructor via e-mail and 1-800 number conversations. At the second level, students observe video files of the instructor as an information provider and an elementary classroom role model. These episodes are open to electronic discussion and reflections challenges. Students are required to respond to specific items and the instructor provides comments. At the third level, students are asked to model what they have experienced in the course in an electronically-driven practicum and then are asked to share their experience with the instructor. The purpose of these interactions is not primarily to assign a grade, but more importantly, to identify with a person (the instructor) and a process (the course philosophy). Two supplements accompany the website text file. One is designed to provide immediate reinforcement of information in the text file. It contains video of instructor and classroom episodes directly related to the text. Viewing episodes are followed by optional or required reflections. The other, a CDROM, is designed as a model of what could be used as an electronically-driven science unit for upper elementary grade level students. The topic covered is "Earthquake Preparedness." This unit was designed to model various aspects of Science, Technology, and Society literacy (STS) and exemplary electronic delivery design. The STS aspects include use of science process skills in which the user is required to conduct laboratory exercises using provided equipment and materials, and then reporting on them. After providing a written report, the user is allowed to view a video of the lab as a verification of their works. Video access and graphics are also provided as enhancements to basic concepts and procedures. These enhancements are particularly valuable for expanding various aspects of technology. Societal ties are interwoven throughout the curriculum and culminate with applications for personal earthquake preparedness. The Earthquake Preparedness CDROM is designed to be highly interactive and user-friendly and can be used in a variety of ways by a teacher. Students registered for the science methods course must use the Earthquake CDROM in some way for a practicum. These uses include using the CDROM as a resource file for information for the teacher, as a station study for small groups, as enrichment for independent study, or as a whole class organizer for a unit on earthquakes. The electronic practicum requirement forces the student to use some of the
same technology around which the website course was developed. As such, it provides an opportunity to use educationally sound, electronically-driven technology as part of their learning experience. Thus we have designed a course that rests on a foundation of proven science education techniques and also places the student in a situation where frontier principles of learning are modeled. The course described above is a required course for all people in the elementary education degree program. Preliminary results indicate that about 1/3 of the students react very well to the delivery system, 1/3 are neutral, and 1/3 are very negative. The 1/3 that are enthusiastic evaluate the course at about the same high level that they would with a live instructor (5.7 on a six point scale). The 1/3 who do not relate well to the technology or who feel primary responsibility for learning rests with the instructor, evaluate the course much lower (3.0 on a six point scale). The net result is a significantly lower course evaluation for the distant education course. The course can be viewed at http://www.awbl.com/classes/education/eled4000.
New Media, Proven Method:
Results of the Beta Test of the First TeleWEBcourse℠

Proven Model

In the early 1980's telecourses became a way for colleges to pool their resources to economically reach new audiences through the new medium of television. The courses were designed to serve national audiences and to meet the curricular requirements of many institutions, using national advisory committees to define the content, select the texts, and consult on the development of the video programs, the student study guide, and the faculty manual. This model has led to the creation of more than 100 high-quality telecourses designed for undergraduate education.

Increased access to technologies in the past 15 years have prompted changes in the way students are learning with telecourses, gaining flexibility of time and place as they moved from viewing one-time broadcasts, to multiple cable castings, and then to videotape. Today's broad availability of the Internet allows students to interact asynchronously with their instructors and their classmates, further enhancing their learning.

The quality, flexibility, and economy of telecourses have led to their wide acceptance by colleges launching distance learning programs. Faculty develop the syllabus and requirements for the students who receive credit from their institution and serve as the learning facilitators for their students and determine the grades. The institution pays a license fee to the telecourse distributor (typically $500 per term) and can enroll as many students as they wish in the course, with a small additional per-student cost. Some, like the University of Maryland, are offering telecourses internationally.

New Media

Since today colleges are turning to the Web as a way to reach distant students, teleWEBcourses are being developed that retain the instructional components of telecourses and fuse them with the interactive capabilities of the Web. The first such course, "Internet Literacy," was piloted in fall of 1997 with two colleges, is being beta tested in spring 1998 with 34 colleges, and will premiere worldwide in fall 1998. "Internet Literacy" is a one-term integrated multimedia learning package that uses the Internet to teach Internet literacy. Institutions are offering the course for either undergraduate or graduate credit, or as non-credit classes. By completing the course, students become Internet literate in three ways: understanding the Internet, doing the Internet, and creating a personal presence on the Internet.

The multiple components of "Internet Literacy" include:
- a Website that links to all of the materials and activities covered in the text;
- an "Internet Literacy" CD-ROM; with more than 200 "show me" videos.
Objectives of Beta Test

The beta test was designed to test the scalability, transportability and implementation of the teleWEBcourse Internet Literacy. Research questions related to

1. Identification of key decision makers and their roles in the adoption and implementation of externally produced Web-based courses
2. Identification of distance learning personnel and their training needs
3. Ease of implementation and operation for both college faculty and administrators
4. Evaluation of SERF, the course-management platform
5. Evaluation and acceptance of the course content by faculty and learners as licensing institutions
6. Evaluation of the course design and its effectiveness in instruction
7. Evaluation of the instructional effectiveness of the course
8. Identification of performance objectives which may differ from institution to institution
9. Identification of the range of options for the academic department and level of the course.

Results of Beta Test

As of this writing, results from seventeen of the 34 colleges responding to a preliminary survey have helped us begin to formulate answers to these key questions. The beta test currently reveals the following:

1. The department in which this course resides varies dramatically from the math department to learning resources; 8 reported offering it in computer sciences. The course is being taught as a non-credit class (6) and as a credit course at both the graduate (1) and undergraduate levels (7).
2. Thirteen institutions responding already have an on-line program in place, with 11 offering a full degree at a distance.
3. All of the faculty rating the book (9) gave it excellent marks; similarly the CD-Rom was ranked very high, with only a few usage-related problems.
4. Six of the reporting beta sites have modified the course to fit specific institutional needs.
5. Six of the reporting beta sites show a direct involvement by the college president in the assessment of the course, with one institution reporting that the president is enrolled as a learner.
6. Overwhelmingly the concerns of the students have come to the forefront with comments such as “need faster server time,” “need a place where students can put pictures of themselves on a class roster.”
7. Ten of the institutions reporting do not now offer courses internationally but 7 of those plan to.

More complete results will be presented at the conference and will be available at <www.pbs.org/als/> after May 25, 1998.

Next Steps

As educational resources burgeon on the Internet and the Web, one of the challenges to higher education is recognizing the barriers to education created by these new distance learning methods. In the coming months additional surveys will be developed and collected, leading to a more complete evaluation of the course. This will be the basis for recommendations for course improvements, including a plan for technical training, improved faculty orientation, and technical support.
Key to the success of any distance learning courseware is effectiveness. Understanding the Web's strengths and weaknesses in the delivery of Internet Literacy will provide us with the foundation for fostering self-directed learning using this medium.
The Language Net Project and the Finnish National Strategy of Education, Training and Research in the Information Society

Brett Dellinger & Ilkka Norri, University of Turku, Language Centre, Finland

The Language Net Project and the Intranet Pilot Project

The Language Net project was begun in October 1996 with a deadline set for completion in September, 1997. The purpose was to plan and construct a net-based hypermedia program for the remedial and complementary teaching of English and Swedish at university level. Funding for the project was made by the Finnish Ministry of Education together with the project partners, the language centres of four major universities in Finland (the Universities of Turku, Helsinki, Tampere and the Helsinki School of Economics). Programming and visual planning were taken care of by the Multimedia Laboratory of the University of Tampere. The overall goal of the project was to create and put on the World Wide Web such material that can be used for self study and the traditional teaching of English and Swedish. The implementation of the program began in the autumn of 1997 with a group of about 20 students in the Language Centre of the University of Turku. At this stage of the project, data concerning the implementation process was collected in the form of student portfolios and interviews. On the basis of this information a pilot study was made in order to prepare for a wider study on the online culture which would develop around the program. The results of the study are expected to be of importance because it deals with the first generation to learn second or foreign languages via the World Wide Web, instead of by way of more traditional teaching methods. The results of the Language Net Project gave rise to another project, the final goal of which is to build a common Intranet for the university language centres of Finland. Both projects follow the guidelines given by the Ministry of Education in 1994. On 13 September 1994, The Finnish Ministry of Education set up an Expert Committee to prepare a strategy for education, training and research in the information society. The deadline for this work was 31 January 1995. The work of the Committee resulted in a strategy document containing both the Committee's opinions and proposals for methods of utilizing information technology to raise the levels of education and research, thus improving the opportunities available to obtain and use information. The Finnish Ministry of Education emphasized the following points:

1. Basic information society skills for all.
2. Development of information products and services.
3. Transition from on-off training to lifelong learning.
4. Evaluation of education and training.

Basic Information--Social Skills for All

The task of the comprehensive school is to give every girl and boy the multifaceted basic skills and competencies required to find and manage information and to communicate. These are basic requirements in the information society and are essential for further education. All levels of the educational system should support the continuous updating of these skills. Adults must have the opportunity to learn the basic skills of obtaining and managing information, communicating and understanding information technology. They must have the opportunity to improve these skills continuously. [Ministry of Education 1995]

The Internet, or its successor, will eventually become an indispensable element of cross-cultural and international understanding in the new European Union, in America, in Asia, and around the world and an important tool for language teachers. Other tools, such as those of applied linguistics and critical discourse analysis, can be used to develop a coherent understanding of the future relationship between public discourse and the new information technologies as they emerge during the first half of the 21st century.

The traditional "one way street" of language classroom information flow, typical of today's public schools, is rapidly becoming "New Media discourse" through information language-learning interactivity. Language learners are now experiencing, because of the newer computer-assisted communications software, the toppling of information control in the classroom. The increased complexity of the computer-aided language-learning experience becomes a positive experience, but a more difficult task for the teacher/facilitator to control. The teacher's role is by no means supplanted by the cyber environment. However, the teacher's absolute authority is replaced by the existence of a multi-authoritative world of knowledge available only on the Web. In New Media communication, such as the computerized language lab of today, students learn to deal with what author Mitchell Resnick calls "decentralized systems." In decentralized systems, "...orderly patterns can arise without centralized control... But many people continue to resist these ideas, assuming centralized control where none exists-for example, assuming (incorrectly) that bird flocks have leaders." Educators and researchers need to develop "new ways of thinking about and understanding decentralized systems."

Focus on Teachers

In the implementation of lifelong learning, teachers' professional skills are absolutely essential. ...Teachers should have the ability to use the media necessary for open and flexible learning and be able to modify and develop material in ways which make it suitable for them to use. [Ministry of Education 1995]

Teacher and classroom autonomy is essential for successful language learning at Finnish universities. The development of teacher
and student native speaker contacts is a traditional part of foreign language teaching which is considerably enhanced by the new computer laboratory and server technologies.

All this calls for enhanced and life-long teacher education, too. The new technology is developing so rapidly that it can often be difficult to arrange suitable courses for the teachers. A common Intranet would be a perfect forum for this kind of on-line education. We long for more interaction between the language centre teachers from different universities.

Research

The university language centre offers a plentitude of opportunities for language researchers. Using modern Net-supported methods enhances the collection and interchange of data. The implementation of the Language Net Program is being studied by Ilkka Norri. His dissertation on this subject will be evaluative in intent (research focused on a particular program, product or method in applied setting, for the purpose of describing the culture around the program, improving it and estimating its effectiveness and worth) and it will employ qualitative methodology (electronic and/or traditional diaries and portfolios, observation, case-studies, interviews, and other methods that ordinarily involve the collection of qualitative data, and its analysis using theoretical and ethnographic approaches).

Evaluation of Education and Training

These new tools will have an increasing role in the evaluation of teaching and learning. We can now easily design tests, exercises, surveys and questionnaires on the World Wide Web which consist of multiple choice and fill-in-the-blank questions. A good way of evaluating are virtual student and the portfolios. Both teachers and students are made to monitor their teaching and learning. The necessary forms for tests and portfolios are designed and put into a Web server. The users then access the form and do the filling out of the form and then click the "Submit" key inside the form. These files can in the future be automatically imported into a spreadsheet and the imported file will become a matrix with each column holding answers to one question and each row a student’s or a teacher’s record. In the future, this kind of system could be dealt with within the Intranet and it will be quite beneficial in team teaching, distance learning, and research situations where it is necessary to test or question students and teachers who are spread out over different geographical locations.

Conclusion

In the 21st century all educators will begin assuming their own unique role as an interactive component of a globalized electronic public information distribution system, one which will function far more effectively than all previous systems of communication and offer enormous advantages to users. This emerging "new information order," say the many optimists who argue in favor of an interactive "cyberdemocracy," will change the concept of individual liberty. A genuinely pluralistic media could be available to all citizens by means of a global system of interconnected computer networks which could guarantee an uncensored give and take of information.

Introduction

3D animation is not as commonly used as video, graphics or audio in World Wide Web (WWW) based learning environments. This is not because 3D animation is any less valuable for educational purposes. It is due to the fact that animation authoring requires much more effort in terms of time and cost, not to mention expert skills. In order to cope with these obstacles preventing a broader use of 3D animation, we present an element-based approach as a new paradigm for 3D animation authoring and propose implementation strategies using the Virtual Reality Modeling Language (VRML) and Java.

3D Animation Authoring

In the traditional 3D animation authoring process, animations are created for building unique scenes where each scene represents one monolithic piece of work. This makes animations difficult to reuse. When compared to the authoring of graphics, an important difference can be observed: reusability may be achieved in graphics authoring by the use of Clipart. Since Clipart can be provided by professional designers in the form of Clipart collections, non-experts are able to create complex graphics of good quality in a short amount of time. However, Clipart in itself is not sufficient for 3D animation generation since behavior, and not just geometry alone, is required. Therefore, we propose enhancing 3D models of objects with object-specific functionality to obtain so-called animation elements. For instance, an animation element “forklift truck” may not only consist of its geometry, but also provide methods like “move forward”, “lower fork” or “take palette”. If considered an object in the sense of the programming paradigm of object-orientation, each animation element in a scene is an individual instance of its class and is capable of managing its state. In our example, a scene - with two forklift trucks stemming from the same animation element “forklift truck” - can be built where each truck controls its visualization according to its state (loaded or not, malfunction or not). An animation element’s methods can be used not only during the authoring of a 3D scene but when presenting the animated scene to a learner, as well. In this interactive animation, the learner can manipulate each object in a scene using the predefined methods.
Implementation Issues

In order to put the concept of animation elements into practice, a suitable technological platform is needed. We propose the use of VRML, a language that can be used to specify animated and interactive 3D worlds and can be considered a de facto standard in the WWW. Using the external authoring interface or the Java API interface of VRML, the behavior of an animation element can be defined using Java programs. VRML can also be used to combine the animation elements into a scene, since VRML implements a hierarchical structure; the VRML scene graph and the animation elements are the basic parts of this hierarchy. Since VRML descriptions, as well as Java programs, can be distributed via WWW, this is a way to implement the concept of animation elements for tele-learning environments. If we assume that the animation author is familiar with VRML and Java programming, she can directly apply our approach, build up a library of animation elements and reuse them for her scenes. However, since this degree of familiarity is not the norm, animation elements have to be provided by a third party and dedicated authoring tools are needed. One tool is the animation element library, a multimedia database that allows the user to browse for required elements, showing the methods they provide. Another tool is a scene editor that allows scene composition using animation elements graphic-interactively. Helpful tools include a conversion tool for format conversion (e.g. VRML to a video format) or a translator that translates sensor data or simulator output in method invocations of animation elements, thereby automatically generating an animated 3D visualization. Most important is the VRML browsing system, usually a plug-in of an Internet browser, such as Netscape or Internet Explorer, that interprets the VRML scene description and then renders it.

Prototypes of the tools mentioned in the last paragraph have been implemented in the context of the CASUS System project. Our VRML browser CASUS Presenter has been built upon Open GL, allowing the use of dedicated hardware and the presentation of VRML scenes with high performance and interaction with low latency, especially on the PC platform. Additionally, it offers special features for presenting the VRML scenes using not only desktop, but also immersive VR. Thus, the scenes can not only be shown on a computer monitor, but also in stereo mode on dedicated virtual reality devices.

Applications

While applying our system, we concentrated on a well-defined application field, since we aimed to achieve a high degree of completeness regarding the animation elements offered for this field. We chose vocational training in the areas of industrial production and logistics. Here, 3D animations can be used to serve communicative goals, explaining processes or showing the function of expensive, unavailable machinery. 3D animation is also especially suited for the visualization of simulation results. The learner is able to manipulate simulation parameters and gain insight into logistic processes. With the help of the presented concept, the amount of effort needed for authoring the scenes can be minimized by reusing animation elements. An additional benefit is that the instructor, as well as the learner, although not being
animation experts themselves, are able to modify the animations. An advantage of using VRML as the basic technology is that it is scaleable. A learner can interact with a VRML scene using special devices in a VR laboratory at an industrial training center. At home, she can continue practicing or reflecting on her experiences on her own PC either alone or together with other learners using the same VRML scene. This also demonstrates a possible realization of laboratories at a virtual university.

Designing a Design Tool for Web Instruction - Project Marigold

Philip Duchastel
Nova Southeastern University
Fort Lauderdale, Florida, USA

Abstract

Project Marigold is building a software tool that assists educators in designing effective web sites for learning. Its aim to incorporate in the tool a distillation of current instructional design expertise faces the continuing challenge of being responsive to the diverse needs of educators coming from different theoretical perspectives. This presentation highlights the design decisions that were made to accommodate this recurring difficulty in the field. After presenting the features and distinguishing characteristics of Marigold, we discuss the prospects for tools of this kind to influence the field of multi-media distance education.

The paper is at http://www.nova.edu/~duchastel/marigold/marigold.html. The project itself is at http://www.nova.edu/~duchastel/marigold/marigold.html.
A Phased Approach to Developing a Set of Requirements for the Use of Virtual Actors in Shared Virtual Learning Environments

Daphne D. Economou
Dr. William L. Mitchell
Dr. Tom Boyle

Department of Computing and Mathematics,
Manchester Metropolitan University,
Chester Street, Manchester M1 5GD, England
email: D.Economou@doc.mmu.ac.uk; B.Mitchell@doc.mmu.ac.uk

1. Introduction

The main aim of this project is to develop a set of requirements and design principles for the use of virtual actors in Shared Virtual Learning Environments (SVLEs). This set of requirements will address issues of pedagogy and interaction (e.g. how can actors be used to structure a learning session in virtual environments) rather than underlying technological concerns (e.g. what computer graphics techniques best suit the generation of the actors). There are three main problems facing the development of such a set of requirements.

Firstly, a large range of variables is involved in the construction of SVLEs. This makes it difficult to isolate which design decisions are responsible for the overall effectiveness of the environment. It is also difficult to identify the inter-play between various factors (e.g. the effects that usability issues have on pedagogic issues). Secondly, there are not many examples of research on the use of "real-world" SVLEs. Thirdly, the current immaturity of the technology underlying SVLEs means that the full potential of the SVLE medium cannot be exploited (e.g. the range of interaction and image quality is often limited).

A possible solution to the first problem is to follow a phased, iterative approach [Boyle 1997]. This will involve the construction of a SVLE in a series of distinct, manageable phases. Such an approach will allow the variables involved in design to be isolated and will also help to identify the effect each has on the effectiveness of the environment. This in turn will simplify the derivation of design principles based on these variables. Comparisons will also be made between the environments constructed during each phase of the project.

To address the second problem it was decided to make use of a complex "real-world" case study. One such exemplar is provided by the work of Manchester Museum's Education Service [Mitchell 1997]. The primary emphasis of a school's visit to the Museum is to enable children to study and work with real artefacts. One particular strength of the Museum is its collection of ancient Egyptian artefacts from the pyramid builders town of Kahun. This collection plays a major part in the Education Service's teaching. It is proposed that the example SVLE be based around this collection.

To cope with the third problem it was decided to initially develop prototypes using a more mature technology (two dimensional (2D) multi-media). This would allow certain requirements of a SVLE to be studied without the overheads of constructing a full system. Later in the project these requirements will be used to construct a prototype using SVLE technology. The evaluation of this SVLE prototype will allow the validity of the requirements to be tested.

2. Project Phases

The project has been divided into three main phases. Each phase will involve the implementation and evaluation of a prototype SVLE. The phases will differ in terms of the degree to which the environments are populated by virtual actors. In addition, the phases will differ as to whether the interaction is external to the environment (i.e. between the users in the real world) or internal to the environment (i.e. between virtual actors within the environment).

In the first phase an environment is being developed which is "non-populated". This contains individual objects that the user can interact with but do not contain any virtual actors. Thus the interaction between users (e.g. a discussion between a student and a teacher about an object) will be external to the environment.
In the second phase there is a transition from a "non-populated" to a "semi-populated" virtual learning environment. The second phase will examine the use of virtual actors in the virtual learning environment. These virtual actors will adopt the role of a knowledgeable participant (e.g. a teacher or museum guide). These actors will either represent a real person (avatar) or an automated guide (agent). The virtual actors will be extra elements added to the environment constructed in the first phase. There is also a transition in terms of the interactions taking place from external to internal.

In the third phase a virtual actor representing the student user will be added to the environment from the second phase. This environment can be seen as being a "fully-populated" shared environment. It will contain virtual actors representing the student, other students, as well as knowledgeable participant. This will allow collaboration and interaction which can be seen as internal to the virtual environment.

An iterative process of formative evaluation will be followed throughout the project. This will indicate refinements that have to be made to the environment, as well as to the set of requirements that have to be followed for the construction of a SVLE. Observation of students and teachers using the environment will be conducted to identify patterns of interaction between users and distinguish the learning situations that occur. In addition the usability (e.g. how easy is it for the users to operate in the environment?) and pedagogic effectiveness (e.g. can the teachers use the environment effectively to accomplish their tasks and do the students learn?) of the environment will be studied.

3. Current Work

The SVLE is based around artefacts from the Kahun collection at Manchester Museum. A set of criteria has been developed for selecting artefacts from the collection for inclusion in the virtual environment. These have been based on a variety of sources including: National Curriculum requirements; English Heritage guidelines for the use of objects for learning; and interviews with Egyptologists, teachers and children. Finally, artefacts were chosen that would allow a range of interaction and learning situations to be studied. The five artefacts selected for inclusion in the SVLE are: senet (a board game for two players); shaduf (a device used for raising water from the river); the mould (used for creating mud bricks); weights and measures (cubit); and a mirror [David 1986].

A prototype senet environment has been constructed using 2D multimedia technology (Micromedia Director). This allows two users to move pieces on the board and access instructions on how to play the game. A pilot evaluation with the general public has been carried out over four days during Manchester Museum's activity week. Observations have been carried out of interaction patterns between pairs of children. These initial findings are being used in the design of experiments under more controllable conditions. Samples of the work can be accessed at: http://www.doc.mmu.ac.uk/RESEARCH/Kahun

4. Conclusion

A phased, iterative approach has been proposed for studying requirements of SVLEs. The phases differ in terms of the degree to which environments are populated by virtual actors and also the degree to which interaction takes place external to or internal to the environment. This approach allows:

- isolation of the range of variables involved in virtual learning environments into phases
- implementation and evaluation of the environment in small manageable phases
- analysis of the outcomes of the evaluations and linkage to requirements for subsequent phases.

The final outcome will be a set of requirements and suggestions for the development of multi-populated VLEs. The phased approach allows these principles to be studied in a systematic manner from the baseline case (the traditional school visit) right through to a fully populated virtual environment.

Problem Based Learning in Medical Education: 
Designing and Evaluating a Multi-User Application for the 
German Curriculum

Christian Elsner, Carl Ludwig Institute for Physiology, 
Liebigstraße 27, 04103 Leipzig, Germany. E-Mail: elch@medizin.uni-leipzig.de

Introduction

Problem-Oriented-Learning Groups (POL-Groups) have become part of the optional curriculum at several 
German Universities. POL-Groups let students learn in a problem and case-based way within small tutor 
guided groups. The benefits of the POL-format are to foster active student inquiry and independent learning 
with focus on clinical problems.

This article describes an approach to put the German POL-format into the web-based application "Kasus 
Online" which allows a group of students and a tutor an asynchronous computer supported information 
exchange on a case-workup. "Kasus Online" bases on parts of concept and screen design of the developed stand-
alone application "Kasus interaktiv" [Elsner 1998]. The application is implemented using HTML-Code, Java-
Servlets and CGI-Scripting. A platform-independent and universal access via the Internet is therefore possible.

Attempts to incorporate computer based training into problem based learning have already been made with 
good results [Schor 1995] [Coulehan 1995] and are just in progress [Nuthalapathy 1998].

Application Description

To use "Kasus Online" 3 students and 1 tutor form a group working on a case. The students' identities are kept 
confidential via an alias. Depending on difficulty and complexity a case is divided into several sessions. Each 
student and the tutor can login to a case session independently and as often he/she wants. Group 
communication is achieved by a built-in messaging system. A new session will be entered if all students and the 
case tutor agree on proceeding with the case.

After the login to "Kasus Online" a student first reviews the information provided in a session independently. 
By brainstorming he/she will then comment the given information/clinical findings for his/her peers. All given 
comments will be displayed in a kind of newsgroup next to the case information it refers to. To discuss certain 
topics and peers' opinions further messages can be added to every item of this newsgroup.

Basing on the subjects of this discussion each student will try to extract relevant information and formulate in 
two separate datasheets:

➢ A differential diagnostic workup for the case.
➢ Specific learning issues/problem questions for the case.

This input is then compiled for a "case learning center" that can be reviewed by the other users and the tutor at 
a subsequent login. In the "case learning center" every student can review and comment all compiled 
information sheets. If the group decides to proceed to the next case session, all "case learning center" 
information will be saved for a review at the end of the case.
As the case progresses and new case information is given, the students will have to set up new statements and discuss findings for their differential diagnostic workup. Students also get the chance to print a list of all piled up problem questions. They can then review their books and study material to answer the questions during the next login for their peers.

The role of the case tutor is to guide the students during their case-workup and forward them to the next case session if they have finished analyzing the given information satisfactorily. He/she gives feedback to single students or the group and helps to get the right learning issues and an adequate differential diagnostic case-workup. For this task a "Gold Standard" of the case-workup will be provided for the tutor.

At the end of a case the students will have the chance to compare their lists in each session with the "Gold Standard" and value their findings in the single sessions of the case.

For the application's screen design the guidelines developed from evaluating the stand-alone application "Kasus interaktiv" are used. The analysis of n=248 questionnaires provided information on user-friendly and functional screen design for a case-based educational application.

**Evaluation Description**

In contrast to normal POL-Groups the potential benefits of the "Kasus Online" application lie in its time-independent and universal accessibility. Further the e-mail based messaging system has the potential to take back group dynamics and therefore improve the written self-expression of the POL members [Coulehan 1995].

In contrast to stand-alone CBT-Tools "Kasus Online" adds the dimension of group discussion and participant identified learning issues and therefore can encourage students' accountability and independent thinking.

To get objective study data on the advantages a POL-Group can take out of Web-based POL-Learning a cross-over study designed for the evaluation of CBT applications will be used [Auhuber 1997]: at the University of Leipzig 24 POL-experienced students and 4 case-tutors will evaluate "Kasus Online" versus normal POL-Group Session learning.

The Use Of Interactive Multi-Media CD-ROM
To Facilitate Health Behavior Change

Alexandra Evans, Artemis Associates, USA, sandra.evans@mail.utexas.edu
Elizabeth Edmundson-Drane, University of Texas at Austin, USA, elizabeth@health.utexas.edu
Karol Kaye Harris, University of Texas at Austin, USA, k.k.harris@mail.utexas.edu

Background

Current technological improvements in the area of computer assisted instruction (CAI) and declining production costs allow health professionals to consider new options for innovative health education/health promotion interventions. The advantages of CAI over more traditional interventions, such as didactic lectures or informational brochures, include immediate feedback, increased interaction between user and the instructional material, user control which allows random access to the instructional sequences, presentation of multiple real life simulations, and a learning atmosphere of anonymity and confidentiality, which is especially important for topics related to human sexuality. However, CAI remains underutilized in health education at a time when health education programs require not only cost-effectiveness but also behavior change as an end outcome.

Screening and early treatment of abnormal cells can reduce the incidence of cervical cancer by more than 90%. In the US, considerable gains have been made toward mass screening, although many women continue to avoid screening or do not follow-through with treatment. Traditional health education programs which focus upon written materials have had limited success in increasing screening adherence in this population. Our goal for this study was to develop and evaluate a theory-driven program targeting behavioral change. The purpose of this paper is to illustrate an example of the transfer of theory to practice using CAI, or CD-ROM in this case, describing project development strategies and issues from the field.

Project Description and Development

"Taking care of Business: An Inside Look at the Pap Smear" is a theory-based multi-media educational CD-ROM that was developed to increase young women's regular Pap smear screening behavior. Through the use of short story scripts, role models, and demonstration (both animated and videotaped procedures), young women learn about the importance of regular Pap smear screenings, personal risks for developing cervical cancer, the meaning of abnormal Pap smear results, dealing with abnormal results, communication with doctors and nurses, and sexual practices that impact the transmission of human papillomavirus (HPV), the virus which is causally-related to about 90% of all cervical cancer cases.

The CD-ROM is divided into six sections, each of which provides scenarios that can be understood independently: Scheduling your Pap Smear, Doctor-Patient Communication, Life Cycle of a Cancer Cell, Anatomy of a Pap Smear, Understanding your Test Results, and Risk Factors for Cervical Cancer. This format allows the user to review only the sections she believes to be personally relevant, and to choose the order in which she views the different 15-20 minute sections. To ensure validity within the program, much of the content and all of the video vignettes included in the CD-ROM were obtained through individual interviews and focus groups with women from a variety of ages, ethnic groups, and educational backgrounds.

The story script was developed within the framework of Social Cognition Theory, with particular attention to cognitive processes that impact affective responses. Moreover, a strong emphasis was placed upon strategies for empowerment and skill building specific to this health issue. Social Cognition Theory is a theory of interpersonal health behavior that addresses the cognitive, emotional, and behavioral dynamics that influence health behavior change and provides implications for intervention. Some of the
constructs of this theory include environment, situation, behavioral capability, expectations, expectancies, self-control, observational learning, self-efficacy, reinforcements, emotional coping responses, and reciprocal determinism [Baranowski, Perry, & Parcel 1997].

A plethora of research exists about cervical cancer and theories of compliance to screening. We synthesized information both from the literature and from interviews with women. Our original intent was to gather women’s stories to illustrate educational features in the CD-ROM, but it became clear to us that experiences surrounding cervical cancer screening are emotionally charged, that large gaps in women’s knowledge exist, even among women considered “compliant”, and that women rarely share these experiences with one another.

We were faced with the problem of educating women about many facets of the experience – terminology, assertiveness, scheduling, interpretation of a wide range of results, etc. Moreover, a major component of our work became learning how to address the risk factors, particularly a sexually transmitted disease for which most women have not considered themselves at risk. We chose a variety of tactics – humor, interviews that included positive and negative experiences, role models, animation, and a physician and nurse interviews providing guidance.

Lessons from the field

The lessons from the field included common CD-ROM logistical challenges such as length and interface issues, but the more interesting features involved the cognitive-affective components of the content. We conducted focus groups following the first iteration of the CD-ROM. The focus groups made the implicit obvious; we were dealing with the great taboos of death and sexuality, and more specifically, sexually transmitted diseases.

The narratives and interviews contained within the CD-ROM accomplished one objective, which was to access the viewer’s emotions and memories, but the intensity of the women’s response was unexpected. The scripts accessed the women’s own memories and meanings, which had not been necessarily positive nor previously supported. Gender issues were pertinent, and they extended beyond the balance of represented role models in the CD-ROM.

We learned that we underestimated the interest levels of our audience. Our initial efforts sought to entertain women to hold their interest and “soften the blow” surrounding the nature of the risk factors. An overarching goal-based scenario tied the components together. Many told us that they did not need to be entertained on this subject, and that the content itself could be intriguing. Feedback to us also confirmed the importance of actual women’s experiences to support the information. Professional actors were not necessary. More important, we learned that new and complicated information carrying an emotional charge needs to be carefully positioned to facilitate motivation and allay frustration.

Further evaluations include continued process evaluations and testing of theory with impact evaluation. In addition, the focus group experience suggested to us that the women valued the opportunity to discuss their reactions and debate and integrate the new knowledge. This observation will also be addressed in the evaluation.

Video Teletraining: Improving the Effectiveness in a Civilian and Active Duty Learning Environment.

Shanan W. Farmer
Naval Facilities Contracts Training Center
United States
sfanner@xi.chbph.navy.mil

Introduction

Over the last decade, new technology has been rapidly changing the way individuals are trained. This is especially evident in the United States Military where budget problems continue to plague the Department of Defense. As a result, new instructional delivery methods are being implemented to reduce the millions of dollars spent on airfare, lodging, and food associated with training military and civil service employees [Belcher 1997]. Several studies have attempted to evaluate the use of Video Teletraining (VTT) systems consisting of sites linked with two-way audio/video communication in the lecture-based classroom [Belcher, 1997; Rupinski, 1991; Rupinski & Stoloff, 1990; Simpson et al. 1991; Wetzel et al. 1994]. The findings of previous studies were that student attitudes and performance on examinations were comparable in the originating and remote classrooms [Wetzel et al. 1994; Worley 1991]. However, most of the research involved low cognitive level classes containing limited case studies and group activities [Bramble & Martin, 1995; Wetzel et al. 1994. The amount and type of interaction and learner feedback has been found to be instrumental in determining the effectiveness of distance learning [Moore & Kearsley 1996]. The live interactive nature of VTT requires that instructors encourage the participation of remote-site students and attend to their needs to obtain help and resolve questions [Simpson, 1993]. Students perform best when their instructors inspire them to take an active role in their learning process [Rosenshine & Stevens 1986; Sullivan & Higgins 1983].

The Naval Facilities Contracts Training Center (NFCTC) is undergoing several course conversions to include remote sites by means of VTT technology. Every course taught at NFCTC requires active student participation in case studies, workshops, and macro exercises. This paper focuses on improving the interaction and instructor effectiveness when VTT is used as an instructional medium for the specialty course, Facilities Support Contracts. Research question: What are the skills and techniques needed by instructors to be effective in interacting with learners in the VTT learning environment?

Methodology

A multidimensional triangulation approach was used in developing an instructional paradigm for ensuring effective learner interaction for the VTT learning environment [Patton, 1993]. The sample size (total n = 94, VTT students = 47) had an average of 7.32 years experience in the acquisition workforce with sixty-four percent having a Bachelor’s degree and twenty percent had completed a Master’s degree. The class was 59% male with an average GS grade of 10.69/15. The following techniques were used to assess the instructor’s skills and techniques in optimizing student interaction: student and faculty interviews, observational recordings of interaction, end of course questionnaires (4 point Likert Scale), VTT questionnaire, and daily feedback forms. Both questionnaires had a 99% response rate. Four different course offerings were compared, two VTT and two traditional. Each of the course offerings had the same experienced instructor.

Findings

Contrary to the literature, the traditional classroom offerings had a higher overall student satisfaction rating than the VTT offerings, (3.75, 3.33 respectively with p < .05). Although, analysis of the final exam grades shows that the students attending the VTT offerings had slightly higher scores than students in the traditional classroom (VTT = 89%, Traditional = 87%). When looking at the final exam grades for the VTT offerings, there was a significant difference (p < .05) in the means between originating and remote sites (94% vs. 87.5% respectively). There was also substantially more student-instruction interaction in the originating
VTT site than in the remote sites 7.45 vs. 4.38 (p < .05). Regression analysis showed that location was a significant (p < .01) predictor of the dependent variable, exam grade, when the target audience was controlled. Other predictors that entered at the p < .01 level were the following: VTT technical ratings, cumulative instructor performance and skill ratings, "Did being randomly called on in the classroom help your learning needs?" and usefulness of Picture in Picture technology in meeting student's learning needs.

Interviews with the students and instructor from the first VTT offering produced several beneficial action items for the second VTT offering. A majority of the students felt that the interaction was minimal, even though there was forced interaction by the instructor randomly calling on the students. When the students from the first VTT offering were asked if they could remember anyone else's name at another site, only one student out of thirty-two could recall another student's name. The student said she could remember him because "he was called on more than most." In the first VTT offering no icebreaker was used. The students only stated their name and current job position. In order to rely less on forced interaction and foster more personal connections, an extensive icebreaker was utilized for the second offering. Forty-five minutes were dedicated out of the 2nd VTT offering for everyone to share their four "C"s of their personality. The instructor noticed a considerable increase in the amount of natural interaction between the remote sites in the second VTT offering. The students in the second VTT offering on average rated feeling comfortable using the VTT equipment one day earlier (p < .05). Their acclamation and comfort level may have given rise to the increase in student interaction. In fact, the only incidence of negative written/verbal comments from the second offering came from the inability of being recognized to speak quicker. A majority of the students from both VTT offerings came in with low expectation levels and somewhat negative attitudes. When the students were asked on the VTT end of course questionnaire, "If given a choice would you choose a VTT classroom setting over a traditional setting?" fifty percent of the students indicated a favorable response (3 or 4).

Conclusions and Implications

Even though the overall satisfaction averages were lower for VTT than the traditional classroom offerings, the student interviews supported a positive response to the VTT learning milieu. The VTT questionnaires indicated that 78% of the students had favorable responses to the question, "Did being randomly called on in the classroom help your learning?" The student interviews concurred with all of the students saying that they recognized the value of the instructor's technique. Detailed icebreakers may take a long time to do in the VTT learning environment, but it should be helpful in promoting natural interaction in the classroom. Table 1 shows a trend that the icebreaker may have increased student feedback ratings for all variables. Ostensibly, the comfort and preparedness level of the instructor will have an impact on the effectiveness of the VTT learning environment. The instructor noticed that her VTT preparation efforts and modifications in the second offering contributed to her feeling that she was teaching in a traditional classroom setting. Continued research should be completed to explore how the learner interactions in the VTT learning environment are different than in the traditional classroom setting. A similar study with a larger sample size may lead to more variables in Table 1 being statistically significant.

Using Interactive Multimedia for Assessment

Dr Tony Fetherston
Multimedia and Learning Technologies
Edith Cowan University
Perth, Western Australia
t.fetherston@cowan.edu.au

Abstract

This paper makes a case for the use of Interactive Multimedia (IMM) product in assessment in schools. By drawing upon the ability of this media to simulate environments and to accept many different kinds of input from the user, it is proposed that IMM can perform valid assessment of classroom learning. Further, through careful design, it can provide valuable insight into the reasoning processes of students.

Assessment is still an important issue in education and in this paper I explore the potential of IMM to provide valid and authentic assessment, using assessment in science as an example. All of the useful functions of assessment (monitoring outcomes, making teaching more effective...) are based on the assumption that the assessment methodologies used are valid. Assessment in science has usually been teacher developed dealing with the taught curriculum, backed with occasional externally developed assessments at exit points from the system.

Traditionally this assessment usually involves pen and paper tests, mostly involving multiple choice questions, which focus on atomistic knowledge - that is, knowledge portrayed in parts, out of context and unrelated to the body of knowledge as a whole. "Decomposition of important knowledge and skill into disconnected bits and the decontextualisation from meaningful situations...virtually ensure their inability to validly assess complex activities" (Resnick, 1994, p523). This method of assessment is widely considered to have low validity when it comes to determining what students know about the topic being assessed. Students usually know much more than can be measured this way and multiple choice science tests do not determine factual knowledge particularly well. In science more valid assessment methodologies should provide opportunity for assessing science skills, be carried out over time, include problems with missing information to allow students to critique the problem and allow students to make up their own questions (Raizen, Baron, Champagne, Haertel, Mullis & Oakes, 1989, p63).

In general, to become more valid, assessment needs to be changed from traditional multiple choice methods (which focus on recognition, recall, are quick, atomistic, measure surface learning, are based on course objectives, and are conducted out of context) to
assessment focussed on students' own conceptions, which is holistic, measuring deep learning and long lasting knowledge, is linked to learning theories, is conducted in context, allows students to express interpretations and is authentic. Interactive multimedia assessment scenarios would have authenticity due to the ability to portray relevant contexts and to provide test items requiring a variety of types of student responses.

The potential to improve assessment by using the computer's interactive and multimedia capabilities to the maximum can lead to the use of many creative testing strategies. For example, constructed response items based on simulation techniques which offer students tasks which are more realistic and closer to those they encounter in everyday life and in education and work settings are likely to be more authentic and valid. It seems certain that the face validity of such items is greater; that is, the perception among subject-matter experts and test-takers that such test items are better measures of the test objectives than corresponding paper-based multiple choice items. Although such items may measure different skills than their multiple-choice counterparts (Ward, Frederiksen & Carlson, 1980), they offer a "window" into the processes used to solve particular problems (Birenbaum & Tatsuoka, 1987) and they may better predict some aspects of educational performance (Frederiksen & Ward, 1978).

The demonstrated product is a work-in-progress. In its present state it simulates a jarrah forest located in the south-west of Western Australia. Dealing with the topic ecology it allow students to interact with the program and, through a series of graded scenarios, allows them to express their understandings in this topic area. A teacher in a classroom could allow a student to interact with the program with the program recording a variety of responses which would allow the teacher to gather a good portrayal of the student’s understanding. Such portrayal is likely to enhance classroom practice and have relevance beyond a particular classroom.

Abstract: This paper discusses new features in hypermedia case studies that are designed to improve the transfer of knowledge and skills to actual job situations for teachers. The case studies embed problem solving activities into authentic case situations and provide opportunities to build multiple perspectives. Prompts are inserted into the program to support reflection and to provide expert models for evaluating decisions. Performance support tools are included to facilitate learning and performance within the hypermedia environment and for later use in actual job situations. The research design is described for determining the use and effectiveness of these new design features as well as the actual impact on children when the tools are implemented by teachers.

1 The Problem

Teacher education involves the development of knowledge and skills and their application to actual classroom settings. The weakest link in preservice teacher education is the translation of knowledge and skills taught in methods classes to performance skills in the classroom (Rule & Salzberg, 1988). Reform efforts in teacher education have recently focused on expanding opportunities for preservice teachers to gain experience in classrooms via increased field placement and involvement in multimedia simulations based on authentic classroom scenarios.

Hypermedia case studies are simulations that provide complete information, expert modeling, and challenges to be solved by the user which mirror those to be faced in teaching roles. Hypermedia case studies go beyond traditional simulation models by allowing learners to take control and responsibility for their own learning through nonlinear access to information, problem generation, and problem solution. Hypermedia cases are active learning environments in which users explore case scenarios through video and audio, gather contextual information, access foundational information, listen to commentaries by experts, define contextualized problems, and revise solutions based on prompts and scaffolds.

Empirical data has recently emerged on the effectiveness of learning through hypermedia cases has been documented. Despite differences in class rank, prior experience with computers, prior teaching experiences, or different learning styles, learning outcomes have been significant and equivalent across users (Fitzgerald & Semrau, 1998; Fitzgerald, Semrau, & Deasy, 1997; Kraus, Reed, & Fitzgerald, 1997). Findings demonstrate that users with differing learning styles utilize hypermedia case environments in different ways, yet overall engagement time and outcomes are equivalent. Based on analyses of user records and on-line products, two concerns must be addressed in improving learning from hypermedia
case studies: 1) engaging users in reflecting on their solutions, and 2) supporting users in transferring knowledge and skills to actual job situations (Fitzgerald & Semrau, 1998).
Instructional Design of Program

Instruction and Management in Behavioral Disorders is the third title in an interactive training series for use in teacher education programs. Three of the programs utilize a hypermedia case study format, and the other two programs provide skill training in classroom observation.

The program is based on case study scenarios in which the user takes the role of a teacher in planning for three different youngsters with significant behavioral and emotional problems in classrooms. Figure 1 displays the main menu screen for the case study program Martelle. Each program has the same overall structure and learning activities.

The computer program contains computerized background information on the youngster and school policies, a resource information base related to behavior interventions, a series of problem solving activities based on job responsibilities, scaffolds for the user related to the activities, and 35 template tools for creating plans for the youngsters. Material on an accompanying Level III videodisc includes videos to observe the youngsters in authentic settings, audio interviews with adults with information about the children, mini-presentations on specialized curriculum, and commentary by experts in the field. The resources and template tools are designed as stand-alone applications for users to have following successful completion of the case study activities. Thus, a direct bridge is provided to support the application of knowledge and skills to real-world use.

Cognitive Flexibility Theory and Multiple Perspectives

The overall design for the hypermedia case studies is based on Cognitive Flexibility Theory, one of the constructivist theories which emphasizes the real-world complexity and ill-structuredness of knowledge. Ill-structured problems are complex and require cognitive flexibility for understanding and decision making (Spiro, Coulson, Feltovich, and Anderson, 1988). A person demonstrates cognitive flexibility when able to selectively use knowledge to adaptively fit the needs of an ill-structured situation. The computer-mediated activities provided through these materials strive to stimulate cognitive flexibility to enable the learner to construct his or her own knowledge based on analyses of complex and irregular situations, to view situations from multiple perspectives, and subsequently utilize that knowledge in problem solving activities. See Fitzgerald, Wilson, and Semrau (1997) for a detailed explanation of hypermedia design based on principles of cognitive flexibility theory.

Performance Support Tools

The nature of preparing workers to perform and/or understand work tasks is changing dramatically. Given the vast amount of information available to workers, it is increasingly important to provide people efficient and effective ways of receiving new information. Through performance support tools and resource databases, workers can have constant access to crucial information and guidance while they are performing tasks. This information may be accessed in different ways, depending on the needs of the worker, creating a cycle of continuous improvement and training (Laffey; 1995; Barker, 1997). Based on the axiom "right time, right place, right form," this program incorporates two new features for hypermedia design—access to on-line resource information and performance support tools for present and future use.
3 Illustration of Key Interactive Features

Problem Solving Activities

Prior to creating plans for the child, the user explores the case study for information, observes the child, gets input from others, assesses the child's setting, and goes through a behavioral consultation interview to define problems.

In this Plan Intervention component of the program, users develop instructional and management plans for the identified problems. Plans are entered into a template form and saved for later retrieval.

Reflective Prompts

Prior to reflection and revision of previously completed plans, the user listens to experts discuss intervention programs from multiple perspectives to encourage the user to broaden plans to settings beyond the classroom.

In this Evaluate Plans component of the program, users can view previous plans at the top of the screen and enter personal reflections into a notepad at the bottom of the screen. These entries are attached to the original plans during this revision step.

A series of four prompts are provided for management plans and four prompts are provided for instructional plans. An example prompt is: Have you involved this child in self-management? Users must evaluate whether their plans meet these criteria by responding "yes" or "no."

If the user enters "no," the notepad at the bottom of the screen opens up and requests the user make adjustments. These adjustments are added to the original plans and personal reflections for documentation.
Performance Support Tools

The resource information base provided in the program contains information on intervention procedures covering a wide variety of techniques offered in 15 categories, ranging from self-monitoring plans to classroom rules to conflict resolution. Each category provides procedural information, examples of plans, tips for implementation, and references.

Users can search for information using the Find tool or by navigating the structured database. The Resources are linked to 35 template Tools on the pull-down menu bar.

Each intervention category offers 1-5 templates for preparing instructional and management intervention materials. The templates are designed for generic use and adaptable for children of different ages and ability levels. Templates for younger children allow the user to select graphics from a graphic library and create very simple forms.

Each of the templates is illustrated in the resource information base to provide models. The 35 template Tools are linked to the Resources on the pull-down menu bar.

To create materials, users simply click on "hot" words or entry lines and input their plans. The template allows the teacher (or capable student) to create personalized intervention materials to support the child in successful behavioral change.

From the template screen, plans can be stored to disk and printed. The user records maintain a cumulative file of entries, time stamp each entry, and log the user's name and time spent in the Resources and Tools.
Figure 7. Sample of Completed Monitoring Card
Audit Trails and User Records

The program time stamps the options in the sequence selected by the user. By computing the differences, it is possible to determine how long the user engages in each section of the program. This information allows the researchers to evaluate the use of an on-line resource component in a performance support tool.

The program also saves to disk all content the user enters into a template which provides a record for the user.

---

4 Research Design

The program is being implemented in three sites during the 1997/98 year to determine its effectiveness as a personal productivity program for teachers. In each site, information on users will be gathered for use as independent variables to enable comparisons of usage and effectiveness across users with different levels of prior computer experience, prior teaching experience, computer anxiety, and ease of access to computer work stations. Audit trail records will be compiled to determine the engagement time of users within each work session and across time, the frequency and duration of accessing resource information within the process of preparing intervention plans through the templates, and user pathways through the materials. The effectiveness of the program will be measured by holistic scoring of the quality of intervention plans created for children within each type of procedure and across time, as well as measuring change in knowledge via a pre-and posttest. A user satisfaction questionnaire will be administered to compile feedback and assist in determining how different users value the various features and tools within the program. Impact on children will be determined by looking at change in children's behavior correlated with implementation of plans by teachers.

5 Summary and Implications

The design of this hypermedia program based on cognitive flexibility theory builds knowledge and skills that go beyond performance within the hypermedia learning environment. Instead of relying on feedback delivered through the program or instructor discussion of the case studies, a series of reflective prompts are placed within the program activities. These prompts support metacognitive reflection and provide expert models to learn to evaluate one's own decisions.

Increasingly, software in the work environment is becoming task-focused to support learning and performance through electronic performance support tools, including on-line references for instant access to information, tools to carry out specific tasks, and help functions to enable the user to carry out a task at the moment of need. Instead of learning to do a task within a piece of software and later using a different software program for a job task, this hypermedia program is designed for integration into actual job settings, supplying the resources as well as the tools.

In that professional practice involves judgment and wise action in complex, unique, and oftentimes uncertain situations, learning to pose and solve problems is central to the role of educators. While research outcomes with the other hypermedia case studies included in this series have been extremely positive, no studies to date have looked at transfer of knowledge and skills to actual job situations and impact on children, the ultimate measure of value. It is hoped that the combination of features of the program—the case study format, a design based on cognitive flexibility theory, embedded prompts and tools, and ongoing access to resources will help bridge the gap between preservice teacher education and performance of teachers in the classroom.

Introduction

As a member of the teaching faculty at Mount Royal College (MRC) I have been involved in the educational uses of computers for almost twenty years and have experienced the various waves of expectations that each computer enhancement has brought, along with the attendant disappointments. Andrews [Andrews, 1997] has outlined two models of teaching/learning: (1) the traditional teacher centered (sage on a stage), and (2) the learner centered, teacher as mentor (guide at the side) model. Model 2 in Andrew's view requires greater use of technology. I have always approached teaching/learning from model 2, with or without technology, and I have viewed the computer simply as a tool, that, if used wisely could improve the productivity or reduce the costs (primarily in time) of performing the duties associated with this approach to teaching and learning. In this I have followed an evolutionary, not a revolutionary, path [see Ehrmann, 1995] to the integration of computers in course delivery. This paper will outline the progress of this approach at MRC using computer managed learning (CML).

The Problem

Facilitating student learning with the use of computers has been difficult for many faculty for a number of reasons well documented in the literature. With all that faculty already have to do, computer use became just one additional thing to learn. Yet there has been a wave of production of multimedia course curriculum materials by universities and colleges, private entrepreneurial firms, traditional publishers, and others. However, a problem that has become apparent is how can faculty implement these materials in a systematic and easily administered way within a course framework that makes it productive in accomplishing the goal of directed learning. In order to realize the full value of all of the interesting and useful curricula materials available they need to be placed in a logical ordering with appropriate student assessment in order to measure if learning is truly being facilitated. An appropriate CML environment or "shell" needs to be applied that can deliver various curricula in a properly structured, sequenced, and integrated course.

The Goal

The advent of computer managed learning (CML) created the possibility of structuring, directing, and assessing students in an orderly manner. The first generation of CML programs were very effective but limited in the type of material and its presentation that could be incorporated. Our current goal is: (1) to maintain the value that early CML added to computer uses in the delivery of course material, assessment of students' performance, and the record keeping for a large number of students; and (2) additionally provide the shell to incorporate all of the curriculum innovations of recent years. The ultimate program will do all of this in an easy to use package that reduces the time and effort of faculty.

Our Experience

Success in economics requires that students achieve the ability to solve a large variety of numerical problems. For students to have the learning opportunities to do this entailed considerable time and effort for instructors in creating and marking assignments in addition to regular exams.

In 1986 we introduced a CML component into the introductory university-transfer economics courses at MRC. The purpose of this innovation was to provide problem assignment opportunities while using the computer to automate the delivery, marking, and record keeping functions. Subsequently, CML was implemented in all of the department's economics classes serving over a 1000 students a term.

The CML software used was supplied by Computer Based Training Systems which was taken over by Campus America. Later versions of this software were titled the Learning Manager System (LMS). We developed courseware in order to implement this software including testbanks of questions, study guides, course maps, and
manuals. The testbanks included standard multiple choice, true and false, matching, short answer, essay, and problem questions.

All of these types of questions (except essay) can be computer graded, and the students' records maintained. The most useful question type for our purposes is the problem type. A typical question would have a programmed function that generates similar but different problems for each student. For example, the students would receive an assignment with standard economic problems to solve through calculations. Each student, however, would be issued specific numerical data for their questions with unique correct answers. Thus, students are encouraged to collaborate on approaches to solving the questions but cannot use other students' answers. Although a very simple system of computer application, this CML system proved extremely valuable to our students and faculty for over a decade of use.

Current Developments

To meet the above goal we are currently implementing a software package called The Learning Manager (TLM) developed by Campus America (USA) in their Canadian office in Calgary. This software provides the "super glue" that incorporates computer generated curriculum material into a course structure and maintains all of our previously produced testbanks, course maps, and study guides. The value of this approach needs to be emphasized. First, all the curriculum material a student needs to use on a computer is integrated in one place—the course map. Second, computer based materials are placed in this course map in the sequence determined by the instructor (curriculum designer) for maximum usefulness.

TLM will allow the department to continue providing the benefits of the CML component of the courses in economics with the same curricular materials while incorporating much more feedback and guidance to students than the old LMS system could. Additionally, TLM provides the management shell for the easy integration of current multimedia resources and the implementation of future production of computer based instructional materials as new course materials are developed by various individuals and outside agencies. This feature will hinder piecemeal development of curriculum that may be used exclusively by one instructor, or that may even "sit on the shelf" unused after being developed because of the lack of its integration into a cohesive system.

The approach taken at MRC illustrates how CML can work as a solution to the problem posed. First we establish the modules of the course and the specific objectives within each module. We have found that the chapters in the assigned text are best considered the modules for CML and then specific objectives created for the chapters (modules). In Economics the publishers generally provide a testbank of multiple choice questions which is adequate for the basic module self tests we incorporate in the course flow. Each module includes a study guide as well as a self test. The study guides include any materials than can be delivered on a computer. For example, we use the interactive tutorials supplied with the textbook by the publishers. Our students have found these chapter tutorials to be very useful. Yet, when we had this type of computer curricula placed alone on computers, students very rarely took advantage of them. When integrated into the CML course map at appropriate points they do get used. We have found that close integration of the CML materials with the assigned textbook works best for students. The self tests are used to assist learning the material and therefore include all kinds of feedback to the student. Our random data problem sets built up over ten years are integrated in the course as assignments with all of the advantages outlined above maintained. Individual instructors are on release time to develop specific computed based teaching materials and we will integrate these easily into the courses to be used by all of the students taking economics. In this way over a long period of time we have a system that grows and improves in assisting our students while promoting collaborative efforts within the department where each instructor (as well as all of the students) obtains the benefits of their colleagues efforts.

Joint Learning Across the Ocean

Introduction

For decades, ink and paper and the postal service have done an excellent job in helping bridge the ocean and aid in bringing about cultural understanding as well as assist in the difficult task of language instruction. Often, initial pen-pal contacts led to student exchanges and influenced lives in unforeseen ways. Today, e-mail has replaced ink and paper. The telephone ("reach out and touch someone," as the AT & T commercial states) allows for easy communication. Chat rooms on the Web are the virtual coffee houses for tech aficionados to exchange ideas. Unfortunately, the Web has also aided the perception that speakers of English do not need to know a foreign language (especially do not need to know German) because the world (and especially Germany) speaks English. Yet, to gain a real understanding of a foreign culture (e.g., German) the knowledge of the language is necessary. Learning about other cultures via English, if that is the only approach we take, is the academic equivalent of colonialism. The same is true for any serious text-based research. To be able to read originals is essential; a translation is always an interpretation.

This intellectual awareness of the importance of learning foreign languages is not enough of an incentive to attract students. A more pragmatic approach is needed. Students have to see how the knowledge of a foreign language directly benefits their professional careers. The nation-wide initiative "Foreign Languages Across the Curriculum" sponsored by the American Council on Education is based on this realization. Unfortunately, most small colleges do not have the resources and faculty to staff such programs. The project "Joint Learning Across the Ocean" addresses this issue and builds on the desire of most students to work on concrete projects. "Learning is doing" remains the pedagogical approach underlying the project. Instead of practicing language skills on tasks unrelated to the actual interests of students, the project tries to find new learning strategies with the help of technology to come closer to the ideal of interest-centered learning.

While the pilot project in German Studies is geared to students with an intermediate level of proficiency in German, follow-up projects include higher levels of language proficiency, for which other courses are being developed, e.g., a "Living German Writer/Artist Series," and a series based on working with alumni in different fields in different countries.

Pilot Project in German Studies

General Considerations

Students in Intermediate German are seldom of one mind in regard to their interests, and rarely is their language competency homogenous. Over the years, various textbook readers have taken these facts into account; instructors have devised different strategies to deal with this problem; the Web has offered new avenues for flexibility. Based on the many ideas found in these approaches, the project "Joint Learning Across the Ocean" attempted to create a learning environment marked by such features as (1) a variety of topics based on the input and interest of the learners; (2) multiple levels of exercises; (3) a combination of didacticized and authentic texts; (4) individualization of the learning process.
These goals were achieved by linking three courses: (1) Landeskunde und Fremdsprachenunterricht (German Studies and Foreign Language Instruction), H. Rössler, Freiburg; (2) Intermediate German, D. Hoffmann, Colgate; (3) Theory and Methodology of College German Teaching, C. Fraser, Indiana University. The Colgate students wanted to improve their proficiency in German and knowledge about Germany; the students in Freiburg needed practice in preparing teaching materials and designing teaching tasks; the students at IU gained first-hand experience in observing an on-going teaching experiment, as well as evaluating both this process and the use of technology.

The Individual Steps of the Project

At the beginning, the Colgate students introduced themselves via the Web and presented the Freiburg students with a wish-list of topics. This meant that all students were trained from the outset in basic HTML and the use of a Web processor (e.g., FrontPage). In today's world, such a training is more than justified and does not detract from the actual goal of learning German. Just the opposite is true; the later use of technology in the German-learning context more than makes up for the hour "lost" in the beginning. After the initial HTML training, both courses, the one at Colgate as well as the one in Freiburg, established course Web sites in German at their institution which contained links to (1) the syllabus, (2) the list of topics, (3) the class list with links to private pages. As experience has shown, most students are addicted to the use of e-mail and like to create personal Web-pages with self-portraits. Therefore, it seemed logical to give them the opportunity to follow their inclinations in German. Their first contacts with their new e-mail pen-pals contained the URL of their private pages as well as the course URL. A first learning contact had thus been established and was then intensified with a first multi-point teleconference. Personal introductions as well as a first presentation of works-in-progress filled the hour whereby this teleconference also provided an opportunity for gaining experience with the new technology using slides, videos, computer, and the camera projection unit.

The creation of the Web-projects was accompanied by a flow of e-mail communication between the participants. This way, German was used in live situations, not only as an abstract exercise. The instructors were always kept informed through electronic copies and could make suggestions for content as well as grammar structures if they deemed it pedagogically necessary. On-line dictionaries and on-line grammars were always available. The final products comprised topics ranging from "Politics in Germany" to "Wine making" and "Fasnacht" besides introducing the Colgate students to Freiburg which is the home for study group programs by Colgate and IU.

Most of the final products had (1) a basic text (with many illustrations)) linked to additional materials and to other authentic German Web sites related to the topic; (2) a glossary with definitions in English and/or German (sometimes illustrated); (3) structural and content-based exercises (graded according to level) for the texts prepared by the Freiburg students as well as German Web sites; (4) answer keys to allow for feedback and independent study; (5) author page. Students learned quickly how to work efficiently with these materials by placing text and glossaries and/or exercises in separate windows next to each other on the screen. One of the distinguishing features of all projects was their freshness and relevance. They clearly showed their authors' enthusiasm and knowledge of all current aspects of German culture. Links to commentary pages allowing any reader to send suggestions for improvements to the authors were an additional aid in keeping the projects updated.

Learning as well as teaching took place on all sides (at Colgate, at Freiburg, and at IU) and was enhanced (1) through postings of questions and comments by the instructors on an electronic discussion forum; (2) international chat sessions; (3) additional teleconferences with Colgate alumni whose field of work coincided with one of the projects under discussion; (4) a final teleconference to discuss and evaluate the project and the use of technology. While discussion forums have the advantage of being accessible to all participants at their convenience and to allow for a structured discussion by threading messages, chat sessions allow for immediate responses to individuals, groups, or all participants and are, therefore, highly stimulating. Finally, making use of alumni through teleconferences is one of the best motivational factors, especially if the alumni are relatively recent graduates. Students can identify easily with them and see how they could use their language skills in the near future.
A final teleconference between the participants served as a sounding board for suggestions on how to improve such joint learning ventures and gave the Colgate students the opportunity to display their improvement in the German language. A TelePrompTer helped to increase self-confidence and allowed participants to give a fluent presentation of a topic of their choice to their audience.
Comparing Student Performance in Independent Study Versus Traditional Lecture Sections
Donna J. Fremont, Computer Science Department, University of Calgary, Canada
E-mail: fremont@cpsc.ucalgary.ca
Norman Giesbrecht, Insight Research & Consulting, Calgary, Canada
E-mail: ndgiesbr@acs.ucalgary.ca

The computer literacy course is taught every semester to over 600 students. Course capacity is always met and many students are refused entry. Students are drawn from many faculties, can be in any year of their program, and can be taking a full load of courses or only one course while working full-time. Because of student demand and the diversity of student characteristics, it was thought that an independent study without formal lectures and labs might give students more time flexibility, appeal to those with a self-directed learning style, and allow more students to complete the course without unduly increasing demand on existing departmental resources.

Course Delivery

Students in both the lecture and independent study sections had access to the text book and accompanying CD ROM, lab work-book, course outline, assignment descriptions, and a course Web site with postings of all written materials and links to related materials. The Web site was also used for facilitating group work on two assignments and E-mail was available for student and instructor communication. All students had access to a computer lab on a drop-in basis for 50 hours per week. Students could also access the Web site and E-mail from home via modem. Students in both sections completed six pass-fail assignments due on specified dates and wrote the same midterm and final exams. Students in the traditional lecture section had scheduled classes composed of three lecture hours and two lab hours per week.

One course section was offered as an independent study in the Winter semester 1997. A one-hour meeting was scheduled each week. About half the meetings were mandatory, and these were used to describe the course outline, hand out materials, introduce assignments, organize group projects, and administer the midterm and final exams. The course Web site was used to post announcements and notes from the mandatory meetings. The instructor attended all class meetings and communicated with individual students via office hours, telephone, and E-mail. One teaching assistant was assigned to the course, and he marked assignments, provided lab support six hours per week, and was available for consultation via office hours, telephone, and E-mail.

Method

Students from both sections of the course completed a survey that identified student characteristics, pre- and post-course computer usage patterns, and self-perceived pre- and post-course overall computer expertise and expertise with E-mail, World Wide Web, and Newsgroup functions. Student id number was used to match survey response with course grade. Students in the independent study section were also mailed an extensive qualitative feedback survey that explored their learning experience and perceptions of the course.

Results

Student Characteristics

Almost half the independent study students took the course as an optional course and/or were motivated to take it to acquire additional computer skills. Only two students took the independent study because the lectures were full - the rest were attracted by the flexibility and additional free-time provided by this format. Students in the independent study section were significantly older (F=20.8; p<.001) and had significantly more years of post-secondary education (F=23.0; p<.001). Their written comments indicated that almost all believed that
their strong self-study skills and previous computer courses or computer experience were characteristics that would help them be successful in an independent study format. Prior to the start of the course, about 90% of students in both sections owned a computer, held an AIX account, and had used word-processing software. However, independent study students reported significantly higher levels of self-perceived overall computer expertise (F=5.5; p<.05), spent a significantly higher number of hours per week on the computer (F=4.5; p<.05), were more likely to have used E-mail (80% vs. 58%; chi-square=3.5; p<.06), and were significantly more likely to regularly play games on their computer (70% vs. 42%; chi-square=7.0; p<.01). There were no significant differences between sections in E-mail, the World Wide Web, or Newsgroup expertise.

Student Performance in Traditional Lecture vs. Independent Study

Following course completion, there were no significant differences between sections in the percentage of students who regularly used the computer to do word-processing, E-mail, library research, or "other" functions, but independent study students continued to spend a greater number of hours per week on the computer (F=3.6; p<.06) and were still significantly more likely to regularly play games on their computer (70% vs. 35%; chi-square=11.7; p<.001). Although the percentage of students who received a grade of "A" or "B" was similar across sections (39% vs. 38%), a significantly greater percentage of students in the lecture section obtained a grade of "C" (43% vs. 21%; chi-square = 7.6; p<.01) whereas a significantly greater percentage of students in the independent study section obtained a grade of "D" or "F" (41% vs. 18%; chi-square=9.0; p<.01). It may be that strong students are able to perform well with either format, but that struggling students need the lecture format to achieve a passing grade. However, independent study students were also unanimous in expressing concerns that inadequate information regarding exam and lab expectations and marking criteria had negatively affected their performance. A majority recommended that the weighting on the exams be reduced and that a higher weighting (and also percentage rather than pass-fail grading) be used for the assignments.

Qualitative Feedback from Independent Study Students

About one-half of the independent study students indicated that the course had met their goals and that they would recommend the course to other students. About one-half the students were "satisfied" with the amount of interaction they had with the instructor, teaching assistant, and/or other students - and the other half were equally divided between being "very satisfied" or "unsatisfied". E-mail, telephone, and office hours / lab time were the primary tools the students used to communicate with the instructor, teaching assistant, and other students. All students had used the text, workbook, course web site, E-mail, and World Wide Web as resources, one-third had regularly attended lectures in another course section, and less than one-third had used the text's CD-ROM and/or found it helpful. Over half the students indicated that some form of practice on-line testing would be helpful and about one-third believed the incorporation of interactive multimedia tutorials and/or required use of the text's CD-ROM would improve course delivery.

The major perceived benefit of the course was time flexibility and one-half the students believed that their most beneficial learning outcome was the development of marketable skills with the Office '95 spreadsheet and database applications (i.e., Microsoft Excel and Access). The major drawback was considered to be inadequate information and guidance regarding exams and assignments and one-half the students believed that more regular class-time with formal instruction and/or guidance could help address this problem. Overall, the students found the independent study format appealing and believed it had potential, but that felt that some changes (particularly in communication and evaluation issues related to the exam and lab assignments) would be needed to realize this potential. Future sections could place greater weighting on course assignments and use them as opportunities for students to develop practical and marketable computer skills and explore areas of personal interest.

Conclusion

An independent study format provides students with greater flexibility and more free time. The format is best suited to mature students who have strong self-study and time-organization skills, previous experience with independent learning, and/or good prerequisite computer skills. To be effective, the independent study format
needs to address issues regarding communication, support for assignments, and evaluation criteria and procedures. An independent study can also allow students to explore projects and areas of interest that would not be possible in a traditional lecture format. A revised independent study is currently being delivered in the Winter 1998 semester which allows students to define and complete individual projects.
Web Supported Learning - A user evaluation of a Media Studies application

Mark Gillham, Kathy Buckner & Richard Butt
Communication and Information Studies Department
Queen Margaret College, Edinburgh, UK
m.gillham@mail.qmced.ac.uk

With the publication of the “Dearing Report” on Higher Education in the Learning Society in 1997 in the UK, there is much pressure on academics to examine ways in which Communication and Information Technologies can be used to enhance the learning process to improve the “quality, flexibility and effectiveness of higher education” [Dearing 1997]. Providing flexible learning environments that can be used in a variety of ways to suit individual students is going to become increasingly important.

Many academics now feel confident to develop their own materials for publication on the Web but the extent to which students benefit from such resources, (particularly on courses which require little prior knowledge of computing) requires further investigation.

Integrated learning environments or on-line courses which require students to interact with each other or with their tutor through the computer have been investigated by several researchers (e.g. [Newman et al 1997]). However in many cases there is a significant learning curve for the students in relation to their interaction with the computer.

We believe there is a role for the provision of support materials on the Web for traditionally taught courses. This type of provision is less demanding of the student in terms of their ability to interact with the computer but nevertheless provides adjunct materials at a relatively low “learning cost” for the student. This may be a precursor to moving more material onto the Web in order to replace all or more likely some of the traditional delivery mechanisms. It is especially likely as an initial step where students are often not already familiar with the Web and in disciplines that are not the first to embrace new technologies.

The site under study was introduced in autumn 1997 to support a second year undergraduate degree module called Narrative and Genre (NAR). This module is taken primarily by students on the integrated Honours degree programme in Communication Studies at Queen Margaret College, Edinburgh. The NAR module introduces students to the economics of the film industry and to various theoretical approaches to the study of narrative and genre.

The site was developed by 4th year students who had previously studied NAR, in collaboration with the course tutor. The Web site [http://jimmy.qmced.ac.uk/usecibuttinarrgent] has as its core a small text based set of seven pages, most of which were written specially for the site. The pages are the menu (the home page with a weekly outline of the module), descriptor (the formal module description), staff (a link to the NAR lecturer’s home page), readings parts 1 and 2 (additional reading texts for each week and weekly lecture overheads), links (a page of links to appropriate and checked external sites) and assignment (examples of previous essay questions).

The aim of the research is to assess the user’s interaction and view of the site as a support mechanism for their study. Of particular interest was that the users of the site are not on a technology course and are not generally found to be technology enthusiasts.

A number of techniques for evaluating on-line and hypermedia courses were examined and it was decided to administer a questionnaire of mostly closed questions to elicit information about the users’:-

- access and use of the site
- evaluation of key criteria (from criteria described by [Gillham et al 1996])
- general views about Web based education
- use of other computer facilities and feelings about computing
- demographic details.

The questionnaire was completed by 38 respondents which is 42% of the students registered for the course. The sample consists of 38% international students, mostly from Norway, and the gender make up is 60% female and 40% male. Eighty-one percent of the respondents are between 18 and 25 years old.
The NAR Web site was used by 90% of the respondents with only four admitting to not using it. The site was highly regarded overall by the users with a large majority stating that it is, essential (39%) or useful (52%), and every respondent stating that it had assisted with their study, either a little (46%) or a lot (54%). They all stated that they would like similar sites available for other modules. Most users accessed the site once every two weeks (31%) or once a month (34%). Access at less than once a month (25%) suggests a single visit. It may be expected that the site would be visited weekly to match the weekly pattern of classes on the course. However only about 9% did this. The information on the site was not added to during the semester, so it may be that students accessed information for several weeks’ work in a single visit. They were asked a series of questions to see what balance between traditional teaching and Web based delivery they favoured [Fig. 1]. It is interesting to see a marked conservatism towards moving away from the traditional forms of tutor contact. All the respondents were of course in attendance at a lecture which may immediately bias the sample. Also, the questions stressed the aspect of tutor contact rather than flexibility in learning as would occur with more of a Web based programme and the popularity of the particular course tutor may be influential here.

Figure 1. Views of students on various type of teaching approach.

It is clear that the students find the Web site a useful additional resource in their study of the NAR module. The site seems to be used by many as a rather static source of information with over half of the respondents accessing it only once a month or less. The material was not changed during the semester, so the batch approach of printing out material and presumably keeping it on file is appropriate. There is no ‘latest news’ area in the site, but given the weekly meeting of lecturer and students in the classes this may be considered unnecessary. Given that the site is not as dynamic as many Web sites it could be reasonably argued that the information could be satisfactorily provided on paper to the students. The only area giving real added value in having a Web site is the links to external sites. Indeed it is this facility that was used most frequently. The site was highly successful in introducing potentially unenthusiastic students to Web based educational material. However with this application there has not been any ‘trade off’ in reducing traditional contact situations. The surveyed students seem resistant to moving further along the path to computer assisted learning; they appear content with what they are familiar.

Teachers Assessing Student's Performance:  
a Proposal for Hypermedia Applications

Introduction

The advantages of hypermedia software are often considered self-evident. They present a variety of information in multiple representations; They provide to student's a dynamic and individually way of constructing their knowledge, in a constructivist learning perspective [Jonassen & Duffy 1991], [Spiro et al. 1991]. Those potentials will only guarantee an effective learning by the students, if there is a "step-by-step" integration of evaluation procedures, both into levels of development and actual use of this software. A great variety of approaches and evaluation methodologies can be found in the literature [Reiser & Kegelmann 1994].

Learning contexts are crucial to the success or failure in educational uses of this type of software. Assuming that each student has his own skills and learning style, the ways they access information and the difficulties they may experience can be tremendously different. Research about assessing student's performance in front of educational hypermedia applications has proposed relevant methods to access and analyse student's interactions with the software, [Crosby & Stelovsk, 1995]. Nevertheless, these studies focus essentially questions about design of hypermedia applications, in a formative evaluation perspective. It is also necessary that teachers, in real context learning, supervise student's activities, discuss their performance and advise them for future work.

The new trends in science learning highlight the need of improvement in assessment science learning. An effort has been made to propose alternative methods and techniques of assessment that emphasise the process and not only the content, such as concept mapping, tasks analyses or student's portfolios [Smith et al. 1993]. Developing computer-based assessment tasks in science is an issue that has yet to be fully resolved [Kumar 1996]. By drawing upon educational software evaluation and evaluation in science learning we believe that we can contribute to the improvement of both areas [Gomes 1996].

Model of Assessment

Although there is a great number of methods that analyse student's performance in front of hypermedia applications, tools designed for teachers should have features especially addressed to them. They should be kept simple: Methodologies of application should not be complex, should not demand manual processes and amount of time; Data visualisation must be simple, facilitating the analyses by the teacher; They should contemplate not only statistical approaches about de visited nodes, links types, time spent at each part of the programme, but also data visualisation that gives emphasis to the original version of student's performance; Analyses should not only focus on the objects of the interface and on the navigation styles but also on the concepts involved; They must emphasis the interrelations between concepts, media resources and applications strategies.

In order to gathered all the information that we can reach by student's interactions with hypermedia, that might be relevant to help teachers in evaluation processes, a categorisation model is proposed, see [Fig.1]. We assume that each interaction results in a specific event with certain types of media resources.

<table>
<thead>
<tr>
<th>An Interaction</th>
<th>Causes an Event</th>
<th>With Media Resources</th>
</tr>
</thead>
<tbody>
<tr>
<td>Identification</td>

<td>e.g. System Navigation Exploratory</td>
</tr>
<tr>
<td>-Hot Word</td>
<td>-Window</td>
<td></td>
</tr>
</tbody>
</table>

Fig 1: Classification Frame

1715
The integration of this classification frame into the process of conception and software development will guarantee a very simple way to collect and analyse data of student's interactions with the hypermedia applications.

The Experiment and Results

We developed tests with nine first years students engaged in higher education. These tests consisted in video record of working sessions with a hypermedia application (*The Way Things Work*, a successfully Edutainment CD-ROM developed from a book by David Macaulay). Each session had the duration of 30 minutes, and students worked in groups of two or three. On the first session they worked freely with the software, to accommodate to software interface and structure. On the second session they had a specific task: “explore what is a computer and how it works”. We codified all the interactions based on the categorisation model.

By classifying interactions and events in the hypermedia system a map was generated where hypermedia application structure, event strategies, and media resources are expressed. To deal with the conceptual level, we identified in hypermedia structure, the relevant events for students to achieve the proposed task the *key concepts*. We present some possible representations of the data collected in the second work sessions, the one that have involved a task, that emphasise:

- Student's preferences for the global themes of the software, by counting interactions percentages on each theme.
- Student's efficiency in accessing information, by counting interaction percentages in events related with key concepts, events related with other concepts and neutral interactions and by counting the number of interactions made until student's reach a key concept.
- Student's navigation style, by counting interaction percentage on theme navigation, system navigation, association idea navigation and exploratory navigation. We also considered the links student's have done between events.

Discussion

With the explosion of hypermedia applications and the growing interest in their use in education, it is important to reflect how can we help our students to take the best profit of them. Data generated by this experience emphasises the potential of evaluation tools especially addressed to teachers.

We found groups of students with great difficulties to accomplish the propose task. One group has visited so few events related to computers. Others, visited almost all the events identified as important, but they could had accessed information in a better way. Reflecting and discussing with students their own performances may help them to develop skills to deal with hypermedia software.

The categorisation frame we proposed allows for a great variety of perspective analyses and the results encourage the integration of this type of tools in hypermedia applications.

Abstract:
This paper provides a brief overview of Problem-Based Learning (PBL) as an instructional methodology. A master’s program in information and learning technologies, designed for classroom teachers using PBL as its primary instructional strategy is then described. Information about program issues, problems, and successes is provided.

The ILT Master’s Program

The Information and Learning Technologies program in the Division of Technology and Special Services at the University of Colorado at Denver (UCD) offers a master’s degree program for practicing teachers. The primary emphasis of this degree program is to help teachers learn to integrate information and learning technologies in student-centered ways in their classrooms. The main instructional strategy used was problem-based learning (PBL).

PBL AND LARGE GROUPS

Most PBL programs are conducted with small groups who meet frequently with tutors. We didn’t have that luxury. There are 20 people in the program and one teacher/tutor. The tutor is critical in helping students reflect on their learning and to remain faithful to the PBL process, so we had to learn how to conduct that reflection and monitor the process either in our absence or with a single large group. Strategies that we tried include:

• Rather than meet with each group individually, we had the small teams prepare for reflection discussions by writing answers to reflection-based questions individually. Then we gave the teams time to discuss their individual responses together. Finally, we brought all the teams together to share their thoughts.
• Infrequently (when there were two of us on site) we met with individual teams, mostly in an effort to monitor the process. Teams tend to fall victim to “production bias.” That is, teams tend to want to solve the problem, produce a product, or “win the race” and avoid things that get in the way of “producing” – things like taking time to reflect on their learning.
• Since the students met only once every two weeks, we gave up significant portions of class period to team meetings and team work. To compensate for missed class time, we used e-mail discussions focused on reflection questions during the times between classes.
We gave reading assignments during class so that part of the class would have something meaningful to do while a team or individuals worked with a teacher. Even though we strongly supported the PBL approach and were prepared to make changes, giving up class time for other activities was one of the hardest things to learn to do. Learning comes from working on the problem and from reflecting. Even after two years, we are still learning and thinking about how to handle class time. The main issues that we learned to deal with include changing student and faculty roles, infrequent class meetings, the necessity to emphasize reflection, reducing student anxiety, and assessment.

Those of us who have used PBL know that there are critical changes in the roles of both students and faculty. Yet, “knowing” and “acting” are two different things. As our program progressed both the students and us became more comfortable in our roles.

Most PBL programs have several meetings per week. We met once every two weeks. To facilitate the PBL approach, we gave up significant amounts of class time for small group meetings. This continues to pose problems for us. The teams need to meet together more frequently and the distances several of the students had to travel made this difficult. E-mail is not always effective. Many of the students waited until the Thursday evening before the next class (Friday evening) to read and respond to the question of the week, leaving little time for thoughtful reflection and reaction from their peers. Some of the strategies we tried include:

- We created small groups based on geographic proximity. This enabled them to get together between class sessions. However, one group was composed of people in rural locations. They were not able to get together.
- We gave up class time for team meeting time.
- We worked on class norms for e-mail discussions (short, single-topic responses, earlier and more frequent reading of e-mail). In fact, we used this strategy a great deal. When we encountered problems in the class, we asked the students to verbalize those problems and then to develop solutions that they would all agree to follow.

One of the things that we as teacher-facilitators learned that probably had little effect on our students is the importance of reflection, whether students are working on a problem or a project. In general, a problem is more open-ended than a project, leaving almost all decisions about where to go with the problem to the students. A project is more narrowly defined and may specify the nature of the final product or solution.

Our notion of doing the program with intensive weeks in large blocks was appealing to our students. Yet, it took us, as teachers, half the program to figure out how to deal with it. It was difficult enough for us to organize 15 hours of class per weekend and then try to subdivide that into time for three separate projects and any other material we wanted to deal with. The students had the same organizational problem, not knowing how to divide their time away from class. They were always overwhelmed. They also tended to want to put in much more time than we wanted them to for each project.

Assessment and grading are continuous problems. As teachers, we constantly wrestle with the conundrum of not believing in grades, but since the university requires them we believe they should mean something. This becomes a greater problem in a problem/project environment based on small groups where everything is always in process and feedback is supportive rather than judgmental.

LESSONS LEARNED

- The courses for our next cohort will be arranged around single problems (contact the principle author for a description of the curriculum for the next cohort).
- Rather than traditional 3- or 6-hour courses, we will assign credit hours based on the needs of the problem — anywhere from one to four.
- We will shorten the length of the weekend meetings. By Sunday morning the students and us were exhausted. We had some fruitful Sundays, but not always. So, we will use Friday evenings and Saturdays for our meeting times.
- We will make a greater commitment to PBL. We will make sure that students understand that the bulk of their meeting times will be in small teams with a tutor. We won’t try to mix traditional and PBL class times together.
• Target a student population that is closer to the university, making between-class meetings more practical.
• In the next cohort, we will be much more systematic regarding assessment and focus on:
  • knowledge in the problem domain;
  • reasoning and problem-solving skills;
  • self-directed learning skills;
  • group process (collaborative skills).
Establishment of a Virtual Consultancy

Gerald Groh, Dr. Ulrich Jehle
GSM GmbH, Azenbergstr. 35, D-70174 Stuttgart,
Phone: +49 (711) 22563-0, Fax: +49 (711) 299-1978, Email: groh@gsm.de

Introduction

Recently there has been an increasing interest in the concept of virtual corporations. The virtual corporation is envisioned by many experts as the solution for a quick introduction of a variety of high quality products at a low cost. But there are still some open questions and problems to be solved.

In this paper the SERVICE project (SMEs pilot for business process design in order to establish a virtual international consultancy using electronic commerce) is presented. The project is partially funded by the ESPRIT programme Technologies for Business Processes (TBP) from the European Commission and aims to build up a virtual consultancy (VC). The VC consists of partners from Germany, England, Greece, Sweden and Finland.

Project Objectives and Approach

The overall objective is to facilitate the participation of small and medium-sized companies (SMEs) in the global market by pooling their resources and exploiting the opportunities offered by the development of electronic commerce. One specific objective is to transform the company-specific business processes into distributed processes, which cross the boundaries between the partner companies.

Accompanying activities in Human Resource Management are necessary for the effective transformation. HRM activities must consist of exchange-oriented, qualification-oriented, coach-oriented and support-oriented tasks. At the same time the suitability of current Information and Communication Technology enablers for the support of distributed business processes in SMEs has been checked.

As SMEs cannot afford to build up their own corporate networks, they depend on the availability of public networks. Public networks can be used by SMEs to establish a virtual private network. Effective sharing of data and collaboration between manufacturing organisations requires technologies that are cost effective, flexible and portable. During the implementation of the pilot, support training, coaching and qualification measures are taken to verify the VC’s efficiency and effectiveness.

The first step was an "as-is" analysis of each partner’s organisation and a clear definition and scope of the pilot. The process analysis provided the basis for the process design which was implemented (pilot implementation) and consequently will be evaluated and disseminated.

Pilots to Be Considered

After the first project phase (process analysis) the consortium agreed on three different pilot categories:

- **Pooling products**: user organisations select products already available and pool them together, so that other partners within the virtual consultancy can exploit them.

- **Glocalise products**: a discussion revealed that glocalisation as a strategy could be employed in cases where products are intended for different markets and need to be glocalised, as well as for multimedia products. The product/service is 'glocalised' by customising details of the product (e.g. language, dialogue, tastes, aesthetics, etc.) to match the preferences of local consumer groups within particular local markets (e.g. countries, language zones).

- **Creating new products/services**: user organisations engage in a process whereby new products or services are developed.
The project itself provides for various, interesting items to be discussed. Following the baseline of the conference we will focus on the aspects of Human Resource Management within this paper.

**Human Resource Management**

Human Resource Management ensures that a company has the right number and type of people at the right place and time, who are capable of effectively and efficiently completing those tasks that will aid the organisation in achieving its overall objectives. Therefore, accompanying training and education activities are vital for the success of the virtual consultancy.

There are four key elements of a human resource management system, each of which can operate both as an outer control and an internal incentive to foster business goals. The four elements are:

- **selection** of people who are best able to perform the tasks defined by the organisation's business objectives,
- **appraisal** of performance to facilitate the equitable distribution of rewards
- **reward**, which motivates employees by linking rewards to high levels of performance
- **development** of employees to enhance current job-related performance, to keep them happy and motivated, and to prepare them for future business opportunities or positions they may hold within the organisation.

Selection, promotion and placement are all related to the internal movement of people across positions and projects, and to the external hiring of people into the organisation. The underlying consultancy process is that of matching available human resources to the projects undertaken within the organisation. This entails defining the skills required to complete the project to the client's satisfaction, and assessing the available people who represent the best fit.

Once the jobs are filled and the tasks are being performed, employees should be rewarded both financially and emotionally for good performance. They also need to be further developed and supported in order to widen their range of skills, thus increasing the number of projects upon which they can work while at the same time increasing their own job satisfaction.

Ensuring that an organisation has an adequate supply of human resource talent and particular skills is by no means an easy task. One of the potential benefits of a virtual consultancy, such as Service, is the ability to draw from a large pool of people with skills and experience in the Human Factors/Ergonomics/Human-Computer Interaction domain.

In order to plan marketing activities and resource requirements, each of the Service partners needs an accurate inventory of the current Human Resource stock held by the other partners. This should include an up-to-date description of the skills and qualifications of each consultant, brief details of major projects upon which they have worked, their preferences and areas of interest, and their own wishes for future development and type of projects.

Any HRM system will contain certain underlying hypotheses about the type of people the organisation employs. For example, we view our consultants as highly self-motivated individuals who seek opportunities to learn, develop and apply their competencies. Management attempts to create a co-operative environment for them, while recognising that the world is an essentially competitive place. The nature of the psychological employment contract between the company and its consultants is "challenging, meaningful work in return for high rewards and loyal, committed service". The degree of participation in decision-making is relatively high, with management encouraging widespread participation in human resource activities. The HRM systems are geared towards a mixture of individual performance (through individual appraisal review/rewards), and collective, group-based performance (through collective bonuses, a matrix-based project team structure, and various company social activities).

**Summary**

The nature of the consultancy services offered at each user site is 'knowledge work' carried out by highly educated and professional members of staff. Knowledge workers tend to have a particular set of work standards,
freed from the tedium of close supervision, and oriented to co-ordination, co-operation, organisation and planning.

The provision of high-quality consultancy services is dependent on the consultants who deliver them. The human resource management processes are thus at least as important as those of strategy, marketing and finance.
1. Introduction

In the German speaking countries, general medical education can organizationally be divided into Pre-clinical Education (comparable to an Undergraduate Program), Clinical Education and The Practical Year. This is normally followed by several years of Internship. The Pre-clinical Education, although organized by the Medical Faculty, depends on the cooperation of other faculties. For example, introductory courses and lectures in Physics, Chemistry, Biochemistry and Biology must be imported from the Faculty of Life-Sciences.

It has long been known that lecturers ideally should present course material as interdisciplinary thematic blocks rather than as subjects organized along the line of their own disciplines. This applies to the life-sciences where courses should emphasize medical relevance and vice versa, where the fundamentals of medicine should be taught with consistent reference to their underlying scientific base. However, thematic coordination within related subjects and even more so across faculties is difficult to achieve and depends on individuals who are willing to sacrifice their time and efforts against their own interests.

Facing this situation, and in order to assist medical students to cope with the growing demands of their field that requires solid, scientifically-based knowledge of medicine and life-long learning, we have developed an Hypertext-based Integrated Pre-clinical Education System as a pilot project and part of the Virtual University of Ulm (VUU). This project is called in German Integriertes Vorklinisches Ausbildungssystem (Integrated Pre-clinical Educational System) or IVA (see Internet address: http://iva.uni-ulm.de).

2. Principles

Many computer-based educational projects are presently available and a lot of hype has been associated with their purported usefulness. Most of this has never been evaluated by a procedure that would hold up to scientific principles. Furthermore, many if not most of these programs cannot easily be integrated into existing curricula and naturally suffer from lack of acceptance. Therefore, our first principle is to

- Ensure compatibility with existing curricula.

Design principles of computer-based projects in our experience lend themselves well to the initiated computer freak rather than to the uninitiated average user. This leads to frustration in a field that attracts students of little techno-mathematical background as in medicine. Therefore, our second principle is to

- Make intuitive usage possible.

Surfers of the Internet more often than not experience that behind a flamboyant facade, real content is lacking. We therefore

- Focus efforts on providing content.

Textbooks unlike hypertext-manuscripts are scrutinized by a professional editing and reviewing system. The customer, although unaware of the details, with respect to quality, relies on the brand-name of the publishing house when purchasing a textbook. The Internet, however, lends itself to anybody willing to provide information. No institutionalized quality assessment ensures the correctness of the information given (although quality seals may sometimes help). This has contributed a lot to the shady reputation for Internet-based educational endeavors. We therefore have developed a procedure to ensure that our

- Contents have to pass through a university-level reviewing process.

Self-representation must be assumed to be the primary goal of many an Internet-based project which does not only pertain to the abundance of homepages but also to many a manuscript which has been uploaded to a server not so much to serve the student as to impress in general. Our principle, however, is to

- Provide the information as a service to the reader.

Hypertext, in contrast to linearly arranged text, can ideally be read by following one’s intuition rather than by following a prescribed path. This may lead to the infamous situation depicted as lost in hyperspace. Unfortunately, it has never conclusively been shown that hypertexts lead to a better understanding and/or more reliable recollection of contents. Rather than relying on anecdotal experience we have decided to

- Develop hypertext-based curricula based on didactical evidence.
3. Materials and Methods

3.1 Hard- and Software Requirements.

Judging from past experience, we have decided to set the minimum requirements for the participation in our project to the present-day industry-standard computer. Compatibility to exotic or outdated hardware is not cost-effective. As we provide true multimedia information, state-of-the-art sound cards, video-boards and network access are requested. A somewhat restricted version of our curriculum is also available on CD-ROM for isolated sites, until it has been replaced by the more capacious DVD-ROM. Servers run under NT (presently V.4.0). Software to develop hypertexts is left to the individual author's liking. Clients are requested to employ the latest version of popular browser software (Netscape or Internet Explorer). To accommodate special features, Java applets are uploaded to clients as necessary.

3.2 Generation of Hypertexts and Quality Control.

Hypertexts are written by a group of authors specially trained and qualified to take into account the fallacies listed above. Subjects are chosen with respect to the curriculum. Authors provide and submit their work in HTML-Format to a non-public server via FTP. Their material is previewed on a bi-weekly conference where recommendations are given to improve the material and to make it compliant with the style of the IVA-project. The material is then submitted to an independent reviewer with special experience in the field. Finally the material is re-reviewed by the project supervisor and transferred to the public server. Feedback from users is used to improve the material further.

3.3 Special Features.

The user-interface of the IVA-Project is based on a frame-set, featuring one frame with the main information and an accompanying smaller frame with auxiliary information. The main-frame features standard hyper-textual material. The auxiliary frame serves several purposes, i.e. to
1. present textual material that has auxiliary character (e.g. reviewing material from the Life-Sciences when dealing with Physiology, or links to medical applications when dealing with Physics).
2. provide access to a medical dictionary which has been specially designed to suit the needs of the accompanying hypermedia-texts.
3. answer to questions and comments when examining the self-test section in the main-frame.
4. give access to a help-desk with real-time audio access to a tutorial service located at the server site.

4. Implementation and First Experiences

Presently, as a core curriculum, material from Physics, Physiology, Histology (as part of the HistoNet 2000 project) and Clinical Case-Studies are accessible from the IVA-Project. The material in Physics and Physiology is considered to be supplementary to the standard course-program and, therefore, is divided into auxiliary material for lectures, seminars, practical courses, and multiple choice questions. Furthermore, a set of well documented clinical case-studies has been included to enable even undergraduate students to link their newly-acquired knowledge to their later profession.

We have been able to examine the experience of some 600 students with this preliminary system using a questionnaire, which lead us to several curricular improvements and encouraged us to pursue our goals.

Acknowledgements

This work was supported by the State of Baden-Württemberg and would not have been possible without the excellent work of Thomas Dombeck, Nicole Kadlec, Ralph Kemkemer, Andreas Ott, Angela Rosenbohm, Martin Streicher, Volker Teichgräber and many other contributors. Ongoing support by the Head of the Department of Applied Physiology, F. Lehmann-Horn and the Dean of Students, G. Klotz is appreciated.

Rethinking Algorithm Animation: A Framework for Effective Visualizations

Steven R. Hansen, N. Hari Narayanan, Daniel Schrimpscher
Visual Information, Intelligence & Interaction research Group
Department of Computer Science and Engineering
Auburn University, Alabama 36849-5347
Email: hansensr@eng.auburn.edu

Computer science students generally find the topic of algorithm analysis and design a hard subject because an algorithm describes a process that is abstract and dynamic, while the methods used to teach them are not. For over a decade, researchers and educators have pursued the notion that using computer animations depicting the dynamic behavior of an algorithm could be an effective tool to help computer science students overcome the difficult task of learning algorithms. In fact, numerous studies and experiments have been conducted to prove that animations can improve learning of challenging, abstract concepts like mathematical proofs and the algorithms used in computer science [Stasko 1997; for a comprehensive survey see Hundhausen 1997]. While the pictures and animations seem to be enthusiastically received by the students, none of the studies have proven conclusively that these visual tools actually improve learning [Catrambone et al. 1996]. Is it because animation is an ineffective teaching medium? Intuition tells us this is not likely.

Ongoing research in the areas of multimedia, usability and cognitive science sheds insight into factors that contribute to the design of effective visualization systems [Price et al. 1996, Narayanan & Hegarty 1997], and suggests that previous attempts at using animation to teach algorithm behavior were unsatisfactory not because of a flaw with animation as a technique, but perhaps because of the approach used to convey the animations. Here, we report on a research project based on the hypothesis that animations are powerful vehicles for effectively conveying the dynamic behaviors of algorithms. Our premise is that a rethinking of algorithm animation design is required in order to harness its power to enhance learning. Our research explores the integration of previous work in algorithm animation systems with recent developments in the cognitive and educational domains to produce a new model for using software visualizations to improve student comprehension. The model is based on learning objectives that drive a top-down design that carefully divides abstract concepts into discrete chunks for learning. Unlike previous work, our model takes a user-centered ("what do we need to show") view rather than a designer-centered ("what can we show") view, and employs hypermedia and multimodal presentation techniques to improve learning effectiveness. We call this framework containing text, diagrams, audio and animation a hypermedia visualization—the term visualization suggests a richer process than merely watching an animation, and the term hypermedia reflects the use of multiple media, links and cognitive tools to help the student form accurate mental models of algorithms.

Under this framework, an algorithm visualization is more than a mere animation. It describes an environment that elicits active student participation using a carefully orchestrated presentation of information in various media (such as animations, text, static diagrams, aural narratives, video and more) with appropriate temporal, spatial and hyperlink connections. This framework extends previous research in several ways:

- Embedding animations within a hypermedia visualization that employs textual descriptions, audio narratives and static diagrams to provide contextual information. So, the focus is not on the animation, but on providing sufficient information in the appropriate media form(s) to meet the learning objective.
- Providing distinct levels of animations to illustrate different views of algorithm behavior. At the highest level, a conceptual view introduces the algorithm's basic operations using animated real world analogies and forms a bridge between the analogy, the abstract components of the algorithm and the concrete graphical representations used to depict the algorithm. Next, a detailed view focuses on and animates specific operations in tandem with pseudocode highlighting and textual explanations. Finally, animations in populated view show the algorithm's aggregate performance and behavior on large data sets.
- Presenting algorithm animations in discrete "chunks" accompanied by explanations of the specific actions being accomplished. By providing these logical pauses, the student can digest each small step before moving on. Allowing the student to adjust the size of the step tailors the flow of information to meet the
student needs. This is in stark contrast to current algorithm animation systems that present the detailed dynamics as a one-shot, stand-alone show that is entertaining to watch but tends to obscure the very details the student needs to learn.

- Encouraging student participation by allowing interaction with the data and using questions that stimulate thinking, foster self-explanation, and challenge understanding. Students are prompted to input data sets of their choosing to explore algorithm behavior more thoroughly. The system periodically poses questions to the student. The simplest form is what we call a ‘tickler,’ which is a question that pops up in random order but always in the appropriate context. Tickler questions focus student attention on specific issues and promote self-explanation as a means to improve comprehension, but the answers are not entered into the computer nor is feedback provided. We place other questions that require student input at ‘articulation points’ beyond which the learner cannot proceed unless/until the question is answered correctly.

We have designed and implemented a hypermedia algorithm visualization system, called HalVis, that incorporates the features described above, and conducted two sets of experiments to evaluate the effectiveness of our approach. Each experiment used a demographic survey to evenly divide the subjects into (1) a control group (referred to as the Text group) that learned selected algorithms using traditional, text-based techniques (specifically using extracts of current textbooks) and (2) an experimental group (referred to as the Algorithm Visualization (AV) group) that learned algorithms using HalVis alone. Experiment #1 evaluated the effectiveness of HalVis hypermedia visualizations using second year computer science students studying the MergeSort algorithm, and showed a significant advantage for the AV group over the Text group. The pretest average for both groups was 2.4 out of a possible 9 points. The posttest average for the AV group was 6.7 while the Text group’s score was 3.8 (F(1,31)=10.9, p<0.003). Experiment #2 evaluated the same hypothesis using third-year students studying the MergeSort and QuickSort algorithms, again, with a significant advantage to the AV group. The HalVis group’s average improvement was 6.9 points compared to a 3.0 improvement in the text group’s scores, and these results are significant (F(1,21)=10.2, p<0.003). Figure 1 shows the pretest and posttest performance of each group in these two experiments, using box plots to further illustrate the distribution of scores and enhanced performance of the groups using HalVis.

![Figure 1. Group learning performance using HalVis algorithm visualization vs. conventional text](image)

Our results indicate that animations can be very effective in teaching students about algorithms when embedded in a carefully designed hypermedia environment. Additional information about this research project and its future direction is available at [http://eng.auburn.edu/departments/cse/research/vi3rg/vi3rg.html](http://eng.auburn.edu/departments/cse/research/vi3rg/vi3rg.html).

Abstract: One of the difficult challenges for tertiary education is to not only develop strong conceptual frameworks in academic areas with students, but also to develop skills in applying this knowledge to typical tasks that the graduates will need to carry out in their profession. This paper describes one such approach using the context of a simulated environmental project brief to develop the research and professional practice skills in undergraduate students. A new package entitled "Researching Lake Iluka" was developed from the successful product Investigating Lake Iluka to which were added modules to describe the tendering and statistical processes and data collection. The results indicated that students who were provided with this "situated" learning context developed skills in an holistic fashion at the time they were needed and understood the need to perform environmental assessments with appropriate controls.

Developing Research Design Skills for Biological Scientists

The balance of content and skill development for undergraduate students continues to challenge Universities and has been raised in reviews of the function of our tertiary education systems. Additionally, governments seek to influence this balance as their educational and financial agendas focus on tertiary education. However, in the applied sciences, there has always been a strong emphasis on vocational skills, and Universities do not always have the resources to give students opportunities to develop these skills in a vocational context. This current study was designed to address this problem in the area of applied ecology.

Natural variation is a fundamental part of all biological systems. In many disciplines within the biological sciences, experimental studies seek to minimize background variation in order to be able to detect even small-magnitude effects of experimental treatments. However, in the field-based disciplines, such as ecology and environmental science, the intrinsic variability is not amenable to minimization in surveys or experiments. A major challenge is therefore to design surveys and experiments, which have the power to detect effects, even against the background variability.

Experimental ecology is sometimes considered to be the preserve of 'academic' ecologists and has little to no place in the 'real world' of management of natural resources, conservation of rare species or environmental issues... This detracts from a more useful focus on whether the work is good science or bad science, regardless of whether it was intended to be applied.

[Underwood, 1990, p 386]

Land managers, students and even academic biologists are guilty of investing a great deal of time and/or money in studies that are simply unable to detect effects of the treatment of interest. For example, we are aware of a major forestry experiment designed to test the effects of logging on the water quality of streams. To answer the question, one large catchment was subjected to a logging treatment and another, nearby, was left unlogged. There were many measurements taken from many locations in each catchment - yet this expensive study could
never do any more than indicate that the streams draining the two catchments differed in water quality because the unit of interest (the catchment/stream) is unreplicated either for the logging treatment or for an unlogged control. [Fisher and Wishart, 1930] nearly 70 years ago criticized this type of simplistic approach to research design in stating 'No one would now dream of testing the response to a treatment by comparing two plots, one treated and the other untreated.'

There is ample evidence that even well-trained ecologists and environmental scientists do not necessarily understand the principles of good experimental design [Green, 1979; Underwood, 1997; Whelan, 1995]. Teaching a better understanding of experimental design typically takes two forms: "dry" classes on experimental design theory, or field-based learning. Our experience in teaching at tertiary level indicates that a combination of "vocational context" and "field experience" are important elements of learning. However, field work and professional experience programs are expensive to set up and are instructor-intense. It is also very difficult to focus on key issues for large numbers of students in a way that will give them any real experience. We reasoned that simulation offers a great deal of potential for this type of skill development, because it offers the opportunity to devise a vocational context for the need to learn these skills and also offers a life-like way to give large numbers of students a way to set up sound environmental experiments with minimal costs.

Simulation

Simulations as learning environments have had a long history of use in education and training and have been based on a variety of theoretical views of learning. Along with increasing computational power, software has increased in complexity so that object oriented systems can now be used to simulate devices of great complexity making use of extensive simulation of this complexity.

The key feature of an educational simulation is that it makes use of a model to represent a process, event or phenomenon, which has some learning significance. The learner is able to interact with this representation and the simulation provides intrinsic feedback that the learner can interpret as the basis for further interaction. The underlying model may be mathematical leading to the generation of numerical results, rule-based with the intention of providing feedback on subjective input, or even context-based in that the learner is placed in a context that simulates a real situation. [Bliss and Ogborn, 1989] have described computer based simulations as programs in which the computer acts as an exploratory tool, supporting a real world activity while facilitating user understanding of the processes involved in complex dynamic systems which may otherwise be inaccessible. Essentially educational simulations are experiential exercises. They are useful wherever real objects or processes are involved in a learning task—they are less dangerous, less messy, and, if well designed, can exactly replicate real world objects and processes. Simulations can not only display aggregated behaviour, illustrating the interactions of objects or processes, but they can also be decomposed into constituent elements which can be manipulated to simulate variation in systems.

Another view of a simulation is that they may be considered as "a special kind of model representing a 'real world' system, governed by a set of rules" [Crookall et al, 1987]. This view is based on models that may be regarded as 'black boxes', with their form and structure hidden from the learner. If the model is hidden, learners are expected to believe in the credibility and authenticity of the model as an act of faith. The model may also be presented in an inspectable form, thus allowing learners to observe how the model operates. In some cases it may even be possible to change the model or at least some of its parameters. A broader view of simulation can be taken if an 'in context' environment is considered as a simulation. In this form, the simulation is designed to place the user in a professionally-relevant context where they can investigate an issue and solve a problem, without necessarily receiving the intrinsic feedback characteristic of the more mathematically or rule-based simulations. While working with such models, the user often comes to see the simulation as a 'real world' in its own right [Crookall et al, 1987]. Such models can be considered as representing real-world systems as either an "in-place-of" or a "bring-to-life" format.

Regardless of the type or format of the simulation, the overriding purpose for simulating systems remains: to provide a learning environment that supports the learner to develop mental models about the interrelationships of variables; to test the efficacy of these models in explaining or predicting events in a system; and to discover relationships among variables and/or confronting misconceptions. Simulations can help learners achieve these objectives by providing a substitute experience for those processes and systems, which by reason of cost, scale, time or risk, would not normally be accessible.
Researching Lake Iluka

The increasing level of sophistication of interactive multimedia applications and their authoring tools provides an incentive for designers to produce software, which fully utilizes the capabilities of such applications. This is particularly evident in many of the simulation-based packages which exhibit a tendency to move away from the earlier reliance on a 'pre-set', 'fixed and repeatable outcome' model, which provided a very simple approximation of the real-world that it was trying to mimic. Within this context, an interactive multimedia simulation package called Researching Lake Iluka was developed based on the award winning package for high school ecology, Investigating Lake Iluka. [Harper and Hedberg, 1993].

The Design Context

The designers exploited the combination of the conceptual power of a prediction model approach together with involvement of the learner in actively constructing knowledge. The simulation allows students to address a typical problem based tender for a government body, research the background to the problem, carry out initial simulated sampling and design surveys and experiments which have the power to detect effects even against the background variability as part of a tender proposal. The learner is then expected to carry out the experiments, collect and analyze the data sampled and to produce a full report.

An authentic context is set through representation of a lake environment with a field study centre and a consultant office. The context has been set at two levels; firstly a coastal lake environment has been simulated to represent a 'real' environment, and secondly, the research design process has been simulated as an authentic task within the lake environment. The package represents a full version of the high school ecology package Investigating Lake Iluka with the addition of the consultant office [Fig. 1]. In addition, the simulation has been designed to employ the real-world metaphors and related resources in such a way that the students used to tools and reference resources in a similar fashion to the way they would use them in real-world contexts, thus reducing the need for complex description and instructions [Hedberg et al, 1994].
<table>
<thead>

<tbody>
<tr>
<td>Gaining background information</td>
<td>User accesses background information by exploring elements within the general parts of the program, the ecosystems and the research resources on common access (video, audio, reference books, etc.).</td>
</tr>
<tr>
<td>Conducting a pilot study</td>
<td>The user can enter the simulation area of the lake (an aerial view) and take a set of readings of any water quality parameter at any number of locations associated with any of the 6 streams.</td>
</tr>
<tr>
<td>Resources for calculation of sample sizes and statistical power</td>
<td>Users can open a statistical methods module within the filing cabinet in the consultant’s desk.</td>
</tr>
</tbody>
</table>
User should not know any more about the system than would be the case in real life

The user is allocated one of three scenarios at random (smell problem, algal bloom, fish kill) and has to identify the source of the problem (which stream(s) and which parameter).

For each scenario, a single cause of the problem is selected at random by the computer (one water quality parameter is at elevated levels in one of the 6 streams)

For each stream, data for each water quality parameter are recorded for each grid cell, embedded behind the aerial photograph. The data were generated to give a particular mean reading and particular standard deviation, with the data distributed randomly among the grid cells.

Thus the data actually obtained by the user depend on (1) the scenario - chosen randomly by the program, (2) the offending water quality parameter, again chosen by the program, and (3) the exact locations of the water quality readings, selected by the user.

A real context illustrating trade-offs

The user acts as an environmental consultant preparing a tender for a large study to uncover the cause of the problem in the lake. The tender has to be competitively costed, yet the proposed study must have sufficient power to detect which water quality measurements are elevated

Unconstrained exploration of the problem

Once entering the program, the user is allocated the scenario by the computer, and the computer then allocates the water quality data to the streams (unknown to the user - but with an encrypted code). Every measurement taken is then costed and recorded on the user’s diskette. There is no limit to the number of readings that may be taken (the cost just keeps going up!).

The user can quit at any time, and return to the same scenario to continue sampling (data and encrypted code taken from the diskette). Otherwise, the user can elect to start a new simulation, whereupon a new scenario and new data set are allocated.

Table 1: A Mapping of Objectives and Activities within the Package

The biological context

In order to redress shortcomings, outlined above, in the training of environmental scientists, both students and professionals, we decided that the following elements were necessary in a simulation package:
1. the ability to gain background information about the system to be studied, as important issues, summaries of existing knowledge and access to relevant current literature;
2. a way for the user to conduct a pilot study, in order to gain information about the amount of background variation in the parameters to be measured;
3. some resources to guide the user in the calculation of the sample sizes needed for the generation of statistical power sufficient to detect a biologically important impact of some disturbance.

In addition, we wanted the simulation package to be realistic at a number of levels including:
1. the user shouldn’t know what the data are until after conducting a simulated sampling program;
2. the context of the simulation should illustrate the real trade-offs, experienced by environmental consultants, between cost and accuracy, and between type 1 errors (false positives) and type 2 errors (false negatives); and
3. the user should be unconstrained in the design of the sampling program, and should therefore be able to explore the problem thoroughly – but with full realization of the real dollar costs of such exploration.
Outcomes of the study

The package has been piloted to the level of tender production with two different cohorts of students, second year Environmental Engineers (n=25) and third year Ecologists (n=15). It is planned to carry out a more extensive evaluation of the package and testing of learner outcomes. These initial studies were carried out as part of the formative evaluation of the package and to support the design of a more detailed experiment. Qualitative data was collected from each student via a questionnaire, student interviews and tutor interviews.

Students report that they experienced no substantial problems nor learning difficulties with the application’s useability, navigation, interface design, media access and access to information about sampling processes and constraints. They also reported that the language used in the package did not pose any concern nor did any lack of any previous experience with computer simulation (25% had no previous experience). Overall most students reported being satisfied and enthusiastic about the use of technology-based media as part of their curriculum. Most students agreed that they would recommend the strategy to future students and, more importantly, would themselves be willing to use the media in the future for similar purposes.

However, two common concerns for many students were the lack of any specific resources describing or modeling the production of a tender proposal, and the lack of a clear understanding of the task that they were to carry out. Even though students were given unlimited time to use Researching Lake Iluka in computer laboratories, they reported being unclear, initially, about how the package related to the assignment task. Despite this concern, the tutor felt that almost all students in both trials were able to produce a tender document that addressed the key issues. Some students immersed themselves within the context and produced reports of a competitive and scientifically sound tender. All except one student were able to develop an adequate statistical model if they request such support. To introduce the assignment task, more context-related explanation will be provided, such as an experimental design tutorial for students weak in that area. Currently, an experimental study is being conducted, which will examine more closely the outcomes achieved, especially the learning gains achieved by working with a set of resources in context compared with similar resources but without the option of exploration nor the simulation of context. This study has shown that the effort involved in building a simulation context and its links to real-world professional skills has been worthwhile. The remaining task

[Tab. 1] maps the package objectives against the activities that were designed to achieve the stated objectives. The simulated consulting experience commences on choosing the consultant office icon. Users are asked to start a consultancy or to continue a previous study. If the user chooses a new consultancy, the package sets up one of three scenarios as the consultancy task and places the appropriate statistically distributed data within the lake environments. If the student does not complete the task at the one time, they are prompted to save their data. When the user continues with an investigation, the application asks for a data file saved from the previous use of the package. The data file has an encrypted header, which is used to set the scenario so that they can continue with the same tender problem and preset data.

For new users, a phone message left on the message systems notifies the user that they should have received a tender document and Lake Iluka Management Committee. Users have access to an Ecological Survey Manual, a filing cabinet which contains 'grey' literature, aerial photographs of the lake, sample tenders and costing ideas, a computer that contains an ecological database, a data logger that gives the user access to data logging in any of the five water inlets to the lake environment and the tender document itself.
revolves around the development of professional skills for those weaker students that might require more procedural help with achieving satisfactory learning outcomes.

Acknowledgments

The authors would like to acknowledge the support of Darien Arthur, Mark Gorodecki and Justine Cox in collecting data and assessing student performance for this study.

Abstract: Since information technologies have developed rapidly, information processing education has become more important and more widely practiced at educational institutions. We are currently designing and developing a computer assisted environment for exercise class of information education processing, focusing on the both assistance for teacher and TAs.

1. Introduction

As information technologies have developed rapidly, information processing education (we call IPE hereafter) has become more important and more widely practiced at educational institutions [Watanabe et al. 96, Kawamura et al. 96]. It is important issue that appropriate IPE is offered to students. IPE is generally classified into lecture and exercise. With regard to appropriate lecture, traditional approaches such as sophistication of educational material and instructional strategy are effective. On the other hand, with regard to appropriate exercise, several new approaches such as introducing CAI system or Teaching Assistant (we call TA hereafter) have been adopted.

Our research work focuses on improvement of exercise for IPE. In the exercise class for IPE, the teacher must deal with additional tasks such as checking student’s exercise activity and so on compared with tasks in the lecture for IPE. Therefore, the teacher generally needs some helpers for the class. As this paper above-mentions, one of the solutions is to introduce TAs into the exercise class. At universities, an exercise form which a teacher and a few TAs assist the students is actually increasing and this technique enhances the performance of instruction in the class.

TAs usually deal with local instructional part of the class respectively and they seldom do their works by grasping the situation of whole the class. Therefore, the above-mentioned solution does not work well, unless the teacher appropriately manage the TAs’ tasks according the dynamic change of the class situation. The arrangement of TAs’ tasks is regard as a new additional task of the teacher by introducing TAs. They generally play roles for assistance of students in the class. However, in general, they are not instructional experts such as teachers. This suggests they do not have enough instructional skill so that it is important to assist their instructional activity somehow.

The above-mentioned analysis requires two kinds of assistance in the class including TAs: one is for the teacher and the other is for the TAs. We are currently designing and developing a computer assisted environment for exercise class of IPE, focusing on the both assistant points. With regard to the former, we are developing a class management application called PROGRESS which monitors the dynamic situation of the whole class and indicate it to the teacher. With regard to the latter, we are developing CAI systems called DAs: Domain Applications for each specific domain. DA is ordinary traditional CAI system but is enhanced to monitor the student’s learning information which the TA use for her/his instructional task. This paper describes the educational features of the both systems based on some viewpoints such as task sharing between human instructors and computer (educational system) and so on.
2. PROGRESS and DAs

For IPE, a new style of the class which a few TAs share the teacher's tasks in order to reduce the loads of the teacher has been increasing. We call the form "class with TAs." The TAs guide students who cannot understand the teacher's instructions. We call such students "student-As" hereafter. On the other hand, the TAs advise students who have understood the contents of class in order to help them stabilize their knowledge. We call such students "student-Bs" hereafter. The ideal style of the class with TAs are following:

- The teacher can command the TAs to assist the students who need assistance immediately.
- If the both students need TAs' assistance, they can get assistance from TAs immediately.

To realize the ideal style of the class with TAs, it is necessary to find students who fall behind and to assist them appropriately. However the class style has several problems and it does not work effectively occasionally. The following are the problems of the class with TAs.

1. Because of number limitation of TAs, they cannot guide many students at once.
2. The student-Bs cannot get advice by TAs while the TAs guide the student-As.
3. TAs' assistance are restricted by the need to monitor understanding and progress status.

To solve the above mentioned three problems, we introduce a CAI system in the class with TAs. We describe our CAI system's features and advantages in the following.

(1) Sharing of tasks with the teacher, the TAs and CAI system
(2) Providing learning environments corresponding to the student's level of understanding
(3) Class management

As for (1), we divide tasks required in the class into two types. One is the teacher or the TAs' task and the other is CAI's task. We can expect the quality of the teacher and the TAs' assistance to improve because of reduction of their loads. For example, the students can ask questions to Domain Application (DA) or the TAs.

As for (2), Most of the students in the classes on information processing have little knowledge about computer and information processing. The students must form, confirm and stabilize knowledge. DA provides three learning environments:

- a trial and error learning environment (TELE),
- a knowledge confirmation drill learning environment (CDLE) and
- a knowledge stabilization drill learning environment (SDLE).

The students-As can study in TELE and CDLE and the students-Bs can study in SDLE.

As for (3), PROGRESS shows each student's progress status, drill marks and ID number to the teacher and the TAs. For Example, PROGRESS shows icons called Learning Status Symbols (LSSs). The colors, shape and motions of LSS differ according to student's progress status. The teacher indicates the TAs to assist students who fall behind appropriately by referring to all students' LSSs in the teacher's machine. The TAs can also guide and advise the student by referring to the LSS in the student's terminal. In addition, DA changes the way of assistance corresponding to the student's progress status according to the LSS from PROGRESS. PROGRESS generates and updates the LSS according to the student's learning status information from DA. LSSs are independent of the contents of class because every DA sends the information in the same form.

3. Summary

We have described a CAI system which assists classes on information processing. Our CAI system consists of PROGRESS and Domain Applications (DAs). PROGRESS assists the progress of class. DA assists the contents of class. Our CAI system reduces the loads of the teacher and the TAs. In future work, we will introduce our CAI system in classes with TAs. We will evaluate our CAI system by considering the reduction of the loads of the teacher and the TAs by sharing of tasks, tasks which CAI system does and tasks which must be done by the teacher and the TAs, and the quality of classes.

Using E-mail to Support a Field-based Reading Course: An Evolution of Who E-mails Who?

Wanda Hedrick
Division of Education
The University of Texas at San Antonio
USA
e-mail: whedrick@texas.net

Stanley H. Hedrick
Director of Student Teaching
The University of Texas at San Antonio
USA
shedrick@lonestar.utsa.edu

In recent years more and more university education students are using e-mail accounts for personal communication with family and friends. It is possible that university instructors can now more easily integrate e-mail use as a means to communicate with these students for course assignments and activities. Computer-mediated communication (CMC) can be used by instructors to meet axiomatic as well as ancillary course needs [Hedrick & McGee, 1996]. This paper presents a summary of experiences over the past two years where e-mail was used for axiomatic needs associated with supporting students in a field-based reading course. The authors acknowledge that the use of e-mail, one CMC tool, in university classes does not present a unique situation. They do, however, offer the experience of two years of manipulating various configurations to find what might work well for this particular instructor in this particular field-based course. The authors hope to stimulate ideas and discussions about the use of e-mail to support field-based courses and to inform research directions in the use of e-mail in field-based education courses.

E-mail Use in Preservice Education Classes

According to a 1995 national study by the Office of Technology Assessment [US Congress, 1995], technology preparation is not currently playing an essential role in the development of prospective teachers. Technology, however, could be logically integrated into teacher preparation programs. Using e-mail as a communication medium between class peers, students and their professors, or students with practicing teachers could provide support for field-based courses. The medium could bridge some of the communication hurdles that can exist in these courses since students are physically separated from their instructors and peers.

CMC may involve the communication of course information such as posting grades or disseminating course materials [Poling, 1994] and journaling [Cooper, 1996]. Additionally, CMC may include deeper levels of communication such as telementoring [Tannehill & LaMaster, 1996] [Traw, 1994], counseling [Poling, 1994] and moral support [Merseth, 1991], and exchanging ideas and information [Hedrick, McGee & Mittag, unpublished paper].

Research further indicates that CMC may facilitate more open and democratic conversations [Meacham, 1994] and questioning between teacher and student [Downing, Schooley, Matz, Nelson, & Martinez, 1988] It may make professors appear more accessible to their students [McComb, 1994]. Additionally, it may encourage engagement of students in course work apart from the regular class sessions [McComb, 1994].
Use of E-mail with Reading Tutors

The education course described in this paper engaged students in field-based tutoring in reading. The course design allowed students to apply the knowledge gained in previous courses to real school settings and real children with diverse needs. Therefore, the bulk of the course experience occurred on an elementary campus and involved a minimum of 30 hours of one-on-one tutoring with elementary reading students. The designated students (grades 1-3) had scored poorly on either a standardized reading test or other indicators such as an informal reading inventory.

The tutors met for three face-to-face sessions before going out into the field. E-mail provided a forum for discussing problems and concerns as well as delivering pertinent information between the tutors and the instructor. The instructor required tutors to e-mail weekly throughout the course with concerns, questions and comments on their experiences. The instructor was available for regular office meetings or phone calls, but e-mail provided the main medium of communication.

Evolution of E-mail Combinations in the Reading Course

For the last five semesters, the tutors have engaged in on-line conversations. Each semester the course instructor adjusted the guidelines in order to encourage increased student engagement, while continuing to make the large class sizes manageable for the instructor. Four different configurations of e-mail dialogue contexts provided over the two-year evolution of the course included: professor to tutor only; professor to tutor, tutor to tutor leader, or tutor to small group of tutors (tutors randomly assigned to groups); tutor to tutor leader, (leaders chosen from initial paper assignment and willingness to help others—group assignment based on knowledge presented in initial paper; tutor to graduate mentor; and professor to tutor and tutor to tutor. Each configuration built on the instructor’s experiences—positive and negative—from the previous semester’s experiences.

Conclusions

The use of e-mail has the potential to build a virtual community of learners where concerns, successes and questions can be shared [Norton, 1995]. Professors can provide support for their students in the field without expending travel time and money to go to the field site. In a large class of undergraduates, a professor could not hear each person talk about their field experiences during the week every week. However, using e-mail, they can. There is great possibility for the instructor to observe student’s misunderstandings and help the student resolve them as the student presents them via e-mail. In this way, the professor provided an “individualized” learning experience difficult to replicate in more traditional class structures. Throughout each configuration, e-mail proved a valuable tool for the instructor to stay in touch with the students and address their needs.

Multi-media Reading Assessment Tutorial Prototype Development

Dr. Wanda Hedrick

whedrick@texas.net

Patricia McGee
Division of Education
The University of Texas at San Antonio
USA
pamcgee@tenet.edu

This project, a work in progress, uses a multi-media platform to create a tutorial that assists preservice education majors in understanding how to assess children in reading. The product will enhance the learning of preservice teachers engaged in field-based experiences. Reading is a high priority in the United States. More frequently local, state, and federal mandates have called upon K-12 schools and universities to improve teachers understanding of appropriate pedagogical practices that will raise the level of reading, particularly in early childhood. A multimedia tutorial can allow just-in-time learning for both preservice education students as well as practicing teachers.

Multimedia and Learning

Hypertext has proven to be an effective medium through which simulated experiences can result in learning [Kahn & Lenk, 1995; Springer & Noblitt, 1995]. "Hypertext enables learners to construct, organize, and convey personal knowledge" [Jonassen, 1992, p. 84]. The more actively engaged a learner is when constructing knowledge, the more likely they are to acquire knowledge than if "they merely use it" [p. 85]. Hypertext can be used to create interactive multi-media instructional activities which support learning.

Multimedia programs provide many cognitive and pedagogical advantages that are particularly crucial in a field-based course. These include:

- user control [Bork, 1991; Marmolin, 1992; Kolb, 1984]
- non-linear organization [Gavora, 1992]
- individualized instruction [Bork, 1992; Kolb, 1984]
- active processing by user [Ropa, 1990]
- multisensory learning [Marmolin, 1991; Jenkins, 1990]

Problems in the real world of the practicing teacher are complex and ill-structured. It is difficult, if not impossible, to predict what problems will be encountered on a day-to-day basis. According to Jacobson and Spiro [1993] hypermedia systems can provide complex and ill-structured contexts that support knowledge construction. Multi-media products can provide a wide range of situations that might occur. When these experiences closely resemble the real world situation, transfer of learning is more likely to occur.

Field-based Teacher Education
Field-based experiences are those in which the preservice teacher observes or is actively engaged in instruction or management of students. Teacher education may vary widely from campus to campus but most programs abide by the premise that field-based experience can contribute to developing skills. Although supported by student testimonials, it is not always substantiated by research [Hollingsworth, 1988; Cruickshank & Amarline, 1986]. There is some evidence that field-based experiences do benefit the novice teacher. In an analysis of perceived learning from a field-based experience, Goodman[1985] found that most students saw these experiences as the most substantive component of their training [Arenz & Appel, 1994].

Preservice teachers often have difficulty transferring what they learn in a class to their experiences in a K-12 classroom. Simulations and case studies can assist students in transferring information by replicating the critical attributes of the authentic learning environment in the schools [Kenny, Covert, Schilz, Vignola, & Andrews, 1995; Thurman, 1993].

**Project Description**

The concept for this project came from *Reading Problems*, a field-based course where preservice teachers deliver one-on-one instruction to children experiencing difficulties in reading. The field-based nature of the course requires students to spend most of the course in the field rather than in class with the instructor. Although there is ready access to the instructor and peers via e-mail, preservice teachers often confront problems while tutoring in the field that require immediate and informed feedback. One major concern for the field-based preservice teachers in this course is diagnosing reading problems. Print materials can not adequately describe these problems since auditory, visual and verbal cues must be analyzed. In absence of a trained professional during the one-on-one tutoring sessions, a multi-media interactive tutorial allows preservice teachers to review common problems and learn to diagnose and respond to these problems. The tutorial provides just-in-time learning as the preservice teacher encounters problems. It can also provide an anticipatory set that makes students more aware of student behaviors when the occur.

Materials development began with a print manual that illustrated a step-by-step explanation and sequence for using five assessment tools. The content came from established and tested reading theories, strategies, and instruments. The manual describes what each tool is, how each looks, how to use each tool, and what the test tells the user. The printed manual has been in use for one year. The second material is a video that illustrates the process of using assessment tools. The third component is the multi-media product that is a combination of the manual and video with an interactive component based on current cognitive processing within computer-mediated environments. The multi-media tutorial assists the preservice teacher in:

- following a reading assessment sequence
- identifying reading problems in K-5 students.
- identifying reading barriers in K-5 students.
- selecting appropriate strategies to resolve identified problems.

The first phase of field-testing involves expert review, followed by observation of undergraduates using the tutorial. Input from these two groups provided the basis for changes made to the prototype.

Collaborative Electronic Library Framework (CELF)

Daniel J. Helm, Jerry W. Cogle, Jr., Raymond J. D'Amore

Digital Libraries Department
The MITRE Corporation
1820 Dolley Madison Blvd., McLean, VA 22102-3481, USA
{dhelm, jcogle, rdamore}@mitre.org

Abstract: The Collaborative Electronic Library Framework (CELF) is an architecture enabling a group of users to build a specialized digital collection organized around a set of topical areas of interest to a community of users. The system provides services to collect network-based information and tools to publish collected information into different topical areas through both manual and automatic mechanisms. Services are also provided to enable users to locate and retrieve useful information from the repository by browse and search techniques. All access to CELF is via a Web browser.

1 Introduction

The Collaborative Electronic Library Framework (CELF) provides an environment for developing an electronic library [Levy et al. 95] using an integrated suite of advanced data processing tools. The system incorporates data collection utilities and categorization services for automatically assigning collected documents into different topical areas. Document contribution and review services are provided to enable manually submitted information to be added to the library. A browse and search subsystem is also provided to enable users to effectively access and "mine" the information repository. Certain concepts of CELF have evolved from the MIDS project [Helm et al. 96], which is an ongoing MITRE sponsored research project involving research and development in the area of information organization and discovery.

One basic principle behind CELF is to provide a framework whereby a group of users can build a specialized collection that is of value to a particular special interest community. A pilot project is underway to test the feasibility of the concept, where a group of participants were selected to build a specialized collection using the CELF framework.

2 System Description

CELF includes two browsable and searchable repositories: a "core" manually generated high-quality collection, referred to as "library," and an automatically generated collection, referred to as "sources." The sources repository contains documents which are collected and categorized by automatic techniques, while the library repository contains documents that are manually published by a group of users. Information contained in the sources repository is collected by recursively harvesting Web documents beginning from manually specified top level URL's, as well as via an integrated search agent [Genesereth et al. 94] that issues canned queries against Web-based search engines to provide a more precise and focussed topic-based collection mechanism. Both the library and sources repositories are available for end-user access. The sources repository also serves as a primary collection that document contributor's will access as a basis for locating documents for inclusion in the core library collection.

Information submitted to the library is initially entered into an HTML form interface, which enables metadata describing a document to be provided, such as URL, title, description, abstract, and topical categories. Documents for which meta-data are entered can be obtained from many different sources, including the CELF sources repository, Intranets, and the Web. In general, only meta-data is actually stored within CELF for all
collected documents. A URL meta-field provides access to the full document stored at the remote location, although an option is provided on the document submission form to specify that a copy be made of the remote document. For copied documents, the URL meta-field points to the local copy and an "external-URL" meta-field provides access to the original remote document. A publishing option is also provided for a document contributor to create a document on their local computer and upload it to CELF.

After a document is submitted for the library repository, it goes into a "pending review" state, where a document reviewer will approve or reject the document using a review interface. Approved documents are periodically added and indexed in the library repository where they are made available to end-users via the browse and search interfaces. Rejected documents are removed from the system. A document reviewer can also add additional comments and/or update meta-data for a document prior to the approval stage.

3 Conclusion

CELF is currently being utilized in a pilot project that includes a group of users who are building a specialized collection focusing on the continent of Africa. The project will run for a number of months and will culminate with a report detailing "lessons learned" as a basis for building a more effective system in the future.

The CELF prototype includes a number of notable features. Among the most interesting are the two-repository approach that is comprised of the library and sources repositories, the contribution subsystem, and the automatic meta-data collection and categorization methods.

Preliminary feedback received during the pilot project has shown that the inclusion of both a manually generated and automatically generated collection proves to be quite useful. Typically, the information content in a manually generated repository can be of higher quality than one that is automatically generated; however, an automatically generated collection can include many more information items. This is primarily due to the fact that automatic techniques enable a larger volume of information to be harvested and categorized. The individual documents contained therein, however, may not necessarily be as relevant to the topical categories to which they are assigned due to recall and precision anomalies [Salton et al. 83] inherent with utilizing automatic meta-data extraction and categorization techniques. The CELF techniques available for enabling document contributor's to easily add documents from the sources repository into the core library repository have also proved to be quite effective. In addition, utilizing the topical profile driven search agent has been a very effective method to improve the relevancy of documents automatically collected for the sources repository, as compared with the technique that harvests documents from entire Web sites beginning with manually provided top-level URL's.

Abstract

There is a great need for improved modalities of instruction for children that have learning disabilities. A new initiative originated by the Touro College called the SECP Project - Special Education Computer Project, a joint project of the Academic Computing Department, Graduate School of Education and a local elementary school, was created to produce software that uses constructivist theories which is centered around the needs of the individual student. This demonstration session will illustrate different software developed by the initiative and the design considerations for the software.

Software Overview and Design Considerations

The software was developed using a software development tool called Toolbook by the Asymetric Corporation. Toolbook is a Windows based authoring tool that is especially useful for creating educational materials because of its ease in combining text, graphics and animation. The design considerations of the educational software were using basic principles of instructional strategies coupled with a teaching philosophy for special education students.

The following where basic design considerations:
- Increased time-on-task
- Increase the relevance and amount of individual feedback
- Performance based progression system
- Pacing instruction to the capabilities of the individual student
- Cooperative learning strategies
- Constructivist learning theories

The SECP Project is on going joint project that has created educational software to serve the special education population. Initial formative evaluations has shown that the students are enjoying using the software and the teachers feel that it is enhancing the educational environment of these special needs students.
Software Description

The software development is based on instructional activities designed by educational experts in the field of education for the learning disabled student. The designer has retrofitted these educational activities to be simulated on a computer. The software development project was performed for instructional activities related to mathematics. The following are a listing of the games with learning objectives.

"Two Up"

Objective: To practice multiplication facts by rehearsing counting by twos, threes, fours, etc.
Grades: Primary through intermediate
Prerequisite Behaviors: Counting by twos, threes, etc.

Bingo Clock Reading

Objective: To give the students practice in associating the time on a clock face, to its written form on a game board, to its spoken form.
Grades: Primary

Fraction for Breakfast

Objective: To help students strengthen their understanding that fractions are subdivisions of whole numbers: also, to build students’ conceptualization of fractions being added together.
Grades: Fourth - Sixth
Hurricanes and Hypermedia:
The Use of Satellite Images in the Study of Rain Characteristics

Abstract: During 1996, coastal North Carolina experienced an unusually frequency of intense weather events, ranging from hurricanes to tropical storms. Due to the unique characteristics of each of these events, the opportunity emerged to analyze the relationship between storm pattern and rain chemistry. A hypermedia system encompassing this data will then be used to help students understand the complex system by which both natural and human-made sources can modify the chemical composition of rain, as well as the resultant environmental and economic impacts of such changes.

Introduction

Coastal North Carolina is subject to a wide variety of weather patterns. Most familiar to the public are the hurricanes and storms which impact the area. During 1996, southeastern North Carolina was subjected to an unusually high number of intense weather events. Among these were two well documented hurricanes, Bertha and Fran, which made landfall in the Cape Fear region less than two months apart. This period also saw numerous intense tropical and coastal storms in the same area. This unusual diversity, as well as frequency of weather events provided an ideal opportunity for the comparative analysis of rain chemistry in relation to storm type and origin, particularly focusing up rainfall acidity as an indicator.

As the availability and quality of meteorological and climatological data has increased rapidly in recent years, so has the complexity of utilizing this data in both research and educational settings. Particularly relevant to the current project is the availability of satellite and radar imagery, combined with ground-based data gathering and forecasting systems. Online and real-time sources for such data are proliferating. The advantage of such media is that they lend themselves to integration into a hypermedia database, particularly one which is not only available online, but comprised of online data from diverse sources, as well. Through implementation of a user-friendly front-end to such data, the complexity of access and use can be minimized, for both researcher and student alike.

The focus of this study, then, was to analyze the chemical characteristics of rainwater in relation to storm type. The resultant data can then illustrate organic factors which can affect the quality of precipitation, as well as anthropogenic factors. In order to facilitate such research, an online hypermedia database encompassing related data and imagery was developed. The database, then, can assist in the educational process by helping students to understand the complex system by which both natural and human-made sources can modify the chemical composition of rain, as well as the resultant environmental and economic impacts of such changes.

Methodology
Data gathering focused upon chemical analysis of rainwater and storm type classification. Rainwater was collected using an Aerochem metric wet-dry sampler. Analysis was performed within two hours of collection, and included measurements of precipitation amount and pH, as well as hydrogen ion, non-seasalt sulfate, and nitrogen concentrations. Storm classification was based upon local climatological data [NCDC 1996] [NOAA 1996b], National Weather Service bulletins [NOAA 1996b], synoptic weather charts [NOAA 1996a], GOES satellite images [NOAA 1996b], NEXRAD images [WSI Corp. 1996], and synoptic maps with a satellite overlay [Purdue University-WXP 1996]. The richness of the dataset, as well as the abundance and diversity of related local and remote electronic data, necessitated the development of a hypermedia database in order to render it usable and manageable. This created an opportunity to integrate these sources into a computer-based hypermedia database accessible via the Internet on a World Wide Web browser, such as Netscape Navigator [Fig. 1].

In this project, in addition to rain chemistry data, the plethora of imagery assisted in the investigation and presentation of the various relationships. In essence, the networked hypermedia database provided access to necessary data in a variety of media formats (including text, graphics, and photographs) which were linked through a simple "point and click" interface. The advantage of such a hypermedia database format over traditional non-electronic media was that it allowed examination of the data in a nonlinear method which did not predispose an approach to the data in a predetermined manner. This is true whether the user is a researcher or a student.

Discussion

The results show that acidity of precipitation from coastal storms, tropical storms, and hurricanes is not significantly different. However, local thunderstorms have been shown to be significantly more acidic. If we are to consider that anthropogenic sources, or those with human-made origins, of sulfur dioxide and nitrogen oxides in the eastern United States exceed natural emissions by at least a factor of 10 [Lindberg 1982], then we have a basis for understanding these results. High levels of these sulfates in local thunderstorms should therefore lead us to implicate human activities in acid precipitation, particularly those derived from local sources.

These results of this project have implications not only for research, but also for education as well. This is especially true since a primary source of acids can be traced to human activities. Therefore, the hypermedia database which was developed can be used not only as an analytical tool, but also as a teaching tool. Its function can then be to assist students in fully understanding the influence of human activities upon acidity in precipitation, through illustrating the differentiation of storm type in relation to acidity levels. However, due
to the complexity of this concept, as well as the diversity of data which illustrates it, a hypermedia database was essential. To this end, the system which was created and utilized embodied the essential aspects of an educational hypermedia system: 1) knowledge presentation, 2) knowledge construction, and 3) knowledge representation [Nelson and Palumbo, 1992]. In addition, the availability of the database through the World Wide Web not only widened the sphere of accessibility to the data, but also provided opportunities for collaboration. It is for these reasons that hypermedia is rapidly arising as a primary approach to the management of complex and related data due to its efficacy in providing a basis for new modes of thinking and communication [Conklin 1987].

New Material Delivered in a New Way

During the spring quarter of 1998, we embarked upon a newly-created course entitled: "The Literature and Culture of Continental Europe after World War II." Though the course did not draw as much attention from institutions within the University System of Georgia as we originally hoped, it did attract one student at Waycross College in Waycross, Georgia, who decided to join the course via the GSAMS (Georgia Statewide Academic and Medical System) Network [http://www.gactr.uga.edu/GSAMS/gsams.html], thus allowing us to incorporate the telecommunications technology into our course delivery methods.

The course gives the on-site and distance-site students an exceptional opportunity to study contemporary Europe. While the main focus of study is the literature of both Western and Eastern Europe, the course also examines the contemporary history and politics of the European continent, focusing on post-war Germany and France as well as on communist and post-communist countries, such as Russia, Poland, and the Czech and Slovak Republics. Because so much of contemporary European literature is linked inextricably to its cultural milieu, this course explores Europe's complicated geography, its religions and religious denominations, its many languages, its economic development, and its popular culture.

The course format is that of a chronological survey which moves back and forth not so much in time, as from West to East - in order to demonstrate the deep, resounding effects of life before and behind the Iron Curtain. The course awards ten-credits and is team-taught - with Ms. Cooke-Plagwitz teaching the segments on Western Europe and Ms. Hines teaching those on Eastern Europe. Both instructors utilize hypermedia and multimedia teaching strategies, including, but not limited to, an online (hyperlinked) syllabus, interactive hypermedia assignments for students, multimedia/computer-enhanced presentations, e-mail and online chat cultural exchanges, CD-ROMS, films, audio recordings, and distance-learning (telecommunications) technology. The course also includes an optional travel component to central Europe, which serves both to unite distance learning students enrolled in the course as well as to underscore the major themes and issues of study.

Why Teach Culture?

The rationale behind the development of this course finds its basis in the Georgia Board of Regents' initiative to "internationalize" the curriculum of the state's educational institutions. The introduction of this course constitutes a vital step in this direction. In order for graduates to be marketable in today's increasingly multicultural society, they must be exposed to cultures and ideas other than their own. Indeed, one of the primary goals of this course is to spur students into recognizing their own ethnocentric perceptions regarding the literary and cultural canon by introducing them to the major themes and works on the contemporary literature and culture of a number of Western and Eastern European countries.

Technological Applications in Teaching Literature and Culture

Technology plays an integral role in the course. Not only have the instructors developed multimedia presentations and hypermedia syllabi, but students are developing and contributing to a course Web site as well as taking part in e-mail and online chat cultural exchanges. A good deal of timely resources and materials, such as the speeches of Vaclav Havel and of Günter Grass, are available on the World Wide Web and have been integrated into the online syllabus. Other offline technology is involved as well, including
films by notable directors, such as Costas Gavras and Krzysztof Kieslowski; CD-ROMs on various poets and writers; and audio recordings of selected speeches and readings.

Course Delivery and Structure

As the course earns the student ten credits (twice the number of the standard single-quarter course), the class meets Monday through Thursday from 1 p.m. until 3:30 pm (twice the classroom time as the standard single-quarter course). In order to allow the instructors to cover their topics as fully as possible, the classes are set up so that both faculty members alternate teaching weeks: one week on Eastern Europe with Ms. Hines, the next week on Western Europe with Ms. Cooke-Plagwitz, and so on. The first course unit, entitled “1945-1955: Postwar Concerns,” begins with a reading of Günter Grass’ novella, Cat and Mouse, and a discussion of an anti-Nazi satire on post-World War II Germany. In the following week, students learn about the political and social concerns of Eastern Europe in the same time period with Heda Margolis Kovaly’s Under a Cruel Star.

The same format is followed throughout the ten-week course, covering the following units: “1955-1965: Communism and the ‘Communist Threat’”, “1965-1975: Pacifism and Revolution”, “1975-1985: Disco to Punk”, and 1985-1995: Reunification and ‘Open societies.’” During their course of study, students are encouraged to choose an author of a topic of particular interest to them and to do extensive research on that topic. A cooperatively constructed course Web site constitutes a common final class project to which all participants contribute with their essays and with any interesting hyperlinks found during their research. Those students who participate on the Central-European tour are also encouraged to contribute photographs and journal entries made during their travels to the Web site.

Variations on a Theme

The course format encourages informal online discussion among the students as well as between the students and the instructors. Web-based forms prove to be useful forums for discussion of many of the works and concepts introduced to the students during the study. This course calls upon the special areas and interests of the faculty members involved. Because the topics are so specialized, it is highly desirable that the course be team taught in order to present these various themes and works most accurately and effectively. In future incarnations of the course, guest lecturers will underscore this commitment as well, and expand the collaborative effort. The course is transferable through humanities faculty members who have knowledge of contemporary European literature, art, music, language, etc., and lends itself very easily to a distance-learning format.
Computer Social Interaction and Individual Cognitive Growth: Vygotsky’s Role of Language-Both Social and Private Speech

1. Introduction

Constructivism is a moderately new term used to define an eclectic collection of theories that include ideas from the 1920/1930’s (Piaget and Vygotsky), 1950/60/70’s (Bruner and translations/interpretations of Vygotsky) and the 1980/90’s (Witrock and Duffy). The glue that forms these varied theories into constructivism is the belief that individuals actively construct knowledge by striving to solve real problems, and that they often do this in collaboration with other learners. In particular there have been many interesting writings comparing and contrasting the early work of Piaget with the writing of Vygotsky.

Although Lev Vygotsky was a peer of Jean Piaget, political issues kept most of his writings buried in Russian libraries until the last quarter of this century. This makes the “dialog” between these two psychologists anecdotal at best.

Among current researchers, it is widely accepted that Piaget underestimated the role of private speech in cognitive development. This paper presents the position that the two theorists were not as much separated by their differences on “egocentric speech” and “private speech”, but rather linked by their ideas that knowledge is constructed via social collaboration. They both believed that the relationship between individual and social environments was much more dynamic than the simplistic division we often accept. Vygotsky believed that the very boundary between social and individual must be brought into question. This is why he stressed his well-known idea of a “zone of proximal development”. He defined this as the distance between the level of actual development and the more advanced level of potential development that comes into existence in communication between unequal partners. He hypothesized that the lower ability individual could partake in more advanced activities that would be above their competence when working alone.

2. Approach

This paper looked at what we could learn from the views of these men (especially Vygotsky) and how we might apply them in a practical manner in the learning environments of computer-based lessons with young
children. A review of current literature was combined with a basic quantitative study to determine if private/social speech affected kindergarten student's task performance on microcomputer based problem solving activities.

Earlier studies have shown that young children's private speech facilitates their performance, but none could be found testing these results in the context of computer assisted tasks. Included were hypotheses to determine: (1) variations in social/private speech (s/ps) between the keyboard (interface) possessor and the paired partner and between the more capable and less competent partner; (2) relationship among frequency of s/ps, task difficulty and improved task performance as related to keyboard possession and computer competency; (3) the effects of task repetition on these activities.

3. Summary

The social collaboration beliefs of Piaget and Vygotsky continue to be important in our study of children's success in a computer environment. Although the study provided no startling results, it did confirm the relationship of private speech and task performance. It also provided some interesting insights into the effects of computers on the use of private speech. In particular we need to further study the effects of various roles in a cooperative learning situation. The keyboard possessor appears to be more inclined to use private speech than his/her partners. This private speech activity may have led to the higher task success rate of the keyboard possessor (as well as the effect of "hands-on" benefits). It was also interesting to note that the keyboard possessor increased the use of private speech at subsequent sessions on the same software task. One could postulate that the keyboard possessor needs less external input as s/he becomes more competent and turns to private speech for further cognitive development.

Although current thought supports the idea that pairing allows for more opportunity for collaborative learning, future researchers and teacher practitioners may want to develop strategies to control this "keyboard-control" phenomena by rotating roles and stimulating social speech activities in multi-session assignments of computer teams. This may help create more level improvement on task success. Simply putting two or more students at a computer with the idea that "teams" will learn together may lead to very uneven results when individual improvement on task is charted. The findings demonstrate the importance of educating parents and teachers about the positive, self-regulatory function of private speech. It also accentuates the fact that computers and networks have created new learning environments that are slowly replacing older settings. The relationships among a student, his/her peers, and the electronic "virtual peer" (computer) must be further studied and the information disseminated; Vygotsky and Piaget told us so, over 60 years ago.
Coupling Physical Artifacts and Abstract Representations

Eva Hornecker
artec, University of Bremen,
Bibliothekstr. (MZH), Postfach 330440, 28334 Bremen, Germany
eva@artec.uni-bremen.de

Most new learning media in classroom tend to separate concrete handling of artifacts from abstract, cognitive learning, as books did all along. Physical experimenting gets reduced for time and cost reasons. Yet physical models play an important role for cognition and communication. Sensuous experience of objects can contribute to conceptual understanding, helps to gain tacit knowledge. On the other hand computers are useful tools for analysis, simulation and animation. They can help us to understand the abstract and complex. Our approach aims at bridging those two modeling worlds: the real world of physical objects and the virtual of signs and images. The project described here will show the feasibility and the possibilities of a computer supported learning environment for the subject of pneumatic circuits in vocational training.

The name „Real Reality“ was coined around 1993 [Bruns et al 93] in contrast to „Virtual“ Reality. The concept [Bruns 93] bases mainly on a tight coupling of real artifacts with virtual counterparts. The real objects are either models of something (e.g. bricks symbolizing houses) or the thing itself. They are used to construct a system on a workspace. Users operate with sensorized hands (DataGlove) or in a scanning environment with these objects while the computer tracks and interprets their actions and gestures. It synchronously assembles a corresponding virtual model, including the dynamic actions of the users hands. Virtual objects may contain further information necessary for simulation or for a help-system. Both physical and virtual system can be used to experiment with. The users are able to freely change between operations on real and virtual objects. In some application areas it is even possible to export control signals generated by the virtual into the physical system.

The envisioned learning environment [Fig. 1] consists of a traditional experimental workbench for pneumatics, enhanced with computer-media. This includes virtual models and multimedia elements. The students build a physical circuit, directing their attention on the actual task, tracked by the computer. Afterwards the virtual model can be used for simulation and further investigation (animation of inner behavior of elements) or for searching errors and optimization. During assembly the computer might also be used to give advice and add explanations on elements. Such commands can be given with gestures or spoken, thus staying in the „real assembly“ mode or space. In order to let students stay close to the workbench and make the desktop computer as obsolete as possible, projection and audio techniques are used for computer output and feedback. If the subject of electrical-pneumatic circuits is taught, the students can write programs on the computer, which not only drive a simulation model, but also control real devices, thus closing the circle: back from the virtual to the real.

In vocational training, some students have a special need to grasp physical circuits in order to get a better understanding of abstract sign-languages. Our system provides visible, instantaneous links between the concrete and its abstract representation, thus helping to abstract, to translate, and to form mental concepts. Concrete artifacts offer an additional possibility to gain theoretical knowledge based on sensual-concrete experi-
ence, as physical and intellectual grasping interact. These ideas are based on Piaget and Aebli. As many technical processes in modern production have lost their former material relation, it gets harder for workers to experience physical properties and to acquire tacit knowledge of the still existing material background. Providing this experience in education & training (encouraging students to experience the obstinacy of the material) may substitute somewhat [Böhle 91]. Our system supports different experimental learning modes within the context of action oriented learning. Concentration on a complex task and physical work space constitute a common goal and a social space for collaborative learning. Students can see each other, interact freely, discussing ideas.

As our project is a feasibility study supposed to explore possibilities and problems, we intend to implement only part of the described. A following European Union project will develop a commercial version, using image processing. Because our DataGloves with electro-magnetic tracking don’t allow us to handle metal we work with wooden bricks as graspable symbols [Fig. 2]. Up to now we are able to build a model of digital or pneumatic circuits. This is tracked by our Virtual Reality system. The resulting scene file can be processed and simulated by our extended version of the freeware simulator DigSim, PneuSim. Ongoing work includes an interface to the commercial simulator FluidSim-P ((C) Festo-Didactic). We developed an on-line connection, sending each event in the physical model to the simulator. This enables asking for help on elements or starting the simulation by gesture. Our work also consists of the didactical foundation for such learning environments and of HCI-issues. What does natural handling mean? Which kinds of multimedia add-ons make sense?

Another project demonstrates the power of the Real Reality concept in the domain of material flow, using small conveyors to model production plants. The conveyors and a robot can be programmed with Programming by Demonstration, manually teaching distribution rules and paths. [Schafer et al 97].

Our goal is to enable people to change fluidly from hand manipulation to abstract work and vice versa. Computers and their interfaces should assist, not get in the way. In the main application areas construction and modeling are central tasks, either in learning or working contexts. The concept can also be used to combine physical and digital planning tools. Related work stems mostly from Augmented Reality and Ubiquitous Computing research, for example [Fitzmaurice et al 95], [Ishii, Ullmer 97], [Resnick 93] and [Suzuki, Kato 95]. In contrast to all of these we do not sensorize the objects and keep a clear division, yet close coupling between physical objects and their virtual twins, between real system and virtual addition.

NTT Information and Communication Systems Laboratories, Japan
Tel: +81-422-59-7996, E-mail: hoshide@isl.ntt.co.jp

1. Introduction

In the field of education, interactive simulation is known for an effective tutoring facility. There are a lot of Intelligent Tutoring Systems (ITSs) on the World-Wide Web (WWW). But, so far the study of a simulation environment in an ITS on the WWW has been superficial. So, we proposed an interactive simulation environment in an ITS on the WWW.

We have developed an ITS on the WWW called CALAT [Naka 95][Naka 96]. The system has a server / client architecture. The CALAT server is implemented as a Common Gateway Interface (CGI) process executed typical WWW server. An ITS process on the server (ITS-S process) employs overlay student model. One ITS-S process manages one student process. A student requires typical WWW browser to use CALAT courseware. Two types of learning material, explanation and exercise are available in the CALAT courseware. First, the CALAT server provides the client with explanation pages for a student to learn new information. Next, an exercise page is downloaded to check whether the student has learned.

2. Design Issues for Simulation Environment

Interactive simulation is an important tool for helping the student to acquire procedural knowledge. But in some cases, on-the-spot experience is difficult to obtain. Examples in NTT Company training include operating procedures for switchboards and transmission systems. So, we are aiming to create, by means of the simulator, virtual environments for such training.

Certain design issues require resolution for interactive simulation in an ITS on the WWW like CALAT.

(1) The function of the simulation

The following functions are necessary for the simulation.

(a) Presentation of sample operating procedures
(b) Provision of a simulated environment in which a student can practice operating procedures
(c) Provision of a simulated environment with appropriate advice

(2) Object-oriented approach

It is important to re-use a simulation environment and other CALAT courseware elements. So, we use object-oriented methodology [Naka 98].

(3) Function distribution between client and server

In creating the simulation environment, it is necessary to examine the distribution of the functions between client and server. The trade-off between the distribution of the functions and the response time is an important concern. For example, if the simulation environment is deployed on the client, the initializing time to download the simulation environment on the client is long but response time under the simulation is short.

(4) Use of multimedia tools for designing graphical user interface components

In designing the graphical user interface (GUI), it is preferable to use multimedia tools currently on the market.

3. A Simulation Environment in CALAT

A simulation is placed as an exercise in the CALAT courseware to provide a student with a simulated environment in which he/she can practice operating procedures. The behavior of the simulated environment is described as a state transition model (STM). According to STM, the input event by student's action triggers the state transition and output
action takes place.

This environment is deployed on the client and consists of three components, a GUI component, an STM engine, and a subset of the ITS process.

To make the response speed fast, an STM engine written in Java/JavaScript is implemented on the client [Touhei 97]. An STM engine connects a GUI component by using the liveconnect function in the Netscape Navigator [Netscape]. Thus students can use a simulation environment with quick response and courseware developers can design the simulation GUI using the multimedia tools that support the liveconnect function.

In this simulation environment, there is no communication between the client and the server during the simulation and ITS-S can not monitor the situation of a student. So, even if a student does not understand the operating procedures and simulation is wastefully prolonged, the ITS-S can not interrupt the simulation. This problem is solved by deploying a subset of the ITS process in the simulator on the client (ITS-C process).

The ITS-C process monitors the state transitions in the STM engine. When the sequence of the student's action goes into the wrong direction or comes to impasse, the ITS-C process interrupts the simulation and helps the student. For example, the ITS-C process asks the student whether he/she wants to stop simulation.

The protocol of the simulation has three sessions: Start, Learning, and Ending.

Start session: First, a student connects with the CALAT server through the WWW browser, and the WWW browser downloads a simulation environment from the ITS-S process.

Learning session: The input event by the student's action is sent to the STM engine through the GUI component. The STM engine checks whether the input event is correct and changes the state. The ITS-C process monitors the state transition in the STM engine to interrupt the simulation timely. Based on the STM, the STM engine controls the GUI component. These procedures are done on the client with no network traffic. The feature of this simulation environment is a point that the ITS-C process can help the student under the simulation.

Ending session: There are two ending patterns. In one, the final state is reached and the simulation is finished. In the other, the simulation is stopped by the ITS-C process or the student. In either case, regardless of whether the student is able to achieve the goals of the exercise, the ITS-C process sends the results to the ITS-S process through a network. The ITS-S process determines the next explanation page based on the result of the exercise.

In the CALAT courseware, the ITS-S process monitors the student's situation while he/she is studying an explanation page, whereas the ITS-C process monitors the student's situation while he/she is studying with the simulation.

4. Conclusion

We have described an interactive simulation environment in CALAT, an ITS on the WWW. Our proposed simulation environment, which is deployed on the client, consists of a GUI component, an STM engine written in Java/JavaScript, and a subset of the ITS process. The advantages for the student are quicker response and helpful advice during the simulation. Courseware developers can design simulation GUI using the multimedia tools that support the LiveConnect function. In future work, we plan to adapt student's mistakes and give appropriate advice that corresponds to them. For example, an subset of the ITS process in the simulator shows next correct operating procedure.

A Survey on the Acceptance of Information Technologies in the Continuous Education

Stephanie Hübe, University of Cologne, Germany, huebe@online.de

Jens Lüssem, Institute of Computer Science III, University of Bonn, Germany, jens@cs.uni-bonn.de

Stephan Sunderkamp, Institute of Computer Science III, University of Bonn, Germany, suenderk@cs.uni-bonn.de

Introduction

The motivation of the learner is essential for the success of learning. In case of the use of modern information technologies in further education we should pay attention to the acceptance of these technologies [Hitzges et al. 1994] together with a good instructional and technical design [Cremers, Lüssem and Sunderkamp 1997]. The acceptance of modern information technologies as well as motivational aspects have a great impact on the design of computer-based learning environments and vice versa.

In this paper we present a broad survey of the acceptance of information technologies from the point of view of participants of traditional further education seminars. The aim of this survey is to investigate the interdependence of the three factors mentioned above.

The Survey

The survey was carried out in order to find out to what extent new information technologies are accepted by participants of further education seminars. The profession of gas and water engineering was chosen for the collection of data, because the group of people working in this field is especially confronted with shorter and shorter innovation cycles and has therefore a high demand for further education. At the same time computers are not the actual subject of this profession, but are used at the most as tools or as components of other technical products. Most of the interviewed persons are graduated engineers and work in upper-middle positions in companies in the supply sector or work as self-employed engineers.

During the survey 394 participants of traditional further education seminars were interviewed on their opinion concerning the use of new technologies in further education. The data were gathered by means of a questionnaire.

15% of the interviewed persons use a computer only rarely on their job, whereas 64% use it frequently. 75% of the engineers neither have an e-mail-address nor access to the Internet. The age groups 30-39, 40-49 and 50-59 come to a proportion of approximately 30% in the survey. The age groups 20-29 and 60-69 are relatively small with approximately 5%.

![Figure 1: The overall judgement on the use of computers in continuous education](image-url)
62% of the interviewed persons generally approve of the use of computers in further education, 26% are indecisive and only 10% disapprove. Figure 1 shows the correlation of the age of the interviewed persons and their judgement on information technologies in further education seminars.

60% of the interviewed persons support a supplementary use of computers (CD-ROM, Internet) as a means of preparing future lessons or to internalize topics of preceding lessons. 32% would approve of computer-based learning environments as a substitution for parts of a traditional further education seminar, whereas only 8% would support a completely computerized seminar without any teacher (see figure 2).

![Figure 1: Correlation of age and judgement on information technologies in further education seminars](image)

**Figure 2: Acceptance of different computer-based training scenarios**

As a conclusion of this part of the survey can be drawn that most of the interviewed persons do not want to dispense with the face-to-face communication with teachers and other learners. This might be explained by the assessment that an increasing replacement of traditional seminars by computer-based learning environments causes a neglect of the social needs of the participants of further education. 47% of the interviewed persons fear that social needs might be neglected if computers are to be used in further education. 27% cannot imagine any change resulting from this, whereas 21% think that the use of computers might even help to improve social contacts. It is important to note that for most of the interviewed persons the personal contact to the teacher is regarded as indispensable as far as queries are concerned. Contact to other learners contributes to the learning success as well. Furthermore, informal technical discussions that occur at traditional further education courses are regarded as another important source of knowledge.

**Conclusions for the Design of Computer-Based Learning Environments**

As we could derive from our survey, computer-based environments used in further education should be designed especially for the preparation of traditional courses and for the repetition of subjects already learned in the course. The integration of communication facilities should be emphasized in computer-based learning environments. We have seen that most of the interviewed persons have a positive attitude towards computerized parts of further education seminars. We should use this motivation to build learning environments that fulfill the requirements we have mentioned above.

Virtual Collaborative Working Environments

Kenn Hussey
Broadband Networks, PO Box 3511, Station C, Ottawa, ON, Canada K1Y 4H7
khussey@nortel.ca

Tomasz Muldner
Jodrey School of Computer Science, Acadia University, Wolfville, NS, Canada B0P 1X0
solid@acadiau.ca

Introduction

In this short paper, we present a specific example of a studio classroom at Acadia University, which we believe applies equally well to any collaborative working environment. Consider a classroom in which the instructor and all participating students have access to networked computers and can interact, for example, through the use of downloadable files, an email facility, and a projector which can display images from a single computer. The instructor is a member of the Faculty of Computer Science, and the students are undergraduates in the Bachelor of Computer Science program and enrolled in the introductory programming course, COMP 1013. The students are organized into groups of four to facilitate discussion of problems posed by the instructor. We expect that the following hypothetical interactions would be possible:

- **Instructor to student**: The instructor gives a student exclusive access to the projector, perhaps revoking other students’ access to the projector.
- **Student to instructor and students**: A student shares her or his group’s solution to the problem with the rest of the class by displaying it on the projector.

TASK Framework

Building on concepts developed in previous research [Hussey & Tomek 1996], we introduce a general framework to support collaborative work, called TASK, which stands for Tools, Actors, Scopes, and Keys. Designing a framework to model a specific problem is somewhat similar to designing an object-oriented computer program; it consists of identifying the underlying objects and interactions between these objects. The collection of all objects relevant to a given problem might be called a problem’s domain. In our electronic classroom, the domain consists of objects such as the following:

- students and instructors
- faculties, programs, classrooms, and groups of students
- files, email facilities, and projectors
- objects providing access restrictions

In modeling interactions between these objects, it is useful to consider different kinds of objects. The TASK framework consists of four basic kinds of objects - actors, scopes, tools, and keys. In the following sections we briefly describe each of these concepts, and how they can be used as a model of our case study. Note that TASK is a virtual setting, defined by the learning activity rather than by the boundaries of a physical classroom.

Actors

Collaboration occurs when two or more individuals engage in actions that are directed toward a common task (hence TASK). As such, we use the term *actor* to refer to the individuals who collaborate within TASK. An actor, then, is the embodiment of a physical user and represents an entity involved in performing an action, for
example a student, an instructor, or a programmer. In our electronic classroom case study the students and instructor are examples of actors. The user embodied by each actor has access to a computer, and the computers are networked. The resulting interactions between actors are direct if no intermediate object is involved, and indirect if they involve a mediator object.

Scopes

We introduce the notion of a scope as a frame of reference for the actions that actors engage in as they collaborate in TASK. An actor enters a scope when it takes on a particular role associated with, or engages in some action bounded by, that scope. Conversely, an actor exits a scope when it is no longer interested in the actions that take place there. As a result, scopes are dynamic rather than static in nature - as actors enter and exit a scope, this scope binds, or holds a set of actors interacting within its boundary. Acadia University, Faculty of Computer Science, Bachelor of Computer Science, and COMP 1013 are examples of scopes in our electronic classroom.

Tools

In describing indirect interactions between actors, it is useful to introduce the concept of a tool. Tools are the primary means by which actions are performed in TASK and, as with actors, they are bounded by scopes. This has two consequences. First, the actions provided by a tool can only be performed by actors bounded by the scope in which it is held. Second, only the actors held by this scope are aware of the results of the performed actions. Another aspect of tools is that they can be taken or dropped by actors, thus providing a means for their displacement between scopes. The downloadable files, email facility, and projector are examples of tools in our electronic classroom.

Keys

Clearly, unrestricted access to all tools by all actors may not be desired, and therefore we define the notion of a key to facilitate access restrictions within TASK. Keys are assigned on a per-action basis; that is, in order to perform a locked action on an object, an actor must hold the key with which it has been locked. Actions can be locked or unlocked, and keys can be granted or revoked, dynamically according to specific permission or privilege needs. The first interaction described above illustrates the use of keys in TASK.

Discussion

The design introduced above can be used to describe various scenarios of teaching in an electronic classroom. However, the TASK framework is quite general; the case study presented here was meant to show its usefulness within a specific domain (education). Other applications of TASK range from simple ones such as file permissions on a Unix operating system, to rather complex ones such as collaborative work in a software development organization.

1. Introduction

Teaching writing in communication courses has normally been done in reporting laboratories. This allows immediate interaction between students and instructors. However, this is only possible if the situation allows students to meet instructors regularly. And this do not happen all the times, especially when there is a shortage of instructors or the instructors are a distance away from the institution. The Information Age on the other hand offers opportunities for doing education in new and creative ways. Technologies are capable of bridging gaps of distance and time to meet the demands for education.

2. Background

An example to this is the teaching of writing courses in the Faculty of Communication at the University of Sarawak in Malaysia. Apart from being new (started in 1992), the university has the disadvantage of being a distant away from mainland Malaysia. Sarawak is situated on the island of Borneo, separated from the mainland peninsular by the South China Sea. By flight, it takes about one hour forty-five minute to reach Sarawak from the peninsula. Shortage of instructors forces the university to engage instructors from the peninsula. However, it is too costly for the university to fly in the instructors every week. Hence, instructors from the peninsula could only fly to Sarawak once a month. Under the present economic crisis, the frequency of visit to the university may even have to be lessened. However, with the advent of new technology, the teaching of writing courses has been made possible despite these constraints. Students, for example, could communicate with their instructors through e-mail. Communication ranges from instructors’ request for story ideas to students’ submission of reports. Assessments of student performances are carried out regularly with a final test at the end of the semester.

This paper outlines the outcome of a study that analyzed the practicality of utilizing new technology in the teaching of writing courses in the context of giving instructions from a distance. It outlines the advantages of learning/teaching writing through the new learning environment. It also suggests steps for improvement and advancement.

3. Findings

To aggregate information from the students a survey questionnaire was designed and constructed. The survey consisted of seven open-ended questions soliciting in-depth documentary, description, and opinion from the students. The effectiveness of the delivery system was evaluated through a self-conducted survey in February 1998, after the students had gone through the system for two semesters. Learning from the experience of Desmond Keegan [Keegan 1995], the e-mail delivery model was evaluated from five aspects:

- Academic Excellence: Could academic excellence be achieved? Was it possible to produce a rigorous university-level teaching and learning system by e-mail
• Access: Did student get access to facility at convenient times?
• Quality of Learning: Would students be hampered with their learning by the absence of lectures from a physically present lecturer?
• Results: Would students be confident of passing? Would their assignment and final examination results be as good if lectures had been done in the traditional manner?
• Status: After the experience would they feel the same format could be applied to other subjects?

2.1 Overall Perception of the system

Students have mixed opinion about the delivery system. While the system has the advantage of speed and not having to have the instructor physically around, some students posed technical problem as a major hindrance. Some of the responses include "Faster but difficult to get respond and" Technical problem.

• While a few students felt that it was possible to achieve academic excellence, the rest were uncertain. However, none “disagree” or “strongly disagree.” One respondent said: “I am not sure but I think many problems need to be solved first before achieving this.” Technical problems were mentioned, in particular “servers continually down.”
• One of the problems faced was that the students felt that accessibility to facility was a little bit restricted. They were not easily accessible at convenient times. One student said: “You will have to book the computer if there are many users”
• However, despite the problem of accessibility, students generally felt confident of passing. One of the response was: “Yes, I’m improving from the exercises done”
• On assignments, students generally prefer works given in class. A student said: “I would prefer to have exercises during class” and “Instant practices is needed. take home assignment should come along to enhance skill.”
• Students felt that their final exam result would be better if lectures had been done in the traditional manner. One of the students explained: “Traditional manner helps in understanding.”
• On the question of whether the same format could be applied to other subjects after their experience, students generally approve the idea. “Certainly, one thing it can cure the boredom and tiredness. A weekend of lectures is not enough to train the students.” However, one student had some reservation, “It depends on what subject it is.”
• On the quality of learning, students felt that having few face-to-face lectures hampered learning. “Sometimes we need direct guidance and depending on e-mail is not enough.”

3. Conclusions

A few conclusions could be made from our experience of introducing teaching news writing courses with the help of e-mail.

First, news writing courses could be taught with the help of e-mail provided face-to-face meetings support them. While students need personal guide, additional exercises through electronic means provided students with additional opportunity to sharpen their skill. Students were happy by the fact although the instructors were not around they could still learn.

Second, to provide efficient communication channel, technical problems need to be solved. While new technologies promise speed, students were hindered from communicating because of technical problems such as server being down repeatedly.

Third, shared facility must be sufficient to cater everybody’s need. Students were facing the problem of getting access at convenient time. Problems raised include having to book for computer time when there are many users.

1. Introduction

Japan and Germany both are well networked industrialized countries. Their educational systems though are highly regulated and conservative with respect to new content. Internet technology is a great challenge for their respective educational systems. Introduction of Internet meets with calls for practising more forms of problem centered instead of subject oriented learning. In both countries consciousness is rising, that children of today have to be better prepared for individual learning and acting, have to be aware of environmental issues, and have to be able to learn and communicate under a global perspective.

We will present some of the basic elements of our different educational systems, identify some of the most common patterns of Internet utilization in schools and then try to point out differences in approaches as well as common solutions to the problem of using Internet for problem centered learning. In conclusion we argue that the introduction of Internet technology into the classrooms has already fostered elements of problem centered learning in our countries and will further speed up this process in future.

2. Problem Centered Learning and Internet in Japan

2.1 Outline of problem centered learning

Problem centered learning is going to be introduced officially by the Japanese Ministry of Education from grade 3 to grade 12 in 2003. It is gaining attention because of necessity of real experience, an international way of thinking, environmental education, information literacy and so on. Up to now students have dealt with these topics in different subjects, but fields like environmental education or information literacy have come to include a lot of content that goes beyond the capacities of each of these subjects.

2.2 Some educational projects with the Internet in Japan

As for the Internet, The Ministry of education plans to connect all schools to the Internet by 2003. At the moment all schools rely on commercial providers or universities. Besides each school is trying various ways to use Internet for children's learning, there are some nationwide projects of collaborative learning on the net like 100 schools project [http://www.edu.ipa.go.jp/kyouiku/100/], Media Kids [http://kids.glocom.ac.jp/MediaKids/index.E.html/], Konet Plan [http://konet.mbc.ntt.co.jp/]. One of the newest trials is to relate children's learning activities with TV programs and TV-related web materials using the Internet. Many collaborative activities, e.g. co-observation of acid rain, and co-survey of folktales, require broad area knowledge. It is needed in these projects that children learn in problem centered way and think from an international point of view. The Internet is one of the most useful tools in these activities.

3. Problem Centered learning with the Internet in Germany

3.1 Internet Utilization in German School

Since around 1995 Internet connectivity has become an issue for national projects. "Schools to the Net" [SaN:http://www.san-ev.de/] is a joint initiative by the Federal Ministry of Research and Education together with German Telecom and other corporate sponsors to connect 10,000 secondary schools to the net by the end of 1998. Some of the states have
ambitious projects, mostly as a public private partnership, too [e.g. NRW http://www.learn-line.nrw.de]. On a local level we find different forms of cooperations and a variety of individual projects like international e-mail projects [Donath 1997].

3.2 Problem centered learning with the Internet

Today there are strong voices that demand educational content not covered by traditional subjects, like media and technology education, environmental and health education, etc. Newer documents of educational policy state that media education will naturally lead to problem centered and project oriented learning, to learning in the context of real world problems, to cooperation with partners outside of school. Projects like SaN also aim at opening up the schools through Internet use. There are examples of successful interdisciplinary Internet projects (ESP http://www.kc.kuleuven.ac.be/esp/; TAK http://www.tak.schule.de/welcome_us.htm and others), but in everyday school life (half day schools, 45 minutes lesson units, few computer rooms...) such projects are often difficult to organize. So mostly the teachers in charge have to take extra efforts like cooperating with another teacher of the same class or offering computer clubs in the afternoon. But even if only conducted within normal subject lessons, experienced teachers notice that many Internet projects turn out to be intrinsically interdisciplinary, because they often require language and communication competency, technical knowledge as well as other subject knowledge [Achtstaetter 1996].

4. Comparison of Findings

We found that many children in our countries are having the opportunity to use the Internet in school. Support comes from national projects, corporate sponsors, universities or other organizations. In Japan enterprises have discovered the potential market quite early, whereas in Germany educators have a tendency to avoid commercial support.

Still, the success of most projects depends mostly on the initiative of individual teachers, as well as on support by university researchers and other voluntary staff. In Germany, students often play an important role as network administrators, whereas in Japan teachers hesitate to share those responsibilities.

Other differences exist at the grade level of Internet introduction: Utilization of Internet is more flexible and wider ranged in elementary schools than secondary schools in Japan. On the contrary, few German elementary schools use the Internet, flexibility with respect to projects is biggest at the junior high school level. This is partly due to differences in grading system, but also reflects a more critical attitude to new technology in Germany, especially when young children are concerned. In Japan many elementary schools have their own computer room, in some of them all children of grade 5 and 6 have their own e-mail address. In higher grades, study for higher education entrance exams becomes more severe in Japan, so there is less room for experiments. According to findings so far the level of abstraction required for collecting useful information and constructing one's own opinion from them might be asking too much from children around grade 4, so the question is, whether meaningful usage of Internet can be made in lower grades and how.

We suppose that Internet introduction into schools in both countries will continue on several levels. Local initiatives will expand as well as national programs, and slowly curricula will come to include problem centered learning with the Internet, too. In the meantime schools will probably open up through the usage of Internet quicker than curricula prescribe it.

On the other hand the current situation is characterized by many experiments, and a considerable part of the teachers is in doubt about the usefulness of the tool. The national programs in our countries both have put networked computers into the classrooms first and then only slowly started to train the teachers. So the most important issue at the moment is content. What do children really learn by using the Internet? Only by communicating superficially and expanding globalism in terms of figures the usefulness of the Internet for education cannot be proved. We will have to investigate how learners reflect their experiences through collaborative learning and communication over the Internet.

A System Based on Rodari's 'Estrangement' Principle to Promote Creative Writing in Children

1. Introduction

Many children do not like writing, and when they do write, they usually write only short sentences. But [Uchida 1986] suggested that when the children are provided interesting material, they do write with enthusiasm. In this paper, we describe a system called Story TElling from Pictures (STEP) that is designed to promote creative writing in children. STEP uses a technique called estrangement [Rodari 1973], in which familiar objects are presented in strange contexts to spark imagination in children. STEP provides sequences (scripts) of pictures, and children practice writing as a game by making stories based on these scripts. Pictures (schemas) are composed of picture elements, which in turn are based on data gathered informally by having children fill out a questionnaire to ensure familiarity with objects in the pictures. Estrangement can be introduced at the schema level (a picture element that does not belong with the others) or at the script level (a picture that does not belong in the sequence). A prototype of STEP was implemented and, on informal experiments with 18 children, we found that many more and longer stories were generated with estrangement than without it.

We present here the background and an overview of STEP, and our experimental results.

2. Background and Motivation

In Rodari's proposed methods to promote creative storytelling in children, 'estrangement' figures very prominently. For example, in the fantastic binomial, a story is generated from the opposition between two unrelated words, for example 'dog' and 'closet'. The more unrelated are the words, the better is their potential for engaging the child's imagination, and the more fantastic is the resulting story. Or, in Little Red Riding Hood in a Helicopter, a story is generated from an idea extracted from a series of words, and another word that is not related to any of the words in the series. For example, Rodari gave children five words, 'girl', 'woods', 'flowers', 'wolf' and 'grandmother', which together suggest the story of Little Red Riding Hood, and then added one more word, namely 'helicopter'. This conflict sparked the imagination of the children, and they made up very creative and interesting stories. [Uchida 1986] also did some similar experiments using pictures instead of words, and confirmed this effect.

A key component of Rodari's use of estrangement is that it is introduced by using material that is familiar to children. Indeed, [Vygotsky 1930] has observed, and we have confirmed in informal experiments with an earlier prototype, that children are more forthcoming and expressive when writing about material with which they are familiar than otherwise.

3. An Overview of STEP

Using data from an informal questionnaire given to 12 children, in which they were asked to describe some of their daily activities and to write names of things which belong at home, school,
playground, etc., we prepared a picture database of 452 picture elements. Each picture element represented some object that is familiar to children. These picture elements were organized into 37 schemas (pictures composed of many picture elements) and 5 scripts (sequences of schemas) [Schank & Abelson 1977]. STEP also has an optional tuning mode, in which children can create their own schemas and scripts.

In STEP, a story structure is defined as a series of pages, where a page is a pair of a picture and a description. A description, in turn, is a piece of (possibly empty) text.

In the making stories mode of STEP (there is also a replay mode that allows previously made stories to be replayed), children can choose to have no estrangement, estrangement in a schema or estrangement in a script sequence. STEP introduces estrangement at the schema level by combining a picture element that does not belong to a schema; and at the script level by inserting a picture in the sequence that does not belong to a script. For this, we use the information inherent in the organizations of schemas and scripts to present strange situations to children to encourage imaginative creation.

4. Experimental Results

We tested a prototype of STEP with 18 children in informal experiments. The results of these experiments are shown in Figure 1 below. The graph on the left shows the average number of characters in a page for all the stories that were completed successfully. The graph on the right shows the same data for younger (5-7 yrs.) children. From this we can see that children consistently wrote longer stories whenever estrangement was present. Indeed, we feel that the crux of creative and imaginative play lies in trying to assimilate strange contexts made up of familiar objects, and precisely this phenomenon is exploited in STEP to promote creative writing in children.

![Figure 1: Effect of Estrangement Factor on the Length of Stories.](image)

Introduction

Through distance learning, tertiary education has become available to an increased proportion of the population. Improved computer and communication technologies have contributed to this change [Jones & Jo 1998]. With the advent of the Internet and the World Wide Web, distance learning has taken a step forward. When courses are prepared for use over the Internet, the designers are usually professional multimedia designers, generally trained in a variety of authoring software packages. They take the content of the educational course and adapt it. However, this may not be the most suitable method. Ideally, the teachers and lecturers should prepare the lessons just as in conventional education. This paper will discuss the current system of instructional program design. A new model, which allows the educator more control and easy modification, is suggested and a template will be proposed to demonstrate this theory.

Current System used to Design Instructional Material

The current system of designing instructional programs follows a three-step process [Fig. 1]. The educator, an expert in the field of study, provides information in the form of content material. This information is given to the multimedia designer, generally a professional, trained in authoring software such as Macromedia Director or Authorware, and a Web language such as JAVA or HTML. There is, by necessity, a certain amount of interaction between the educator and the instructional designer as objectives and strategies must be established and the sequence of delivery must be determined [Penney 1981]. During this interactive phase the designer will be constantly updating and improving the material until the finished product is completed.

![Diagram of the current system to design educational material for Internet-based education](image_url)

Figure 1. Current system to design educational material for Internet-based education.

There is no denying that this system works. What this paper is offering is an alternative method of design that may allow the educator more control, not only of the content but also of the time and place of preparation and include easy modification. It would be more productive if the educator
could both create and design the instructional program for Internet delivery. This system would be more efficient by reducing the preparation time and expenditure, and also avoiding misinterpretations between the educator and the designer.

New Authoring System using a Template

With this new system the template would only need to be designed once by the multimedia designer. There would, of course, be a large range of templates to suit the many presentation styles, fields of study, age groups, learning styles and learning strategies.

This system would also follow an interactive pattern. The designer would prepare and provide the templates. The content material would be provided by the educator who interacts with the template program, entering data, reviewing and refining as the instructional program develops. This process is represented below [Fig. 2].

![Diagram](image)

**Figure 2.** Template-based Authoring System Model. A template can be retrieved based on the nature of the subject, teacher’s preference or learning strategies.

Conclusion

In this paper the current system of Internet-based, instructional program design has been discussed and a new model proposed. This research is presently underway and a template authoring system for Internet-based education is being produced. The new system will allow the educator the increased control and easy modification suggested, along with reduced preparation time. Ultimately, the educator will be provided with a range of templates, each offering a specific appearance, various learning strategies and content-specific style. This research aims at providing a better, more efficient system in a user-friendly, interactive multimedia setting.

1. Introduction

The World Wide Web (WWW) cannot guarantee learning. The rich media and linkages available on the web are not unique to WBI. What is unique is the pedagogical dimensions that it can be designed to deliver. These learning dimensions determine the WWW's ultimate effectiveness and worth. The design of WBI should focus on the goals of the lesson, the needs of the learner, and the nature of the task involved [Rieber 1994]. Factors in the hypermedia environment, such as visualization, goal orientation, motivation, and structure, must be taken into account so the design of WBI enhances the educational opportunities of the learners.

2. Hypermedia

Hypermedia can be effectively developed as an instructional tool based on information processing theory and dual-coding theory. Through information processing theory, hypermedia environments can capitalize on the following: gaining the learner's attention, informing the learner of the objectives, stimulating the learner's prior knowledge, providing scaffolding, eliciting performance, providing feedback, assessing achievement, and enhancing retention and transfer [Gagné, Briggs, & Wagner 1992]. Dual-coding theory assumes two independent, but interacting cognitive subsystems [Paivio 1971]. A verbal system is responsible for the processing of verbal information while an imaging system is responsible for processing pictorial information. Only through sound design principles based on these theories can hypermedia reach its potential as an instructional tool.

When designing a hypermedia environment, careful attention must be given to the media used. Hypermedia should be enhanced by the use of the multiple modes of media to convey meaning. According to the dual-coding theory [Paivio 1971], information is processed through a verbal and nonverbal channel; therefore, enhanced semantic connections can be developed in a learner's memory by the use of multiple media. Common types of media used in WBI are text, graphics, animation, and sound. Whether or not a medium's capabilities make a difference in learning depends on how they correspond to the particular learning environment and how they relate to the needs of the tasks and learners. The design of instruction is instrumental in utilizing the medium's capabilities.

Although instructional problems can be classified as well-defined or ill-defined, they differ with respect to their complexity and specificity. The course objectives should be clearly stated to the learner and the design of the instructional environment should revolve around the goal of instruction. When a learner's attention is partially focused on the objective, the learners' disorientation is decreased and their retention is increased [Beasley & Waugh 1996]. The knowledge of the objective enhances the learners' goal orientation. Clearly articulated learning objectives and goals for learning are imperative for the learning process; therefore, by providing learners with a goal for browsing or aiding them in developing goals gives the learners a stake in the learning process and focuses their mental efforts in a positive direction.

Motivational conditions include attention, relevance, confidence, and satisfaction -- ARCS model of instructional design [Keller 1987]. It is imperative that the instructional designer gain the attention of the learner, make the content relevant to the learner's personal needs, support learners' confidence by enabling them to achieve, and foster their satisfaction through consistent rewards. Expectancies and values are an integral aspect of motivation. First of all, learners must believe they can succeed; they must have a high expectancy about their task performance. Second, learners must believe there are benefits in performing a task; they must place value on the task itself [Ormrod 1995]. Extended, challenging, meaningful, and
collaborative learning enhances motivation. Motivation can also develop learners’ confidence which enables them to persevere longer, engage at a deeper level, and learn more.

Several problems of learning in a hypertext environment arise from the structure of the hypermedia environment. Instructional designers must continually struggle with the unique capabilities of the computer without disorienting the reader. This problem of disorientation facilitates the cognitive overload of the learner and diminishes the instructional capabilities of hypermedia. In an ideal web-site, the structure is evident to the user and the information is organized coherently and meaningfully. Designers often include navigational tools which help learners organize the structure of the web-site as well as the connections of the various components. The text can be standardized to convey meaning; the interface design can imply relationships between items and the buttons can be clear, visible, and accessible. Structural considerations in the design of a hypermedia environment can aid a student in developing an overview of the environment.

3. Conclusion

WBI should capitalize on the positive aspects unique to its environment. The environment should focus on the needs of the learner rather than the learner accommodating the knowledge base [Nelson & Palumbo 1992]. With the potential of WBI in educational environments, instructional design must translate design issues and theories of learning into plans for instructional environments. While there are vast amounts of research on ways to present instruction via text and other linear approaches, such as computer-assisted instruction, there is little research on the design and presentation of nonlinear instruction.

By providing goal orientation, multiple media, motivation, and structure, the individual needs of the learners are accommodated through the design of WBI. By allowing learners to set goals and reflect on the information provided in the WBI, the learners’ attention is focused and they are able to see the interrelatedness of ideas. The use of multiple forms of media provide the learner with rich and realistic contexts for multichannel learning. The learners' motivation is increased when they are in control of the navigation of the hypermedia environment and encounter realistic examples. Finally, the structure of the environment can be designed so it is user-friendly, simple, and the interconnectedness of ideas is clear.

Since there is a lack of research on WBI, we must rely on the research on hypermedia and extend this research into the realms of the WWW. Factors in the hypermedia environment, such as visualization, goal orientation, motivation, and structure, must be researched so WBI can reach its potential. Through research on WBI, we can determine the following: the impact of visualization on the learning and retention of knowledge, the importance of setting goals for learning on the learning and retention of knowledge, optimal motivational elements within the environment, and the optimal navigational device to enhance students' learning.

Schools of Helsinki 2001
Information Technology Project

Mr. Heikki Karjalainen, European Affairs Coordinator
Information Technology Project, Helsinki City Education Department
Helsinki, Finland. E-mail: hkarjala@edu.hel.fi

1. Background
The Finnish Government decided in 1994 that Finland should be turned into an information society. The Ministery of Education made a strategy how this could be realized. At the same time the Helsinki City Education Department was preparing an Information Technology Project that was accepted by the City Council in 1995. This five year project started in 1996 and is worth FIM 200 million (34 MECU).

2. Schools of Helsinki 2001
The main objectives of this project is to develop information technology and services in the general and vocational education in the present decade so that:
- from the standpoint of general education:
  - schools can provide each student with the prerequisites of the information society as well as the basic skills required for the acquisition of necessary information, information management and basic communication skills
  - The primary and secondary education can give to each student the practical basic skills in information technology
  - The use of information technology as a tool can be increased in different subjects on the basis of the new curriculum.
- from the standpoint of vocational education
  - The institution can give such information technology skills that correspond to the continuously changing and increasingly international demands of working life.

The core network is serving the whole city and about 125 schools out of 175 (March 1998) have a local area network (CAT-5) and multimedia PC's in every classroom. These schools have been connected into the Internet with at least 512 kb lines, some will get ATM connection later this year.

A notable in-service retraining program -ICT for teachers- has been going on since 1996: every teacher may attend free ICT courses for ten days; last year more than 4300 teachers participated these courses lasting 1-3 days each.

3. ICT at Schools
The schools are using ICT in many ways. All computers have been equipped with basic software: text processing, spread sheet, database, www-browsers and e-mail programs. Pupils in upper comprehensive schools and upper secondary schools have a chance to produce multimedia works with text, images, sound, animation and videos. Problem solving can be practised by doing programming exercises. Pupils write their papers and presentations by means of various programme applciations. Students may produce their own www-home pages.

Multimedia programs, World Wide Web and CD-ROMS are used to find information which is later evaluated and reproduced by the students. Special education have their own educational programs.
Pupils write music, shoot videos and edit them, compile statistics and illustrate them with diagrams, calculate probabilities and edit school papers on computers. Forty schools are working together to produce a multimedia CD-ROM about the local history.
Language teaching makes use of interactive educational programmes. Multimedia equipment enables the pupils to practise listening comprehension and speech communication individually. Every new word can be looked up in an electronic dictionary and the written exercises will be checked right away. Pupils learn new words and practise grammar by playing educational games.

Some schools have facilities to design and make knitwear with the help of computers and to embroider cloth with a programmable sewing machine. Pupils can design trendy clothing and let the computer draw the patterns according to the given measurements. In some schools, pupils make chess pieces with a computer-controlled lathe.

Even the smallest children are eager to use computers. Already in preliminary teaching, computers help the pupils to learn the letters and to practise reading, writing and doing sums. A good example of innovative use of computers is provided by a class that has started to write books on computers. The group that includes both Finnish and immigrant children edit the texts and make them even look like real books. This project has been most beneficial for the children's Finnish skills.

4. "net.edu.hel.fi"

There has been a need to develop the pedagogical use of the computers and the use of the Internet/Intranet for normal and special education, serving as well the immigrants and different organisations. That is why a virtual site called "net.edu.hel.fi" has been produced for all schools. This is a site in the Helsinki Educational Intranet that opens automatically when a teacher or a student logs into a computer at school. This interactive site is to help both learning and teaching.

The net.edu.hel.fi consists of two collaborative main parts:
1) A virtual school using different forms of ODL starting 1998 with special interactive courses arranged for upper secondary schools and materials produced by teachers.
2) An interactive site/schoolyard where the students can meet freely and produce their own material. All users are automatically identified by LDAP-server thus minimizing unidentified junk mail and making it easy for teachers to create and maintain courses on the Web. Structure is based on NT-windows platform and run by CGI-scripts (programmed by Perl language). No Java or java-sripts are included. So all the processing is done in the server, not in various workstations.

All three school levels will have their own different starting pages like an entrance hall. There are links to different subjects, courses, news-servers and other relevant links. Students may register to courses that can be administrated co-operatively by 1-4 teachers. A student shall collect his/her works to a digital personal portfolio which his/her teacher is able to see as well.

The teachers may create co-operatively ODL courses, transfer any digital material to special archives (including digital library with direct links to search engines as well), leave messages to their students or discuss with other teachers using the Web. Special Multimedia Delivery system has been created so that all teachers may order any audiovisual or other material and various equipment from the Education Department’s Media Center using a normal web browser.

The interactive site is more informal place for the students to meet and to find information what they need when making decisions that affect their whole life. This material is produced in co-operation with students, authorities and different organizations.
An Interdisciplinary Multimedia Project Course

Dr. Anthony S. Karrer, Department of Electrical Engineering & Computer Science
Loyola Marymount University, Los Angeles, CA 90045-8130
(310) 338-5100, akarrer@lmumail.lmu.edu

Abstract: At Loyola Marymount University, we are currently defining the curriculum that will compose an interdisciplinary multimedia program. It is aimed at students from a variety of majors and includes courses in graphic design, multimedia design, on-line design, educational software, and a one-year interdisciplinary project course. The new interdisciplinary project course is aimed at bringing together students from a variety of different areas on campus whose skills can be combined to create interesting multimedia software. The focus of the course will be team-based development and understanding various technical and creative skills in multimedia software development. This paper looks at the design of the project course, its results so far and the issues of creating an interdisciplinary project course.

1. Introduction
At Loyola Marymount University, we are currently defining the curriculum that will compose an interdisciplinary multimedia program. This program will be aimed at students majoring in graphic arts, computer science, English, script writing, video arts, studio arts, management, marketing and education. The current design includes courses in graphic design, multimedia design, on-line design, educational software, and a one-year interdisciplinary project course. The new interdisciplinary project course is aimed at bringing together students from a variety of different areas on campus whose skills can be combined to create interesting multimedia software. The focus of the course will be team-based development and understanding various technical and creative skills in multimedia software development.

The project occurs over two semester courses designed to be taken in sequence and are entitled: Multimedia Software Design and Multimedia Software Production. The first semester takes a multimedia project from initial concept and client kick-off through a prototype and initial usability studies. It looks at the early stages of multimedia program development including project concept, audience analysis, needs analysis, creative & visual treatments, CD-ROM & Web technical issues, interface design, media format issues, authoring languages, and multimedia project management. The second semester takes the multimedia project from prototype through full script and final production. It looks at script writing, video production, audio production, graphics production, authoring, program engine development, media integration, packaging, marketing and duplication.

2. Course Design
The overall design of this course is an attempt to maximize the understanding of real multimedia projects. The only way to fully appreciate this subject is to experience it first hand. Thus, the project, which has a “real client”, is the counter point of the course. This year we are creating a project for the Admissions Office with a working title of LMU and You. It will be a marketing piece for the university designed for accepted students who are trying to decide which university to attend. The course has students enrolled from graphic arts, computer science, English and business. This project is particularly good for a first offering because the students already understand the content and are proving to be good subject matter experts.

The real essence of the course is to capture the nature of multimedia in terms of working with people who are specialists in their discipline and who do not necessarily view and talk about the world in the same way. At the same time, students are under pressure to meet deadlines, learning a new process, applying the skills they’ve learned in another context and are working on a team for the first time. This gives us real learning opportunities for understanding team, social and cultural issues that are very important for successful multimedia projects.
Of course this means that the result of the course is highly dependent on the abilities and dedication of the class members. However, I find that most students become very excited and dedicated once they start working with a client and have a chance to utilize their knowledge in their respective disciplines.

In order to control the content and to assign grades, the course is structured around a very controlled development process modeled on processes used in multimedia production companies. Part of the intent of the course is for the students to not only hear about this process, but to live it and to live the issues that arise on a project that involves people from other disciplines and a real client. Grades are based on various “deliverables” which are written and/or spoken reports. These include project proposal, design document, creative treatment, prototype, usability study, script, alpha, beta, final presentation. Each of these are detailed with examples in course handouts. On most of these documents, I provide free feedback prior to its final grade and before it goes to the client. This extra feedback loop slows the process but greatly increases the students understanding of each deliverable, the concepts behind the deliverable and improves the quality of the result.

3. Results So Far

The result of the class so far is extremely positive. Students are engaged and are learning a lot from the course. The biggest issue so far is lack of time class time for presenting the “real content” of the course. Most of the class sessions are spent discussing the project, the next deliverable and issues that are coming up in getting work done. We have had to scale back lectures on related subjects and use the students interest to guide what will be presented. At the same time, this allows us to focus on the issues that are really going to be accepted and learned by the students as part of the project. While we may want to investigate alternate course scheduling plans, from our experience with the computer science project course, this is an extremely effective learning approach and the lack of time does not really impact learning. It’s primary detriment is the impact on the ego of the professor who may feel that more learning is occurring even though they are lecturing less.

4. Broader Issue

The broader issue that this course raises, and in some ways the entire multimedia curriculum raises, is where the curriculum fits in the university. In other words, is multimedia part of art or computer science or is it a new discipline? My view is that the answer is that multimedia is inherently multidisciplinary and is not a new discipline. The ideal for medium and large scale multimedia projects is to have students trained as specialists in their respective majors who understand the issues facing other specialists on a team. Thus, students at a university should participate in courses outside of their major to understand the issues that face those specialists. For example, a computer science student should be exposed to the issues and concepts that underlie graphic design, video arts, studio arts, management, marketing, script writing, etc. At the same time, the computer science student should be training to be a specialist in designing and implementing programs. After all, a computer science student is likely to work on multimedia projects as a programmer and there is little expectation that they will have the same graphic design skills as a good graphic designer. Thus, the goal is not to make the computer science student into a great graphic artist. The goal is to make sure that the graphic artist and the programmer can work together to leverage their respective skill sets to create the best possible result. While I feel strongly that this is the right approach in theory, in practice there is a hard organizational problem of who owns the curriculum and who provides lab space and all of these other mundane questions.

5. Summary

The project course by all indications is and will be a big success at LMU. Across the campus, there is great interest in the project and the larger multimedia curriculum. Students are eager to participant because of the challenge and the fun learning environment that the curriculum offers. How this course can scale to incorporate more students is an interesting problem. Another interesting problem is the challenges for a university in instituting this kind of course and this curriculum. The current university models do not hold for this inherently interdisciplinary study.
1. Introduction
This trial is among eight schools in Keio Academy. They are Keio Hiyoshi (Boys) Senior High School, Shiki (Boys) Senior High School, Girls Senior High School, Shonan Fujisawa Junior and Senior High School, Futsubu (Boys Junior High School), Chutobu (Co-ed Junior High School), Yochisha (Co-ed Elementary School), and Keio Academy of New York (Grades 9 - 12). We've built an international dedicated T-1 line between Keio Schools in Japan and Keio Academy of New York. Among Keio Schools in Japan, there is a high-speed campus network of Keio Academy. The minimum speed is 1.5Mbps. Last year we've made experimental trials in Keio Academy [Kato 97]. We have developed CALAT [Nakabayashi 95], which is web-based educational system for self-study and now developing the integrated CALAT, which is combined with communication tools. They are E-mail, BBS, Chat, TV-Conference, and so on. Using these tools, teachers and students make collaborative activities through this system. We've been making some experiments and evaluations.

2. Communication tools
CALAT is a web-based Intelligent Tutoring System (ITS), aimed for self-study. In the real educational field, a wide variety of communication tools is needed for both teachers and students. So we provide many communication tools integrated with CALAT.

(1) E-mail
Time difference is very critical issue between USA and Japan. These non real-time communication tools are good to overcome this issue.

(2) Web BBS (Bulletin Board System)
This is also asynchronous communication tool. Web BBS is efficient to use because users should have only web browsers. No mailer is needed.

(3) Ordinal Web Page
This is needed for sharing the activities and schools themselves among eight schools.

(4) Video Conference
This is sometimes needed, not every day. It promotes a smooth communication and establishes a good reliability among teachers.

(5) Video Broadcasting
Video broadcasting is effective for distance learning and distance meetings. Not only US school, even seven schools in Japan are widely spread in Kanto, Japan. It makes possible to join the lecture and meeting from the remote place.

3. Educational trials
Some projects are planning, using this international educational network. Some of them are within a local school, but others are collaborative projects across schools.

3.1 Mathematics
We provide the new simulation environment in CALAT [Hoshide 98]. Using this system, students can learn math in the interactive environment and a teacher supervises students' progress in real-time. We are planning to make a math contest among some schools.

3.2 Language (English)
Collaborative work is made between the USA and JAPAN. In USA there are a lot of up-to-date information resources, such as newspapers, TV, etc. And students in Japan can know the way of thinking in USA. They can use CALAT and web-based BBS to learn and communicate the topics, which are set by a teacher. The objective
of this project is to extend English ability and to promote communication skills.

3.3 Biology
This international project is to deepen the understanding of the scientific topic especially in biology. Students in Japan have knowledge of technical terms of Japanese, but they don't know them in English. The objective of this project is to extend the language ability, to promote the communication skills, and of course to acquire the scientific knowledge itself.

3.4 Earth Science
Weather station measures temperature, humidity, wind speed, wind direction, etc. Weather camera captures the real-time images and saves them on the web server. There are many web sites that provide the real-time picture, astronomical telescope, and images from satellite camera. We provide the weather information and real-time pictures of the schools in USA and JAPAN. Information of temperature, humidity, etc. and images are saved on the web servers. Teachers and students can see the information and pictures in real-time. And they also retrieve the old information and images from the web server. This up-to-date information brings good incentives to students for learning earth science.

3.5 Virtual Festival
School festivals are made and managed by school councils. This virtual festival brings the mutual understanding of each school and promotes the student activity.

3.6 Cyber University Campus
High school students especially in New York have a lot of concern of the department of Keio University and its campus. But they have less opportunity to visit, so we provide cyber university campus with rich video data. It will provide a hot information of Keio University to high school students. They can ask questions to university students via Web BBS.

4. Conclusion
We make the networked international educational trial. We provide CALAT as well as communication and measurement tools. Now we've prepared the network configuration and started the trials. A lot of projects are planning or running now. We'll be able to show the detailed results at the conference.

The Relationship Between Learner's Goal Orientation and Their Cognitive Tool Use and Achievement in an Interactive Hypermedia Environment

Heather A. Katz, Doctoral Candidate
Department of Curriculum and Instruction, University of Texas at Austin, USA
hakatz@mail.utexas.edu

1. Overview

This short paper summarizes Katz’s dissertation research (in progress) which proposes to extend the relationship between goal orientation (GO), self-regulated learning strategies (SRLS), and achievement in traditional learning environments (TLEs) to an interactive hypermedia learning environment. First, relevant previous research that reports on this relationship will be highlighted. Next, the linkage of this relationship to cognitive tool (CT) use in an interactive hypermedia environment (IHE) will be established. Finally, expected results and the paper’s relevancy to current theoretical assumptions will be discussed. The following elaboration of GO, SRLS, CT, IHE will give clarity to this paper:

Similar to [Wolters et al. 1996] and [Ames 1992], GO is empirically conceptualized and measured as a reflection of individual characteristics (i.e., approaching, engaging in, and responding to achievement situations) that learners bring with them to a learning task. SRLS are “actions and processes directed at acquiring information or skill that involve agency, purpose, and instrumentality perceptions by learners” [Zimmerman 1989 p. 329]. Similarly, CTs are defined as devices that assist learners to accomplish cognitive tasks such as information processing and in general, learning comprehension [Lajoie 1993]. An IHE requires learner control in computer-based applications to access multimedia information resources via non-linear, user-determined, navigational paths [Burton et al. 1995].

2. Theoretical Background

2.1 Goal Orientation, Self-regulated Learning, and SRLS

The following highlights (a) relevant goal orientation (GO) research; and (b) the relationship between GO, self-regulated learning, self-regulated learning strategies (SRLS), and achievement. First, in traditional learning environments (TLEs), the type of GO that learners adopt can yield different adaptive or maladaptive patterns of affect, cognition, and behavior and help to explain why learners perform either positively or negatively in academic situations. Traditionally, goal research has used a two-goal theory (mastery, performance) when investigating how GO affects learners’ cognitions, behaviors, and motivation. However, current research [see Urdan and Maehr 1995] has stated the need to migrate from this traditional two-goal theory to a three-goal. Recent research [see Wolters et al. 1996] has done this by separating the performance GO into two separate GOs—extrinsic and relative ability, in addition to the learning GO. Similarly, this paper moves beyond and proposes to investigate learners’ mastery, extrinsic, and relative ability GO in an interactive hypermedia environment (IHE). Such investigation can yield GO research that is more comprehensive and discover if results from an IHE are consistent or divergent to previous GO research of TLEs. Second, [Hagen and Weinstein 1995] provide theoretical and empirical evidence for the relationships among mastery and performance GO, self-regulated learning, SRLS, and achievement in TLEs. Such current research purports that mastery GO students use more adaptive SRLS and have a higher incidence of positive achievement outcomes; while, performance GO learners generally use less adaptive SRLS and experience a higher incidence of negative achievement outcomes. Consequently, it is important to note that learners can simultaneously adopt both intrinsic and extrinsic GOs and still have positive achievement outcomes [Pintrich and Garcia 1991].

Moreover, [Wolters et al. 1996] empirical research lends further support to this relationship: learners’ (a) learning GO yielded more adaptive motivational and strategy use; (b) relative ability GO yielded positive academic outcomes in motivation, cognition, and performance; and (c) extrinsic GO yielded maladaptive and negative patterns of motivation, cognition, and performance. Hence, the aforementioned theoretical and empirical evidence of this relationship in TLEs lends support for the proceeding linkage to SRLS and CT in an IHE.
2.2 Cognitive Tools in Traditional and Interactive Hypermedia Environments

Knowledge of this empirically supported relationship between goal orientation (GO), self regulated learning, self-regulated learning strategies (SRLS), and achievement can benefit both further research and the design of environments and educative experiences that facilitate individual positive achievement outcomes [Ford and Nichols 1991]. Applying this knowledge to the investigation of learners' cognitive tool (CT) use in interactive hypermedia environments (IHEs) can achieve the aforementioned. For example, the CT and SRLS definitions in [Overview] lend support that SRLS and CT are analogous—they both assist learners to acquire, process, and comprehend information. Moreover, research declares that CTs in computer environments can support cognitive processes, such as, memory and metacognitive processes (i.e., SRLS) and allow learners to engage in otherwise unattainable cognitive activities [Lajoie 1993]. Thus, it is apparent that CTs can also support SRLS. Therefore, it is theoretically deduced that the function of CTs within an IHE is twofold: they can (a) serve as SRLS, and (b) support SRLS. Hence, CTs in traditional learning environments (TLEs) and IHEs are similar in that they both provide learners assistance to elaborate, rehearse, and organize when processing information. However, they differ in that, TLEs require learners to initiate CTs; whereas, IHEs can make CTs readily available in a tool bar, provide guided CT instruction/tutorial via animation and sound, and prompt for CT use. This proposed research intends to investigate the following CTs in an IHE: bookmark, notetaking, sitemap, index, glossary, and help. Additionally, the IHE will provide introduction and tutorial instruction to orient learners to correct and appropriate CT use. Specifically, the following research questions are proposed: How will learners' goal orientation influence cognitive tool use in an interactive hypermedia environment? What effect will this have on learner achievement? What is the relationship between learners' goal orientation, cognitive tool use, and achievement in an interactive hypermedia environment? Expected results are similar to GO research findings discussed in [2.1] where mastery GO learners show greater CT use and extrinsic GO learners show less. Moreover, contribution of new GO results are expected from investigating a three-goal theory (mastery, extrinsic, and relative ability). Thus, yet to be determined results are expected to divulge if relative ability GO learners display CT use unique or similar to that of their mastery and extrinsic GO peers.

In conclusion, given the aforementioned theoretically grounded and empirically supported relationship between GO, SRLS, and achievement in TLEs and the linkage of this relationship to the two-fold function of CT use in IHEs, it is assumed both relevant and significant to extend this relationship to an IHE. This can allow for (a) theoretically grounded investigation of the relationship between learners' GO, CT use, and achievement in an IHE; (b) the extension of GO research from a two-goal theory to a three-goal theory via including relative ability GO; and (c) significant results to further interactive hypermedia research and design.

Introduction and Conceptual Framework

Education in most nations is in a state of major transition. It is a globally shared perception that if we could fix our schools we could better our societies. Policies resulting from national studies commonly reflect dual intents in increasing both student achievement scores and technological applications to the learning process. Too often, however, these goals are pursued separately rather than in tandem. This work shares one particular strategy for connecting technological skills and student learning.

This paper is grounded in two guiding concepts. First it distinguishes between the automating and informating capacities of technology as identified by Shoshana Zuboff (1988). Automating technologies make existing work more efficient. Informating efforts, on the other hand, cause people to think differently about the work they do and to use technology to redesign and reorganize that work. Second is grounded in contemporary research regarding learning, particularly the work of Howard Gardner (1993). We apply these beliefs to an electronic variation on a useful teaching strategy in the social sciences known as the culture box.

Curricular Application

Findings of the Teaching for Understanding (Wiske, 1997) project at Harvard University detail the importance of integrating skills and knowledge. Culture boxes help students and teachers to create meaningful links between personal identity and historic and contemporary shaping events in their world. And using Internet resources in the construction of a culture box encourages students to apply both new content knowledge and electronic skills in order to demonstrate an understanding of historic, geographic, economic, political, and social concepts.

Sarason (1993) claims there are four distinct curricula in most school settings. They are the official curriculum, the taught curriculum, the learned curriculum, and the tested curriculum. What students learn about their world is not necessarily what teachers teach. Nor is the curriculum presented to students necessarily apparent in what schools assess. We know too that curricular content, particularly as presented in traditional textbooks, has not necessarily reflected the cultural identities of all children. Use of the Internet as a resource, however, facilitates linking micro aspects of self to macro elements a larger cultural map. The history of the past decade affirms that individuals are not passive recipients of the prevailing culture, but active agents in reshaping personal identities and the larger society. Social historian Alaine Touraine
(1988) notes, “The theme of identity... must be played by the actor... as an appeal to life, freedom, and creativity.” The presented cybercube, an electronic variation on the traditional culture box, facilitates this role, and at the same time enables the learner to utilize many dimensions of intelligence.

Case example

Choosing the contents of traditional or electronic culture boxes remains a personalized experience. Each part of the process involves making choices, choices that involve people, places, and events, and the significance of connections. Culture boxes creators must order text, photographs, videotapes, or audio clips within their presentation. Some choose to arrange their culture box contents chronologically. Others prefer political, social or economic themes. The example examined at this conference, located at www.shol.com/educate, reflects the individual and cultural identity of Tom Jones, whose identity portrays an era contemporary cultural labels as “baby boomer.” Specifics of the construction process can be found at this site also.

Conclusions

As connections between schools and society grow increasingly misaligned communities are demanding changes in the ways schools do business. Today’s educational challenges require teachers who can use more relevant and more meaningful resources and strategies and who can redesign and restructure traditional teaching/learning transactions.

Preliminary Report on HyCLASS Authoring Tool

Akihisa Kawanobe, Susumu Kakuta, Hirofumi Touhei & Katsumi Hosoya
NTT Information and Communication Systems Laboratories,
3-9-11, Midori-Cho, Musashino-Shi, Tokyo, 180, Japan
Tel: +81 422 59 3934, E-mail: nobe@isl.ntt.co.jp

1. Introduction

Various simulation environments have been used to enrich intelligent tutoring systems (ITS). Single-user and multi-user simulations using VR environments have been developed to support procedural knowledge acquisition [Rickel & Johnson 1997]. Likewise, HyCLASS [Kato et al 1996] is a simulation environment which also features learning by observation. In this paper we describe HyCLASS as an environment to facilitate procedural knowledge acquisition. The knowledge acquisition process revolves around learners’ experience with manipulable 3D graphical objects in the virtual shared space. These objects can be complicated and thus are not trivial to produce. First, it is very difficult to model the target logically. Second, implementation of the target simulator is a time-consuming procedure including production of modeling data of the target. The HyCLASS authoring tool is designed to ease the process of building the learning material from the perspective of reusability and visibility of operations on the graphical objects.

2. The hierarchy of learning materials

HyCLASS learning materials are hierarchical in terms of their constituent objects and behaviors. Learning materials comprise one logic part to describe simulation behavior (described under point 3 below) and one or more learning material components which are reusable units. Learning material includes several graphic files and sets of behaviors attached to the graphical objects. The user of the authoring tool can attach various behaviors to the graphic entity such as “push” or “get”. The graphic entity corresponds to a manipulable object in the HyCLASS runtime environment. Several behaviors are grouped into one behavior set. For example, the “on” and “off” operation for the switch can be recognized as one behavior set. Each behavior set is categorized into predefined types, switch type, dial type or no type. Each behavior set (except no type) holds a control variable to express its status. The switch type holds a boolean variable, the dial type holds an integer-like variable. Using this control variable, the simulation can recognize the current status and change this status according to input events. One behavior consists of several behavior units. A behavior unit is the implementation of a movement, sound or other multi-media outputs. The author selects the behavior units and enters them on the behavior time sequence chart according to when they want them to be invoked. For example, a power switch of a video deck needs movement, sound and modification of its material. Authors should select suitable behavior units and align them according to their sequential order.

3. Logical part of learning material

Various behaviors defined on the graphical objects should be related to emulate the simulation target. For example, the TV set and video deck, which are implemented as learning material components, should be related so as to “play” the video on the TV screen. The authoring tool provides a sheet to describe relationships among behaviors, using the key terms: trigger, condition and action. The trigger is the user-initiated event within the HyCLASS environment. The condition is the requirement for the execution of the actions. The action comprises one or more behaviors to be invoked when the condition is satisfied. There may be more than one condition clause or action for a single trigger. The structure is similar to the switch/case statement in programming languages.

4. Current Status of HyCLASS viewer and authoring tool

The HyCLASS authoring tool (Fig.1) runs on Windows NT4.0 and Windows 95. The authoring tool requires
the VC++ environment to compile new learning material. This aspect will be improved in the near future. The HyCLASS viewer does not require a high-speed network. It runs comfortably, for example, over a 64k ISDN line. Within the HyCLASS runtime environment, the learning material is implemented as a Dynamic Link Library (DLL). During the development of the learning material, the authoring tool saves the logic and component inflammations HyCLASS intermediate code (H-CODE). Subsequently, to run the learning material within the HyCLASS environment, the authoring tool can be used to generate source code from the H-CODE, which is then compiled as a DLL.

5. Conclusion

The hierarchical structure of HyCLASS learning material enables “cut and paste” of the components in each layer: learning material components, graphic entity, behavior set, behavior and behavior unit. This substantially reduces the effort of authoring. Learning material components can also be imported from other learning material. This aspect promotes the reuse of existing learning materials.

Using the authoring environment shown in Figure 1, authors can browse the behaviors attached to the graphical objects and modify them on the fly. Tree-like presentation of the components enhances the author’s sense of the hierarchical structure.

H-CODE is more than description of the learning material and less than a script language. H-CODE is quite easy to learn, and serious developers may wish to extend this code directly. However it is possible to develop learning material with the authoring tool without any knowledge of H-CODE.

6. Future Works

The HyCLASS authoring tool currently requires the VC++ environment to compile learning materials. We are now developing the next version of HyCLASS, which reads HyCLASS intermediate code directly to generate the 3D graphical objects and their behaviors.

VIRLAN

VR Community for Children to Learn and Speak European Languages

Dipl.-Ing. Fabian Kempf

Markt Strategie Team Information Engineering
Fraunhofer-Institut IAO
Nobelstrasse 12, D-70569 Stuttgart, Germany
e-mail: Fabian.Kempf@iao.fhg.de
www: http://www.swt.iao.fhg.de

Introduction

Currently, language learning is either class tutoring based or self-learning based using the following learning material: traditional books, audio tapes, video tapes, CD-ROMs. Each medium has its advantages and disadvantages and has not been proven to be the best and the unique tool for language learning.

It has been proven that the best way to learn a foreign language is at early age and in a real world context. The project called VIRLAN - supported by the European Community in the form of an ESPRIT programme - proposes to create a virtual world in which children can learn by interacting with foreign children without leaving their school or home environment.

The underlying technologies are now available to achieve this goal: wide availability of Internet access, VRML tools, tools for 3D realtime multi-user environments.

Thus, the goal is to set-up a virtual realtime language learning network for primary school children throughout Europe.

Consortium

A European consortium, consisting of four research organisations (UK: University of Wales Swansea, Finland: University of Jyvaeskylae, Greece: Institute for Language and Speech Processing, Germany: Fraunhofer IAO) an leading educational publisher (Germany: Klett), and two software companies (Germany: Blaxxun, Greece: Exodus) will design, develop and evaluate the language learning network during the next two years.
Description

The VIRLAN language learning network will allow young children to come together, as if they were physically present in the same place. Through facilities of virtual reality and avatar technology, the children will be able to "enter" the central meeting place and from there "travel", via the Internet, to different virtual countries, in order to meet and communicate with other children.

All virtual countries environments will be built upon open templates, such as interface templates for setting up a local country site, edutainment templates, linguistic templates for the incorporation of dictionaries and phrase books, etc. The software, with the templates and the methodology to set-up a local site will be included in a localisation kit, to be sold to local distributors, according to the licensing method.

VIRLAN will be used in primary schools as a complementary tool for language learning, but it will also have the potential to be used for child-to-child communication on a private basis at home.

During the validation phase, an extensive and thorough evaluation of the proposed approach will be carried out in 6 European countries and in Canada.

The goal of the project is to take advantage of the emerged global telematics infrastructure (Internet), as well as the latest advances in virtual reality and multimedia technologies, in order to develop and setup a virtual-reality language learning network for primary school children throughout Europe. This network will provide a new, highly innovative approach in language learning through the virtual interaction among children in a lifelike, fun environment.

The VIRLAN project intends to enhance, adapt, and integrate emerging technologies, in order to provide and validate an innovative experimental learning network for young children, which will encompass the latest trends in VR, VRML, 3D multi-user worlds, and multimedia. The current project brings two significant innovations: on the one hand, it intends to create a virtual reality language learning environment, offering real 3D representations and interactions. On the other hand, it intends to provide a language learning experiment for a target group with very specific requirements and needs, namely to primary school children. For that reason, the envisioned network has to be very user-friendly, easy-to-use, and entertaining for children.

As the partners involved in VIRLAN are leaders in their fields world-wide, the proposed project will combine world-class skills into a highly innovative service. The resulting network will keep all benefits of existing state-of-the-art virtual environments, and add 3D interactive representations, intuitive navigation, identification with the location, as well as "intelligent" assistance.
Skill Development in Multimedia Production - The Case of Singapore

Chua Siew Keng
Head, Division of Electronic and Broadcast Media
School of Communication Studies
Nanyang Technological University, Singapore
tskchua@ntu.edu.sg

Introduction

Despite the importance in multimedia and wide area networks in Singapore, there is very little published research on multimedia development in the country. At the same time, there is no research, to my knowledge, on skills development in multimedia production in Singapore. This paper is part of a larger research study to report on and analyse, the results of a survey using ethnographic research methodologies. The survey respondents is a structured sample drawn from the major providers of multimedia skills development including tertiary institutions, government, quasi-government and corporate institutions. The survey is aimed at soliciting a wide array of data from the respondents to elucidate present and future constraints of and to project directions for, multimedia skills training. However, since it is being presented as a short paper, this paper will only discuss the multimedia education approaches adopted by the various government tertiary institutions in Singapore.

Multimedia Skills Development Study

Multimedia development skills training courses have only very recently been mounted in tertiary institutions in Singapore. This was mainly in response to the Singapore government's plan to develop information technology skills for the 21st century and to its push to provide high speed end-to-end infrastructure such as 'Singapore ONE', Singapore's 'national intranet' which is designed to use internet protocols and technologies to provide its citizens with a range of governmental, cultural and electronic commerce services. It will enable 'Singapore One' partners - both government and corporate - to plan on intense application of multimedia in delivery of services to corporate and personal network service customers. If these services were to eventuate, highly sophisticated multimedia skills are likely to be in heavy demand in Singapore. Internet-based multimedia skills availability is, then, one of the critical success factors for 'Singapore One', along with network construction, certification, security and marketing. In line with government plans to focus on IT training the two national universities and the four polytechnics started courses in high-end IT courses in the late '80s and early '90s. Recently, in response to the plans for the Singapore ONE initiative which was launched last June specifically multimedia content development and technological skills programmes were mounted at the technological university and the four polytechnics. Although there were only a sprinkling of course components in multimedia production training previously, almost all the polytechnics since 1997 have mounted full blown course programmes leading to substantial multimedia development skills. Since these courses are so new, not surprisingly there have been no graduates and therefore no testing of the industry appropriateness of these graduate skills as yet.

In Singapore, tertiary education is divided into three tiers. The first tier comprises the two national universities. About 20% of all successful high school leavers enter the universities while about 40% of the same enter the four polytechnics or the second tier of tertiary education. The third tier comprises the vocational institutes. The universities have complementary specialisation in education and training. The polytechnics run technological and technical courses with a strong vocational slant such as in engineering and computing and award diplomas rather than degrees. Vocational institutes, on the other hand, provides strictly skills training in the trades.

Generally, all the four polytechnics offer courses in multimedia development skills, including world wide web design and production skills. These course programmes lead to diplomas such as the diplomas in digital media
design, in multimedia software engineering, in multimedia computing, in data communications and networking and in information technology.

The entry qualifications are minimum 'O' level results for polytechnics and 'A' levels for universities. Basic subjects include English and mathematics and science subjects. For one polytechnic selection also includes interviewing shortlisted applicants who may be required to submit portfolios which show evidence of creativity and imagination. Interviewees may also be required to complete drawing/design exercises. The process seeks to ascertain applicants' aptitude, attitude, knowledge and potential for visual communication. These programmes constitute three-year full-time courses. Each of these have an intake of between 50 to 100 students per academic year.

The programmes have been designed to:

a) meet increasing demand for digital media professionals both locally and worldwide.
b) provide education and training in both creative and IT skills centred on the art and science of computer animation, multimedia and games design.
c) Provide a broad understanding of the graphics and media industries.
d) Provide training and technical knowledge in computer software development and multimedia computing.

Training range from multimedia programming to computer animation, graphic design, integration of video and audio effects and design and management of multimedia systems. Students will also learn about technologies that support multimedia production.

Course content and skills training area:

There are two main areas in which multimedia training/education takes place in these institutions:

a) Computing software skills including multimedia programming, database programming for multimedia information systems, network programming for multimedia communication systems and multimedia programming for windows.
b) Content production skills including converting linear, analog material into digital material such as digital video and audio, multimedia title design, multimedia title authoring, managing mm project, animation, interactive multimedia project, games design, virtual reality and development tools as well as basic art and graphics design, design for advertising, information graphics and packaging design and environment graphics.

Recently, however, there is an awareness that creative and artistic skills training is also needed. This is a difficult area to implement at institutional levels as currently the school and tertiary education curricula place high emphasis on examination skills and information retention.

Course methodologies, facilities and staffing

Courses include lectures, research work, case studies, laboratory workshops and hands-on tutorials, group and industrial projects and industrial attachments. In most institutions at least 50% of course time is allocated to laboratory practical work. Students also undertake a three-month industrial project and a 6-month industrial attachment where students work on live projects in the industry during their final year. All the polytechnics have very good high-end equipment and facilities ranging from high-end graphics capable computers to both Macintosh and PCs, digital audio and video equipment and edit suites. However, there is generally a shortage of academic staff who are qualified to teach in this area and hence the ratio of staff to student is generally not as adequate as in the other disciplines. Almost all staff are expatriate staff with a mere handful of local staff and these have been trained overseas.

Conclusion

So where will the graduates go? The polytechnics envisage that their graduates will enter the multimedia industry of interactive entertainment, games production, computer animation, CD titles development, corporate communications and education. Graduates are likely to work as computer animators, multimedia designers/producers, content developers, computer graphic artists, games designers or developers. Careers will
also include multimedia programming, multimedia consultancy, multimedia database specialists and multimedia network specialists.

It would seem, then, that the tertiary institutions have positioned themselves well in responding to the demand for multimedia production professionals. However, as the bulk of the graduates are not due to enter the industry until at least a couple of years from now, there is therefore a severe shortage of such professionals which cannot be entirely met by foreign expertise. At the moment most content production has been farmed out to organisations which have expertise in their bases in North America, Europe and Australia.
Using Multimedia to Improve the Assessment of Language Learning

Dorry M. Kenyon
Division of Foreign Language Education and Testing
Center for Applied Linguistics, Washington, DC, USA
dorry@cal.org

Abstract: In the United States, widely accepted standards for evaluating oral proficiency are provided by the Speaking Proficiency Guidelines of the American Council on the Teaching of Foreign Languages. Through live workshops, the Center for Applied Linguistics (CAL) has trained thousands of teachers to assess student oral performances using the Guidelines. To extend this training, CAL has also developed self-instructional Rater Training Kits. CAL is currently attempting to improve this training by harnessing the capabilities of multimedia to develop a self-instructional, adaptive, interactive training program.

While multimedia has been used increasingly for language instruction, student learning also needs to be assessed. In the United States, widely accepted standards for evaluating oral proficiency are provided by the Speaking Proficiency Guidelines of the American Council on the Teaching of Foreign Languages [ACTFL, 1986]. To effectively apply the criteria of the Guidelines to the scoring of performance samples, raters (usually foreign language teachers) require specialized training. The Center for Applied Linguistics (CAL) has trained thousands of teachers in the Guidelines through one- and two-day workshops, a traditional approach. While workshops are effective, they can be costly in time and money, and can offer logistical challenges.

To extend the benefits of training beyond workshops, CAL has also made it available through self-instructional Rater Training Kits (RTKs) [Kenyon & Stansfield, 1993, August; Kenyon, 1997]. These kits consist of several audiocassettes containing student performance samples and training booklets. Samples of student speaking proficiency are drawn from the Simulated Oral Proficiency Interview (SOPI). The SOPI is a tape-mediated speaking test based on the ACTFL Guidelines that elicits speech by means of a tape recording and printed test booklet [Kuo & Jiang, 1997]. The test presents examinees with either seven or 15 (depending on the level of the examinee) relatively authentic, context-based speaking tasks. Examinee responses to the test tasks are recorded on a separate examinee response tape. Responses to each task range from 45 seconds to one minute and 40 seconds, depending on the complexity of the task. To score the examinee’s proficiency, raters evaluate the examinee’s task performances using the criteria of the ACTFL Guidelines. Examinees receive a final rating on the nine-point ACTFL scale based on their performances across the test tasks.

While the RTKs allow for individualized instruction at a time and place suitable to the trainee, we believe that at least four limitations of these kits can be improved through multimedia. First, no matter what their prior experience, all trainees must work through the materials in a similar, linear fashion. Second, due to practical space limitations of the audiotape, trainees can receive only a relatively small number of exercises to practice their rating skill. Third, working with audiotapes means that when trainees want to listen to specific samples, they must rely on manual rewinding and fastforwarding entire tapes, a time-consuming and inefficient process. Finally, the kit provides no opportunity for additional exercises if a trainee still lacks confidence in some levels of the rating scale, nor is there an easy way of quickly moving through the materials for persons who have had previous training or are already very familiar with the ACTFL Guidelines.

Using Authorware 4.0, CAL has developed a multimedia program that improves the self-instructional rater training process by allowing trainees to develop their skills in a way that suits their needs and adapts to their ability as raters. The program contains three sections. First, trainees progress through vital introductory information on the Guidelines and the SOPI in a manner that facilitates their theoretical comprehension of the material. The introductory material is broken down into units, each of which is introduced with a "pre-test." Trainees completing the "pre-test" activity successfully have demonstrated prior mastery of that material and may go on to the next unit. Otherwise, they learn the introductory materials in smaller units through hands-on
activities. A "post-test" activity for each unit ensures that the materials have been learned successfully.

Upon completing the first section, trainees enter the "hands-on" training mode of the program. Here they first listen to sample examinee performances on one of the 15 SOPI tasks. These samples illustrate the different ACTFL proficiency levels, allowing trainees to hear benchmark examples of what they have been introduced to conceptually in an order that makes sense to them. The use of multimedia allows trainees to easily control what samples they listen to, the number of repetitions, and the sequence.

When trainees are ready to practice (or refresh) their new knowledge and skills, they can select the exercise for the task. This section tailors the presentation of new examinee responses on each SOPI task to the rating ability of the trainee. Trainees test their ability to accurately rate student performances by listening to and rating individual responses one at a time. These pre-rated performances are drawn from a large pool. For each task, after trainees listen to the first performance randomly selected by the program, they enter their rating. The program then gives them immediate feedback, keeping track of the trainees' correct and incorrect ratings. An algorithm in the program requires trainees to correctly evaluate a predetermined number of samples at specific ACTFL levels to successfully pass the exercise. The program does not select additional exercises for performance levels the trainees score correctly the first time. However, if trainees are having trouble rating two adjacent performance levels correctly, for example, the program will automatically provide additional exercise samples at those levels. In this way, the program is adaptive to the skills of the trainees, while providing ample practice to develop the rating skill. For trainees who cannot successfully complete an exercise portion for a particular SOPI task, the program will alert them to review all training materials on that task and attempt the exercise again. For each task, the pool of exercise performance samples is large enough for the two complete attempts to pass the exercise.

The final section of the program explains how to award examinees an overall global proficiency rating based on their performances on separate tasks. It provides trainees practice in rating examinees across several tasks, as well as in assigning global ratings.

An advisory council has evaluated a Spanish prototype program, which will soon be pilot tested with Spanish language teachers. The program will be evaluated in terms of its clarity, usability, efficiency, and effectiveness in training in the assessment of oral language proficiency. In this way, we will evaluate how multimedia language assessment training has provided improvements over more traditional approaches.

An Assessment of Engineering Undergraduate Distance Learning Programs

Maria Lorna A. Kunnath
mak05307@pegasus.cc.ucf.edu
Doctoral Candidate
University of Central Florida
College of Education
Major: Instructional Technology

Abstract: The study discusses the practice of distance education in universities worldwide with particular attention to universities in North America. The study revealed that cooperative and consortia type institutions composed of member universities offer the advantage of delivering a wide variety of courses at the time of demand compared to single independently operating distance learning universities. Quality of learning in distance delivered education can equal traditional mode of delivery depending on the quality of faculty-student interactivity, information transfer and student attitude. The paper concludes by saying that distance delivered engineering education suffers from the traditional university evaluation criteria, norms and expectations imposed on it. It needs to establish its own standards with respect to assessment and evaluation of educational outcomes and validation of skills and competencies of its graduates in the workplace.

Distance education reverses the traditional way of providing education to the learning community. Instead of students coming to the university to get that needed education, the university instead comes to the student.

While 40% of competitive improvements are derived from direct investments, 60% of competitive advantage comes from advances in knowledge or innovation (Carnevale, A.P., 1992). In 1995, 21% of all adults participated in work-related adult education. Majority of this percentage took courses provided by businesses or professional organizations. Colleges and universities or government agencies provided others. Workers in the executive, professional and technical occupations were most likely to receive on-the-job training. Distance education is able to address this critical learning need.

The latter half of the 1980's and the early 1990's saw the emergence of many distance learning consortia based on satellite television and large industry of 'business TV' delivered by satellite (Moore and Kearsley). Two advantages that are attributed to consortia-delivered distance education are: its capability to offer a broad selection of courses and the strong competition that exists among the member universities in terms of offering the best quality courses in the most timely manner. The customer's (students, employees, companies) needs dictate what courses are in demand and marketable (Moore and Kearsley 1996).

Established in 1985 and based in Fort Collins, Colorado, the accredited National Technological University NTU is a cooperative effort of 47 universities providing for graduate and continuing education for the busy engineer, technical professional and manager. NTU has no faculty or campus of its own and relies on courses taught by faculty of participating teaching universities. The National Universities Degree Consortium NUDC is a consortium of 13 accredited universities across the United States working together to offer over 1,000 courses, 3 credit certificates, 11 Bachelor degrees and 24 graduate degrees through distance education. Funded by the National Science Foundation with matching funding provided by participating institutions, the Southeastern University and College Coalition for Engineering Education SUCCEED is a coalition of 8 southeastern engineering colleges managed in the college of Engineering at North Carolina State University. It is committed to a comprehensive revitalization of undergraduate engineering education. SUCCEED's curriculum model called CURRICULUM 21 conveys the coalition's theme "Engineering Education for the 21st Century". The Florida Engineering Education Delivery System FEEDS was established by the Florida Legislature in 1982 to deliver graduate engineering education, primarily at the master's level to engineers throughout the state at their place of work through distance learning technologies. Independently operating Distance Learning universities offering different

certification in engineering e.g. associate, pre-degree, degree, diploma, post-graduate, continuing education, certificate and training exist worldwide. The Peterson's Directory of Distance Learning database revealed 24 universities offering undergraduate distance learning. Further exploration revealed that there are other well-established Distance Learning Universities.

**Technology, Access and Interactivity**

Distance education began its life through correspondence utilizing one of the earliest forms of communication i.e., print, which occurred on an international scale. The origins of some of most important ideas and techniques that are being used today have its roots to century-old events that occurred globally. Began in the form of correspondence study, distance education evolved into a total systems approach pioneered by Charles Wedemeyer which was adopted by the 'Open Universities' principally the British Open University. This approach used print, broadcast and recorded and distributed by radio and television. An Overseas Development Administration 1995 Education Report\(^2\) revealed varied perceptions about distance education. The United Kingdom looks at it as a grown market, The United States views it as a second-class option and Developing Countries are yet to be convinced of its benefits. The report cited cultural adaptability, attitudes, local point of contact and student support as factors necessary for its success.

The most popular Distance Learning technology is the videotape system. Telecourses offer the convenience of taking classes while at home or in the office by way of the student's television sets. Online courses facilitate instruction to any student who has a connection to the Internet. This is usually supported by a host of other technologies such as 2-way video conferencing live and interactive and electronic mail. Boston University's interactive-Compressed Video system utilizes three state-of-the-art PictureTel videoconferencing system. These systems transmit at speeds of 56-384k (full motion video) capability. Stanford University's Stanford Instructional Television Network SITN utilizes a digitization and compression of courses in video format and stored on a video server making it available as an on-demand video streaming environment.

Distance education practitioners were the first to see the promise of the technological revolution as a means of unlocking the door of access for students and help distance teaching institutions become the leaders of the 'New University' (Hall, J., 1996). However, some distance learning critics would argue that since learning resources are scarce, bringing in more students would dilute the quality of these resources (Ehrmann, S.). With advances in technology these resources e.g. books, communication facilities, calculators, etc were mass produced making them widely available to many learners simultaneously with enhanced quality. Today the computer has taken over as one of the most important, if not the most important learning tool in accessing learning resources and enhancing learning at the same time. On-line communication facilitates communication between one another, transfer text/data files, obtain information from computer databases transcending time and space constraints. Computer Mediated Communication CMC or Distributed Learning Environment is a new medium in education and more specifically, distance education (Kaye, A.). The basic structural element of CMC is that all communications are stored on the system and are retrievable. Hence these information are researchable, downloadable and usable at any time. Its drawbacks include requiring access to expensive essential telecommunications facilities and equipment and familiarity with the technology itself. The interest is high in spite of these barriers because like the spoken word it is spontaneous and flexible. It is a powerful medium for communication and cooperative learning. Possible predictors of success in using CMC/DLE in distance education would depend on the teacher's interest and familiarity with the technology, trust in the value of cooperative learning and sufficient time to assess student contribution. Success of CMC use will also depend on the student's being able to overcome all techno-socio-economic barriers in achieving mastery of the medium.

**Quality of Learning**

\(^2\) Distance Education in Engineering for Developing Countries byilham, T. and Gilmour, R., Education Research Serial No. 13.
Research and evaluation studies show that achievement and satisfaction of students who learn via
technology can equal those of students in regular classrooms (Johnstone, S. 1996). There are various
factors at play in that transfer of learning. Information transfer is one. A survey of 400 students in two-
way telecourses between 1988-1990 revealed that the amount of information transferred was the best
predictor of learning and the strongest predictor of satisfaction was information transfer (Walker. K., 1992).
Another factor linked to meaningful learning is interaction with faculty. This has been shown in several
studies linking interaction with learning. Oklahoma Televised Instruction System 1992 survey showed that
83 % interacted with the instructor all the time and did not feel disadvantaged when it came to access to
services. The same study revealed that distance education students performed equivalently in civil
engineering but performed better in business, humanities, science and social science. The students cited
problems with the telecommunication system, instructor style, method of instruction and lack of library
resources hindered their performance. In a 1993 survey of 30 video-based distance education students of
an independent university in various courses, course completion was directly correlated with faculty
initiated contact by telephone call to their students (Towles, D. and others, 1993). A survey of
teleconference DL students delivered by two Canadian universities revealed that the goals of deep learning
and critical thinking were achieved when teleconference took place more frequently such as on a weekly
basis compared to a bi-weekly frequency (Anderson, T. 1994).

Delivery mode is another factor that can have an effect on learning. A study was done of the same graduate
class in Management Technology delivered in the traditional method at Georgia Institute of Technology
and the University of Alabama at Hunstville and by studio broadcast to students enrolled at National
Technological University NTU at Colorado. In that study, the traditional students outperformed the remote
students on the examination calling for understanding and articulation of basic concepts. However the
older NTU students outperformed the traditional students on questions calling for application and synthesis
of course materials.

Student's attitudes on the distance education mode can also have a significant impact on the quality of
learning. Students at Valdosta State University expressed a less positive reaction to the physical distance
learning environment and to the overall course. At a large midwestern university (Remote site) Telecourse
students were compared with (Broadcast) traditional students. High grades for telecourse students were
associated with greater expediency, greater self-sufficiency and less compulsiveness. For traditional
students high grades were associated with greater conscientiousness, emotional stability, soberness, shyness
and liberalism. High rate of student retention and satisfaction with studies at the Open Polytechnic of New
Zealand were attributed to students receiving a pre-enrollment counselling booklet.

Several factors can affect distance learners' satisfaction with interactive televised courses viz.
Instructor/Instruction, Technology, Course Management, At-site Personnel, Promptness of Material
delivery, Support Services and Out-Of-Class Communication with the Instructor (Ball State University
survey).

Faculty attitude to distance education is mixed. A survey of faculty members in 57 public institutions
revealed attitudes towards distance education. In general, faculty attitude was positive but became negative
when it was applied to their own programs or courses. Experienced distance education practitioners and
community college faculty had an overall positive attitude than faculty at four-year institutions. Faculty at
4-year institutions expressed positive attitude towards videoconferencing. In a 1994 evaluation of the
seven Annenberg/CPB New Pathways to a degree learning projects of seven institutions, faculty was of the
opinion that mediated teaching was not comparable to face-to-face environment. While the efficacy of
technology is becoming less of a question in distance education the focus is being shifted to surrounding
issues such as feelings of isolation of distance students who do not have any human contact with their
instructors; how to provide effective advising and academic support services to distance students and a
guarantee of continued support to electronically delivered program until the distance students complete
their program.

Accreditation is a process that gives public recognition to educational institutions that meet published
standards of quality. It is a fact that distance education is "becoming widely accepted but yet is still not
mainstream and employers skeptical of a degree are likely to be even less accepting of one from an
unaccredited school" (Occupational Outlook, Summer 1996 Vol. 40, Issue 2, p22).
Technology has precipitated a new era of educational paradigm. Distance education faces an enormous challenge because it is an evolving field and is heavily dependent on a rapidly changing telecommunications industry. The standards by which educational quality of a distance-delivered course is still based on norms set by the traditional university. If distance education will be judged through its own merits, it needs to have its own set of criteria for evaluation and not entirely based upon standards accorded the traditional university. On assessing the educational quality derived from a distance-delivered course emphasis would need to be placed on the quality of its graduates and outcomes of the educational process such as the skills and competencies acquired and validated in the workplace.

The construct of a “learning community” has increasing prominence both as a means for understanding human performance and learning outcomes and as a vision for guiding educational reform. Researchers see special value for the utility of learning to performance in learning that is situated in the authentic activity of a community, such as a profession, a trade, or an academic discipline. These professions and disciplines create communities of practice wherein learning takes place through experience and induction takes place through apprenticeship. In these situations we can view learning as not a type of activity, but rather as an aspect of all activity. An implication of situated learning for educational institutions is the need to provide students with participation in the authentic work of communities of practice.

However, schools are not places of “authentic work” they are places for preparation and development, and the model of communities of professional practice may not be appropriate for school-based learners. [Scardamalia and Bereiter 1994] propose a knowledge-building community as a goal for educational reform. The knowledge-building community is based on a model of the academic or scientific community that is focused on building new knowledge. Their conception of a knowledge-building community emphasizes intentional learning as the product of the educational community of practice. This contrasts with a focus on expert performance held by other communities of practice. Communities of practice in educational institutions must engage students in knowledge building. Learning to learn becomes the authentic practice of schooling.

In some ways all communities are learning communities or they would cease to exist. High performing learning communities, however, can be defined as enterprises that place a special value on developing the capacity to learn, see learning as the outcome of the authentic activities of that community, use the outcomes of learning as scaffolding for future activity, and enable activities as social practices (e.g., not bound by arbitrary isolation of individuals, such as individual seat work in school).

Educators, such as Scardamalia and Bereiter, recognize the potential of technology to transform educational institutions from traditional transmitters of acquired knowledge to learning communities engaged in knowledge-building. This view of network-augmented learning differs from web-based courses similarly to the way that the experience of a graduate research assistant differs from that of the freshman student in the lecture hall course. Advancing technology has diminished the economic reasons for this distinction.

Dimensions of a Learning Community

Traditional educational institutions differ from learning communities across a set of dimensions. Some of the key dimensions are:
Abstract vs. Authentic: Traditional forms of scholarship isolate knowledge into domains for advanced inquiry. Schools have adopted these abstracted domains of knowledge for providing students with a knowledge-base for citizenship and employment. A learning communities model places learning and inquiry into the practice of the community, thus requiring integration and authenticity.

Hierarchical vs. Networked: School curriculum is organized into hierarchies of modes of instruction and sequences of knowledge and skills. Learning communities create networks of people and resources to enable right-time, right-place and right-form learning support.

Static vs. Dynamic: Curriculum represents an approved canon of knowledge. Learning in a community adapts to challenges and opportunities. In a sense the curriculum is found in the situation and new knowledge is dynamically added to the community memory as new situations are taken on and mastered.

Telling vs. Modeling: Situated learning is more likely advanced through role models, trial and error, and demonstrations rather than didactic lessons.

Testing vs. Assessment: Greater emphasis is placed on self-assessment and building the capacity of the learner to make beneficial assessments.

Grading vs. Reflection: In learning communities we expect that individuals will take more responsibility for their own development because they have authentic consequences for their actions.

Technology Enablers of a Learning Community

Technology has great potential to enable a learning community, especially the new technology of inter and intra-nets and network computing. Three key technological enablers for moving toward the Learning Communities side of the dimension matrix are:

1. Articulation of experience: media representation enables the user to communicate experience more directly to others.

2. Making sense of experience: Access to mediated representations of the experiences of others can enable the learner to compare and contrast experiences. These processes support reflection and develop a perspective for making sense of personal experience.

3. Contributing to the sense making of the community: Networks and the web create a potential audience for experience that can change the relationship of the learner to the sense making process for the experience. Having an audience, and in a sense a customer, can drive the learner to a deeper and more thorough processing of experience.

New network services support these enablers and offer the potential to design education based on a learning community model rather than on the traditional model of instruction.

References

I. Introduction

A learning system can be useful in any application area where it is expected to be used by people with different goals and prerequisites. An adaptive system tries to overcome this problem by presenting differently information to learners. This paper presents an ongoing research on creating an Intelligent Tutoring System allowing a distance learning via Internet/Intranet networks.

II. WHAT IS CAMELEON

CAMELEON is the English acronym of Computer Aided Medium for LEarning On Network, It's a system running across the Internet/Intranet, allowing teacher introduce his/her course and the learner to study (presentation of the course materiel, assessments, etc.) via an adaptive interface.

III. Why CAMELEON

CAMELEON is the French word of chameleon, which is small lizard famous for changing its skin color according to their surroundings and so to adapt itself to the environment. We plan to have and adaptive systems, which can compare the student’s model and the domain model and thus automatically change its teaching style.

IV. Architectural considerations

Because of the absence of the teacher during the learning session, the teacher should have an initial interaction with the system before that the students use it, in order to define the teaching behavior and material and then after to evaluate the students’ work. This means that an authoring system in which the teacher is able to specify all the teaching material and teaching style is a definite requirement. A separate system would then deliver the teaching to the student.
V. Architecture of CAMELEON

The teaching system consults the learner module then selects from the knowledge domain the concept or the topic to consider, it also selects a tutoring style from the strategy domain to generate the corresponding Web page [fig. 1].

V.1 LEARNER MODULE

The learner module has four main components: a Learner Model Library, a Stereotype Library, Implicit Acquisition Rules, and an Inference Engine.

A learner model is the knowledge about the learner, either explicitly or implicitly encoded that is used by the system to improve the interaction [HOOK 1996]

It contains the model of the individual learner which is to be regularly updated in the course of his/her interactions with the system.

V.2 DOMAIN KNOWLEDGE

The domain knowledge contains:
- The contents to be taught
- The relations between different parts of the contents that may influence the teaching sequence.

All of the above knowledge are created by instructional designers when they create instructional material using the authoring system.

V.3 DOMAIN STRATEGY

The domain strategies denotes coherent set of guidelines (Theories, models, rules, constraints, algorithms..) for the creation selection and presentation of course contents.

VI. Current status and future work

We are currently implementing the authoring language supporting the writing of the course material in the Arabic, French and English languages.
In a near future, we plan to elaborate the learner model by including some cognitive characteristics that are relevant for the learning processes, like cognitive style or reasoning abilities.

1. The project and the courseware

Traditionally, teaching linguistics at universities is very much a talk and chalk activity. Lectures are delivered in a very restrictive classroom discourse in which lecturers discuss ideas and linguistic issues with the help of a few teaching tools such as overhead projector, video and cassette. Though the Web has provided university teaching with a new paradigm, linguistics is still a land virtually untouched by Web explorers. Our project was an attempt to investigate theoretically and practically how the Web can be used to promote the teaching of linguistics (including applied linguistics), particularly in off-campus mode.

The initial stage of the project was to identify the key areas in general linguistics that the Web can make the best contribution. It was obvious that those areas or branches of general linguistics which dealt with speech production and visual illustrations were the appropriate candidates for developing web-courseware. They were phonetics, developmental psycholinguistics and communication disorders. The following discussion will briefly explain why the Web can play an important role in teaching those subjects and this will be followed by a detailed presentation of a courseware teaching phonetics and linguistic variation.

Phonetics: It deals with speech production. Articulatory phonetics describes how speech sounds are produced. The articulatory process involves the use of speech organs such as the lung, larynx, tongue, jaw and teeth. Each plays an important part in creating various types of speech sounds, tone, and intonation patterns. The IPA (International Phonetic Association) symbols are normally used to give students of linguistics some ideas of how human speech sounds are produced. Unfortunately, they are just written symbols and students can perceive their real production quality through cassette and video which are not always available at the right time, particularly in off-campus teaching. In addition, students of phonetics need to hear English spoken by speakers of different sociolects and dialects. In other words, they need to develop some awareness of different English varieties such as Australian English, American English, cultivated English, non-standard English, Singaporean English etc.

A Web-based courseware can facilitate the development of phonetic awareness by providing students with graphics and sounds which illustrate accurately the articulatory process, sounds, speech samples of different dialects and sociolects.

Developmental psycholinguistics: Students of developmental psycholinguistics need to hear speech samples of children of different age groups in order to ascertain their stages of linguistic development. This is normally shown in written texts in which children's speech samples are transcribed phonetically. The disadvantage of this approach is that it tends to portray more accurately syntactic information about child language development and less phonetic information. The problem mentioned above can be easily handled in a Web-based courseware which can provide samples of children's speech in a written text and oral text. For instance, a sample of a five-year-old girl talking to her father can be recorded and transcribed phonetically on the Web. Students can click the written text to hear the authentic speech produced in this social context.

Communication disorders: The severity of linguistic problems can be mild as seen in children with misarticulation or serious as in case of aphasia caused by lesions in the brain. It is important for students of communication disorders to hear and see a variety of deviant speech samples of speakers with communication disorders. It is no use just to introduce students to the concept of expressive aphasia without showing them authentic samples produced by aphasic patients. A Web-based courseware can provide visual and spoken
language samples of speakers with communication disorders. The visual information includes transcribed texts as well as graphic information illustrating types of disorders. For example, deviant sounds produced by children with misarticulation can be heard and visual illustration of the way in which articulators are involved in the sound production process can be presented.

The initial part of our overall project was an attempt to develop a courseware using modern Java technology for teaching phonetics and different varieties of English on the Web. For example, Java applets was embedded in a Web-browser to play speech sounds and utterances in different English varieties. This courseware was used to support undergraduate and postgraduate courses dealing with language education in the Faculty of Education, particularly for off-campus teaching.

This project uses Java technology in the Web, for instance, embedding Java applets in Web-browser, to produce sounds and utterances with accompanied facial expression. Students can make use of two kinds of perception cues to recognise speech varieties on the Web:
- Graphic cues: different shapes and movements revealed through facial expression. For example, the shape of the mouth is rounded for the back vowels and spreading for the front vowels.
- Speech cues: sounds and utterances spoken by different individual speakers of different regional and social dialects of English. For example, students can hear the difference of English accents when they are introduced to samples of speech spoken by Broad and Cultivated Australian speakers.

2. Courseware prototype

As the main aim of this project was to teach linguistic awareness, the key task was to produce a practical courseware which has the following features:
- Content on phonetics and linguistic variation.
- Speech samples on three linguistic units: word, sentence and conversation.
- The use of Java technology for the Web to simplify the prototype without the involvement of other software and computer applications as seen in some courseware.

The courseware consists of the following components: content, facilitating experiences, and Resources. These three components represent different roles that the Web can play in teaching and learning.

Content component: The four content areas are phonetics, dialect, sociolect, migrant English. Each content area consists of five items or sub-components: 1) Modules: lesson-typed presentation, 2) Problems solving tasks: learning by doing, 3) Basic terminology: key concepts, 4) Review: what has been learned, and 5) Key references: important readings.

Facilitating experiences: Learners are provided with activities or facilities which can be used to enhance learning. This option consists of: 1) Stimulating questions: For arousing intellectual curiosity, 2) Feedback: About the courseware for improvement, 3) Test: In the form of mini-test with results, and 4) References: Including key references and others.

Resources: This function of the courseware includes: 1) Practical work, 2) Resources: for individual and group conferencing, and 3) On-line help: common problems.

3. Conclusion

In our past teaching of linguistics awareness, demonstration of speech samples on different English varieties was carried out in lectures with the use of audio-visual equipment. It was a big disadvantage for our off-campus students and for those who were absent from those lectures. This courseware was introduced as an alternative approach to teaching linguistics to university students. It is a stepping stone for continuing our work in the development of linguistics awareness courseware dealing with developmental psycholinguistics and communication disorders.
A Methodology for Matching Technology to Educational Objectives

The purpose of this paper is to present a methodology that helps educators determine what technology they need to support teaching to educational objectives. This methodology consists of operationalizing learning objectives into the knowledge students need to learn, determining what sensory/learning experiences are required to enable students to acquire that knowledge, determining what learning environments can provide those experiences, and then selecting technology that can create those learning environments. Each step of this methodology is discussed in turn.

Operationalize Educational Objectives into Knowledge Requirements for Learning

The first step in our methodology is to translate educational objectives into their underlying knowledge requirements for learning. Our approach is based on our Integrated Knowledge Structure or INKS framework. Using INKS, an educator can operationalize an educational objective into the problem solving strategies, procedures, factual concepts, and causal principles to be learned. We illustrate our methodology using the National Research Council (NRC, 1996) science standard for grades 5-8 that students learn science as inquiry. The standard includes:

1. Identify questions that can be answered through scientific investigations
2. Design and conduct a scientific investigation
3. Use appropriate tools and techniques to gather, analyze, and interpret data
4. Develop descriptions, explanations, and models using evidence
5. Think critically and logically to make the relationships between evidence and explanations.

Actually, these steps collectively may be viewed as a science inquiry problem solving strategy. For the sake of brevity, we pick one of these steps, design and conduct a scientific investigation, and only map out some of the procedural knowledge components. These include: develop a hypothesis, design an experiment, collect data.

Translate Knowledge Requirements into Sensory Stimulus Requirements

Next, we translate the INKS-based knowledge requirements into sensory stimulus requirements. The goal of this is to determine what educational experiences a student needs to learn the appropriate knowledge. We provide a sample set of three dimensions to categorize the sensory stimuli. The dimensions are: modality (e.g., visual, auditory), fidelity (how realistic does the learning environment have to be?), and configuration (e.g., is there spatial grouping of stimuli, temporal sequencing?). The table below illustrates this process for the scientific investigation example:

<table>
<thead>
<tr>
<th>Procedure</th>
<th>Modality</th>
<th>Fidelity</th>
<th>Configuration</th>
</tr>
</thead>
<tbody>
<tr>
<td>develop hypothesis</td>
<td>visual</td>
<td>low</td>
<td>spatial and temporal grouping</td>
</tr>
<tr>
<td>design experiment</td>
<td>visual</td>
<td>low</td>
<td>spatial and temporal grouping</td>
</tr>
<tr>
<td>collect data</td>
<td>visual/auditory</td>
<td>high</td>
<td>spatial and temporal grouping</td>
</tr>
</tbody>
</table>

Select a Learning Environment

The next step in our methodology is to select a learning environment that will present the kinds of experiences outlined above. The learning environment takes into account both the type and the fidelity. Learning environment types include such things as live or simulator-based practice, text-based instruction, lecture, etc. Fidelity relates to how close the learning environment must be to the actual experience in order to achieve the desired level of learning. We present some illustrative guidelines for mapping sensory stimulus requirements to learning environments.
environments. We present a continuum of non-classroom based instructional environments. Each are intended to represent a higher level of fidelity and can typically accommodate the ones that precede them. The environments (while illustrative and not exhaustive) are: text, graphics, audio, video and simulation. Given these environments, we present a hypothesized table of what the minimum required learning environment would be for a learning objective of a specified sensory modality, fidelity level and configuration.

**Table 2: Minimum Required Learning Environments for Learning Objectives.**

<table>
<thead>
<tr>
<th>Sensory Modality</th>
<th>Low Fidelity Sensory Stimulus Requirement</th>
<th>High Fidelity Sensory Stimulus Requirement</th>
</tr>
</thead>
<tbody>
<tr>
<td>independent</td>
<td>No Configuration</td>
<td>Spatial Configuration</td>
</tr>
<tr>
<td>visual</td>
<td>all environments</td>
<td>3-D graphic</td>
</tr>
<tr>
<td>auditory</td>
<td>audio</td>
<td>stereo</td>
</tr>
</tbody>
</table>

We apply this analysis to our running scientific investigation example:

**Table 3: Minimum Learning Environment to Teach Each Knowledge Component of Scientific Inquiry.**

<table>
<thead>
<tr>
<th>Knowledge Component</th>
<th>Modality/Fidelity/Configuration</th>
<th>Minimum Learning Environment</th>
</tr>
</thead>
<tbody>
<tr>
<td>develop hypothesis</td>
<td>visual/low/spatial and temporal</td>
<td>graphics sequence</td>
</tr>
<tr>
<td>design experiment</td>
<td>visual/low/spatial and temporal</td>
<td>graphics sequence</td>
</tr>
<tr>
<td>collect data</td>
<td>visual and auditory/high/spatial and temporal</td>
<td>simulation</td>
</tr>
</tbody>
</table>

**Develop Technology Requirements**

Once the minimum required learning environment is established, the next step is to determine what technology will be used to deliver the instruction. We present sample technologies and their current capabilities:

**Table 4: Current Capabilities of Sample Technologies and Media.**

<table>
<thead>
<tr>
<th>Technology</th>
<th>Maximum Learning Environment Supported</th>
</tr>
</thead>
<tbody>
<tr>
<td>print</td>
<td>graphics</td>
</tr>
<tr>
<td>interactive courseware</td>
<td>video/simulation</td>
</tr>
<tr>
<td>videoteleconferencing</td>
<td>video</td>
</tr>
<tr>
<td>Internet</td>
<td>graphics/audio</td>
</tr>
</tbody>
</table>

We can apply the above technology capabilities to the scientific investigation example:

**Table 5: Technologies to Support Teaching Scientific Inquiry Knowledge**

<table>
<thead>
<tr>
<th>Procedure</th>
<th>Minimum Learning Environment</th>
<th>Educational Technologies</th>
</tr>
</thead>
<tbody>
<tr>
<td>develop hypothesis</td>
<td>graphics sequence</td>
<td>all</td>
</tr>
<tr>

AOFwb - a new Alternative for the MBone Whiteboard wb

J. Lienhard,  
G. Maass  
Institut für Informatik  
Albert Ludwigs Universität Freiburg  
Germany
email: {lienhard|maass}@informatik.uni-freiburg.de

Abstract: This paper describes a new whiteboard for telepresentation and teleteaching. The whiteboard substitutes a blackboard or an overhead projector used in a computer aided lecture, which is digitized and transmitted to remote locations. We examined different tools like showcase, xfig, powerpoint and the MBone wb and combined the most useful features of these tools in our own AOFwb. Thus we implemented a tool which can be used as a graphic editor, a presentation tool or a tool for teleteaching.

1 Introduction

For telepresentation [Gemmel and Bell 1997] a wide variety of whiteboards is available. The MBone wb, the whiteboards from cooltalk (a netscape plugin) or from inperson (a tool on IRIX Workstations) are well known. However they are very restricted in their features. Most of them support only drawing objects and writing simple text.

We have been using the MBone wb [Eriksson 1994] to deliver a substantial amount of lectures. Our experience shows, the features offered by existing whiteboards are far from being sufficient. In particular, this observation applies to sessions, which include graphics, images or external applications can be realized using our own AOFwb [Bacher and Ottmann 1996].

2 Description of the AOFwb

When preparing a lecture you usually write down your ideas and you create a paper or transparencies by hand or by using TeX, powerpoint, showcase. If you want to use the MBone wb for telepresentation, you must create a postscript-file from each page. We have developed a language similar to SGML, that we use to save a document. Thus you can edit your prepared page while giving a lecture.

In the following, we explain the available features to prepare a lecture and to edit the pages. Similar to showcase you create text as a block or as line-text. If you want to change the colors of some objects you can select and group them for editing the color. The possibility exists to use a mesh with snap option to make the drawing of some objects easier. For talks with mathematical or physical content a Latex-formula editor is included. You write the formular in TeX and point it to the position, where it should be placed. Pictures can be put in the background (tiled) or in the foreground.

When you finished the preparation of a lecture, the document is saved and can be reloaded later. Additionally the pages of this document are visualized as thumbnails, to give the lecturer an association, which page is next. Another useful feature for telepresentation is a telepointer also implemented in our AOFwb. While giving a lecture all actions can be transmitted to remote locations, recorded and later replayed.

3 Conclusion and further work

With our AOFwb you can prepare, transmit and record a lecture with only one tool. Our next step is to combine the classic style of lecturing by means of blackboard and chalk with the modern technology. This can be
realized with a *lecture board*. In this case the screen is projected on a special board with a video-beamer. A pen is used to substitute the mouse. In this way the author can perform most of the actions on the board.

**Availability**

The prototyp of our whiteboard *AOFwb* and the neccessary viewers to replay the recorded lectures are available for *Solaris, Irix* und *LINUX* platforms at our ftp-server:

ftp://ftp.informatik.uni-freiburg.de/pub/AOF/AOFwb/

Creating HyperMedia Materials For Russian Language Studies

Martina Lindseth, Department of Modern Languages, Wabash College, USA, LindsetM@wabash.edu

Jacqueline M. Kaminski, Department of Modern Languages, Wabash College, USA, KaminskJ@wabash.edu

1. Introduction

This paper discusses and demonstrates Russian materials created for use in second language instruction at Wabash College, a small liberal arts college located in Crawfordsville, Indiana, USA. We will detail the evolution patterns and pedagogical foundations and concerns of our work with custom software, specifically faculty and student responses to such endeavors.

2. Background

Wabash College faculty opted for creating a digital computer language lab in favor of purchasing the more traditional language lab consoles which primarily use cassette media. In order to achieve the goal of creating the digital lab, a computing specialist was hired to coordinate technology initiatives among language faculty. In order to accommodate the need for audio-lingual work which would otherwise have been accomplished with a console system, faculty collaborated to create a simple HyperCard template called *Listen and Respond* which is used as a digital tape recorder.

3. Implementation

The template learning curve for both faculty and student users is not steep. Custom audio materials are created by faculty in less than 10 minutes and made available immediately via server to students for practice and testing use. Students and faculty both found using these materials easy and more productive than traditional time-consuming one-on-one interviews or tape-recorded activities in the target language.

Employing these materials proves more useful than traditional methods because of the following characteristics: there is random access to questions; corrections and feedback can be adjusted to student skill level and learner type (visual and/or verbal); their use is less time-consuming than meeting individually with students or using tape recorders; oral skills can be more realistically addressed compared to former practices of using written answers to verbal cues; materials are easy to modify and are readily available for use as testing or oral homework assignments; students and faculty can keep recordings on file.

4. Point of Departure

More recently, using a dedicated Modern Languages Computer lab containing 24 Mac7100/80s, Wabash faculty have been successful in creating lab or template materials that utilize a wide variety of multi-media, bringing cultural realia into each language course. These materials address various language skill levels. Both faculty and student assessment of template use has been positive, as development of materials in various languages has shown.

5. Specific Application

1808
One such example we created for Russian is a multi-media program based on a speech by Boris Yeltsin. This utilizes the simple audio and verbal response template (Listen and Respond) described above and combines it with various authentic materials. Beginning with a taped speech made by Yeltsin from SCOLA (Satellite Communications for Learning), which gives full rights to educational facilities for classroom use, an advanced tool for the Russian curriculum was developed. Ultimately, this combined an interactive text of the speech in Russian, various forms of Russian audio (Yeltsin’s actual speech, a native-speaker, a slow native speaker), options for speech segmentation, images, HyperLinks to news articles and cultural websites maximizing updatability, a glossary, online help, an English translation (text and audio), cultural hypertext sections, and finally, oral questions and verbal response options for students to test their comprehension.

6. Objectives Of Software

The described materials integrate skill development on three different levels: listening, reading, and speaking. Cultural information is provided with the objective of facilitating full comprehension of the text so that all elements combine to address the needs of students with varying skill levels (intermediate to advanced). The students must acquire a keyword vocabulary to answer the questions at the end of the exercise. The level of difficulty of questions can be manipulated by the instructor to meet individual student needs. Components of the program can be updated to counter the predisposed obsolescence of political texts. Developing these MultiMedia materials for Russian is a pilot-project which can serve as a template for teaching other languages or working in other disciplines pursuant to the languages across the curriculum movement.

7. Evolution And Assessment

Assessment on two different levels was a driving force in the development and refining of this program. Student test-runs were conducted, and the faculty were able to assess comprehension by listening to student responses to content questions. We conducted a comparison of comprehension of students who used the computer template and those who did not. We found that the students who had completed the computer exercise had a higher comprehension than the ones who only accessed the video. Further, of the students using the computers, we found the same high levels of comprehension regardless of differing language skill levels. Students evaluated various components of the program which led to modifications and improvements, as well as provided data regarding benefits of our custom-created software over traditional lessons or commercial software.

8. Conclusions

Creating custom multimedia materials for Russian has proven pedagogically sound and of great benefit to students. Incorporating realia, addressing various skill levels, combining media, and continually assessing materials and course objectives has proven successful. Since enhanced student learning is the central goal in using technology, one student’s comment summarizes the results of our work: "Almost overnight, the Department of Modern Languages was modernized beyond recognition. Students were able to use a new program called "Listen and Respond," which allowed the professor to assign oral questions and have students record their responses. One such template was a program which allowed students to watch and listen to native Russians speak. After listening to one speech by Boris Yeltsin, I answered questions, and was able to access background information on a number of topics. All of this made that speech much more enjoyable and meaningful. The questions could be accessed at anytime and repeated as often as one wished. Aside from the obvious advantage of increased practice time, the new technology created a more relaxed atmosphere and
allowed the student to proceed at his own pace...Personally, I did not expect the changes to come so soon or all at once. Now, the available technology has made the study of foreign languages more complete."

Examining Teaching and Learning Aspects of A Web Design Experience

Min Liu
Department of Curriculum & Instruction, University of Texas at Austin, USA, mliu@mail.utexas.edu

1. Project Background and Theoretical Framework

A distinction has been made between learning from computing and learning with computing [Jonassen 1994]. Learning from computing refers to situations in which computers are tutors, while learning with computing emphasizes the use of computers as cognitive tools to extend human minds. It is this second use of computing that has become the focus of educational research in recent years. Educators argue that when students are learning with computing, they engage in an active partnership with the technology and are able to construct their knowledge with the assistance of the technological tools [Jonassen 1994], [Salomon, Perkins, & Globerson 1989]. One specific way of learning with computing is to engage students as multimedia designers. Literature shows that the benefit of a learner-as-designer environment is the opportunity to integrate a variety of activities such as designing, researching, presenting, and reflecting, and tap a diverse set of higher order thinking skills in one single meaningful context [Carver, Lehrer, Connell, & Erickson 1992]. Recent research studies have shown some encouraging results in this area [Beichner 1994], [Lehrer, Erickson, & Connell 1994].

To implement such a learning environment, the author engaged a group of university students in designing a web project for a real audience. This web design experience occurred in a graduate level course of Interactive Multimedia: Design and Production. This course is offered to the students in the College of Education at the University of Texas - Austin. Students attending this course include teachers, educational technologists, and future instructional designers. It is designed with an intent to provide students with a learning environment where they can apply the theories of the multimedia technology into practice. To simulate real-world multimedia production and encourage collaborative learning among the students, students attending the course are asked to design and produce, collaboratively as a class, a web site on multimedia uses at the University. The audience of the web site is students, teachers, and other individuals who are interested in knowing how multimedia is used at the University of Texas - Austin.

2. Project Process and Activities

Using literature on the topic and practice in the multimedia industry as a guide [Liu, Jones, & Hemstreet in press], a four-phase instructional model was used for the web design project: (1) Phase I: Planning, (2) Phase II: Design; (3) Phase III: Production; and (4) Phase IV: Evaluation & Revision. The emphasis for the planning phase was to identify the objectives, audience, available resources of the project, and determine the timeline of the project. The focus of the design was to apply and adapt instructional design theories and principles for the recent web technology. The production was a hands-on phase in which students produced the media elements and put the pieces together into one coherent web site. The evaluation and revision phase was an on-going phase for getting feedback from different parties and making revisions to the site. Table 1 [Tab. 1] details the specific activities related to each phase.

This web design experience has the following characteristics: (1) the classroom was simulated as mini-multimedia production house in which students assumed various roles of being a writer, a video producer, a programmer, an artist, a project manager, or several at different times. Each week, students negotiated in the group the tasks they would carry out based upon the guidelines given by the instructor. Each student was responsible for a certain part of the project and his/her work would feed into the work of others. (2) The design and production process was a group process from the beginning. All the decisions on the interface, media selection, content, fonts/styles were based on group consensus. Each group was responsible for the quality of its section and at same time for making sure its section was consistent in design with the sections from other groups. (3) Students were engaged in the design process very similar to the practice in the
industry (Liu, Jones, & Hemstreet, in press). They identified the needs of the project and learned what was needed for completing the project. Because the final project had a real audience, students needed to be aware of the audience's like and dislikes throughout the project.

3. Teaching and Learning Issues

From an instructor's perspective, this web design experience illustrates several important points. The constant change of the technology demands the continuous change in the teaching practice. It is important for instructors to continue inventing ways to enhance teaching with the technology and use technology as tools to extend students' thinking. Providing scaffolding in different ways is essential for the success. While it is important for the instructor to provide a structure to the course, he/she must create an environment where students are free to think and be creative. Teaching with rapid change of technology is a challenge and instructors must be willing to learn continuously with the students.

The authentic aspect of the learning experience motivated many students because they perceived it as helpful to get them better prepared for the job market. The collaboration and interaction among groups enhanced students' understanding of the web technology. The team work offered students an opportunity to engage as professionals and learn to cope with others. The tools the students learned and the web site that they accomplished gave them a sense of accomplishment and enriched their portfolio. A number of the participants from the project have played key roles in a number of subsequent projects.

In the presentation, the teaching and learning aspects of the experience as well as the design process will be shared in detail. The web site will be demonstrated.

Institutions of higher education are being pushed to choose alternatives to the traditional modes of course delivery by a number of forces. Increasingly “non-traditional” populations are requesting access to higher education opportunities which may not be conveniently available or reasonably affordable through the current infrastructure. Business and industry are seeking “qualified” employees from “just in time” training. States are asking higher education institutions to increase the number of residents holding advanced degrees and certificates, to provide options to building new campuses, to develop creative ways to meet the needs of an increasingly traditional student population, and to play a role in moving welfare recipients to paid employment.

In order to serve the needs of these forces, Texas Tech University is turning to distance education options. According to Moore and Kearsley [1996], “Distance education is planned learning that normally occurs in a different place and as a result requires special techniques of course design, special instructional techniques, special methods of communication by electronic and other technology, as well as special organizational and administrative arrangements.” By selecting distance education options, Texas Tech is overcoming barriers that have kept it from serving potential clients in the past.

Texas Tech University formed the Telecommunications Infrastructure Fund/Distance Learning Vision Committee in the fall of 1996 to develop its mission of distance learning. That visions states that:

Early in the next century Texas Tech University (TTU) must establish itself as a national leader in changing the paradigm of higher education and health care via distance learning as part of its goal to become a national Tier I comprehensive institution. The necessity of responding to needs at appropriate times and locations convenient to students across the world, as well as across the campus, is the primary force driving this transition.

Texas Tech is making progress toward achieving its mission. Presently in place are a Distance Learning Strategic Planning and Policy Council; the Division of Extended Learning; the University Library System; the Teaching, Learning, and Technology Center; HealthNet; KTXT-TV; and the SCATE consortium.

The Distance Learning Council is responsible for monitoring and recommending academic policy impacting the integration of distance learning into the “culture” of the institution. The Council is also addressing the practical aspects of faculty involvement in program development and implementation.

As the largest distance learning program of its kind in the United States, Texas Tech University’s Division of Extended Learning has extensive experience in designing and delivering self-contained curriculum. The Division offers over 200 courses through open enrollment to nearly 50,000 students in 50 states and 16 foreign countries. These courses do not follow semesters and can be completed at the student’s own pace wherever he or she may be. Extended Learning courses are delivered using a variety of media which include WWW-based courses; computer-based courses; courses delivered via interactive video; courses using “transportable media” including video tape, audio tape, and CD ROM; and “hybrid” courses designed to use combinations of these delivery technologies. To serve students who do not have ready access to technology or who are constantly traveling, Extended Learning maintains much of its course inventory in a print-based format. On the college level, Extended Learning has a complete curriculum for a Bachelor’s in General studies, and collaborates the colleges of the University to provide a wide range of distance delivered courses and programs. On the public-school level, Texas Tech University Independent School District offers a public high school diploma program at a distance, a middle school curriculum, and an elementary school curriculum. Professional development and personal enrichment courses are also available to students at a distance.

The Division also provides a student services team, a distance learning bookstore, an instructional design team, counseling/advising services, and faculty incentives and training. The student services team is comprised of eight full-time student services representatives who are available five days a week to provide
personalized help and support to distance learning students. The distance learning bookstore ensures that students all over the world receive all required materials for courses promptly and efficiently. The instructional design team works with University faculty to ensure the quality and accessibility of all distance learning courses. Faculty members receive instructional design support for the design and development of their distance delivered courses. Production specialists are available to support the production of various media components of the courses and adapt them to the selected delivery medium. Extended Learning counseling services are available in person or at a distance. A full-time, qualified college advisor helps students select appropriate courses to complement their degree programs free of charge to students. Extended Learning offers grants to faculty members interested in using technology to create distance learning courses and group training sessions on the effective instructional design of distance learning courses.

The latest technology is integrated into the Texas Tech University Library System search and retrieval systems. The System consists of a variety of on-line services including TechPAC, the catalogs for four University libraries. The system provides access to a number of library catalogs at other major universities. Extensive coverage for periodical indexes, abstracts, and other bibliographic and full-test databases is provided by FirstSearch and other database suppliers. Additional on-line features include an interlibrary loan request form, a monthly listing of new books, and new items about the TTU libraries. CD-ROM databases are available which include indexes, abstracts, and government documents.

The Teaching, Learning, and Technology Center (TLTC) enhances distance learning by training faculty on the use of the Internet through competitive grants, roundtable discussions, and teleconferences. In addition, the TLTC maintains a faculty computer lab with both PC and Macintosh computer hardware and software. TLTC personnel conduct workshops to train faculty in the use of technology.

Texas Tech University Health Sciences Center's (TTUHSC) HealthNet utilizes its extensive distance learning network as follows: (1) a two-way interactive video system links the four campuses of TTUHSC, (2) a digital satellite television network supported by interactive audio delivers continuing professional education, (3) a two-way interactive video system links rural primary care with specialists at tertiary centers for diagnostic and consultative support, (4) a two-way VSAT, satellite-based, interactive video system provides interactive education to any location in the continental U.S., and (5) a Ku Band teleport facility delivers programming to Texas state satellite networks as well as to any Ku Band capable receive sites in the continental U.S.

KTXT-TV is a noncommercial educational television station. The broadcast operation includes a seven-channel cable system capable of feeding instructional television programming to classrooms throughout the campus, and a multiterminal telecommunications receive-only earth station providing the university's principal access to communications satellites. The station broadcasts approximately 105 hours of diverse programming each week to a 60-mile radius of Lubbock reaching a population of approximately 380,000.

Texas Tech University is a member of the Southwest Center for Advanced Technological Education (SCATE)--a consortium of colleges, universities, schools, and business and industry partners partially funded by a grant from the National Science Foundation. The mission of SCATE is to promote advanced technological education through exemplary efforts in curriculum development, program improvement, and distance education at colleges and high schools. The focus of SCATE has been to experiment with and demonstrate how advanced technological education could be delivered over distance learning systems to improve access. The Center has focused on the development of a distance learning infrastructure, preparing technical faculty to function in interactive distance learning environments (using both the Internet and interactive television), and revising and developing ATE curricula for delivery through such systems.

Texas Tech has distance learning options which may be modeled by other institutions to deliver courses, degrees, and professional development to students at their chosen locations and at their own pace.

1.0 Introduction

This paper describes the development of an interactive, distributed, multimedia system (PATSy). When completed, it will serve as a repository of brain-injured patient cases and their test data for use by speech and language therapy students and researchers in the neurosciences. The aim of PATSy is to teach students how to generate hypotheses and diagnose the source of speech impairment in brain-injured patients.

1.1 Changes in Educational Teaching Methods

The development of PATSy addresses several current challenges to clinical educators. Education in the health professions is turning increasingly towards case-based teaching where knowledge of the subject is represented in the form of many example cases that embody the relevant principles. This method is advocated in the teaching of knowledge intensive domains such as medicine and law. In these domains, it is difficult to give a set of rules to the student that they may use to make inferences or deductions [Williams, 1993]. Case-based teaching has been demonstrated to be effective but it requires students to have access to a fairly large database of patient cases. [Hmelo, 1995] has shown that medical students taught using problem-based learning produce more accurate diagnostic hypotheses than non-problem-based learning students.

Speech and language therapy students traditionally receive clinical skills training during placements at hospitals and community centres. This of course, is an important and vital part of their training. However, in some areas of the U.K., there is a problem of access to brain-injured patients. Even where brain-injured patients are available, the quality of a student's experience in acquiring clinical assessment knowledge depends upon the type and variety of patients available during their placement period. For these reasons, some students' assessment experiences, knowledge of various speech disorders, etc may be acquired on a somewhat ad hoc basis. Under current regimes of clinical training, students usually do not have any interactions with brain-injured patients until they are on clinical placement. It would, of course, be more desirable for students to have access to patient cases prior to this time. They would then a) be familiar with an adequate range of speech disorders and b) have more technical knowledge of assessment before meeting 'live' patients.

1.2 Aims and Objectives

A demonstration prototype of an interactive multimedia patient assessment training system (PATSy) has been implemented. The full version will address the training issues described above. This clinical resource will be an adjunct to current clinical training practices. PATSy will: i) support teaching approaches such as case-based teaching, problem-based learning, student-based guided exploratory learning and traditional lectures; ii) provide more control over the range of cases to which students are exposed; iii) provide a standardised corpus of cases against which each student's performance may be appraised; iv) allow students to engage in assessment training independently of the clinic setting and at times convenient to the student; v) allow students to practise and experiment without compromising ethical requirements. The full system will contain data from many speech and language disordered patients. Data for each patient will consist of a short (1-3 mins) digitised video film clip of the patient speaking with the therapist, digitised audio recordings of the patient undergoing a range of assessment tests and graphical images showing patient responses to pictorial test stimuli.
2.0 A Sample PATSy Session

This section describes a typical student interaction with PATSy. Using a standard, Javascript and Quicktime capable Web browser, the student logs into PATSy, selects a patient from a menu of cases and observes a video clip of the patient speaking. She is then required to formulate a clinical hypothesis based on her initial observation of the patient. The student then 'administers' a neurological test to the patient by selecting the desired test from a structured menu. A wide range of test data will be made available for each patient, consisting of medical history data plus assessment data based on the presentation of visual and auditory stimuli. Students will be able to step through any test item-by-item. For example, in a test where the clinician presents auditory stimuli, the student will be able to listen to a digitised audio clip of a clinician presenting the test items to the patient followed by digitised audio clips of the patient's actual responses to those items. An example test item is shown below [Fig. 1].

![Figure 1: Example test item. In this test, the student can play a sound file of the (spoken) stimulus (in this case the word "shoe") and then click on a second button to reveal the picture that the patient pointed to in response to the stimulus (red arrow).](image)

The full version of PATSy will record which clinical tests were 'administered' by the student and in what sequence. A note-taking facility for users will also be provided. Following a PATSy session, the student will be able to print out the test log and notes. These can then form a basis for discussion with the lecturer or tutor in a problem-based learning session.

3.0 References

At least four key clusters of factors impact and mutually influence each other in every learning situation, including Internet-based learning: a) characteristics of the learner, b) learning goals, c) nature of the learning media, and d) appropriate learning skills and strategies (Lyman in press).

This paper focuses on one of the factors most neglected relative to the Internet: learning strategies. In the dizzying excitement about the possibilities for using the Internet to support learning, much of the emphasis has been, somewhat understandably, on what the medium has to offer. For example, Martin (1997) has identified five types of Internet sites available to support learning: a) databases, including on-line libraries and virtual museums, b) learning communities, e.g., listservs and collaborative study projects, c) classes and tutorials, d) simulations and games, and e) multipurpose learning centers serving as sites and conduits for a variety of learning experiences. However, questions of how learners can most productively employ various Internet resources to learn effectively have received much less attention.

Needed Learning Strategies

In order to take advantage of the vast opportunities afforded by the Internet for learners, they need appropriate strategies. Learners must develop information literacy involving the ability to:
1. know when there is a need for information
2. identify information needed to address a given problem or issue
3. locate the needed information
4. evaluate the information
5. organize the information
6. use the information effectively to address the problem or issue (Brevik as cited by Rakes 1996, p. 52).

The need for these skills is heightened in the context of Internet-based learning, especially when the Internet can induce information anxiety, so vast is its capacity for data archiving and access. The Internet’s vastness, relative newness, and ever-developing nature only intensify the importance of developing appropriate learning-to-learn, critical thinking, and problem-solving strategies.

However, we continue to lag behind in helping learners to develop appropriate Internet-based learning strategies. The use of search engines provides a good example. Novices and even expert users of the Internet are hard pressed to understand the relative advantages and disadvantages of different search engines and their appropriateness for different purposes (Maddux 1996). Even as one may gain, often through personal trial and error, familiarity with a few favorites, new tools become available whose specific search capabilities are unknown.

Navigating hyperlinked information represents another challenge. Effective navigating calls for the highest possible familiarity with the topic (obviously a barrier for novices to a subject) so as to target the most relevant information. An important navigational skill is the ability to resist delving into intriguing links containing seductive information which, however interesting in its own right, is not relevant for present learning goals (Quinlan 1997). However, a learner must at the same time be able to recognize when new found information necessitates modifying one’s original goals, thus changing the nature of the search. Navigation skills and strategies are complex, recursive processes, about which much more needs to be understood if we are to help Internet-based learners become more effective.

Even if a learner can successfully navigate the Internet while investigating a topic, as the student locates relevant information the question of information management comes to the forefront. Thus students not only need planning and navigational skills, but also database, spreadsheet, and presentation skills (Metcalf & Nolan 1997). Learners need organizational tools to put information gleaned from the Internet into databases arranged according to learners' own purposes and needs.
Likewise, learners need spreadsheet skills to effectively summarize, manage, and represent information from the Internet in different forms, for example, tabular and graphic displays. Finally, learners need a new array of presentation strategies, i.e., multimedia presentation strategies to communicate their understandings in ways that appeal to their audiences. Obvious presentation skills include building web sites to communicate learning project findings.

Promising Directions

As this paper was being written, insufficient systematic attention could be found in the literature concerning development of learning skills and strategies specific to an Internet based learning environment. However, promising directions are suggested by the National Educational Technology Standards Project (Thomas & Bitter 1998). This project is developing performance indicators for learners, many of which have direct relevance for Internet based learning. The indicators address performance in five domains:

1. Basic operations and concepts
2. Social, ethical, and human issues
3. Productivity tools
4. Communications

The National Educational Technology Standards Project represents one example of much needed systematic attention to learner performance in technology based environments.

Catching Up

Internet based learning if it is to live up to the early promise and, in some cases hype, will depend on increasing our attention to standards for learning strategies for the Internet. To neglect research and development of learning skills appropriate and indeed indispensable to the Internet is to undermine the potential of this evolving medium to meet the multifaceted goals of learners.

Design of a Collaborative Distance Learning System

Madhumita and Kanji Akahori
Center for Research and Development for Educational Technology
Tokyo Institute of Technology, Tokyo, Japan
{mmita, akahori@cradle.titech.ac.jp}

Introduction

To facilitate collaborative distance learning for problem based learning (PBL) a computer based teaching-learning system has been envisaged. The system is consisted of three main modules. These are Teacher module, Student Individual Learning Module and Collaborative Learning Module. In the Teacher Module the faculty can go through tutorials and help menus on general instructional strategies for PBL before setting the problem. Similarly in the Student Module learner can get help and instruction on cognitive strategies for solving a problem and developing the concept map of their learning respectively. In the Collaborative Learning Module learners get cues on how to carry out discussion and peer review. It also facilitates collaboration among teacher and learner(s) and among the learners. Using this system the teacher can access the progress of an individual learner and the group activities at any time.

One of the effective uses of such an instructional system is to support work on a task undertaken collaboratively by a number of dispersed teachers and students.

Description of the System

In order to design the system we did background researches on identification of cognitive strategies [Madhumita 97a] and on the effectiveness of collaborative learning [Madhumita 97b]. We have proposed an instructional model for the system and developed its functional model. The design of the present system is based on the profound educational research findings.

A special feature of one of the Start screens consists of space provided for recording the courses already taken by the student. This information would be particularly helpful for the teacher in designing the introductory session and tutorial 1.

The screen on the formulation of objectives, shown as ‘Objectives of the Course’, in the flow diagram, would provide some sample objectives developed on different domains of learning. These examples would provide a clear idea to the teacher in order to formulate objectives.

Introductory Session screens consist of facilities for the teacher to provide a background, and to explain basic terminology and concepts that the student is supposed to know before going through the course. At this point the student has the option to go through the course or not to go through the course. The student can make the decision by referring to the objectives of the course and the introductory session by using the HyperCard facility.

After the student opts for the course then he/she is directed to go through an Entry Test. The Entry Test is designed by the teacher based on the prerequisites of the course and following some guidelines on test construction with appropriate examples through the system.

For the preparation of content of Tutorial 1 the teacher considers the courses already taken by the student and his/her performance in the entry test. After this every student’s performance in the entry the computer from its database accesses test and courses already taken by the student in order to form mixed ability student-groups for PBL. The teacher may decide group size. The group size may vary from three to five.

Each group of students is now faced with a different Problem Statement. A problem should be designed in such a way that there is a mismatch or at least a gap between the students’ knowledge and the problem. Before stating the problem teacher would be given instruction on the construction of problem. Immediately after the problem statement each students-group gets a set of Problem Solving Strategies. Explanations of these strategies have been included in the system.
Problem solving strategies may be selected manually by the student by taking into consideration the available resources and latter may be discussed with other members of the group or may be left to the computer. The system as envisaged would have a component of strategy selection based on the problem type in that case the teacher would be required to click the appropriate Problem Type. Teacher would be provided with a list of problem types, e.g., prediction, explanation, invention, etc. If, the teacher is not clear about the problem type he/she may access the definition and example of each type from the help menu, which would be provided in the system.

In the Group Discussion 1 students would be provided with instructions through the computer on aspects to be taken into consideration in the session. For example instructions such as: interpret the problem, discuss about strategies, make a timetable, divide the task, if required. At this stage the students would be provided with techniques of group dynamics by the system. Similarly, instructions would be provided for group discussion 2.

Every student’s progress through self-study is recorded in a database with date and time. This facility would allow the teacher to monitor the progress of the student, in terms of how much time the student is spending on the course and the information collected by him/her is relevant or not. Teacher and students can interact through tutorials and Feedback Session. Students of a group can interact with each other through group discussion 1 or group discussion 2. Students would get guidance on concept map formation through the system. As we know that concept mapping is a useful spatial learning strategy. Therefore, concept maps have potential, especially for assessing students’ structural knowledge.

The teacher considering the student’s progress and concept map developed by the student prepares tutorial 2. Student who does not need tutorial 2 may proceed to Probable Solution of the problem.

Besides improving the process of developing performance assessments, peer review can yield a profound result: the beginning of a truly professional relationship with colleagues. Peer Review and Teacher’s Feedback on the probable solutions leads to the most Suitable Solution. At this stage, the system would support decision making by evaluating the probable solutions against the teacher’s comments (accessing from teacher’s feedback) and students’ decision (accessing from peer review), and a set of preset criteria. Teacher may proceed for Performance Assessment of each of the student separately and also their assessment as a group using a checklist generated by the computer. Peer members assess each other on performance in problem solving using a checklist generated by the computer. The assessment of both teacher and students’ would be compiled by the system and would be displayed as student’s result and group score along with qualitative feedback.

Work in Progress

We are working on the development of the system, using HTML programming language. We plan to hold the interaction among the group members and the teacher using NetMeeting. This will be a web based Teaching-Learning-Evaluation system. We plan to implement the first prototype of the system in order to evaluate our system for further developments and modifications.

Acknowledgement

Further work on the research and development of the system would be conducted under the Japan Society for Promotion of Science postdoctoral fellowship grant.
Teachers' Work and the Technology Bypass

Lawrence V Mahon
Department of Education,
Victoria University of Technology
Australia
lmahon@dingo.vut.edu.au

No one is shocked to realise this conglomerate of extras and incentives is offered to high flying executives in the business world. While this is part of the life of the executive, the lowliest members of the corporate office take notes, publish and disseminate all the workings of the place using the latest in computer technology. The Pentium 200+ PC is never turned off. The answering machine is attached to the PC, and can perform functions only dreamed of a few years ago, the mobile phone is directed to the answering machine, which is attached to some paging device – all with the intent of moving information to the appropriate location as rapidly as possible.

The office can run without anyone attending - enquiries being referred through a series of telephone keypad entries to their correct (more or less!) destination.

Yet, in education, coloured chalk is seen as the big innovation.

Industry has taken to the new technology to such an extent that its integrated use in the workplace is now widespread, relevant and, most of all, presumed.

Schools and education systems are different. It is rare in Australia to see a full and comprehensive use of Information Technology, other than as a replacement to the typewriter, to change the nature of teachers' work. The equipment is old- more suited to a museum collection than to educate the current "next generation".

The staff is uninvolved in the school-based decisions about the technology, and is indeed often unable to be involved due to lack of knowledge. With severe cuts to education budgets generally throughout Australia, money for professional development is grossly inadequate, while tied to the pet projects of the government of the day. Soon after the current government in Victoria was elected, an “innovative” satellite dish project was initiated. Each public school was issued with a satellite dish, and encouraged to tune the children in to “interactive” programs, such as Japanese language classes. There was, and still is, too few teachers of Japanese to cater for all needs. The government’s definition of “interactive” was telecast one direction, fax back from schools. The project, according to teachers, has bordered on total failure, while at the time a great public relations exercise, that bled from the education system many millions of dollars. The chances for real and positive change diminishes further.

The front office in the average Australian school is well equipped with technology, to serve the needs of the principal, and to enhance the workload of the administration people. The chief school administrators know the value of the right equipment, but the will to enskill teaching staff in a variety of new and innovative practices, and to resource their classrooms seems, on the evidence, to be lacking at a variety of levels.

In Victoria, Australia, schools are responsible for the management of their own budgets. Self managed schools. The number of children at any one school determines the number of staff assigned to the school, and the budget deemed "appropriate" is also assigned to the school. One needs to question the government pronouncements on numbers of children per teacher under this scheme compared to the anecdotal evidence that exposes it for the fiction it is. In Victoria we are told there is one teacher for every 15 children. In a survey of schools in the western region of Melbourne, involving approximately 70 teachers, the minimum number of children in any one class is 22, the maximum is 34, and the average is almost 30. There often appears to be a misrepresentation of 100%. It also appears that if every adult member of the school community is included in the count, i.e. the principal, the specialist teachers, the special task staff, the government figure is closer to the mark. That, of course, does nothing to ease the stress on the teacher of a class of 30 active children, with the consequent drop in attention per student.
It appears the same stretching of the truth is employed to bring the number of children per computer to a level that will satisfy the parents/voters.

The Victorian government boasts one computer for every 7.5 children in State Government schools.

On the same survey previously mentioned, many classrooms had no access to computers. Others had equipment up to 15 years old. A few had access to a laboratory of Pentium based computers.

But with the current industry standard being a Pentium based computer, and with that standard applied to classrooms, for Victorian classrooms, there is one computer for every 75 children, a figure 10 times worse than the figure offered by the government authorities. In a world of communication, access to Internet, and multimedia authoring, to suggest that anything less than the best is good enough for schools sits uneasy with the author.

While the use of information technology in the classroom learning environment is increasing relative to the funding for equipment and professional development, little advancement has been made when considering the workload of the teacher.

The nature of teachers' work lends itself to the widespread use of information technology. Teachers' work, according to the teachers surveyed, is varied in its nature, and incorporates knowledge from a wide variety of fields. Teachers identified "educator" as one of their key roles, but for many sessions throughout their working day, by no means the most time consuming.

The survey asked teachers and Year 2 undergraduate teacher education students working with them to document the teachers' role in the first hour of each day.

It soon became obvious that "normal" was not a definable term for the classrooms being observed. Variations of the teacher's role occurred from day to day in the same classroom. Variations also occurred at different class levels, and also dramatic variations occurred between different schools, both private and public.

Four main headings have been used to group the roles teachers see occupy their professional time. These are:

- Educator
- Administrator
- Counsellor
- Health care worker

On many occasions these roles overlap, involve other significant people in the children's lives, and occur in class time, school time and after hours, as well as the first hour.

Teachers are expected to teach, but the results of this survey indicate there are many other expectations, within the first hour each day, that interfere with that primary role. Collecting money from students appears to be one of the key roles expected of teachers. For reasons as varied as lunch orders to school fees, and special money raising events through to collecting savings on behalf of banks, teachers' work of teaching takes a lower priority.

Marking the attendance roll is also on the first hour, and in Victorian schools, is required to be taken by 9.30 am. Depending on the number of students in each class and their ages, this task can take up to ten minutes of class time. There is a recent decree from the Department of Education that requires these numbers to be sent to head office by a certain time each day, and to occur twice per day.

In many schools in the Western region of Melbourne, well documented as being predominantly lower socioeconomically than many other areas of Melbourne, another key role of teachers is as a counsellor to parents who drop their children at school. In the schools associated with this survey, counselling of parents was an almost daily occurrence, taking both time and energy from the teachers.

Other tasks, such as administering minor first aid to children who may sustain a playground injury is also a very regular, daily occurrence, that requires administrative support, even for a minor scratch.

Teachers also find that the school administrators (principals) interrupt the flow of their work on a regular basis, with calls through the intercom for a multitude of reasons, all apparently urgent at the time. On other occasions children from other grades arrive at the door with special requests from their teachers, adding to a feeling of collegiality, but again interrupting the teaching/learning flow in the classroom.

Interruptions are the norm, rather than the exception. From attention seeking children, bathroom attendance, inappropriate physical contact, boisterousness, through to the resultant behaviour from lifestyles entrenched in...
poverty, such as aggression, timidity, lack of concentration and others, it is easy to see that teachers' work is not simply defined.

How can information technology assist teachers achieve their goals, which are the goals of the general community?

If we were able to peer into the distant future, would we see:

- computers networked throughout a school, and with an investment in some identity scanning equipment?
- Would each child be issued with a "smart library card", also able to be linked to parental bank accounts?
- Would the computers at the school be linked, from the library to the main office, to the other classrooms, and the school canteen, and perhaps to the local banks?
- Parents might have access to some terminals at the school, a system of passwords having been developed.
- Smart card readers installed at each classroom door, and the entrances and exits to the school? Children leaving and entering the school grounds and the classrooms swiping their cards through the readers?

Automatically, the following would have occurred:

- Children's attendance would be recorded.
- Any absences would be recorded. At an appropriate time, absentee's homes would receive an automated phone call, requiring the keypad response informing the schools of reasons for any absences, and knowledge about them.
- Children absent one day would receive an automatic update in their computer log regarding any missed information upon their return. This would also include all the missed school work, as the teacher does her planning and organisation on a computer.
- The school canteen would automatically receive any lunch orders from the appropriate children, and have them delivered. The smart card would have the amount automatically deducted.
- Teachers from other grades would need to email messages rather than hand deliver them, allowing the responding teacher to choose the moment, rather than be constantly interrupted. The school principal, in cases other than REAL emergency situations, would need to do the same.
- Perhaps close to 40 minutes in the first hour would be given back to teaching and learning. Over the course of a week, this is approximately an extra half day - or in Australian terms, an extra working month every year.
- It is also acknowledged that teachers don't see this approach as a high priority, as they are aware of the realities in education funding in Australia at present.

There are five key hopes those surveyed have identified for the next five years for their classrooms:

1. ongoing professional development in Information Technology
2. access to computers for their classroom (5 or 6 in each room)
3. classroom access to Internet and the World Wide Web, and other appropriate software
4. ongoing technical support for their classrooms and
5. reducing class sizes

It is interesting to note that the teachers have not included any personal gains in these key hopes.

Teachers have recognised the value of sophisticated Information Technology in the teaching and learning environment of their classrooms. Governments have recognised the importance of adequate equipment in schools, otherwise there would be no need to misrepresent the schools' access to the technology. Parents also know that Information Technology is a key to their children's future. All that is needed is the funding. So simple!
There is no doubt that significant progress in both educational technologies and their integration into classroom teaching has taken place over the last decade. The growth in the use of microcomputers in schools especially has been staggering [see OTA, 1995]. Growing access to the World-Wide Web has given students a new information resource which often outstrips their school library.

Despite this progress, many educators who use new technologies have not taken full advantage of the possibilities they present for restructuring basic approaches to curriculum and pedagogy. As Michael Hannafin noted in 1992, "Advances in computers and related hardware technologies have far out-stripped prevailing design methodologies. The field remains insulated from developments of considerable consequence for improving learning" (p. 49). In such a fast-moving field, however, it must also be acknowledged that there is a growing body of theory and practice which incorporates constructivist epistemologies and collaborative curriculum designs into technology-rich classroom environments [see Adams & Hamm, 1996; Koschmann, 1996]. Canada has been a primary site for some of these developments [see Harasim, 1995; Scardamalia & Bereiter, 1996].

In the province of Ontario, a recent Royal Commission reinforced earlier government policy statements strongly supporting both integrated approaches to curriculum, and expanded use of information technologies [Ont. RCoL, 1995; Ont. Min. of Ed., 1995]. Yet, as the Royal Commission report pointed out, much of the potential of educational technology is as yet unrealized, poorly developed, and little understood. The ways in which recent developments such as local-area networks and World-Wide-Web access are to be incorporated into the curriculum are yet to be specified. Despite the repeated emphasis on the principle of integrated curriculum, there has been little guidance given as to how exactly teachers in the upper grades are to transcend their traditional approaches to curriculum, and the subject boundaries which have for so long guided their professional practice [see Goodson & Mangan, 1996b].

The Watershed Information System is a response to these challenges. It has been designed and implemented by a collaborative team of university professors and researchers, private software developers, business sponsors, and teachers and students in provincial high schools. A pilot project was begun in 1996 (with funding from Environment Canada and several private sources). It is spearheading the application of leading-edge information technologies in the high schools of the Grand River Watershed, in and around Cambridge, Ontario. The concept, originated by architect and environmentalist Fred McGarry and his colleagues, is to build a multi-layered database of economic, demographic, and environmental information, keyed to finely-detailed digital maps of the area. Using custom software (ecorp connections) which projects a computer-rendered version of the map onto a monitor screen, users can point-and-click on various parts of the map to call up information about the natural features, buildings, history, and demographics of the region.

The uses of such a finely detailed database are many and varied: students can explore local history, genealogy, economic development, and environmental change. Equally important, however, is that the database, when fully developed, will be accessible to anyone in the community, via the World Wide Web. Individual citizens who wish to research their family history, or the context of a heritage building site, will be able to do so, by using the database from any Internet-connected computer. Existing community resources, such as oral histories and private memorabilia collections, have been incorporated into what are being called “neighbourhood databases.”

The educational purposes of The Watershed are not limited to its use as a storehouse of information, from which students can make “withdrawals.” They are also expected to make important contributions. The neighbourhood databases will be continuously updated and expanded by the users themselves. The major contributors will be high-school students, working on course-related assignments. Class projects developed to date, for instance, have included the mapping of a cemetery in the town of Blair. For each headstone, the
epitaph was recorded as text, a video image of the stone was captured, and the precise location was determined using surveying techniques. All of these data were then incorporated into the on-line database. Teachers involved with this and similar projects reported such enthusiasm among students that many continued participating after school hours, and even after classes ended for the summer. The students who took part in this project not only came into direct contact with some of the important historical artifacts of their town, but practised skills in mathematics, media studies, English, historiography, and computer science. [see Pollock-Ellwand, 1998].

As interesting as the educational applications are, the Watershed has also been designed to promote the restructuring of relationships among the participants in significant ways. Although the software systems are being developed specifically to support this project, the developers are not simply selling a software product to schools. Instead, each installation is financed by a contribution from private industry. The contents of the database will be publicly accessible, and owned in common by all participants, through a non-profit organization known as The Copper Trust. Once the basic implementation of the system is accomplished, further development will be conducted through a democratic process, which will use the telecommunications abilities of the network to conduct ongoing dialogues and “town hall” meetings among participants. Students, teachers, and private users will have equal input to these discussions. An “on-line academy” will supervise annual awards recognizing “best practices” in using the system. These awards will be given based on feedback from all participants.

Within the school system, development of integrative curriculum design is being conducted as an action-research project, involving teachers from several disciplinary areas in different schools, working in cooperation with each other and with a team of university-based researchers. Participating teachers develop new lessons by working together and exchanging ideas, with the goal of using the technology to promote cross-disciplinary learning and a collaborative model of student interaction. University researchers provide theoretical background, and convene reflective sessions on the problems and possibilities of the initiative [see Goodson & Mangan, 1996a]. Negotiations are under way to provide participating teachers with graduate-level course credits from the universities in recognition of their work, as well as support from their school board in the form of release time and conference travel subsidies.

Through these various aspects, The Watershed is using educational technologies as a catalyst to radically transform high school curriculum and pedagogy, school-university-private sector partnerships, and the relationships among the various teachers and learners who make use of the system. Our goal is to at least partially realize the vision enunciated by [Adams and Hamm 1996]: “As state-of-the-art pedagogy is connected with state-of-the-art technological tools, it will change the way knowledge is constructed, stored, and learned.” (p. 217).

Introduction

In order to meet the ever-increasing need of the electronics industry for engineering professionals, Computer Based Learning Centres are being established to ensure the required amount of university and polytechnic graduates in this field.

Computer-aided training and learning requires a high level of interaction between the computer and the learner in order to ensure the quality of the learning in situations where the role of the teacher increasingly resembles the role of a tutor. In addition to machine-human interaction, interaction with peer learners (peer support) has been observed to be beneficial for the student. When considering sparsely located learners (distance education), this human to human interaction requires adequate tools and abundant support from the telematic systems. In this paper, examples from the two interaction types, machine-human and human-human are described. In addition to these, the demonstration scenario of computer based training is briefly represented.

The Institutes of Higher Education (IHE) pilot of the IDEALS project (in the EU TELEMATICS programme) is currently in its demonstration phase (until June 1998). The IHE pilot is demonstrating the interactive learning environments as well as co-operative learning (teamwork) and authoring between three European universities located in Germany, Portugal and in Finland [Ideals 95]. In the demonstration phase, the evaluation of the learning process and the evaluation of user satisfaction are also conducted. A special contribution by the Raahe Laboratory of the University of Oulu (RATOL) to the IDEALS-project, in addition to the produced User Interface Programming course, is the linkage of the telematic CBT-system to the real CASE-environment [Paaso and Manninen 97].

Machine-Human Interaction

In the course material of the IHE pilot, the proportional division into the various learning process phases is as follows: Presentation 30 %, Exploration 50 %, Tests 20 % [Paaso et. al 97]. This reflects the view that the computer is utilised to its height in the experimenting and exercising phases of the learning process. This suggests that there is no point in using the computer merely as a replacement for a book.

There are two main implementations of machine-human interaction specially tailored for the programming course conducted at RATOL. The first one is the Virtual Compiler, which is used for practical experimenting with the programming projects in a safe learning environment. The second implementation is the didactic tests which, in turn, are designed for small-scale quality assurance of the learning [Deming 93].

The Virtual Compiler simulates the features of the real compiler, although in a much restricted scale (see Figure 1). The virtual environment provides the learner with the opportunity to explore, modify and test some ready-made software components without causing the system to crash. This feature can be obtained by providing the author of the course with the freedom to accurately set and specify all the modifications that the learner is allowed to make to the program. The possible modification points are clearly visible to the learner and, thus, make it easier for the learner to maintain the appropriate course of action. After adjusting the modification points, the learner compiles and runs the program, which, in turn, enables him or her to view the direct results of the modifications in the actual executing environment.
The Virtual Compiler is a fast and effective method for the learner to study the different aspects of the programming project. The immediate feedback produced by the system ensures that the learner is not forced to struggle ineffectively in order to obtain sensible results. The "guiding" role performed by the system also prevents the learner from going astray and, thus, reduces the overhead of the learning process by keeping the learner on the right track.

At the end of each section of the course material the learner is required to pass a test based on the newly acquired knowledge. The majority of the tests is intended solely for didactic purposes and, thus, will not affect the overall evaluation of the learner. The aim of the didactic tests is to force the learner to sufficiently study each section of the material before proceeding onto the next section. This is ensured by creating a course flow containing a repetitive loop, which guides the learner back to the beginning of the section and, eventually, forces the learner to repeat the test after going through the contents once again.

The tests also serve the learner in that they are the final phase of the actual learning process. The answers are immediately evaluated and commented on by the computer and provided to the learner for reviewing. This method of repeating the tests (with various question configurations) enables the learner to absorb at least some level of information. Figure 2 illustrates a sample of the test feedback.

The utilising of the user profiles collected about every user of the learning environment may alter the configuration of the questions, i.e. the contents of the tests. This method makes it possible for the course material author to create a test structure which, based on previous tests, emphasises on the weak points of the learner.

![Figure 1. The Virtual Compiler](image-url)
Computer Driven Human-to-Human Interaction

In addition to the machine-human interaction, there are features in the demonstration course that significantly motivate, activate and even occasionally force the student with human-to-human interaction, either directly or telematically. The virtual laboratory formed by individual workstations (connected to a single learning environment) provides adequate means for communication, and even encourages co-operation and interaction between the various parties. Apart from these sufficient means of communicating, it is the responsibility of the course designer to steer the learners towards a more interactive learning style, i.e. collaborative learning. One example of this is, for instance, that every software module included in the programming project to be accomplished as teamwork, should contain a great level of interaction with other modules in order to ensure the need for communication and co-operation [2]. The interaction between the team members is thus “goal-driven” in a natural way, although in reality the members are steered towards this interaction by the computer. The interdependence between software modules “forces” the various team participants to approach the problems collaboratively, even when the entire group is geographically widely spread.

Demonstration of the Learning Environment

The aforementioned interactive learning techniques and environment are being demonstrated in the Raahet Laboratory of the University of Oulu between May 1997 and July 1998. The demonstration includes a total of 60 students (B.Sc. and M.Sc students) who have selected the optional Computer Graphics course as part of their curriculum. The course, which is being carried out with the aid of telematics and CBT, and without conventional lectures, consists of approximately 16 hours of studying and experimenting (including short exercises and tests). At the end of the learning phase, the students are required to produce a final software development project in collaboration with the other group members, i.e. implementing software modules for a common user interface window (“goal-driven” co-operation). All communication between learners is handled with the aid of telematics. The final evaluation of the learners is conducted through a written exam, which is performed at the end of the “lecturing” period.
Conclusions

The great need for engineering professionals requires new methods for increasing the output of graduates from universities and polytechnics. One proposed solution is the Computer Based Learning Centres, which enable more efficient and integrated learning, even in sparsely populated areas.

To ensure the high motivation and illustrative level in the CBT, a high level of interaction between the computer and the actual learner is required. In addition to machine-human interaction, the human-to-human interaction with peer learners (peer support) is also beneficial for the student.

The Institutes of Higher Education (IHE) pilot of the IDEALS project is currently undergoing the demonstrating of the interactive learning environments in practise, in three European Universities. The demonstration phase will end in July 1998.

1. Introduction

Within a project named CoLoS, twelve groups of scientists from eight European countries are working together to explore the didactic potential of modern computers and to develop adequate learning material. CoLoS stands for Conceptual Learning of Science and reflects our major goal of using modern technology for a better and more direct approach towards presentation and understanding of basic concepts in science and technology [Härtel 94]. Within this group a method was implemented to overcome the obstacle of complex interfaces, that usually constitute a barrier between the contents to be learned and the support provided by the computer.

The proposed method is based on a control mechanism using Internet standard TCP/IP communication protocol. It allows controlling our simulation through active links within a Java-powered HTML document. It offers to any teacher or authors the choice to make the adequate selection of interaction accessible to the learner and to define the proper balance between freedom to explore and guidance to successful learning experiences. All applications developed with our authoring tool, Xdev [Esquembre 94], automatically include those communication possibilities.

In order to show the capabilities of the above-mentioned procedure, the application to a short course on Resonance in Mechanical Systems is presented in this short paper. The application used for this purpose is xyZET [Härtel 96], a simulator developed at IPN (Kiel, Germany) that allows to show the behavior of sets of particles interconnected by different interactions or acted on by external fields. The didactic part consists of a short HTML document with the content that we want to teach, and with the necessary control on the simulation in order to allow a guided instruction on the selected topic.

Control method.

One simple, and very effective, way to write the didactic text that accompanies a simulation program is to produce an HTML file that can be read with any of the nowadays so popular Web browsers. These files allow not only reasonable editing capabilities, but are also prepared for hypertext behavior and can be distributed from a central depository over the network. This facilitates the distribution and maintenance of the related documents.

At this moment, and though new tools, like Java, are very popular standards that have improved the state of the art in the recent years, some computation- or graphic-intensive - simulation programs must still be created separately, since these browsers are not suitable for creating this kind of presentations. Hence, the simulation program runs as a separate process in the operating system and we need a way to interact from the HTML file (i.e. the browser that is reading it) to the simulation and viceversa.

Some browsers also allow the reverse process, that is, changing the text according to changes of the simulation or to user interaction with it. We do not explore this feature in full. More interesting for our purposes is the possibility of changing the behavior of the simulation from the user interaction with the browser that contains the learning unit.

In our case, and since we use UNIX and Windows 95 or NT as our software platform, we use the standard TCP/IP mechanism, present in most computers with network connection, for interclient communication.

With this method, a simulation program written in any of the most popular languages can, with some added libraries that we provide, offer a series of commands in natural language as equivalents for internal procedures and export this list of command strings to be used in other applications. In technical words, the application
turns into a specialized TCP/IP server. Other programs, acting as TCP/IP clients, can send messages to this simulation program that will cause some internal procedures being executed (initialization of some variables, start/stop of the simulation, load of a file, and others).

The actual implementation of client programs that we use in our HTML files is a small Java applet that represents a button. This button can be customized using the applet parameters to read different messages, with different colors, fonts and other effects. When this button is pressed a message is sent to a machine in the network (usually the local host) at a specified port. This is also configured via parameters, thus providing with a single applet a wide range of use. The server program, i.e. the simulation that is being controlled, will be listening at the specified port in order to receive and process the message.

This recent work improves and extends a previous implementation that we used for X window programs under the UNIX environment [Esquembre 96]. There we exploited the Inter-Client Communication Conventions Manual present in these systems [Scheifler 92]. Both systems have proven to be simple to implement and very effective in their educational usage.

2. Resonance in Mechanical systems.

Resonance is an omnipresent phenomenon in nature and it is included in all Physics curricula at an introductory level. Therefore we have selected this topic, and have chosen mechanical systems as concrete examples because there the effects are good to demonstrate and to visualize as compared with electrical or acoustical systems. In this didactic unit we use xyZET to simulate the resonance in systems like pendulum, mass-spring and vibrating strings. This unit has been designed and used for training high-school teachers.

The basic content of this document has been distributed in the following sections:

1. The phenomenon
2. Background knowledge
3. Some Examples of mechanical systems with natural frequencies
5. Experiments with resonant systems (forced oscillations)
6. Theory of Forced Oscillations
7. Energy analysis

After a description of Resonance and the systems that show that behavior (Section 1), an introduction is made to the basic knowledge needed to understand the main concepts involved (2). In Section 3 some systems capable of showing a resonant behavior are presented using xyZET: Pendulum, mass-spring, vibrating string (fundamental and higher order modes) and vibrating membrane. Section 4 explains how the different systems can be characterized by measuring their natural frequencies and other relevant parameters. A comparison between the “measured” results and the theoretically predicted ones is also included, together with some assignments for the user. In sections 5 the resonant behavior of the mass-spring and vibrating string systems is analyzed in detail. Sections 6 and 7 include a revision of some advanced concepts, always with the support of the simulations. This didactic unit has been tested with high-school Spanish teachers. A translation into English is also available. In this document, the active links to control xyZET do not work.

Abstract: We have been developing the Hypermedia Pronunciation Power Program which helps students of English As A Second Language to improve their listening and speaking skills. When using this program, students see a movie of a native speaker. They can then imitate mouth positions as well as the sound of a native speaker. In addition, we are including two new features. With the new features, students can record their voice and can compare graphically their intonation with that of a native speaker. Moreover, students can make a listening practice with noises added intentionally, and they can also hear echo effected voices. We think this feature is useful for ESL advanced class students who can understand what native speakers are saying fairly well but cannot always understand every person. This paper describes the outline of the Hypermedia Pronunciation Power Program.

1. Introduction

Students of English As A Second Language desire to acquire clear and correct pronunciation of English words, phrases, and sentences but sometimes have difficulty in this area. ESL students cannot expect to greatly improve their pronunciation simply spending a few hours in a pronunciation or oral skills class. Materials are needed that allow students to work on their pronunciation skills in a language lab. These materials can be used on their own or as a supplement to a class.

In order to fulfill these needs we have made an English conversation education support system [McCarthy, Matsuno, and Swan 1997]. This system includes a video of native speakers pronouncing individual sounds, words and sentences. The learner is then able to imitate the mouth position as well as the sound of the speaker. The system includes opportunity for practice and includes materials designed to keep the learners interested while studying. Added to these features, we included two new features. We call the new system Hypermedia Pronunciation Power Program (HPPP). One of the new features allows students to record their own voices and to compare graphically their intonations with that of a native speaker. The second feature can create various kinds of noises, and can add them to original sounds. It is sometimes difficult for ESL learners to understand a person, who has a peculiar way of speaking, even if the students can understand a familiar person who speaks rapidly, like a radio announcer. In order to cope with those problems, students can make a listening practice with noises added intentionally, and they can also hear echo effected voices with HPPP.

2. Outline of HPPP

2.1 Required Hardware

To use HPPP, a student will need a multimedia personal computer with a soundboard and CD-ROM, which runs Windows 95. In other words, HPPP does not require any special equipment, as almost all of the computers produced at this time are equipped with such kinds of devices. However, it would be more convenient if a computer is equipped with a video capture board. Teachers would be able to make their own materials including video movies, and students would be able to check the shape of their mouths when speaking English.
2.2 The previous version of HPPP

In the previous version, HPPP offered the following three features.
[see McCarthy, Matsuno, and Swan 1997 in detail]

1. Students can listen to a teacher's explanation - how students should shape their lips and where they should place their tongue in order to make the target sound.
2. Students can see a movie of the teacher pronouncing the words and sentences, and can imitate the teacher.
3. Students can check their listening ability.
   Students hear the quiz sentence. Take the "th" sound for example: ten words containing the "th" sound or similar words containing the "s" sound are selected at random. The student then hears a native speaker say a sentence containing the quiz word. The student must decide if the word they hear was a "th" word or a "s" word. As the sentences are chosen at random, the student cannot memorize the correct answers - they will be different each time.

2.3 Added new features

2.3.1 Visual Voice

It is sometimes difficult for ESL students to judge whether their pronunciation is correct or incorrect, even if they can hear a playback of a recording comparing it to a teacher's voice. We examined the Microsoft voice recognition system to judge students' pronunciation. This system, however, is too severe to understand ESL students speaking as it is developed for English native speakers. HPPP helps students improve their pronunciation using a graphic pattern. When students want to make a practice for intonation, for example, students listen to a teacher speaking and see the teacher's stress pattern graphically. After ascertaining the teacher's intonation with both their ears and eyes, students can record their own speaking, and then can hear the playback of the recording comparing the teacher's intonation pattern with their own.

2.3.2 Noise Maker

Ordinarily, most English conversation support tools try to make students listen to clear speech. This is true for ESL beginners, we believe, but not for advanced level ESL students. Some of ESL advanced class students, as we mentioned above, can understand a person who speaks clearly like a radio announcer, but cannot understand a person who may have a peculiar or unusual way of speaking. HPPP can create several kinds of noises, and add them to a teacher's original sound. Students can make a listening practice under discords added intentionally by HPPP, and they can also hear echo effected voices. This is a kind of virtual reality. Students can make a practice under the situation as if they were in a crowd of people and/or on a busy street. A teacher does not have to offer all those materials. All the teacher has to do is to prepare materials recorded clearly word for word. HPPP can playback it slowly for beginners or faster for seniors with various kinds of noises.

3. Conclusions

We have reinforced HPPP. New added features are aimed at ESL advanced class students. A lot of ESL students are eager to acquire the correct way of speaking. However, we do not think HPPP is completed. We are not ESL teachers. We have developed HPPP from one ESL student's standpoint. Therefore, we would like to offer the HPPP to ESL teachers. We would appreciate it if some ESL teachers could use HPPP and give us their feedback to develop it into an even better teaching tool.

A Genetics-Like Taxonomy to Describe the Navigational Effect of a Link

Dr John Messing
School of Information Studies, Charles Sturt University
Wagga Wagga, NSW, Australia
jmessing@csu.edu.au

More than any other attribute, making associative links between two locations within the data, is the cornerstone of hypermedia. Bush's (1945 p106) "selection by association rather than indexing" was an early description of this process although Macknight (1996) suggests that its origins lie a thousand years earlier in the practices of medieval scribes and scholars. A great deal has been written about link mechanisms and the consequent process of using these to move from one part of a system to another.

Links are not all the same. [De Young 1990] addressed the issue of link type by defining a taxonomy which included links that indicated the nature of the data at the destination, structured sets of links, links which define relations and those which identify a finite number of steps that together form a unit. In the Hyper-book implementation, [Catenazzi 1993] used a classification that was a mixture of the nature of the data involved in the link and the source of the data. [Richards 1994], identified links which have a constant target, contextual links in which the target varied depending on the location of the link, typed links which were similar in operation to class links [Messing 1993], [Messing 1994] and intelligent links which involved calculation of the strength of a relationship based on user profiling or expert system techniques. [Tomek, Maurer & Nassar 1993] suggested an entirely different approach which calculated indices for the relevance of each link and allowed the resulting values to categorise the links.

One attribute that was not properly addressed in any of the above taxonomies, is that of the navigational effect that a link has. If navigation is such an important component of hypermedia use, then one would have thought that such a taxonomy would have been established by now. Geneticists have, since the days of Gregor Mendel, used a method of describing the characteristics of an organism in terms of a set of different forms of a particular trait, an allele. When such a technique is applied to links, a useful way of describing the nature of a link results. Given the highly researched nature of hypermedia navigation this might prove a useful and easily extensible, taxonomy.

One of the basic traits of links would whether they do or do not result in a change of node location as a consequence of following that link. The alleles for that trait could be represented as n (new node) and s (same node) or in the style used by geneticists, N (new node) and n (same node) where the capital letter version of a dicotomous trait represents having that attribute while the lowercase version indicates its complement. This is consistent with the "hj-link" and "w-link" operators proposed by [Catenazzi 1993] (p98). Further differentiation of link types could be based on the type of data involved at the source and target. Alleles for the type of data could be represented by t, g, a, v to denote the media type (text, graphics, audio, video). Other traits such as whether the link target occurs in the existing window or a new one could easily be added to the taxonomy.
The sample space of possible link types is determined by the number of traits that one is interested in investigating. For example, in a study which seeks to analyse link activity in terms of navigational effect on nodes (N, n) as well as data type at destination (t, g, a, v), there would be 8 different genetic combinations or 'types of organism' (Nt, nt, Ng, ng ... etc.). Link classification based on navigational effect, data at source, data at target and window effect would consist of 2 x 4 x 4 x 2 possible link types such as Ntgtw (New node from a graphic link to a text target in the same window i.e. clicking a graphic button that displays some text on a new node).

Practical demonstrations of the use of this type of taxonomy are not difficult to construct. [Messing 1997] used such a taxonomy to produce link activity ratios and measures which were able to objectively combine data from hundreds of links. Simply categorising the links available in a hypermedia / multimedia application may provide valuable insights for the designers. Being able to focus on individual traits of links may allow results from quite different research projects to be more accurately compared.

The purpose of having such a taxonomy which caters for many different link types is to be able to report, in a consistent form, the research associated with links without having to resolve the conflicts between the many different ways of describing link attributes. It is possible for instance to interpret past research on disorientation in terms of link types which carry the 'N' instead of the 'n' gene. Rather than inventing a variety of different descriptive classification schema, a researcher need only discuss the attributes of the particular 'gene' to be added. Such an approach has proven extremely successful in the biological sciences and may serve a similar role in hypermedia.

WWW-Publication

Using the World Wide Web as a medium for publication is of special interest to all subjects at school. The students could change from passive recipients into active producers of information; an unbeatable advantage for the appropriation of subject matter [Emig 77]. The creation of a school homepage could be a first start – spreading the subjects – in the production of multimedia hypertexts, it could be the basis for all school publications and support the "corporate identity" with the institution school.

The advantages of using the Web as a medium of (hypertext-)publication are:

- The motivation for text production arises out of real (communicative) needs;
- The Web itself offers a lot of material for the creation of texts;
- The number of potential readers, the audience is enlarged;
- Worldwide publication leads to intrinsic motivation and therefore to a higher awareness of the texts' quality.

Theses and results from own experiences concerning the work on designing a homepage with students are listed below [Meyer 97]. The homepage itself can be find at: http://www.shuttle.schule.de/do/stg/

Getting Started

A school presentation is a complex and extensive write and design-project, especially if a multimedia hypertext is the objective. Therefore the typical scheme of a writing-process (collection and organisation of material, production, revision) will not be realized in normal 45-minutes-lessons. In order to concentrate and focus on the product (homepage!) and to get foreseeable results, we decided to work on the project limited in time (three weeks in the afternoon). Before our undertaking was started, all necessary hard- (scanner; cd-drive; microphone with soundcard; videocard) and software were installed and tested extensively (we use almost sponsored commercial software or common freeware and cheap shareware programs). At the beginning inexperienced students should be introduced to the basics of all used software, so that there is not such a great division in experts. These steps help to avoid a domination of technical problems while students create the demanding homepage.

Study Group

Presenting a school needs a high degree of division of labour (according to interests, capabilities) and of team-working [Zammuner 95]. To enhance the ability of cooperation, the total number of students should not be too large (a
maximum of 15 to 20 students). After decision on the writing themes were completed, smaller groups (1-3 students) were built for every topic. To promote the writing capabilities of younger students, we made excellent experiences with mixed aged student groups (13 to 18 years).

The Unknown Hypertext

The production of a multimedia hypertext needs an idea of the overall construction and capabilities of linking concepts and references. Most students are unfamiliar with the reception and production of multimedia hypertext. First of all they have to train their ‘synesthetic’ reception of hypertext [Schmitz 97] by reading and discussing its characteristics and opportunities [Wichert 97]. We have realized this by simply “surfing” through preselected homepages (e.g. schools).

Following this phase the active production can begin by drawing special attention to the structure of a hypertext school web. We used a great poster for the visualization of all possible themes and links. After making necessary arrangements for principal layout styles and dates for regular plenum discussions, all students began to collect material (text, graphics, sounds, videos) and scan, write, visualize, paint, play, cut, morph it.

The Unknown Audience

Especially younger students are not sure who the reader of their text will be. That is why a fictive reader has to be imagined, a fact that does not promote the quality of text products. Therefore motivation and quality could be supported by the implementation of a real audience (e.g. partner school) or through communicative functions of a web page (e.g. e-mail, guestbook, form for comments, counter statistics). All students were proud to receive an e-mail with a comment from a reader and everyone revised their own hypertext afterwards. Because a homepage has to be actualize, some students still work in their leisure time on the never ending project.

Every student gave a positive judgement on the project. They emphasize the production guided innovative work with references to many subjects. The methodology of work should be find a way in the normal classroom lessons. Positive feedback was given also concerning their own roles. The chance to create a public text in an atmosphere of free ideas and cooperation gave the students a high degree of responsibility which is not typical for schools.

Learning Environment for Integrating MOO-based Interaction and Online Local History for the Social Studies Classroom

Karen L. Michaelson, Ph.D., Center for Technology, Education, and the Community, Eastern Washington University, USA. kmichaelson@ewu.edu

Cynthia Mullins, Center for Technology, Education, and the Community, Eastern Washington University, USA. cmullins@tincan.org

Social studies teachers are presented with the challenge of making both historical materials and contemporary societal issues engaging to the student audience. Students need to understand the economic, social, and political climate that shaped their community, and which continues to have an effect on how decisions are made which touch their daily lives. An interactive environment, which helps the student to understand history and the contemporary community, while at the same time allowing for alternative futures to be built, is ideal for such a task because in combines a factual knowledge-base with the opportunity for hands on development of the environment and peer-to-peer discussion.

CivicMOO is a project which links an interactive online learning environment — a MOO — with a rich historical database of local history materials. The MOO provides a text-based virtual representation of Spokane, Washington and the surrounding rural counties. It models neighborhoods, street corners, rural towns, and specific geographic and cultural features such as parks, buildings, churches, and businesses. The specific descriptions of each neighborhood or community are built gradually by the users themselves. The opportunity to describe a geographic or cultural feature in narrative form provides a rich opportunity for the writing curriculum, as well as for social studies activities.

CivicMOO will have a “transporter” which allows users to view the geographic region, its neighborhoods, and communities, in the future. Alternative futures can be built for different points in the time continuum, which express a given user or users’ view of what an area might look like 20, 50, or 100 years hence. Thus, a group of students might model the small town of Chewelah with parks, and a ski resort; while a group of civic leaders might create a future with an industrial economic base and high employment. These views co-exist in the “future” and can be debated and discussed. A singular asset of CivicMOO is that it is used by community leaders for planning and discussion, thus exposing students to real-life political debate and the struggles of various stakeholder in planning for their community’s future.

CivicMOO also developing a “time machine” which allows a virtual reconstruction of the geographic area at different historical periods. To enhance historical understanding, a database of historical materials is linked to CivicMOO, which can be accessed from any point in the online time continuum. Materials include primary source documents and pictures from regional museums and libraries. Many of these materials would not ordinarily be available to for classroom use. Students and others can build the historical database itself by gathering oral histories, family photographs and memorabilia which can be archived online. These activities can be part of the classroom activities planned around the use of CivicMOO. A number of issues and challenges have played a role in the development of this interactive environment:

Security
To encourage interaction, CivicMOO has seminar rooms, lecture halls, and places for casual discussion which are available at all historical, present, and future time periods. Because the MOO operates on a free, public access, community computer network, appropriate levels of security have to be designed to preserve the space for educational use and civic discussion without squelching creativity and vigorous debate. Open access, typical of the MOO environment has the potential to overwhelm our dial in capacity as casual users seek a place to "chat". (Chat is disabled on the network as a whole.) CivicMOO thus allows visitors to roam around, observe, and select items for further exploration, but venues for discussion must be reserved ahead of time. We are assigning some discussion space on an experimental basis to specific individuals and groups who will control their own times and guests as they need them.

**Linkage**

The text-based MOO operates in a telnet environment, while the historical materials are web-based. At this point, both sessions cannot be online simultaneously. While there are effective means of switching between the two sessions, it is easy for an individual to get “lost” while moving between.

**Organization and Selection of Information**

Historians often have a decidedly different notion from that of the classroom teacher as to what is the most important historical material to be put online, and how these materials should be organized. The archivist’s need to have online materials catalogued by universally-accepted standards, and the historian’s goal of putting significant research collections of primary data online must be balanced against the educational needs of K-12 students. Our solution is to use universal standards for cataloging, but create a front-end with an easy “who, what, where, when” search mechanism that allows the less sophisticated user to move through the materials efficiently. And, while the long-range goal of the overall historical database project is to get significant collections online, in the short-term, materials are being selected to mesh with the essential learning goals for each grade level of Washington state schools.

**Historical “Truth” in an Online Environment**

The issue of veracity of historical data has stimulated some of the most energetic debate in the planning process for this project. As the historians point out, there is a substantive difference in the quality of data between a diary, a treaty, and a fifth grade student’s oral history collected from her great uncle. While some historian’s wish to exclude student-produced data, teachers feel that its presence is critical to the growth of the database and the students’ understanding of historical processes in the region. First-person narrative is intrinsically interesting to most K-12 students, who can compare their current lives to the context, manners, and morals when grandmother was a girl. Additionally, the view of what is historically “true” over time changes, as the points of view of minority and other excluded populations are incorporated into accounts derived from general’s diaries and the artifacts associated with the elite. Our temporary solution is to have a cautionary statement on sections containing oral history or other less “true” materials. Long-range, we would like to have a section on historiography, geared to the understanding of various grade levels.

**Teacher Involvement**

Involving teachers in MOO development has been somewhat challenging. Teachers have been more comfortable with the use of the content-based database, rather than the somewhat confusing process of using and building in the MOO. To some, the text-based MOO seems “old-fashioned” when compared with current graphical interfaces and activities.

Our Learning Environments
Shaped by Our Tools...a.k.a. McLuhan

Brian L. Millhoff
millhoff@uog9.uog.edu
University of Guam
Instructional Media - RFK Memorial Library
UOG Station, Guam 96923 USA

In the 60's Marshall McLuhan began to address how our society was changing due to the effects of technology. Many of the academics of the time guffawed at his jingle-like "gibberish" and decried his academic histrionics which made pronouncements for our future. Well, the time has come to "drop this jiggery pokery and talk straight turkey ..." (Joyce, on McLuhan & Fiore) "the word is out - it goes without saying". The presence he saw, now surrounds us.

In this paper I'm really addressing how the instructional design approach known as 'Constructivism' is really a reflection/reaction to the changes in our societies that have been compressed into slogans by McLuhan. Could the re-discovery of McLuhanism lead to further cognitive/technological adjustments in instructional design?

"The youth today reject goals. The want roles-R-O-L-E-S. That is, total involvement. They do not want fragmented, specialized goals or jobs." (McLuhan, & Fiore, 1967, P.100) This paradigm shift, with roots in the 60's, is the foundation of the Constructivist 'engagement - learning' which provides learners with opportunities to self-select, plan, organize, design and monitor their own research and problem solving. Is 'constructivism' an attempt to substitute the students' interest in 'media' the tools of learning and communication for an interest in subject (Kuhns-quotes McLuhan, 1956)?

"Electric circuitry is orientalizing the West. The contained, the distinct, the separate - our Western legacy - are being replaced by the flowing, the unified, the fused." (McLuhan, & Fiore, 1967, P.145). Constructionism is seeking to capitalize on diversity, emphasizing the importance of distributive expertise. The instructor mentors 'learning communities' while coordinating content experts, technologists and educational resources and students in this 'cognitive apprenticeship' (Savery, 1995). “As new technologies come into play, people are less and less convinced of the importance of self-expression. Teamwork succeeds private effort.” (McLuhan, & Fiore, 1967, P.123)

Instructional design under constructionism appears to be reciprocal, recursive, transitory in functionality and constantly calling on a variety of skill(s) and/or individual(s) to be executed,
creating new all-encompassing learning environments. McLuhan said, "...nothing inherently impossible in the computer, or that type of technology, extending consciousness itself-as universal environment... extension of conscious itself" (Kuhns-quotes McLuhan, 1956)

The Winn's suggestion "that what students actually learn is determined by the situation in which learning takes place (the environment)" (Winn, 1997). McLuhan has written volumes on how our new environments are the media, that technology which actually becomes our 'subconscious' that "are not just containers, but processes that change the content totally" (Kuhns-quotes McLuhan, 1956)

"The classroom is now in a vital struggle for survival with the immensely persuasive 'outside' world created by new informational media." (McLuhan, & Fiore, 1967, P.119) Instruction, that Socratic basic of the University, is in a tremendous upheaval. Our passive learners, who have received the wisdom that we the dispensers and managers of knowledge deem important, are now in revolt. They are beginning to actually "shop" for instruction and learning in a worldwide market out of our control. In a similar problematic state, university instructors are being called upon to design instruction, facilitate knowledge acquisition, satisfy 'bottom-line' requirements of a 'customer' and compete with unseen cyber institutions.

As our "world tends to become a single classroom or a non-stop seminar" (McLuhan, 1969, p.37), we teach in a "global village of continuous learning and total participation in the human dialogue, the problem of settlement is to extend consciousness itself and to maximize the opportunities of learning... a community of continuous learning, a single campus in which everybody, irrespective of age, is involved in learning a living." (McLuhan, 1969, p.41)

Contrary to what you might think, McLuhan did not like the changes he observed about him, and like most of us he resisted altering his thinking and behaviour. Early recognition and adjustment to change is not seen in our 'rear-view mirror'.

"We shape our tools, and thereafter our tools shape us."
A Laurillardian CAL Design Method - Developed and Implemented

Michelle Montgomery Masters  
Department of Computing Science  
University of Glasgow  
United Kingdom, G12 8QQ  
michelle@dcs.gla.ac.uk

Introduction

At ED-MEDIA '97 a paper entitled “Developing a Laurillardian CAL Design Method” was presented, discussing design methods for Computer Assisted Learning (CAL) and proposed that existing methods were based on out-of-date educational models. The paper suggested that a more suitable educational model was Laurillard’s Conversational Framework. The paper then described how the model was being used to help develop a new CAL design method. This current paper discusses how the new design method was actually produced, what the new design method consists of, plan of evaluation for the method and presents preliminary evaluation results.

The Design Method in development

Schneiderman says that “Design is inherently creative and unpredictable.” CAL design can be made less dependent on the particular skills and talents of a few artisans by applying some science to the design process, embodied in an explicit design process. As Schneiderman goes on to say “in every creative domain, there can also be discipline, refined techniques, wrong and right methods, and measures of success.” In order to impose such a discipline, it was necessary to find some way to use Laurillard’s conversational framework in an instructional design setting. The discipline comes from the imposition of the conversational framework on to a CAL design by the instructional designer. To make this a reality, it was necessary to work out when and how to use the conversational framework.

Traditional methods for capturing knowledge on the way activities, such as Instructional Design, are performed have relied on the use of observational techniques such as video recording or interviewing. Ethnographic studies common in anthropology and sociology research, combine passive observation with detailed interview data. However, since the basis for the CAL design method discussed in this paper, is an educational model that is not in established practice, these approaches to generating design methods are not possible. Scenarios have in the past been used in place of observational studies in such situations. A Scenario is “a narrative,” “it is a description of context, which contains information about users, tasks and environments.”

Jack Carroll says that scenarios can help to ensure that computer systems are “easy to learn/easy to use,” that they “smoothly augment human activities.” MacLean and McKeal found two distinct roles for scenarios.

1) Supporting the generation of design ideas.
2) Evaluating a proposed design.

This work adds a new use for scenarios –

3) Supporting development of new design methods.

Maclean & McKeal call type 1) scenarios envisioner scenarios. The fundamental idea behind the use of envisioner scenarios being that they “drive...and contribute to the evolving design.”. Although scenarios have been used in the past to envision interactions with an implemented system, these statements seem also to apply to the creation of a design method.
The Design Method

The design method has been named "The Practical Design Method" due to its practical nature. The method is currently paper based and contains the following documents.

1. **The Teaching and Learning model**
The Practical Design Method is based on the Conversational Framework developed by Diana Laurillard. The framework is described and shown how it is used in the Practical Design Method.

2. **Cost and Time issues**
Cost and Time are extremely important issues when developing CAL. This section highlights these issues.

3. **Aims and Objectives**
The starting point for any design is to state the aims and objectives of your intended CAL. This section explains how to write aims and objectives.

4. **Activity Implementation Chart**
The Activity Implementation Chart provides the designer with textual descriptions of how activities from the Conversational Framework could be implemented dependent on the teaching mode chosen. The teaching mode can be human, computer or some other means e.g. via a book.

5. **CAL Case Studies**
The Case Studies illustrate via screenshots how activities in the Conversational Framework have been implemented in existing CAL packages, providing the designer with some ideas on how to implement the activities in their own systems.

6. **The Design Method**
A step by step guide to implementing CAL into your curriculum referring and using the other sections of the Practical Design Method Document.

7. **Design Templates**
The method comes with a series of blank templates which the designer completes to document their design.

Evaluation of Design Method

In order to evaluate the proposition that the Practical Design Method enhances CAL design, a number of evaluations are being conducted. The evaluation techniques used come from the domain of interactive systems. A mixture of qualitative and quantitative evaluation methods are being used. A series of case study evaluations are being conducted with academic designers of CAL systems. Prompted interviews have been conducted with the designer to provide some formative feedback on the design method. Formal questionnaires have been designed for the academic designer to complete when they have reached the end of their CAL design. Quantitative design experiments are also planned to provide further evidence that the Practical Design Method has improved the CAL design.

Interim Evaluation Results

Designers from a number of academic disciplines are using the design method to design their CAL packages and associated materials. Initial interviews with developers have indicated positive experiences using the method and
designers believe it is enhancing their design. The evaluations of the design method are continuing. The results of these evaluations will help to identify any difficulties designers had using the Practical Design Method and help fine tune and improve the design method.
THE ENCYCLOPEDIA OF INGREDIENTS:
DEVELOPMENT AND IMPLEMENTATION

Me. E. Mostert, Unit for Telematic Education, University of Pretoria, South Africa (Emostert@cbt.up.ac.za)

Dr. A.S. Blignaut, Dept of Home Economics, University of Pretoria, South Africa (Seugnet@Sciencia.up.ac.za)

THE PURPOSE OF THE MULTIMEDIA ENCYCLOPEDIA

Vegetables, Module 1 of the Encyclopedia of Ingredients, is the introductory volume in a series on ingredients generally used in the preparation of foods. Good eating and good cooking depend on the knowledge of ingredients and how to use them. Learning about these raw materials takes time and study and, in some cases, years of training. Yet, in this multimedia encyclopedia, vegetables as ingredients are graphically illustrated and described in detail, providing the learner with extensive information, not found in any other single resource.

The intent was to compile an information resource (along the lines of an encyclopedia) on vegetables available on both local and international markets. Although this information resource was initially aimed to become part of the training materials for the instruction of undergraduate learners, secondary education learners and as a tool in the food industry, the following categories of users of the multimedia encyclopedia are envisaged: both undergraduate residential and distance-education learners from the Departments of Home Economics, learners enrolled in various food-related courses at technicons, cookery schools and informal training institutions; food technologists, recipe developers, cuisine writers; caterers, buyers and marketers of food lines in commerce.

A TEAM APPROACH

The subject expert and educational practitioner, Seugnet Blignaut, initiated the program and the idea was proposed to the Unit for Educational Technology (now the Unit for Telematic Education), University of Pretoria. After the preliminary design of the concept for the multimedia encyclopedia, it was decided to use a team approach for the design, development and implementation. The instructional authoring task was allocated to El-Marie Mostert and the other stakeholders for this project, as indicated in the following section, were identified.

EDUCATIONAL PRACTITIONER

Two post graduate students from the Department of Home Economics, under the supervision of the educational practitioner, researched, gathered, and categorized the contextual aspects to be addressed in the encyclopedia, namely the identification, classification, selection, preparation, seasonal availability, storing, processing and nutritional value of vegetables. After this the subject expert evaluated and expanded the content where necessary.

INSTRUCTIONAL AUTHOR

The graphical screen layout was authored mainly on-screen using the Quest Net Plus multimedia authoring system. The educational practitioner and the instructional author worked closely together on a weekly basis. A graphical artist was engaged to operate in conjunction with the instructional author and educational practitioner in designing an appropriate look pertaining to the contextual aspects of vegetables and general feel of the contextual contents. The result of this collaboration, after much iteration, was the choice of an unusual green background with contrasting red navigation buttons. Although this color combination generally signals red in terms of colorblindness, no negative feedback from a wide variety of users was encountered. An additional task of the graphical artist was the scanning and preparation of the numerous graphics included in the multimedia encyclopedia. It was the total commitment of all the parties concerned that enabled the successful completion of the project. The importance of perpetual interaction between the subject expert and the instructional author of an multimedia application of this nature should be emphasized.
CHARACTERISTICS OF THE MULTIMEDIA ENCYCLOPEDIA

The main features of the multimedia encyclopedia can be described as an interactive interface with navigation buttons, enabling the learner to retrieve information regarding the description, shelf life, seasonal availability, variety, history, buying, preparation, nutritive value and processing of a large variety of local and internationally available vegetables. A search pertaining to individual vegetables can be undertaken by means of a variety of mechanisms, e.g. selecting a vegetable alphabetically by name, by typing in the name, by category, the season of availability, type of food processing and by nutritive value.

The emphasis in the multimedia encyclopedia is on the retrieval and processing of information. As there are many advantages to the use of database-type applications, learners may become disorientated within the vast amount of information whilst executing mindless search operations. Although the multimedia encyclopedia can be used as a stand-alone application, a worksheet was developed to assist both the educational practitioner and the learners to plan and facilitate effective learning.

IMPLEMENTATION OF THE MULTIMEDIA ENCYCLOPEDIA

The multimedia encyclopedia was implemented in the learning program of an introductory foods subject course (Foods 210) pertaining to the Home Economics, Dietetics and Food Service Management fields of study. The learners from two different programs, namely the residential-learner program (from the traditional population of the University of Pretoria) and the distance education learner program (from the previously disadvantaged communities), were enlisted for this mentioned subject course. The learners accessed the multimedia encyclopedia by means of a computer network. This proved not to be ideal, as twenty, or more students, simultaneously attempting to access the multimedia encyclopedia, caused severe overloading of the network.

EVALUATION OF THE MULTIMEDIA ENCYCLOPEDIA

Formative evaluation of the program was undertaken by four groups, namely (1) three instructional designers from the Unit for Educational Technology not involved in the project, (2) external education practitioners, engaged by The Institute for Educational Media of the South African Association for Research Development in Higher Education's multimedia competition, (3) the residential-learner group, and (4) the distance-learner group. The program was accepted favorably by both groups of instructional designers and educational practitioners. Within this limited scope, and due to the significance, only the crucial points of critiques will be elucidated, as these problem areas should be addressed in the designing and authoring of Vegetables Version 2 [Table 1].

<table>

<tr>
<th>POINTS OF CRITIQUE</th>
<th>RECOMMENDATIONS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Lack of interaction</td>
<td>● Enable cut, copy and paste functions of both text and graphics</td>
</tr>
<tr>
<td>Lack of student control</td>
<td>● Improve means of navigation throughout the multimedia encyclopedia</td>
</tr>
</tbody>
</table>

TABLE 1: IMPORTANT POINTS OF CRITIQUE AND RECOMMENDATIONS REGARDING THE FORMATIVE EVALUATION OF THE MULTIMEDIA ENCYCLOPEDIA

Both learner groups were positive in their appraisal of the encyclopedia and many expressed the desire to own a copy to use at home or in the place of work. Numerous learners indicated their frustrations regarding the inadequate means of navigation and the lack of speed of the application when accessed from the computer network.

SUMMARY

Sequential development pertaining to these critiques has already been instigated. Some improvements to the mechanism of effective navigation through the encyclopedia is relatively easy to perform (e.g. the numbering of consecutive screens), and a "home button" can be added without much difficulty. However, providing learners with meaningful procedures for the exploration of information (e.g. Boolean searches), and locus of control pertaining to its retrieval and processing, proves to be more difficult. Assistance concerning this will be requested from the programmers of the authoring system used in the compilation of the multimedia encyclopedia.
Approaches to Integrating Pedagogy and Multimedia: 
An Expanded Definition of API

Arthur R. Murphy, Research Scientist
Georgia Institute of Technology
Center for Rehabilitation Technology
490 10th Street
Atlanta, GA 30332-0156
arthur.murphy@arch.gatech.edu

Introduction

Improving the design of learning environments is complex. As the boundary between teachers and students is altered by multiple technologies, evaluations of interactions become more intricate. Methods developed by computer science for complex design may be useful.

Computer science defines an API as an Application Program Interface: a collection of formats for connecting disparate pieces of software. The use of this convention enables programs which were not initially designed as integrated components of a single system to be dynamically linked into functional combinations. An additional effect of this convention is that systems become more flexible. Changes made to various individual components can be more easily synchronized. Thus APIs extend the range of ad hoc systems, creating a single consistent interface rather than a set of incompatible and inconsistent functions.

Are there similar conventions for a Pedagogical Interface? Are the separate components of an education system consistent in their instructional goals? Do students experience a single interface, a consistent boundary layer, between themselves and the objects of instruction: teachers, textbooks, and media. Or does pedagogy appear to fluctuate inadvertently? Are academic goals and objectives reinforced in a comparable way by each component of the education system? As educational complexity increases, what heuristics exist for the integration of media and pedagogy into a coherent organic entity?

This paper will argue that, despite the complexity of systematically defining the entire model of pedagogy, a formal interface definition enables a specific environment to be more flexibly designed and evaluated. The use of an API can help identify significant variables. This process can be extended to form guidelines for coordinating changes in academic systems as increased technology use occurs over time. Systematic transformation—maintenance of a coherent pedagogy—may be the most important factor of the student—instruction—technology interface. Thus, congruent modification of teaching methods, textbooks, and media, may be more significant for learning improvement than a major change in any single artifact.

The Value of the API Metaphor

Although the meticulous vocabulary of computer science may seem inappropriate to an organic taxonomy of education, two advantages can be derived from the use of the API metaphor: a methodology for defining complex relationships can be initially implemented as a few variables at each contact layer (e.g. the student—instructor layer, student—student layer, student—technology layer, instructor—technology layer, etc.); the process of formalizing the structure of each of these boundaries improves awareness of the potential redefinition of pedagogy afforded by new modes of interaction. (i.e. if multimedia presentations assume a more central role in some instructional environments, the pedagogical side effects may become more obvious when the interactions are quantified.)

Clearly, the full implementation of such a scheme is overwhelming. Indeed, within the computer industry, arduous discussions by multiple software designers were needed to formalize API agreements. Initial program development time was often increased by using these techniques. Some programs were more complex to write this way. However, the authentic benefits created by published standards made it possible
for anyone to integrate his/her work into an existing context. The academic community may benefit from similar conventions for the harmonious use of multimedia artifacts within diverse pedagogy. An evolving new API — the Adaptable Pedagogical Interface — seems valuable.

**API Incentives: Distance Learning; Multimedia Tools**

Increasingly, adult education is becoming asynchronous. Although the essential goals of the curriculum may remain constant, distance education and interactive learning systems may alter some essential forms of pedagogy. Several subtle changes not easily measured by current evaluation techniques influence the nature of student-teacher interactions. For example, a classroom assumes synchronized learning; Internet access, although occasionally synchronous, is primarily a method to offset time and space constraints.

Many changes of this type appear to represent movement away from a traditional teacher-centered role toward an environment in which virtually all information is mediated by computer. Although the use of technology does not inherently remove the teacher as the central focus of instruction, collateral tendencies to use computer systems as a repository for lesson plans, handouts, presentations, student work, and customized curricular material from other sources, mean that much information exchange occurs through a computer, and can often occur asynchronously.

The apparent effects of computer based exercises and collaborative learning techniques have relegated teachers from "the Sage on The Stage" to "the Guide on the Side." Indeed, one of the primary goals of this API methodology is to formalize what interactivity occurs at which level in terms of time, objective, and function. Such a perspective acknowledges a migration toward a technology mediated knowledge infrastructure, but seeks to avoid a belief that technology per se will improve instruction.

Just as the use of an API convention in the computer industry forced clear answers to questions which had traditionally been proprietary and ambiguous, the use of an Adaptable Pedagogical Interface will provide a clear definition of an iterative model of improvements in technology tools and encourage more rigorous answers to the following types of question:

- Clarify how much tool expertise is required for teacher and student.
- Encourage the development of a property list for all objects in the learning system.
- Enable evaluation of hours of contact / interface by object.
- Document the focus of presentation / activity / reflection by object.
- Automate standard record keeping processes.
- Compute statistics which correlate learning gains with significant variables.
- Provide for consistent evaluation of data across environments.
- Provide for migration of data across classes.

**Challenges:**

Innovation has traditionally meant the adoption of new technology — the mechanical processes of the industrial revolution. Yet, education is not a mechanical process, rather organic responsiveness to interplay within dynamic learning environments. Part of the advocacy of an API for education is not in its potential value as a method of quantification. Rather its primary value may be as a stimulus for thought experiments:

- How do we quantify the time, place and mode in which learning really occurs? (i.e. immediate measurable results vs. long term concept maturation.) What method correlates the observable rigor of test scores with the anecdotal evidence of the shortcomings of technology. Is the conceptual scaffolding of computer assisted instruction comparable to the mentoring of a human assistant? How different are these variables?

The supposition of this paper is that the development and attempted application of this API methodology will provide a framework to bridge the qualitative ethnography of observation with the quantification of objective metrics. The proposed API, as applied to a specific controlled environment, may provide both an extensible container for quantifiable results and a focus for the larger questions raised by the increased infusion of technology into education.
Facilitating Graduate Nurses’ Transition into the Workforce with Interactive Multimedia

Associate Professor Som Naidu
Multimedia Education Unit, The University of Melbourne, Melbourne, AUSTRALIA, 3052
e-mail: s.naidu@meu.unimelb.edu.au

Ms Mary Oliver and Dr. Andy Koronios
Department of Nursing, Faculty of Sciences, The University of Southern Queensland, AUSTRALIA, 4350

Instructional problem
Current practices in the preparation of nursing students for a successful transition into the workplace is reported as being ineffective. Meanwhile, the Graduate Nursing and Preceptor Programs offered by the hospitals to facilitate the transition of graduate nurses into the workplace are under tremendous strain. It has been suggested that in order to prepare better nursing graduates for the challenges of the workplace, there must be improved collaboration between the employing organizations and the Universities which offer Nursing education programs.

Instructional solution
In attempting to address this need, we developed a learning environment which sought to present critical aspects of workplace-related issues in an interactive multimedia format for use by final year nursing students and graduate nurses on entering the workforce. The material presented on the CD-ROM attempts to simulate the complexities of life in a typical hospital, and in so doing making the education of graduate nurses and students case-based and authentic.

Learning activities incorporated in the courseware require users to make decisions about the best course of action, and source of information regarding each case or problem. Users are also able to discuss the cases presented to them in the multimedia environment and reflect on how they might have addressed the situation. This learning architecture reflects a situated cognitive model of learning where students and graduating nurses are coached in the development of their strategies for recognizing learning opportunities and critical thinking with the help of authentic cases.

We have not recommended throwing out all the textbooks and abandoning students in a welter of diverse information sources presented in this multimedia environment. On the contrary, we suggest leading students very carefully through unstructured problem situations from multiple perspectives and sources of information, providing careful instructional feedback, not only on content mastery but also on the skills of information-processing, critical thinking, and clinical decision-making.

Theoretical foundations
This project follows from the premise that if we are to prepare better nursing students and also graduating nurses for the challenges of the contemporary workplace, we must shift our focus from a content-centered to a problem-centered and case-based approach. A problem-centered and case-based approach to teaching and learning is underwritten by a “situated cognitive” model of learning, the primary propositions of which, as outlined by Savery and Duffy (1995) are as follows:
• knowledge evolves through social negotiation;
• understanding is gained through our interactions with authentic cases and in situ;
• cognitive conflict is the stimulus for learning, and also determines the organization and nature of what is learned.

One of the best architectures reflecting this approach to learning is Problem Based Learning (Barrows, H. S., 1994, Barrows, H. S., & Tamblyn, R., 1980). In this multimedia learning environment problem based learning and case based reasoning is used to improve current instructional practices in the education of nurses for their transition into the workplace (see Figure 1 below).

Implications for advances in learning
This project proceeded from the realization that current practices in the preparation of nursing students’ successful transition to the workplace upon graduation are ineffective and deficient. Moreover, it was of the view that more of the same kind of education was not going to be very useful and argued for a radical shift in the approach to this component of nursing education. A shift which would combine powerful educational technologies and proven learning strategies to build a technology enhanced learning environment. This environment is innovative in two ways. First, it integrates powerful technology with problem based learning and case based reasoning in an integrated learning environment. This adds to the currently burgeoning enthusiasm in the use of interactive multimedia for enhancing learning and teaching effectiveness. Secondly, it comprises a significant shift away from current practices of teaching and learning towards one that is problem-and case-based. In this environment student assessment is situation-specific and as such authentic.
**Figure 1: Technology Enhanced Case-Based Reasoning**

- Learners encounter cases/problem situations as they enter the learning environment.
- They explore cases/problems at two “case conferences” in the multimedia environment.
- Their goal in this environment is to develop an action plan for managing the patient situation.

**Phase I: Case encounter**
- Learners encounter the case at handover where they are explained its history and pathology.
- Their goal in the simulation is to develop an action plan for managing the situation in the given case.
- Their success is measured by reports they receive from their supervisors and peers.

**Phase II: Reflecting at case conference I**

<table>
<thead>
<tr>
<th>Becoming aware</th>
<th>Seeking solutions</th>
<th>Making decisions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Learners listen to the stories and experiences of expert practitioners.</td>
<td>They ask experts questions about their work experiences.</td>
<td>Learners develop a tentative action plan for feedback from supervisors.</td>
</tr>
</tbody>
</table>

**Phase III: Reflecting at case conference II**

<table>
<thead>
<tr>
<th>Raising issues</th>
<th>Seeking solutions</th>
<th>Making decisions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Learners explore new and related issues to the problem by reviewing sources of information.</td>
<td>They ask experts additional questions about their work experiences.</td>
<td>Learners develop their final action plan to submit to their supervisors to receive feedback.</td>
</tr>
</tbody>
</table>

**Phase IV: Developing an action plan**

- In this phase learners have their action plans accepted by supervisors and receive feedback on their decision making.

**Development**

The development of this interactive multimedia courseware product adopted a user-oriented approach (Goodyear, 1995) which comprises ongoing testing and formative evaluation of the prototype by experts in multimedia courseware development, content experts and a selected sample of intended users. This multimedia environment is being developed using Asymetrix’s Multimedia Toolbook™, a quasi-object-oriented, event-driven development system for Microsoft Windows™. Toolbook™ combines database functionality, text manipulation, hypertext, drawing capabilities as well as a full-featured programming language called OpenScript™ which allows the developer to program object behavior. Toolbook™ offers all the advantages of a prototyping tool and is best suited in projects where user initiated changes need to be made during the development process. This prototype is currently undergoing a series of iterations of progressive development. The highly modular nature of object-oriented programming allows the developer to test each object and its behavioral characteristics.

**Evaluation**

Our approach to the monitoring and evaluation of the outcomes of this project is utilization focussed. As such our focus is on the use and utility of the instructional innovation for nursing students, their lecturers, graduate nurses, and other stakeholders such as the employing institutions. Formative evaluation of the courseware prototype has been carried out in a semi-structured format with individuals and small groups of people in the Multimedia Education Unit at University of Melbourne, the Department of Information Systems, Faculty of Sciences at The University of Southern Queensland, and clinical staff at St Vincent’s Hospital in Toowoomba, Queensland. Comments from these sessions were noted and analyzed. Modifications and enhancements to the multimedia prototype were made on the basis of consensus from such feedback. Major modifications were carefully examined and before implementation, additional advice was sought from content experts. Final evaluation of this multimedia learning environment will involve focus groups and questionnaires to ascertain user perceptions of the efficacy of such a product.

Introduction

The Information Age has provided abundant opportunities for the expansion of traditional education programs for many institutions. Distance education technologies that enhance the dissemination of knowledge are continually improving in capabilities and becoming more affordable. The new technologies have provided instructors with the technologies necessary to reach new student populations and expose traditional students to new peer groups. Distance delivery technologies have enabled the dissemination of educational opportunities to student groups who were previously geographically isolated. Although many institutions have jumped on the distance education bandwagon by purchasing the technologies necessary for distance education, few have provided for the necessary associated faculty development opportunities as an essential part of the distance education process. Faculty desiring or required to teach via distance delivery are often forced to “learn-by-doing.” This method is difficult for the faculty, unfair to the students, and may be contrary to the educational mission of most institutions. In order for distance delivery to contribute to the effective education of new target populations, faculty must be trained in the use of the technologies and educated in the ramifications of the technologies for them and their students.

Course Dynamics

Distance education courses utilize technologies that are so integral to the course that they influence the course content itself. The type of technology used, lecture style, length of lecture, construction of class discussion or roundtable, type of assignment, and mode of testing can all be influenced. Knowledge of this influence is necessary in order to construct a syllabus that will work effectively, making the mode of communication a more basic part of the course structure. Without an understanding of the technology involved, the mode of communication itself becomes a hindrance to not only the classroom, but to the actual dissemination of knowledge itself.

There is some debate in the university setting concerning the adequacy of using teaching assistants to teach courses. The teaching assistant generally has an undergraduate degree in some field with little or no teaching experience, but is equipped with a teacher’s manual. Asking an instructor to deliver a distance education course with essentially no training on the equipment is analogous to the teaching assistant dilemma. To effectively deliver a class via distance technology, the instructor must have both knowledge in the field being taught and knowledge about the technology being utilized. A non-trained distance education teacher may feel that he or she is being required to teach a course in a new field with only a teacher’s manual and text in hand, trying to keep at least one class period ahead of the students. In addition, there are added feeling of inadequacy when the inexperience becomes obvious to the students, possibly lowering student confidence in the instructor’s abilities. There is little question that this situation compromises not only the use of distance education, but the quality of the course as well.

Group Dynamics

Group dynamics are definitely impacted in a distance delivered class. For example, in a course offered via interactive video, the class “group” is generally at least two separate groups attempting to merge into one. The primary group is that which is physically with the instructor. The secondary group is that which perceptually resides in the television. Every group develops what is known as boundary perception. This basic phenomenon
is the ability to determine who is and is not a part of the group, and is essential to the survival of the group. This perceptual division of the local and remote groups must somehow be eliminated or at least minimized to ensure effective progress in the class. The instructor needs to encourage this merging through activities and assignments in the beginning of the semester. This is difficult for the untrained faculty member to accomplish. Specific methods can be presented during faculty development to facilitate the merging of the groups.

The second area of impact regarding human interaction deals with the lack of flowing visual interaction between the groups. Although the vocal aspects of interaction via distance delivery are frequently in “real-time,” allowing all students to hear what is happening as it occurs, the visual is frequently absent or involves data compression that differs significantly from face-to-face interaction. The greatest area of impact rests in turn-taking behaviors. The way an individual knows that it is his or her turn to speak in a conversation is through pause time, eye contact changes, altering the tonal pattern of the voice, and posture adjustment. Although the students can note the pause time and tonal differences in an interactive video setting, the eye contact and posture adjustment are not easily read.

As people feel uncomfortable when the pause time becomes too long in a conversation, someone will generally take over to break the pause. In the televised situation, those students in the secondary group are not given the eye contact or posture adjustment cues to read, thereby increasing the chance of the primary group monopolizing the interaction. The students in the secondary group will especially not want to interrupt or seem rude when the class is first beginning, encouraging the pattern to develop and carry through the duration of the course. The students in the primary group will be quite focused on the instructor and each other, reducing the chance that they will look to the television to try and read the other group’s members to see if they have something to say. The instructor also must make an effort to specifically ask questions of the secondary group to ensure that their questions are answered, as well as to draw them into the discussion. Faculty development can address these issues to ensure that the faculty member is adequately prepared to handle these situations and facilitate meaningful interaction between groups.

Conclusion

The process of distance education has been studied and is being studied in depth. The focus is generally on improving the technologies rather than enhancing the capabilities of the instructors through formalized faculty development programs. Faculty development needs to be approached in a proactive manner with faculty learning prior to presenting a course via distance delivery, rather than solving problems associated with distance delivery in a reactive manner at the expense of the students and the faculty member. Key areas that need to be addressed in the training include use of the technology and the effects that the technology have on course dynamics and group dynamics. Careful planning for faculty development can enhance the experience for the faculty member and the students, thereby increasing the likelihood of continued effective interaction.

An Online Digital Photography Course For High School Teachers

Bonnie Nardi, Brian Reilly, Reinhold Steinbeck
Former Research Scientists, Advanced Technology Group, Apple Computer, Inc., Cupertino, CA, USA.
E-mail: research@ltiweb.com

1. Introduction

This report describes our experience designing and conducting two online digital photography courses for high school teachers while we were researchers with the Apple Classrooms of Tomorrow (ACOT) program and the Knowledge Management Technologies group at Apple Computer, Inc. The aim of the course was to enable teachers to incorporate new photography technologies into their classrooms effectively and explore tools and activities that advance the Internet's potential for online staff development.

2. Background

In previous research, we had studied a digital photography class at Lincoln High School in San Jose, California. We were impressed with the way sophisticated technology was being used in a high school classroom to great effect (Nardi and Reilly, 1996a, 1996b) in an ethnically and socioeconomically diverse school. The students enjoyed creating digital photos and learned about both art and computers. Computers need to be effectively integrated into the curriculum to be interesting and useful to students, and at Lincoln High, the digital photography class was an art class that used computers. The students were taught about composition, color, lighting, and other general principles of photography. They also learned skills peculiar to digital photography such as manipulating and blending images, but the focus was always on the art.

Many teachers would like to offer digital photography to their students but they don't quite know how to get started, or they may feel isolated if they are the only one in their school with such an interest. To meet these needs, we decided to design an online course in digital photography for high school teachers. We hoped this would be an effective way to reach teachers and give them access to others with shared interests.

3. Course Design and Implementation

The development of the course was a natural extension of our research model of working intensively with end users. After we had learned so much about digital photography in the ethnographic work at Lincoln, and recognized the need for education for high school teachers, the CD-ROM—created to document the classroom experience at Lincoln—became a tool in the next phase of our research. We built the online course on the scaffolding of our in-depth experience in a school as documented in the CD-ROM.

We hired a high school teacher from San Jose who teaches digital photography and whom we had worked with in the past to plan the curriculum and conduct the first course. The second course was taught by two students from the first course. We also provided the Web-based learning environment. From a research point of view, we wanted to learn whether simple tools such as chat and bulletin boards could be used effectively for staff development.

Each course ran for eight weeks and involved six assignments that had been adapted from the classroom digital photography course previously taught by the instructor (such as colorizing and manipulation). The demand for the courses was overwhelming. The first time we had 150 applications and the second time 304 (with little advertising). We were able to accommodate 15 students in the first course and 25 in the second course. One issue we tried to address through the assignments and our choice of participants was the balance between a tool emphasis (Adobe Photoshop) and a digital...
photography emphasis. We deliberately chose applicants who mentioned how they would apply digital photography with their students and avoided applicants who expressed an interest in learning Photoshop. We tried to steer the assignments towards photography and away from just learning the tools.

4. Web-Based Learning Environment

ACOTNet, the Web-based learning environment that was used as the vehicle for the courses, included a regular password-protected Web space that contained course content (syllabus, resources, chat transcripts, links to other Web sites); an asynchronous online conferencing system enabling course participants to post their reflections on weekly assignments, include their images, and let others read and respond to these messages at any time; and a text-based chat application with the ability to dynamically share images, documents, URLs, video and audio in a freeform work space or canvas (shared documents or images could be seen immediately by everyone participating in the live chat session).

5. Course Evaluation

What we learned, in a nutshell, was that the simple constellation of online tools we used for the course—chat, bulletin boards, email, and Web pages—worked very well to create a community of high school teachers interested in digital photography. Many online courses use the distance learning model of instruction in which content is delivered to students and they use the Internet to discuss their work and meet with an instructor and other students (Collis, 1996). We took a somewhat different approach. Rather than focus on the instructional aspects of the course and attempt to recreate the classroom experience, we decided to emphasize the differences that an online course can bring to the learning experience, especially the possibility of developing a sense of community in which sharing ideas and enthusiasms with others is the key focus.

Initially, we hoped that the postings of each student's work as well as their reflections and comments would be the key feature, which would help form a learning community among the participants. We were skeptical of the whole idea of chat based on personal experiences and even considered using chat only on a limited basis. Much to our surprise, the weekly chat became the central event each week. After the third or fourth week of the course, the students were arriving early and staying late at the chats. By the end of the course, many of the students were so attached to the chats that they asked to use the chat room on their own and continued to meet for several weeks, at which point they wrote a proposal to continue their online course experience by creating their own web pages on the ACOTNet server.

Students enjoyed most of the assignments, but were particularly enthusiastic about the last one, which involved collaborating via the Internet on a collage with another participant in the course. Here, the students shared images via email, discussed their plans using email and chat, and produced either a single image or variations based on the same set of images. One of the most exciting tools that was used in the second course was the chat application with integrated canvas. The participants immediately recognized the potential of such a tool for real collaboration over the Web.

While many participants mentioned the technical problems they encountered with the chat and discussion software, those who completed the courses were generally excited about their experience. The final assignment, which involved collaborating via the Web with at least one other student in the course, was mentioned as a particularly stimulating and challenging in several evaluations. While participants enjoyed the collaborative assignment and the way it helped them get to know others in the course, it was the last assignment, and as a result, the value of the community building that took place was short-lived. In the second course, we incorporated some suggestions to speed up the process of participants getting to know one another. These included requiring a personal web page as the first assignment (optional in the first course and done by only one student), structuring the way students comment on other students' work so that everyone's work will be reviewed each week, and splitting the class into smaller groups for two chats per week.

Issues in the Development and Delivery of Distance Learning Classes

Lisa Neal

EDS
Three Valley Road
Lexington, MA 02173 USA
+1 781 861 7373
lisa@acm.org

Abstract: We are investigating the use of collaborative technologies, including intranets, email, audio- and videoconferencing, chats, NetMeeting, Virtual Places, and WorldsAway, to teach classes to geographically-dispersed participants. We have found that the use of multiple technologies provide an effective alternative to face-to-face instruction with rich communication and a strong sense of community. However, the use of each technology was far more complex than we had imagined at the outset. There were striking differences between distance learning and face-to-face classes including instructor preparation and lecture style, student interactions, and the importance of establishing protocols. We are expanding our investigations by developing entirely asynchronous distance learning classes.

1. Introduction

Corporate education programs are searching for ways to reduce the cost and increase the availability of education. At EDS, we taught classes on Emerging Technologies in Human-Computer Interaction (HCI) and Emerging Technologies in Collaborative Environments to EDS employees globally. Delivery technologies were selected based on cost, availability, and perceived or hoped-for (at least in the first delivery) effectiveness, and were matched to objectives in order to select and deploy the most appropriate technology for each class meeting. Feedback was used to make adjustments to the type and mix of technologies used. In the process of planning, delivering, and evaluating the classes, we learned how to match tasks to technologies and the subtleties of the technologies employed. In planning subsequent classes we incorporated many of these lessons.

2. Class Structure, Topics, And Students

The courses were structured as a four-week instructor-led seminar with guest speakers and student research projects. Guest speakers were able to lecture or lead discussions without being constrained by location. Students juggled work and class commitments. Class sessions were typically three times a week for 2 - 2 1/2 hours, which seemed to be an appropriate length of time for the students to fit into their work schedules. Extensive evaluations were conducted at the end of each class, and informal evaluations were done during the classes.

Four Emerging Technologies in HCI and Emerging Technologies in Collaborative Environments distance learning classes were taught to date by the author to approximately 80 students. These classes were interspersed with on-site face-to-face classes, which offered the author a reminder of the many differences between the two situations. Students in the distance learning classes were in many countries; the only problem we experienced delivering a class to international students was the narrower window in which classes could meet due to different time zones. Many of the enrolled students in the distance learning classes would not have been able to participate in a multiple-day class due to work commitments or travel costs.

3. Distance Learning Technologies

A variety of technologies are currently being used to replace or supplement the face-to-face classroom [1]. EDS was attracted to a hybrid approach based on the Open University’s success [2]. We chose not to strictly imitate the Open University’s approach since we had more distance learning methodologies available at EDS than the Open University instructors had at their disposal.
Of the technologies available at EDS, videoconferencing, audioconferencing, and a variety of Internet-based conferencing tools were selected based on cost, availability to participants, appropriateness for the course structure, and their potential to provide an interactive virtual classroom. A Web site was built that included the class schedule, syllabus, evaluation forms, RealAudio and text transcripts from class meetings, student projects, and student biographies. The initial Web site led to the development of a Virtual University, which was the repository of the materials classes and provided information not only to enrolled students but to other employees as well.

The technologies we selected varied in how easy they were to use, how comfortable their use was for the instructor and students, and the learning situation which they best facilitated. We discovered that protocols had to be established for each technology, and that the instructor played a key role in establishing and enforcing the use of protocols.

Problems with the use of individual technologies led to the combining of audioconferencing with Internet-based technologies in order to have high quality audio along with visual information and chats. Tools that were used included Virtual Places, a hybrid IRC/virtual world, which was useful for the expressiveness of the avatars, for the web-based information that could be displayed, and for the "tour buses" that avatars could "ride" to visit Web sites together. NetMeeting was added for application sharing, the electronic whiteboard, and chat; the audio and video components were not heavily used. A virtual world, WorldsAway, was used for class parties. Students gained further experience with these technologies in collaborations for projects, and many started to use the technologies during and after class as part of their work teams.

4. Conclusions

We found that the use of multiple technologies provided richer communication than any one technology alone. The use of the technologies proved, in itself, to be a valuable pedagogical experience. While none of the technologies provided the visual cues of face-to-face, the multiple technologies fostered a significant amount of interaction and students remained engaged during class sessions. The strength of the relationships students formed with the other students and the instructor is largely attributed to the mix of technologies, each of which fostered varied personal communication styles and allowed people's personalities and senses of humor to be apparent. The humor in some students' home pages and in their virtual world visits greatly increased their familiarity with each other. This led to better team projects and to the sense of community and networking that is typically a by-product of education and is especially important in a large organization [3].

Students were better able to fit classes into their work schedules when the classes required no travel and met over a longer duration with shorter sessions for each class meeting. Students reported that this schedule increased their retention of material and facilitated deeper exploration into materials since students were using their own open-ended time rather than being given a fixed block of time in the classroom for exercises and readings.

From the instructor perspective, class preparations were more time-consuming and complex than anticipated at the outset or than required for classroom teaching. Delivery was compounded by the challenges of managing technology and the greater difficulty of facilitating interactions without visual cues. It is also challenging for the student to absorb information given the abundant distractions in their office or home when taking a class.

We are now investigating the development and delivery of asynchronous distance learning classes. We are discovering the significant differences between the development of asynchronous and synchronous distance learning classes.

Managing Self-Directed Learning in a CALL Environment

Karen Yeok-Hwa Ngeow
Language Education Department, Indiana University, Bloomington, USA
Email: yngeow@indiana.edu

Keng-Soon Soo
Instructional Systems Technology Department, Indiana University, Bloomington, USA
Email: ksoo@indiana.edu

1. Introduction

Two current concerns that language teachers have are promoting “how to learn” strategies and meeting diverse needs of learners. If we are to emphasize the importance of learner autonomy and learner diversity in our classrooms, we need to consider the possibility of designing an environment that allows learners to be self-directed, that is, to manage their own learning.

The research on learner autonomy shows that learners who are actively involved and who take responsibility for their own learning process tend to develop a higher level of awareness of how to learn (Trim, 1996). At the same time, learning styles research also leads us to believe that instructional design that is aimed at meeting learners’ different learning preferences helps enhance the learning process (Reid, 1995). It is no longer debatable that everyone learns differently, and the crucial issue about learning styles and autonomy is not merely about how well students learn, but how much support we can offer them in approaching learning. We believe that all language teachers should be entrusted with the obligation of helping students learn optimally, even while learning differently (Soo, 1998).

2. Principles of a Self-Directed Learning Environment

This paper discusses the design of an undergraduate ESL program in a Malaysian university where students and teachers collaborate to develop a computer-assisted language learning curriculum based on self-directed learning principles. These principles are created based on the theoretical bases of learner diversity and learner autonomy. The three principles are: (a) placing ownership, responsibility, and choice with the learners, by negotiating a learning contract between teachers and students; (b) catering to a variety of learning preferences, by exploiting a wider range of resources and learning options; and (c) driving motivation and self-efficacy in learning, by setting attainable and inspiring goals for the students.

This design is based on a learner-centered curriculum, where the teacher includes the students as far as possible in the planning and implementation of the language learning curriculum. For instance, there is continual negotiation of a learning contract concerning curricular demands and students’ individual learning goals, and students are constantly encouraged to offer suggestions to enhance their learning conditions according to their learning preferences at different points of their learning process.

3. A Case in Point: The MCALL Project

This paper focuses on the design aspects of a self-directed learning environment in a study conducted to assess the effectiveness of multimedia computer-assisted language learning (MCALL) as compared to conventional teacher-taught classes (Soo and Ngeow, 1998). The experiment, which involved 188 ESL freshmen, took place at Universiti Malaysia Sarawak (Unimas), a university that was established in 1993.
Being a newly established university, Unimas had to deal with the problem of a mismatch between increasing numbers in student enrollment and resources that could not meet the demands of this increase, particularly in terms of teachers and room availability. The proposal to set up a multimedia computer-assisted language learning laboratory to offer self-access English classes attempted to deal with this problem.

To graduate from the university’s ESL proficiency program, students were required to obtain a passing grade equivalent to 550 on the Test of English as a Foreign Language (TOEFL). When students first enrolled in the program, they took an entry test to determine their TOEFL scores and their corresponding proficiency level in the university’s ESL program. Individual students consulted with a language teacher-manager to draw up a learning contract on individual learning goals and strategies. These strategies involved negotiating various aspects of the language learning process, for example, students’ preferred times and pace of study, target levels of language achievement at various points of the semester, and types of activity involvement.

Following that, students enrolled in a multimedia computer-assisted language learning program that used the software, English Language Learning Instruction System (ELLIS) produced by CALI, Inc. (available at http://www.cali.com). The ELLIS software was a suitable program for use in a self-directed learning program because of its many features, among which are more than 200 hours of modularized video and audio clips of native-speaker interactions, students’ self-checks and feedback on learning progress after completion of each language module, and modules that are set up to focus on either a grammatical or a communicative aspect of the interactions. In addition, students were given opportunities to learn from other resources such as reference materials and group discussions. The teacher-manager of the MCALL project also assigned advanced level proficiency students as mentors to groups of 5 - 6 students. The student-mentors acted as a liaison between the MCALL teacher-manager and the students, and were responsible for monitoring group members’ progress and attendance records. When students completed their negotiated number of learning modules, they could then decide when they were ready to take the qualifying test for each proficiency level, and would do so after consultation with the teacher-manager about their learning progress. On attaining a level equivalent to 550 on the TOEFL, students were awarded a certificate of achievement. This certification of their language proficiency represented a significant indication of students’ achievement as well as documentation of their proficiency level. Students with this certification could then move on with confidence to take higher-level language courses that are discipline-specific or job-related.

4. Implications

The implementation of self-directed learning within a multimedia computer-assisted language learning environment is significant for many reasons. With the increasing number of students enrolled in ESL programs in universities and community colleges, it is prudent and timely to consider alternatives to classroom language instruction that can provide students with optimal conditions and relevant resources for language learning. Students should not have to be reduced to a homogenous group by teachers who have neither the time nor the resources to cater to diverse learning preferences. In addition, putting students through a self-directed learning experience gives them the opportunity to view themselves as learners who are self-determined, decisive, and can be held responsible for their own learning – all of which are traits for the development of lifelong learning skills.

1. Distance Learning: Reasons for Change

The new social, professional and personal demands resulting from the fundamental changes introduced by the information society will have important repercussions for professional work and consequently for vocational and professional training at all levels.

This paper aims at giving an overview of the state of the art in distance learning and its recent evolution. Within this frame we will discuss the educational use of WWW, examining some theoretical and methodological aspects that seem to us of foremost importance.

Working students ought to be self-directed or autonomous and independent learners and are willing to take an increased degree of personal responsibility for their learning and working. Adult trainees like to be regarded as partners in the pedagogical process.

Open and Distance Learning are the adequate methodologies that promise greater effectiveness, more learner-centred approaches and better quality of interaction.

What we are seeing with these new learning environments is a transition from traditional models of training to completely new paradigms of learning, such as problem-solving and decision-making through the use of multimedia simulations.

This transition is technology-related.

Distance learning is changing for the following reasons:

- The economical and social contexts are different.
- The number of unemployed workers is increasing and the need to be retrained.
- Knowledge has become one of the most important economical forces.
- Knowledge is rapidly expanding and its life becoming increasingly shorter.
- Companies need to change to survive in the market.
- Investing in the human resources seem to be the only way for a sustainable development.

Distance Education evolution is due to all these changes and is considered as one of the most adequate and attractive means to face them.

We can say we are now in the third generation of Distance Learning but how can we justify this statement?

The terms first, second and third distance learning generations refer to three different models that are linked to the development of production, distribution and communication technologies.

The “first generation” is correspondence teaching, based in printed material in which trainee-trainer and trainer-trainee feedback processes are slow and sparse.

The “second generation” is called the multimedia distance teaching, developed since the late 1960’s, integrating the use of print material, audio cassettes, videotape and to some degree computers. Feedback processes include telephone counselling and some face-to-face tutorials.

Communication with the trainees has been marginal and among trainees more or less non-existent. Because the technologies available up to now are one-way or two-way communication technologies but they are not yet interactive.

The “third generation” that we can call “Net/Web generation” is mainly on-line, highly interactive, supported by several on-line services.

2. Distance Learning, WWW and Communication Theory.
Communication and learning as a social process, will be the key elements in the conceptual development of the third generation models of Distance Learning. It is not possible to promote the notion of learning as a social process without access to interactive communication facilities. So WWW appears as the implementation of the old utopian dream of the first theoreticians of communication theory among whom we find MacLuhan. Networking enables asynchronous and synchronous communication among people wherever they may be and no matter when. It appears as a new concretization of the MacLuhan “global village” on a worldwide scale.

Jean Cloutier in his book “L’Ere d’Emeroc” imagined the human being able to receive and to send messages as well. For him only self-media could improve both individual and social communication. WWW is a good example of self-media. Consultation of hypertexts on a screen incites the user to integrate reading and writing activity into one sole process.

The most important on-line facilities are:

- Electronic Mail
  The advantages of e-mail are numerous: 24 hours a day accessible, easy to access, location/time independent, free open-entry and open-exit, private learning, group messages (trainees and trainers can send information), private messages and so on.

- Computer Conference
  Individual trainees can join conferences on specific subjects of interest. It is asynchronous too, participants are not obliged to be present and active at the same time.

- On-line databases
  Information can be stored in databases on the same host computer which is used for e-mail or computer conferencing system. So it is used for electronic mail or computer conferencing and it is more economic than traditional information sources.

3. Main Issues and Ideas

3.1 Educational Content for the Web

It is clear that instructional designers and distance educators can add value to technology-based training and it is particular true in what concerns the design of the learning environment specially content, that requires certain pedagogical characteristics, including facilities for: dialogue between trainee and materials (information); between trainee and content author (tutor), between trainee and trainees, always providing feedback.

Another aspect deals with providing multiple access points to information on the Web and different ways of navigating in this medium, what makes content relevant and accessible.

As for narrative, the Web is problematic because its key features are linearity, temporality and causality), while the Web is non-linear, non-temporal and does not afford explicit representations of causality. So in narrative texts designers need to: keep hyperlinks to a minimum; avoid breaking texts down; employ media elements that can enhance or help narrative and avoid embedding interactive tasks into narrative texts.

The most successful application areas of Web training are: Communication - Research and Problem Solving.

There are different kinds of computational learning environments that can be used: Programmed Instruction; Computer Assisted Instruction, Intelligent Computer Assisted Instruction, Cognitive Learning and Knowledge Construction among others.

The trainee must be active and interactive; the learning environment must be rich, complex and structured.

3.2 Delivering Instruction on the Web

The WWW emerges in Internet as the easiest and most popular way to access and its possibilities for training are boundless.

WWW-based courseware must not restrict itself to delivery of educational content. It must be based in some model of instruction and learning.

Why to use the Web?

It represents a new way of looking at instruction - at how it is organised and presented. It is simultaneously a delivery medium, content provider and subject matter.
When to use the Web?
The Web uses text, graphics, interactively and to a lesser extent video and audio.
It is most useful when used to explore intellectual and verbal knowledge and to a lesser extent when
exploring affective learning. Due to its versatility and interconnectedness it offers one of the most effective
ways to work with trainees who are spread geographically and it is easy to update to meet the needs of
changing subject matter.
The Net has two real advantages over other media. The first one is due to the fact that it conveys video and
sound what a book does not, is more interactive than a videotape and unlike the CD-ROM it links people
from all over the world cheaply. The second one is that it can also be a content provider and it is the largest
and most complete information resource.
In what concerns the trainees and tutors they can interact with the learning materials.
There are two main types of delivery: printed delivery - here the trainee decides to print out the course or
part of it and interactive delivery - the trainee studies the materials from the screen interactively.

3.3 Conclusions

To achieve the most cost-effective use of the Web major changes are required in the institutions. There is a
need for re-structure and for open and distance educators to re-think and re-define their roles.
“Change will be neither swift nor easy” and many educational leaders are not aware of it, while many users
are rigid in their attitudes to use new technologies.
Restructuring with technology involves a shift to learner-centred instruction, cooperative learning for
trainees and collaborative efforts for tutors.
The question is no longer how to use the Web to do the same thing better , but to change practice to reach
new goals as a tool in creating, implementing, managing and communicating a new conception of training
and learning, as well as a system to support it.
We are dealing with a new medium so we must need some humility and to up-grade our skills because it is
changing very rapidly and it is almost impossible to keep up.
Global Web based courseware involves adequate content design and delivery of instructional material
structured according to some pedagogical and learning strategies.
To sum up we can say that to use and explore the Web training resources implies the survival of the
educator/trainer within his lifelong learning system.

Using "Brainzone", an Assessment Tool for the World Wide Web

Beverley Oelrichs
Department of Physiology & Pharmacology, The University of Queensland, Australia, oelrichs@plpk.uq.edu.au

Alison Bailey
Department of Physiology & Pharmacology, The University of Queensland, Australia, a.bailey@mailbox.uq.edu.au

Increasing enrolments at Universities have encouraged a move towards flexible delivery providing the opportunity for students to access educational materials from a distance and in their own time. Concurrent with this comes a need to manage assessment in a similar manner. “Brainzone” is an assessment tool developed by Educational Multimedia Services of The University of Queensland to enable lecturers to deliver all aspects of the assessment cycle through a web browser.

“Brainzone” allows lecturers to design a complete exam with a variety of question types including multichoice, drag and drop and short answer. Questions can be randomly selected from a pool and graphics can be displayed for any question. The student’s response is marked and feedback given on completion of each question. A student report is generated enabling the progress of individual students to be checked by the lecturer and the exams can be ‘formative’ with the student allowed many attempts or ‘summative’ when the exam is available over a limited time with only one attempt allowed. Password entry is required for both staff and students and the interface is attractive and easy to use with no need for any html skills. [Strassburger, 1997], [The Staff Guide to Brainzone, 1997]

“Brainzone” was trialed in a number of Departments in this University in 1997. Pillai-McGarry, [1997] found it a valuable teaching tool in a subject where the marking of assignments had been time consuming for staff. She recognised the need to introduce some of the students to the World Wide Web and included detailed instruction on the use of the tool in her information sheets. She concludes that “under formative conditions “Brainzone” was found to be a useful tool for student learning and self-assessment. The ability to provide feedback to students also makes it a valuable teaching tool.”

Since 1994, the Department of Physiology & Pharmacology has used Computer Based Assessment for both formative and summative testing in first and second year subjects, using our departmental network and Macintosh computers. In 1997, “Brainzone” was trialed for formative tests in first and second year subjects with enrolments of 500-1400 students. The tests used to date have been simple best of five MCQ and the “Brainzone” interface enabled easy entry of questions and tracking of student performance. They were made available in the last three weeks of first semester and throughout second semester. In first semester about 25% of the students used “Brainzone”, this increased to 30% in second semester with up to 55% in some of the classes.

A total of 416 first year students responded to a questionnaire about their use of computers and departmental computer facilities. Of these, at least 91 had used “Brainzone” (though 177 students left this question blank altogether) and rated it on a 1-5 scale as shown below. [Tab.1]

Table 1: Rating of "Brainzone" by Student Survey
As anticipated, the best students used the tests most [Fig.1] which largely reflects the higher motivation levels and better study patterns of students who chose to use the tests, but, as you will see, the results are encouraging enough to promote “Brainzone” use to all students.

When a student’s end of semester mark in first year was related to their OP and the end of semester mark in second year was related to the end of semester mark in first year, it was clear that the best students performed the best on the exam. This was expected. However it also revealed that all students that used “Brainzone” did better than their counterparts who did not, including the students with an OP >10. [Fig.2] Even when the motivational factor is excluded, there is evidence that the tests significantly improved final examination marks. “Brainzone” tests were written first for the topics typically considered most difficult by students. Consequently it is not surprising that students who did not make use of “Brainzone” did significantly worse on the exam in the topics covered in “Brainzone” tests. They also did not perform as well on the topics not covered in “Brainzone”, whereas the “Brainzone” users did quite well.

If “Brainzone” tests in only a limited number of topics which are introduced very near the end of a semester can make an obvious difference to student performance, we expect “Brainzone” to be much more valuable for students when all topics are covered and the tests are available early in the semester. Data from second semester 1997 will be compiled early in 1998.

The above results confirm our expectations based on our study of use and performance by students using our Departmental Networked Computer Based Assessment. The real step forward is the use of the Web enabling much more flexible access by both staff and students. Combined with flexible delivery of lectures and bulletin board access to the lecturers, the tool takes us well into the future where students will be able to plan their learning to suit their individual needs.

"Brainzone" is available via the World Wide Web (WWW) at http://brainzone.ems.uq.edu.au. At this site there is a demonstration of an assessment exercise as well as the access points into the system for registered staff and students.
A Network-Based Tool for Organizing Second-Language Vocabulary

Breffni O'Rourke
Centre for Language and Communication Studies
Trinity College
Dublin 2
Ireland
e-mail: orourkeb@tcd.ie

1. Theoretical Background

There has been in recent years, in both applied and theoretical linguistics, a certain shift in focus away from syntactic structure and towards the lexicon as being in a certain sense the engine of language. In many influential linguistic formalisms (including ‘mainstream’ Chomskian theory and unification-based frameworks such as HPSG), the syntactic rules component has had much of its complexity stripped away in favour of a more richly structured lexical component. This transfer of explanatory power in the formal domain has coincided with increasing interest in the lexical dimension of language acquisition and use, in both first and second languages. For example, [Peters 1983] has demonstrated the pivotal role of lexical units in first language acquisition, while [Pawley and Syder 1983] have argued for the importance of lexicalized sentences and sentence stems in nativelike performance. Such considerations have in turn given rise, in the field of language pedagogy, to much interest in ‘lexical approaches’ to language learning [e.g., Nattinger and DeCarrico 1992, Lewis 1993, Little 1994].

Given the foregoing considerations, it is clear that teachers’ perpetual emphasis on the importance of learning vocabulary is not at all as wide of the mark as might have been implied by the syntactic focus of much applied linguistic research in the first two decades after the Chomskian revolution. What is more, a lexical approach to language learning dovetails with at least one precept of the communicative approach to language teaching, namely, the insistence that where learners are made to focus explicitly on form, the association between form and meaning should remain foremost in their considerations [Little 1994: 105]. Both in recent linguistic formalisms and in an intuitive sense, the interface between meaning and form occurs in the lexicon.

2. Functions of the lexical organizer

The development of the prototype Java program presented in this paper is motivated by these theoretical considerations, but also by a very practical one: it has never been obvious how learners can structure their vocabulary notes so as to make them easy to exploit as a learning resource in the future. Learners need a system that can accommodate their own, idiosyncratic, and probably frequently changing ideas of vocabulary organization, something that is very difficult to accomplish on paper. The lexical organizer presented in this paper is a tool for use in a self-access language centre. It is designed to facilitate the recording of vocabulary in a way that is flexible enough to do justice to the complex and dynamic nature of the interlanguage lexicon, meeting the learner’s need to retrieve vocabulary items according to multiple taxonomies and allowing him to record various kinds of information associated with lexical items – collocations, usage registers, authentic examples of use, and so forth. The flexibility derives from the organizing principle, which is hierarchical, in conjunction with the possibility of duplicating items across categories and subcategories. A further crucial aspect of the system is the fact that its interface allows learners to visualize relations between items and categories, without predefining or implicitly favouring any particular taxonomy, provided that it can be expressed as a hierarchy. Drawing tools allow the learner to further define relations between items in a given (sub)category. The program incorporates a mechanism for self-testing of collected vocabulary items.

1874
3. A collaborative technology

The organizer has a further possible role beyond that of recording and structuring new vocabulary; it can be used in addition, and simultaneously, as a workspace for planning written composition. For example, a top-level category might contain lexical items relevant to the chosen topic, with subcategories, nested to an appropriate depth, for sections, paragraphs, etc. In this role, and since, as a Java applet, it is Web-based, it is a potentially powerful tool for asynchronous collaboration. Multiple users, perhaps working together on a group writing project, may share an organizer, using it to co-ordinate their ideas and create a structure for their text arising out of relevant lexical items. In this way, concern with structure would arise out of a primary focus on meaning as embodied in lexis, in a manner analogous to the child’s acquisition of her mother tongue [see Little 1994]. When used in this collaborative mode, the program becomes “a highly visible part of shared experience” [Roschelle 1992] and thus a truly collaborative technology.

1 Algebraic Semiotics

Semiotics is the theory of signs, symbols and meaning. It originated at the start of the century, and has been developed and applied to many disciplines, amongst them linguistics, media theory and educational psychology. Much of this work is imprecisely formulated, lacking rigorous mathematical foundations. This is unfortunate, because a rigorous theory of semiotics would benefit several fields, one being user-interface design.

A promising recent formulation is Goguen's algebraic semiotics [Goguen, Mori, Lin 1997], which combines ideas from algebraic specification and social semiotics. Mathematically speaking it is based on category theory. A category is a collection of objects or mathematical structures of the same type (such as sets, groups, or vector spaces) together with morphisms (functions or mappings) that relate one object to another while preserving its structure. The nature of the morphisms depends on the type of objects being mapped, and so morphisms contain information about the objects' structure. For example, morphisms between groups map identity elements to identity elements. Morphisms between sets do not. This is because groups have more structure than sets, identity elements being essential components of this structure.

In algebraic semiotics, the objects are sign systems. Examples include alphabets, numerals, the menus and other controls used in a graphical user-interface, and Unix commands. The theory formulates the nature of sign systems and mappings between them,
enabling one to discover how faithfully a mapping from one system to another preserves the structure of the first.

2 Algebraic semiotics and user interfaces

As a simple example, consider a set of files $F$, and two user interfaces $C$ and $M$. Both $C$ and $M$ allow the user to print specified files. $C$ is a command-driven interface: the user types print followed by a filename. $M$ is a menu interface: the user selects a file, causing it to be printed. Consider $F$, $C$, and $M$ as sign systems, the signs being filenames, and consider mappings from $M$ to $F$ and from $C$ to $F$. In $M$, the user can name only files that exist in $F$, and can name all such files: there is a 1:1 mapping between $F$ and $M$. In $C$, the user can type any filename, whether or not that file exists: there are many filename signs in $C$ that are not in $F$, so “file not found” errors can arise in $C$. $M$ is therefore less error-prone, because it more faithfully reflects the structure of $F$.

3 Algebraic semiotics and computer-based education

The standard notation used in a course is one sign system; its representation on the computer is another. We can use algebraic semiotics to reason about how faithfully the computer representation preserves the standard notation, and hence to improve the quality of teaching. We claim therefore that algebraic semiotics suggests a profitable methodology for interface design and notation in a way well-suited to computer-based education.

4 Web based education

The Web is a user interface, so algebraic semiotics can be used to improve Web-based teaching. Goguen has done this in Web-based teaching of proofs in algebraic specification [Goguen, Mori, Lin 1997]. We believe his approach applies to a wide variety of educational topics.

We are investigating its use in conjunction with Paine’s Web authoring tool Web-O-Matic (WOM). WOM is based on System Limit Programming, a programming paradigm arising from the “objects as sheaves” paradigm [Goguen 1975]. WOM is also based on category theory, and so fits particularly well with
algebraic semiotics. We claim that the combination provides us with powerful tools, not only for mounting courses on the Web, but also for ensuring their quality.

Use of Multimedia Applications in Ecological Tourism

Abstract: "Protects the Environment," "Ecologically Designed," "Made from Recycled Paper" is the small print that we find on many products today available in the market. There is an increasing environmental awareness entering our daily lives. Computer Software is being used to highlight this consciousness. Software applications can be environmentally oriented as well as any other product. They can be designed to serve ecological purposes either directly, like in the case of computer-based applications for keeping track of energy consumption, or indirectly, in educational programs.

This paper describes the development process of multimedia software designed to educate and provide awareness of ecotourism in Costa Rica. Ecotourism is a form of nature-based travel and recreational experience that combines a respect for nature and local cultures with economic development incentives. It uses revenues from tourism for the funding of local conservation programs [Boo 1991]. While ecotourism is an educational response to problems linked to traditional tourism (overcrowding, resource depletion and degradation), this software integrates this response to an alternative method of traveling: it provides a non-destructive method of visiting ecological attractions. It also includes a training program designed for developing or enhancing an environmental appreciation by tourists desiring to visit the ecological site.

The review of the literature on educational technology shows that very few technological instruments are used to further the environmental cause, providing access to information and promoting learning of environmental issues. Multimedia technology offers the opportunity to fill the information gap and to encourage the preservation of ecological sites. Following this premise, the goal of the designers of the software is to provide a sustainable and entertaining alternative to direct visits. One reason to discourage tourism to nature-based areas is the prevention of environmental damage to endangered species or sites. This damage is often associated with uneducated tourists [Lindberg & Hawkins 1995]. In order to prevent this unnecessary destruction of the environment, an educational/training program explaining the "Do's" and "Don'ts" of ecological tourism was developed. This program provides a virtual contact with the environment while recommending alternative training options and background reference readings and videos.

Created during a Hypermedia Development course, the multimedia software, "Ecotourism on a Computer Screen: Ecotourism in Costa Rica," incorporates stills, graphics, videos and sound clips. Hotwords (the hyperlinks available with the authoring tool used to develop the application) enable the user to refer to text-related photographs. Since one of the endangered species in Costa Rica is the Snapper turtle, turtle-like buttons are shown frequently on the screen as navigation icons to traverse the software. The paper details lessons, applicable in a learning environment, experienced in the development of the software. Specifically, some techniques were successful, like the choice of embedding graphics over linking. Other techniques were not successful. Many of these procedures faced in the class project are repeatable, while several others should be avoided or implemented differently. In order to provide some useful hints for multimedia development both at the storyboard and programming levels, these alternatives are evaluated. Suggestions for facilitating a semester-long multimedia project are provided.

Work in progress includes testing the effectiveness of multimedia software for ecotourism. This research focuses on the assessment of users' reactions to environmental visits before-and-after exposure to the technology. To this end, on-line surveys are administered to comparable populations of MBA students attending Information Systems courses (http://www.gwu.edu/~pkatia/survey) in form of pre-test and post-test. The pre-test survey includes questions that identify respondents' environmental attitude, the post-test survey (completed after CD-viewing) includes multimedia authoring questions as well as selected pre-test questions. Although the survey
is anonymous, students enter their answers through a Web Browser and a networked computer with the same IP address. Pre-test and post-test answers can be matched in one observation for the same individual to display whether the exposure to the application has altered the response pattern. Preliminary frequency data confirm a general improvement in environmental awareness, willingness to recycle, and higher acceptance of the idea of "virtual travel." Associating statistical validity to the framework expands the limited application of multimedia technology in this direction. This positive feedback can promote a more extensive application of the software and the idea represented. It can render the software even more environmentally oriented and beneficial than many other products available in the "recycled paper" market.

hayale@beitberl.ac.il

Abstract: In this study we examined whether there are gender differences in the preferences to different designs of multimedia learning interfaces. In the study we assumed that design characteristics add to the interest in learning and we developed taxonomy of design of efficient user interfaces both for boys and girls. The research included ninety children from three kindergarten classes, who were exposed to interactive multimedia stories. The research subjects, with the help of a polymeter (Lampert 1981), answered to questionnaires which examined their overall relationship to the kindergarten, their previous experience with a computer and their level of satisfaction with the various interfaces. The research findings indicate that there is a significant difference between boys and girls in the influence of the design of the learning interfaces on their level of satisfaction with the different interfaces. The boys were more familiar with computer games and looked for assistance through navigational buttons, whilst the girls tended to ask for help with the game. Girls preferred to include writing into the game and also preferred colourful screens full of drawings, which changed slowly. It was also found that the boys preferred green and blue colours, whilst the girls preferred red and yellow. Generally it was found that girls preferred the components of the Mise-en-scene interface, and boys preferred the components of the Montage interface.
This paper describes the research developed by the authors in their respective Ph.D. thesis, one in Computer Science and the other in Learning Technology. The objective of this work is the development of learning situations and the related multimedia resources, that will be used in the implementation of a DILE (Distributed Interactive Learning Environment) for teaching Descriptive Geometry in first grade university courses in architecture and engineering at Londrina University – Parana- Brazil.

Descriptive Geometry is a Geometry branch that allow representation of 3D objects in two dimensions by the way of double orthogonal projections. The students in this discipline think that it is very abstract and difficult to understand. The comprehension of its concepts have a fundamental importance for architects and engineers when in professional activities they need to represent ideas in a project form, to visualize an object and to transmit to the workers how to execute the tasks.

When we talk about representing the three dimensional space by only two dimensions, we talk about projections. This is the simplest way to transform space in plan. To have a projection take place, rules and conventions must be followed. Baracs notes in [Baracs 1992] that "to limit our skills only to know how to project, it is like learning how to write without being able to read". The passage from plan to space is not a teaching object.

In the working drawings, learners use plan elementary Geometry knowledge to do all the descriptive procedures (that are algorithmic), necessary to solve the proposed problems but the learners must first visualize the situation in space (heuristic) through the reciprocal passage between the plan of the working drawing and the geometrical three dimensional space through the projections method [see Monge, 1789] conventions. On the other hand, we can solve problems more or less simple without space visualization. The projections method permits it, but to solve more complex working drawings, specially when we handle solid modeling, the spatial visualization is indispensable to reach the right solution. Permitting this practice of not visualizing, we create in the student's mind the habit of solving the working drawings only with reasoning in terms of the plan and in this way they don't develop spatial visualization, necessary to solve complex working drawings and especially modeling. Some spatial visualization capabilities are necessary to acquire the working drawing "lifting" notion.

The absence of scholar activities in projective geometry and spatial representation can be one of the reasons for which the students have difficulties when they need spatial-visual capabilities. An other reason is the absence of spatial visualization capabilities. Several authors [see Vasconcelos 1996] agreed that "the capability of spatial visualization is an individual particularity but a learning process can develop it".

Dreyfus in [Pallascio et al. 1992] relates that researches about learning had demonstrated the utility of visual resources to allow the comprehension of several mathematics concepts, and not only in geometry. Students must be prepared to understand the representations proposed to them, and that we can teach them certain specific techniques to permit spatial representation development.

What we want is to conceive a system that takes into account the "past" of students that didn't have the possibility, at the right moment, to develop:
spatial visualization capability and
the interpretation and representation of space through perspectives and projections.

This system will consider the whole of student difficulties to learn Descriptive Geometry, the possibility to strengthen the teaching–learning of Descriptive Geometry and to facilitate the development of spatial visualization capabilities by using technology. We create these conditions through the development of learning situations where learners will have the possibility to manipulate geometric objects and to represent them with the help of microworlds and multimedia resources to facilitate the comprehension of the more abstract concepts that are hard to visualize.

Bishop in [Bishop 1989] makes a distinction between the visualization objects and the visualization process. The visualization objects identified by Presmeg in [Presmeg 1986] are the concrete image models of kinesthetic and dynamic space forms. The visualization process is the "visual treatment" of abstract information and figural information interpretation. The visual treatment of abstract information is a process that transforms the abstract relations and the non figural information in mental images. That includes also the manipulation and transformation of visual representation in mental images. This process does not have any relation with present material stimulation.

The process of figural information interpretation is a capacity that can be explored by specific experiences. Bishop in [Bishop 1973] asserts that “structured and manipulative materials can encourage the creation of visualization capabilities and the visualization properly said”.

This kind of material can be implemented with advantage in computers, by appropriate software, that allows space objects manipulation.

Conclusion

The utilization of interactive multimedia material facilitates visualization and contributes in a positive way to the understanding of Descriptive Geometry concepts. Computers is a powerful tool for graphic representation, it can permit objects visualization, representation and modeling in direct manipulation of space geometric objects when it runs specific microworlds and educational software that uses multimedia resources. The learning systems must also offer to students feedback and interactivity. In this way, the students are free from boring manual graphic operations. The change in working tools requires necessary changes in the way of teaching, not only related to the learning subject but also in terms of the didactic methods.

The learning situations developed take advantage of the following types of multimedia resources: visualization of 3D objects from working drawings representations, direct manipulation of 3D spatial forms representations that allow observation from different points of view, interactive working drawings in direct manipulation of geometric objects, interactive manipulative projections (a change in a projection causes changes in other projections), animation and video sequences.

1. Introduction

Parallel and scalable systems are obvious approaches to overcome the performance bottlenecks of current computing systems. However, the success of commercial systems lies well behind the expectations: one of the main reasons is the lack of automatic generation of efficient scalable code, and the others are related to the long learning curve and to the lack of integrated development environments (IDE). This communication addresses the latter issues: the design of a remote and interactive training course for parallel and scalable computing. Current research on interactive courseware stresses the availability of facilities to experiment with - the parallel computing resources in this case study - which also improves the learning results [EPIC (1998), Cornell (1998)].

The work presented here describes a model to combine the existing tools for the development of parallel applications, in a user integrated environment with support for remote learning through a Web browser. Two relevant functional issues were considered in the model design: the computation and the pedagogical issues. Only the computation issues are covered here: the interface and integration - of WWW facilities, operating system (host machine) and development tools (host machine) - and the tools for the target parallel machine.

This paper describes the proposed model and the prototype system currently under development. The available facilities for the project were based on a Parsytec MC parallel computer, at University of Minho, in Braga, Portugal. The resulting course will be available at the Web site of its Computer Centre (http://www.ci.uminho.pt/parcium), where a registered user will be able to follow the course.

2. The model

The proposed model follows a client-server architecture, illustrated in Figure 1. The client is the user system, while the server represents the centralised facilities at a university computer centre. The user node contains three main modules: the Web browser, the IDE front-end and services. The Web browser is the interface to both the remote resources, and the IDE front-end. The IDE front-end integrates the existing development tools and adds access to external services, e.g. email, X.Windows server, video-conferencing. The Web browser also handles the references to URL addresses at the IDE front-end - e.g. on-line help HTML pages - presenting an unified view to the user.
The centralised facilities contain the parallel system and five main modules (Fig. 1). The http server launches and monitors the IDE backend, and controls the access to courseware materials, providing a more secure runtime execution environment. The IDE backend replies to the IDE front-end messages through appropriate requests to the parallel development and runtime tools, and to the user workspace modules. The parallel development and runtime tools module controls the execution on the parallel environment.

In a typical remote learning session, a registered user accesses the courseware material through a Web browser. Concepts can be better understood through programming and running examples: the user Web browser launches an IDE front-end instance, which requests the remote http server to create a corresponding instance of the IDE backend; this backend creates a copy of the requested example in the user workspace at the remote system. The user can then modify the remote coded example, and access the parallel runtime environment - including the visualisation tools - to execute the programming example with the appropriate system/configuration parameters.

The described model supports any courseware with different multimedia materials, by placing the restrictions on the Web browser capabilities/plug-ins: the approach places no media limitations on the IDE modules. However, the availability of interactive graphics and multimedia services - such as visualisation tools, video servers or videoconferencing with remote tutors - may require a high bandwidth connectivity between the client and the server.

3. Prototype system

A prototype system is under development to evaluate the model. To design a modular prototype architecture, based on the client-server approach, the object-oriented paradigm was followed [Meyer 1988, Wegner 1990, Wirsf-Brock 1989].

Java was selected to implement the IDE front-end and IDE backend modules. A relevant feature of Java is that it is based on the approach of translating the source code to a virtual machine standard code, following the approach taken already by some early Prolog compilers. This feature led to a high portability of the code, end user autonomy of the runtime environment (e.g. operating system) and higher availability of support libraries (e.g., for network programming [Elliott 1997]). Experimentation with this prototype system will lead to the refinement of the proposed model.

4. Conclusions

The model presented in this paper led to the development of a prototype system, under tests, with reduced functionality. The work carried out so far suggests that the proposed model is well adapted to the development of an environment for remote learning, namely for the implementation of an interactive course requiring direct access to remote resources, such as in parallel programming.

More work is required to further refine the current prototype system. One possible evolution that has already been identified is the move some remote functionality towards the end user, to lessen the communication traffic and to reduce the bandwidth requirements.

MULTIMEDIA DESIGN TO TEACHER TRAINING: GUIDE TO ANALYSE THE CONTENT OF ADVERTISING

Del Moral Pérez, Mª Esther
University of Oviedo (Spain)
emoral @pinon.ccu.uniovi.es
Collaborators:
Pérez Pastor, Roberto
Del Moral Pérez, Marta

We are presenting a multimedia tool which may be useful to teacher training:

- This multimedia tool tries to provide them with resources and strategies in order to make them capable of using mass media in the classroom.
- It presents guides to analyse mass media.
- It shows formulas to be exploited in a didactic way: radio, comic, press, advertising, musical video clips, TV news bulletins, cartoons...

In short, it offers new methods to teachers so that they can introduce mass media in the teaching/learning process.

Nowadays, mass media have been in the National Curriculum (LOGSE, 1991) as useful tools which can represent an important help to the rest of the curriculum areas. Moreover, it is necessary to be familiar with mass media to make it possible its understanding and be able to use it as a new means of expression.

Perhaps the most important—and the most difficult—challenge, for teachers, is to identify specific school activities where technology and mass media can help them to improve existing conditions or to create important educational opportunities that did not exist without them. As part of this process, teachers decide what they need so that these changes may occur. This process of determining where and how technology and mass media fit is known among users of educational technology as integration.

"To me, it makes no sense to propose ‘the media’ as a separate bit of the curriculum... The media are not a separate part of our experience... They are inextricably bound up with the whole complex web of ways in which we share understandings about the world, a web which includes gestures, jokes and hairstyles as news bulletins, opera and architecture; books as well as television." (Bazalgette, 1991)

The paramount aims of our proposal are:
- Make good use of the educative potential of advertising spots.
- Analyse the formal content of advertising in a critical way.
- Discover creative formulas to transmit messages with a commercial and persuasive purpose.
- Rescue a didactic character of advertising for the different educational areas (sciences, languages, maths, geography...).
The program has been developed on CD-Rom with Visual Basic programming language. It includes text and audiovisual information including images and videoclips. It is easy to use since it follows the metaphors of a book. Its contents is accessed by clicking on an included menu.

This tool's main objective is to facilitate the integration of mass media into the educative process. It consist of interactive sites in which advertisement.

This teaching tool includes numerous practical examples to develop in class with students of different educative level. There are thought-provoking full of suggestions activities that can be carried out either by small groups of students or the whole class.

The approached topics are:

- Advertising stereotypes.
- Advertisement structure.
- Expressive resources: color, music and sound.
- Language and vocabulary used in advertisements.
- The cultural message transmitted.
- Advertising characters: their roles and meaning.
- Real and fictitious advertising styles.

To sum up, this multimedia program can become a useful tool for teachers who are concerned about bringing up to date and innovative tasks into the classroom, and exploring the impact of mass media and particularly advertising in our current society. Teachers cannot ignore the influence of mass media.
Presenting Educational Contents in Nonlinear Narrative Structures by Conversational Virtual Actors

J. Piesk, G. Trogemann
Department of Computer Science / AV-Media
Academy of Media Arts Cologne, Germany
piesk@khm.de, trogemann@khm.de

Abstract: This paper applies the autonomous animation of a conversational virtual actor for presenting educational contents. The scenario of a virtual educationalist is combined with nonlinear storytelling. Our research in autonomous virtual actors focuses on multimodal conversation that combines verbal-vocal with nonverbal-nonvocal natural language generating synchronised speech, facial movements, gesture and body posture of a 3D character. This scenario combines findings from computer science, linguistics and psychology.

Introduction

In media such as the book, television, film, video, etc. narrative and pragmatic contents are mediated mainly in a linear manner. Even in new interactive on- and off-line media, an active participation of the recipient is limited to the activation of hyperlinks by mouseclicking.

By the use of a conversational virtual actor we want to put a computer-generated 3D-figure at the interface between the recipient and the content that is to be mediated. The virtual actor's facial expressions, gesture and body posture should complete its verbal-auditive utterances. The aim of this research project is to introduce natural interpersonal communication structures to computer-based education media. The limitations and possibilities of nonlinear conversational and dialogue structures should be explored in combination with the nonverbal behaviour of the virtual actor. Some of the scientific question formulations resulting from this task are:

- In what way is the reception behaviour influenced by the 3D-figure and the nonverbal communication in comparison to a pure auditive or textual reception?
- What is the impact of the interactivity of the dialogue form to the communication - compared to a mere linear reception of a conventional spoken or written text?
- Which nonlinear narrative and conversational structures are suitable for this scenario?
- How does the degree of interactivity influence the educational results?

Concerning the investigation of socio-emotional effects of computer-simulated nonverbal behaviour ([Bente, Feist, and Elder 96], [Bente and Otto 96]) we cooperate with the institute of Differential Psychology and Communication Research at the University of Cologne. [Bente 96] distinguishes three „degrees of immediateness of contact between recipient and screen person“ ([Bente 96], S.9). Our research intention is to be classified on the third level: „Direct interaction with mutual contingency between media user and screen person“.

Autonomous Animation of Virtual Actors

This research project is build on top of the work ([Actor 97], [Fleischmann, Opalla, and Mähler 96], [Piesk 97]) of the character animation group - an interdisciplinary group of computer scientists, animators and designers headed...
by Prof. Dr. Trogemann. Our current implementations of autonomous 3D-characters are a Virtual Storyteller and a Virtual Educationalist. The interaction scenario realised by these conversational virtual actors comprises the users textual input, natural language processing, emotion-based triggering of a textual response and its audio-visual performance by the 3D-character's facial expressions, gesture, body posture and voice. The speech synthesiser Hadifix [Porte, Krämer, and Stock 94] is integrated in our implementations.

Nonlinear Dialogue Structures

In the first prototype (VISTA - Virtual Storytelling Actor) a conversational cactus is used to tell its user the story of Alice's adventures in wonderland [Carroll 89]. Originally this story was told to a school girl who made questions and raised objections. The book is therefore a linearisation of an originally nonlinear dialogue structure. [Piesk and Trogemann 97a] describes the implementation of the Virtual Storyteller.

Virtual Education

[Piesk and Trogemann 97b] describes an additional implementation of a conversational virtual actor as emotion-based learning environment - the Virtual Educationalist [Fig. 1]. Here the 3D-figures verbal repertoire does not consist of a story. Educational contents are mediated instead. The 3D-character cactus has been designed for the german children and youth program of the WDR (a german TV-station). The autonomous version in the shape of the Virtual Educationalist should take advantage of the emotional relationship that a member of the target group (children) develops for mediating educational contents. Emotions displayed by the figure's facial expressions, gesture and body posture serve different functions in form of motive, feedback, and intermittent accentuation of effect (see [Piesk and Trogemann 97b]). An online-connection adds the knowledge of online-databases (e.g. language dictionary [Jung et al. 97]) to the virtual educationalist's verbal repertoire.

Current Research

The research project in this paper is the symbiosis of the two concepts of the Virtual Storyteller and the Virtual Educationalist described above. The idea is mediating educational contents via entertaining story lines. The young recipient can approach the core of a topic on multiple paths via different story lines. The story is presented during a natural language dialogue with the child using the characters nonverbal behaviour for enhanced communication. In our current research in this field we focus on two areas: nonlinear dialogue structures and the synchronisation of the 3D-figure's verbal and nonverbal behaviour.

I Introduction

In 1998 and 1999, the Sprachenzentrum (language centre) at the Fachhochschule Gelsenkirchen will be setting-up three new multimedia language laboratories at campuses in Gelsenkirchen, Bocholt and Recklinghausen. Special emphasis is being placed upon:

- the implementation of new media in language instruction
- the development of both traditional and multimedia self-access language learning facilities
- the provision of further education in languages for specific purposes

In each lab, up to twenty learners will have access to a broad range of interactive multimedia language learning resources. Additionally, access to satellite television broadcasts from six satellites will be provided, along with language learning materials on video cassette. In order to support cross-campus team learning, the three language labs will be networked.

II Concept

Software for Language Teaching and Learning: English, French, Spanish, Dutch.

Software products for teaching and learning all four languages will be introduced. The software will address the demands of learners of different abilities and interests both in terms of level and content. In order to provide learners with a flexible learning environment, the software will be introduced in a number of different ways, including the use of programmes:

- in seminars (in which an instructor is present)
- for self-access
- for language reference (dictionaries, encyclopedias etc.)

Initially, a total of 80 programmes of this nature will be provided. An increase in this number is expected, however, as new products become available.

III Challenges

The multimedia language learning software will be both Mac (HFS) and PC (ISO 9660) compatible. Learners will be able to work interactively with either format from the same workstation. Learners may also choose to interact with one another using desktop video cameras, which will form part of the standard user interface.

The language labs at each of the three campuses will be networked, so that learners can communicate cross-campus with one another. This will enable cross-campus project work, either in pairs or in teams.

IV Solutions

Software Administration
The language learning software will be administered centrally using a RAID-system, a CD-ROM server and CD-ROM jukeboxes. Some programmes will have to be made available locally at each workstation. Use of the software will, however, be possible from all 21 workstations.

**Server**

Pentium servers will be installed running Windows NT as the network operating system. The use of Windows NT will allow both Macintosh and PC 'clients' access to the programmes in ISO and HFS formats.

**Workstations**

Each language lab will provide twenty learner-workstations and one instructor-workstation. Apple PowerPCs will be used throughout. As extras, the PowerPCs will also include PC-cards (Pentium processor) and MiroMotion video-cards; they will each have desktop video cameras (FlexCam) and an additional headset connected. The integrated network-card can also be used by the Pentium PC-card. The operating systems will be MacOS8 (Macintosh) and Windows 95 (PC). Using a simple macro, learners can switch between the two operating systems. In this way, both Mac and Windows software can be accessed from each workstation.

**Visual User Interface**

The visual user interface for the workstations will be designed using Macromedia Authorware. Via a system of menus, the learner will be guided to the language learning programmes of his or her choice. In so doing, the learner will be asked to choose materials for one of the four languages on offer, orienting themselves toward the programme type of their choice. An introduction to each of the programmes available will be given in order to help the learner to determine if the software is appropriate to their needs.

**Network**

The language labs will be networked using Ethernet and a switching-hub. This will provide each workstation with a bandwidth of 4 Mbit/s. The advantage of this over fast-Ethernet or FDDI is that standard components can be used, for example, the Macintosh network-card present in the PowerPC.

**Communication**

Via the network, each workstation will have access to all of the software available in the language lab in both formats (HFS / ISO). This will allow each of the workstations to work with the same programme simultaneously. Using communication software (TimbuktuPro for Mac and PC) and a conferencing software (Skopeo for Mac), learners and instructors will be able to communicate with each other and use the same language learning software. This will also be made possible cross-campus. A permanent network connection between the three language labs will be available for this purpose.

**Satellite and Video Equipment**

Learners will be able to access twenty-seven satellite channels via six satellites (Astra1A, Astra1B, Eutelsat II F1, Eutelsat II F3, Hispasat, Panamsat). In addition, language learning materials on video cassette will be provided, including commercial materials and video broadcasts of particular interest saved to video. Five video recorders will be available to learners to enable further broadcasts to be recorded. Access to broadcast television programmes and to video materials will be possible from five television sets. In order that all five television viewing stations have simultaneous access to all the channels available, two satellite dishes will be installed which will each receive the signals from three satellites.

Abstract Education in a postmodern world will have to change its stripes dramatically. Otherwise, it will be an impediment to the actualization of our potential; an absurdity when you consider that the recognition and pursuit of possibility is the business of education. The diffuse but intensifying sentiment that we must go beyond the constraints of the modern perspective is one that we educators must comprehend ourselves, learn to explain to others, and, most importantly, act upon. Our profession is challenged to assist in the birth and development of this new world view and determine how its own metaphors and methodologies perpetuate the modern perspective and frustrate the emergence of the postmodern era.

How is computer technology going to contribute to the development of postmodern education? We are increasingly recognizing the importance of narrative learning to the educational process. The power of metaphor to guide and transform knowing is also an integral facet of our changing perspectives on curriculum. The computer, however, is most easily applied to modernist approaches to instruction. This presentation illustrates how multimedia can be used to integrate technology with changing notions regarding teaching and learning.

The postmodern perspective, still forming, yet amorphous, will characterize our new approaches to cultural definition and life. The old is on the way out, but the new is still unformed. Nonetheless, we can't stay the way we are, and we can't go back to a simpler age. We have to design and build a "new home."

Education in a postmodern world will have to change its stripes dramatically. Otherwise, it will be an impediment to the actualization of our potential; an absurdity when you consider that the recognition and pursuit of possibility is the business of education. The diffuse but intensifying sentiment that we must go beyond the constraints of the modern perspective is one that we educators must comprehend ourselves, learn to explain to others, and, most importantly, act upon. Our profession is challenged to assist in the birth and development of this new world view and determine how its own metaphors and methodologies perpetuate the modern perspective and frustrate the emergence of the postmodern era.

Postmodern education will be characterized by the understanding that the best form of learning is active, the forging of understandings and meanings on the part of learners. The formulaic installation of factoids into passive, quiet minds is not good schooling, regardless of how convenient it is behaviorally or measurably. Schools in the postmodern era will increasingly recognize the idiiosyncratic, constructivist, and intrinsic nature of learning that promotes capable, thinking, responsible, and active citizens.

Evidence is mounting that learning requires active participation. Knowledge can be acquired passively, but then it is knowledge that will not thrive; it will be weak and anemic knowledge, and the mind will be quick to discard it as irrelevant. It does not take on the "aliveness" of knowledge that the learner mulls over and ponders, seeking to fit it into his or her developing intellect.

A hopeful indicator of the emerging shift in our cultural perceptions regarding the educational endeavor is the growing recognition of brain-based education. Our present pedagogical practices don't mesh with the brain's biology. Psychologists and brain biologists essentially agree that the human brain learns actively, and in context. The passive reception of congealed knowledges (separated from the flow of learning) does not make biological sense.

The mind actively searches for meaning in its natural, ever-evolving context. The biochemical function of the brain is to somehow make sense out of nonsense. Brain-based education refers to the development of the capacity to understand. This process is one where threads of knowledge change the web of understanding and then the changed web alters the kind of threads it incorporates. Passive learning, which too often includes which is computer-assisted, impedes this kind of mental development.

Passively acquired—or injected—knowledge is either stillborn or soon withers and dies; it does not become fused into the life of the mind. Thinking and knowing are an interdependent dynamic. They give the tension and resolution of rhythm to each other. It is thinking that breathes life into knowledge, and it is the gaining of knowledge that keeps thinking from stewing within itself. Acquired knowledge provides thought with new foundations from which to expand. It is thinking that gives learning the element of active participation. Thinking constructs new understandings from the acquisition of new knowledges, for, as knowledge is born, it must be fused into developing intellects.

These are just a few of the changing perspectives on the interactive/emergent nature of teaching and learning. The postmodern education movement is increasingly constructivist in its understanding of how the best learning occurs. The most vital and democratically healthy learning is something that is initiated in the minds of learners themselves. It is not crowded out by instructional techniques that are excessively focused on training. Self-directed thinking should not be suppressed by schooling-imposed knowing.

Can computer technology integrate with these changing notions regarding the educational process? It will mean the incorporation of narrative learning, illustration by metaphor, and the idiiosyncratic inspiration of learner-initiated thinking. These are questions that must be answered if the evolution of computer education is to contribute to the emergence of postmodern instruction.

A particular postmodern concern—the spirit of democracy within the process of schooling—could be assisted enormously by instructional technology. But there is a seductiveness that pulls the opposite way, the application of computers to further the traditional,
modernist theories and practices of education, where teachers are curriculum implementation specialists and students are recipients of programmed knowledge.

A touchstone story for postmodern teaching is *The Three Little Pigs*. It helps introduce an ongoing dialogue about the development of integrity and the phenomenon of gaining experience. In our revised version, the houses represent integrity and the wolf represents bad circumstances, as in "the wolf at the door." The story is about how we develop the personal strength and responsibility necessary for the gaining of experience—as well as education for integrity and initiative. The narrative weaves in well with discussions regarding the thinking of John Dewey, Erik Erikson, and Alfred North Whitehead.

Using presentation software, we created a multimedia presentation of our rendition of the story. The visual narrative provides technological assistance to a postmodern way of teaching, where storytelling is blended in with theoretical and practical discussion. The story of *The Three Little Pigs* itself communicates the importance of identity construction, personal ownership, and the phenomenon of experience.
An Investigation of the Use and Impact of the Internet in Coping with an HIV-Positive Diagnosis

Patricia M. Reeves, M.S.W.
Department of Adult Education, The University of Georgia
River's Crossing, 850 College Station Rd., Athens, GA 30602-4811 USA
Tel: 706-542-2214, Fax: 706-542-4024, E-mail: preeves@coe.uga.edu

Introduction

Since its emergence in 1981, the human immunodeficiency virus (HIV) has posed one of the greatest health threats the world has ever known. This incurable virus and precursor of acquired immune deficiency syndrome (AIDS) continues to exact a staggering human toll. As of December 1996, AIDS has claimed the lives of 6,400,000 individuals worldwide. While the spread of HIV beyond the boundaries of the gay community weakened some prejudicial barriers, it did not completely eradicate the epidemic of bigotry and blame that often accompanies HIV infection. Consequently, coping with HIV has never been merely an issue of dealing with the physical consequences of the disease. There are myriad social, emotional, and psychological issues with which HIV-positive individuals must also contend.

For individuals infected with HIV, social support is a critical factor in coping with their medical condition. Obtaining and sustaining the support of others is usually accomplished through a network of friends, family, and community-based service organizations. The circumstances of some individuals, however, may preclude the use of one or more of these sources of support. For example, a newly diagnosed individual, fearful of discriminatory action by an employer should word "get out" about her/his positive status, may be reluctant to seek assistance from a local service organization. Further, lack of proximity to family and close friends is an often-cited reason for insufficient social support, as is progression of the disease itself; it is not uncommon for late-stage HIV infection to render an individual homebound. For these reasons and numerous others the Internet, with its wide array of services, provides a viable alternative for individuals who cannot or who elect not to pursue traditional avenues of support. Electronic mailing lists, bulletin board services, computer-based support groups, and World Wide Web sites devoted to every conceivable disease are among the online resources that have turned the Internet into a treasure trove of information for individuals coping with life-threatening illnesses. The Internet has arrived as a force in our lives, and medical information and support constitute two of its more important uses [Mayer and Till, 1996].

The Internet "will affect adult learning in ways that we can only dream about" [Fleischman, 1996, p. 18]. It provides an especially fertile context for informal learning -- the type of learning most commonly employed by individuals coping with a life-threatening illness. Informal learning is a loosely structured learning activity undertaken by individuals without institutional direction and is both reflective and active [Eastmond, 1995]. Informal learning is the primary means by which adults learn at work and at play and is characterized by "involvement with other people, real problems and authentic tools and resources" [Johnson, 1996, p. 7]. Heuer found that the online discussion opportunities afforded by the Internet provide a "rich, flexible environment that serves as a context for informal learning" [Heuer, 1997, p. 122]. Schrum and Berenfeld likewise underscore the capacity of the Internet to provide informal online educational opportunities [Schrum and Berenfeld, 1997]. The Internet also provides a natural venue for self-directed learning. Self-directed learning embraces the notion that the individual learner is "capable of assuming considerable responsibility for and control of learning activities when such opportunities are provided" [Hiemstra and Sisco, 1990, p. 283]. In fact, "the world of electronic communication assumes and demands that people take initiative for their own learning and growth" [Schrum, 1993, p. 193].

Although anecdotal accounts of the usefulness of the Internet in coping with a life-threatening illness have been regular features in the popular press, the ability of the Internet to facilitate informal learning has not been systematically investigated. The purpose of this study was to investigate the use and impact of the Internet in coping with an HIV-positive diagnosis. For what purposes do adults report using the
Internet in coping with their illness? What is the impact of Internet use on their self-reported ability to cope with HIV infection?

Research Design and Findings

This study, doctoral dissertation research that is a work-in-progress, employed a qualitative design to study the use and impact of the Internet in coping with an HIV-positive diagnosis. The sample selection of respondents was purposive, and the following criteria were used for inclusion: (a) participants were at least twenty-one years of age, (b) they have been seropositive for HIV for at least six months, (c) they have utilized the Internet in coping with HIV for at least six months, (d) they were at a sufficient level of physical functioning to comfortably endure a 90 minute face-to-face interview and agreed to a brief follow-up interview (by telephone or email, their preference) if a review of the transcription of the first interview revealed a need for clarification or further discussion, and (e) they live in the Southeastern USA. A semi-structured interview format was used to interview ten respondents (six males, four females), most of whom were located through the AIDS Survival Project, an AIDS service organization in Atlanta, Georgia. The respondents ranged from 27 to 47 years of age; eight are Caucasian, one is African American, and one is Hispanic. Level of educational attainment spanned high school to Master’s Degree. Data are being analyzed inductively using the constant comparative method [Glaser and Strauss, 1967]. Because this research is a work-in-progress, only tentative findings can be presented in this short paper. (The research will be completed in May 1998, and a more complete report will be given at the ED-MEDIA/ED-TELECOM ’98 conference.) A preliminary analysis of the data reveals that HIV-positive adults are using the Internet to find a range of information (general to condition/situation-specific), for social communication with other HIV-positive individuals, to engage in advocacy, and for “escapism” from HIV-related stresses. In addition, the research indicates that Internet use has impacted the participants’ ability to cope with HIV by augmenting social support, promoting empowerment, and facilitating their ability to help others.

Significance of Study and Implications

Although the use of the Internet in promoting formal opportunities for learning (e.g., for the delivery of instruction) is a much investigated phenomenon, little attention has been given to its potential to advance opportunities for informal learning. Substantive information in the form of interpretivist research that provides a rich description of the use of the Internet is needed if the Internet is to be considered a viable resource for addressing the psychosocial needs of individuals coping with life-threatening illnesses. The findings of this study will be useful to HIV-positive individuals engaged in the ongoing struggle to cope with their illness. It will also be helpful to individuals coping with other life-threatening illnesses, as well as to instructional designers and program planners who serve the resource and learning needs of online constituencies.

Distance Education Courses about Interactive Multimedia: Problems and Solutions

Geoff Ring
School of Multimedia and Learning Technologies
Edith Cowan University
Australia
Email: g.ring@cowan.edu.au

Introduction

Increasingly, university teaching and learning experiences are being replicated independently of time and place via appropriate combinations of technology-based resources (the Internet, the Web, CD-ROM, etc) and conventional teaching and learning resources. As part of this world wide trend, the author is currently involved in trialling the delivery of selected distance education units in Interactive Multimedia (IMM). The resources for these units are being delivered in multiple formats: Internet/Web, CD-ROM and paper. Like many other educational researchers and practitioners around the world, the author is searching for ways to increase the educational gains possible from using the Internet and CD-ROM technologies while continuing to seek to optimise the integration of other learning media and resources. This paper focuses on the unique issues and problems encountered when the educational content involved is IMM.

While ECU has used a range of technologies to support distance education courses for several years, it was not until 1997 that IMM units were first offered to off-campus students via electronic delivery. The delay in offering these courses was partly due to the belief that the delivery of in-depth courses with IMM content posed unique and significant (if not insurmountable) problems. The author perceived a need to evaluate the initial experience of delivering IMM content to off-campus students electronically and did so in a qualitative manner through the eyes of the developers, tutors and students. The evaluation was a pilot study for more formal evaluation studies to come.

Description of Pilot Project

The project looked at the process of development and implementation of two multimedia units, IMM 4102 Digital Resources and IMM 4103 Interface Design, for delivery to off-campus students. IMM 4102 was developed initially as a Web site supported by conventional paper-based resources (a CD-ROM was later produced when students were having problems downloading large files). IMM 4103 was initially developed as a “Web site on CD” with most of its software running “locally” under a Netscape browser, although software demonstrations, examples and utilities were also included on the CD-ROM (an actual Web-site was subsequently established). The URL for IMM 4102 is: http://liswww.fste.ac.cowan.edu.au/Courseware/IMM4102/ and the URL for IMM 4103 is: http://malt.ed.ac.cowan.edu.au/exunits/imm4103/. The implementation of the units was examined from the perspective of the tutor and the students. Questionnaires and follow-up interviews were used to gather data from the developers and tutors while phone interviews were used to get the inputs from students.

Observations from the Pilot Project

1. A range of practical problems became evident early in the study. The major problems were: difficulties in submitting large Interactive Multimedia (IMM) assignment files as email attachments (an ftp site has now been established); lack of access to full versions of IMM applications software (trial versions were too limiting); learning problems with students who had no manuals or tutorials for IMM applications software (presumably, they lacked a legal copy!); problems in submitting assignments because files couldn’t be saved in trial versions; and computing infrastructure hassles of various kinds. The existence of all these problems was clearly impeding the capacity of course designers to focus...
more on pedagogical issues. Nevertheless, the developers did remark on the importance of social interaction, the provision of concrete experiences, improved content interactivity and relevant and contextual assessment - all aspects in keeping with cognitive and/or constructivist views of learning.

2. Course developers and tutors clearly need to be aware of the computing facilities available to the students and the nature of their Internet connection. This is more difficult for off-campus students because tutors can't see their students' systems. This problem was further exacerbated for the IMM students in the pilot study because they required computing systems with greater capabilities than students in "non-computing" fields. IMM courses require students to have access to relatively powerful personal computer environments and relatively fast Internet connectivity. Even if these requirements are met, however, current bandwidth limitations of the Internet also mean that CD-ROM based resources are usually necessary (as well as conventional distance education resources).

3. The students in the pilot study appeared unwilling to embrace the electronic forum opportunities provided for communication. This problem appeared to be far greater than that previously experienced with electronically delivered units for "non-computing" students. This issue warrants further investigation.

4. Copyright problems were heightened by the nature of the subject matter. One tutor wanted to illustrate the content with examples of work done by others (2D and 3D graphics, video, sound, sections of multimedia applications) and yet could not do so unless the copyright was cleared - a time consuming process. Courseware development teams could resolve this issue by having a media developer who can create original media. There is also a case to be made for a well structured process for obtaining clearances from the copyright holders.

5. Units which require the learning of specific multimedia software packages face the issue of students not having access to all of the expensive software packages required. To some extent this can be alleviated by providing the students with "demo" versions which are usually available on the Internet at no charge, but the restricted capabilities of many of these are often too limiting. Attempts to negotiate site licence rights for ECU students for study purposes have been largely unsuccessful. Unfortunately, it may be necessary to require students to purchase this expensive IMM software as a course requirement in the future.

6. Student feedback for one of the units indicated a desire to see a range of examples of typical assignment work (multimedia software files) on the unit Web-site, a deficiency that is already being addressed. The CD-ROM for the other unit did contain a wide range of examples of past student work.

Conclusion

The face-to-face interaction experienced by the majority of today's on-campus students plays a key role in sharing ideas and experiences and generally adding a social dimension to the learning environment. While it has been argued that most students prefer face-to-face interaction (Simonsen, 1995), for many of them, the convenience of "on-demand" access from any location will often outweigh the limitations placed on personal interactions. For off-campus students in IMM courses, however, the availability and usage of multiple and reliable communication channels with their tutor and their peers appears to be the most effective single means of overcoming many of the problems brought about by the unique nature of the content involved. It seems likely that a variety of approaches to personal interactions within learning environments will emerge over the next decade and that many will provide the best of both worlds as they attempt to balance virtual and direct interaction. In the long term all learning environments will have some of the attributes of technology-mediated learning and it will always be important to strike an appropriate balance between virtual interaction and face-to-face interaction.

In the prevailing climate of economic rationalism within which many of the world's educational institutions must survive, economic reasons are frequently given for using technology-mediated learning approaches, particularly the Web, for the delivery of instructional materials. It is important for educators to ensure Web delivery occurs in order to achieve sound educational goals, not simply because it may offer practical and economic advantages. While the author believes that for this to be achieved we need to base design for the electronic delivery of curriculum on a sound theoretical base, searching for such a theoretical base has been the subject of other papers (eg Ring and McMahon, 1997). Nevertheless, it is hoped that the documenting and reporting of qualitative data concerning the electronic delivery of IMM content, as given in this paper, will be of assistance to educational researchers in their pursuit of such a theoretical base, whether it be for the Web as a sole learning medium or whether it be for the use of the wide mix of technologies likely to be necessary for the provision of optimal learning experiences in the 21st Century.

The design, development, and delivery of educational materials is undergoing a remarkable evolution from a traditional lecture format to a media-rich information landscape delivered via the World Wide Web. As an alternative model to the traditional, linear presentation of information, instructional designers have sought new methods for structuring and representing relationships between widely diverse ideas and concepts. The term "information landscapes" was first used by Florin [Florin 1990] who visualized "virtual towns" or "intellectual amusement parks" where abstract concepts could be brought together within a single metaphor.

With the explosive growth of the Web, the potential for the development and widespread use of information landscapes becomes more apparent and meaningful. This is due to the fact that the Web is now considered to be an essential information-gathering tool found on an increasing number of desktops. However, this growing access to new information has created significant problems for users who must navigate through vast amounts of data to locate desired resources. At first, hypertext seemed to provide a solution to navigation problems but as more and more resources have been developed based on hyperlinked information, users face a staggering number of navigational choices. There has been no unified framework that helps bring information together and reveals the multi-layered relationships and connections that are not always apparent.

MacNeil [MacNeil 1998] proposes one possible solution by emphasizing the distinction between hypertext resources and information landscapes:

In contrast to the discontinuous jumps between flat pages provided by the ubiquitous hyperlinked Web browser, an information landscape provides a continuum of paths from place to place, conserving context by allowing loose, but spatially meaningful, relationships between information objects. Navigation of such spaces should not only reveal needed and appropriate information, but should do so in such a way that the journey itself has meaning.

The paradigm shift from a static, paper-based structure to the interactive electronic experience of an information landscape offers exciting new ways to engage users by providing a supportive climate filled with educational content. In this context, students with widely different backgrounds and learning styles can explore multiple pathways designed to encourage active exploration and analysis. A framework provided by Jonassen [Jonassen 1994] proposes that a learning environment should provide multiple representations of reality, focus on knowledge construction, not reproduction, and support collaborative construction of knowledge.

We have designed a Web-based information landscape, what we are calling a "Webscape," that supports this framework by including a rich variety of content; challenging, cognitive explorations; intuitive navigation structures and user-oriented interfaces. This Webscape model presents a theoretical foundation for the development of a comprehensive educational Web site with a large database of information, interactive components and a variety of multimedia resources.

In the Webscape model, educational content specialists work with both instructional and graphic designers as well as technical specialists in a collaborative team environment to create interactive experiences for users and develop a wide assortment of online materials. Using both standard hypertext markup language and a variety of emerging technologies such as Adobe's Portable Document Format, Javascript and Dynamic HTML, the
Webscape can incorporate many different interactive experiences ranging from simple point-and-click interaction to more sophisticated examples such as data manipulation and analysis, problem solving, and reflective discussion. Rather than just presenting lists of hypertext links on a given topic, the design team’s role is to create multiple paths for the student to navigate through the information. The Webscape should contain an interesting and significant set of electronic experiences that have been pre-screened, organized and presented in a way that gives it meaning and synthesizes the most important details from the overwhelming amount of data that is available on the Web.

In education, these electronic interactions may be used by instructors and students to explore course content through the use of hypertext, interactive graphics, multimedia elements, and collaborative areas where asynchronous discussion takes place and assignments may be uploaded and viewed by the entire class. The collaborative discussion is managed through Hypergroups, a Web-based interface for traditional listservs. Through this mechanism, students and the instructor are able to post questions and comments that are then automatically generated as Web pages and threaded by date, subject and author. This Web structure facilitates sharing of ideas in an intuitive, user-friendly format that is already familiar to the students.

Management tools are used to create interactive quizzes and examinations, individual student pages for feedback and progress in the course, and final course evaluation forms. Additionally, in some educational projects, the option for users to provide their own stories and viewpoints is incorporated into the design. Many different forms of data are collected through these resources and returned to the design team through e-mail and data files that may then be collated, analyzed and used in the ongoing development of the project.

One example of an educational Webscape is the Untold Stories project (http://www.coe.uh.edu/untold-stories), developed by a team of University of Houston faculty members and graduate students working closely with content experts and an advisory panel. This site grew out of a book and video documentary that recounts the events that led up to the desegregation of public spaces in Houston, Texas during the late 1950s and early 1960s. Through more than 12 years of research, the book and film development teams gathered a great deal of information that was used in the production of both the print and film media and will now be shared as Web resources.

The Web site is being designed to facilitate the navigation and exploration of a multifaceted collection of research on Houston’s desegregation. Users may choose how to navigate through the information in three different ways: by a timeline, by people involved and by accessing multimedia resources. Multiple perspectives of each event are provided; these enable users to see many sides of the same story and draw their own conclusions about what took place. For example, when one of the leaders of the desegregation movement is arrested, the Web interface allows users to investigate this episode from several different viewpoints: the person being arrested, the police who made the arrest, the political leaders in Houston, and the news media. In addition to text versions of transcripts from participants who took part in the actual events, both audio and video materials are also available that help tell the story in a clear and interesting manner. Oral histories are also being collected which will added to the Web site and extend the scope of the project.

As the Web continues to transform the way information is shared, developers must gain the skills needed to create meaningful electronic information landscapes. It is imperative that these Webscapes be filled with useful, and easy-to-navigate resources that allow users to create their own knowledge structures. The major challenge that designers and developers face is creating their own framework or structure through which appropriate information may be located and the exploration of new information becomes possible.

The 24-hour Language Lab: Extending Traditional Media Services with Digital Streaming Technology

Gloria Rohmann
Head of Electronic & Media Resources, New York University Libraries, Bobst Library, 70 Washington Sq. So., New York, NY 10012, Telephone: 212-998-2534, Fax: 212-995-4070, E-mail: gloria.rohmann@nyu.edu

1. Introduction

This paper will describe the background and first phases of a two-year program to apply the new digital streaming technologies to traditional academic media center services in support of foreign language teaching and learning at New York University.

The project was begun in the summer of 1997, when it was determined that the development of streaming media by such companies as Progressive Networks (now RealNetworks) could deliver acceptable-quality digital audio using TCP/IP connections. It was also deemed important that the technology had reached a commercial "critical mass" of acceptance by World Wide Web content providers, so that media materials converted to these formats would continue to be commercially supported. A server was purchased and configured to deliver multiple streams of live and encoded streaming audio.

Phase Two began in the winter of 1998. A key faculty member in the College of Arts and Science was contacted and a pilot project designed to convert to digital streaming audio targeted sections of each chapter of the audio cassette tapes used in the teaching of Introductory French to undergraduates. The publisher provided a standard agreement allowing unlimited duplication of the tapes for students in the class. Sample files were created and technical considerations of storage and bandwidth noted.

In spring and summer 1998, a selected group of students and instructors will work with the files to determine the ways that audio prepared and delivered in this way can be used by students and teachers to enhance access and interactivity without the creation of new audio content.

In fall 1998 the project will be extended to support undergraduate Spanish and Italian audio materials. Only NYU students will have access to the streamed files. This will be accomplished by configuring the media server to restrict access by domain (nyu.edu). Workstations will be installed in the Media Center for access to the files. Students will also be able to access the files via TCP/IP using T1 networks installed in dormitories and in computer labs on campus, or via modems off-campus by means of passworded Internet accounts supplied by NYU.

2. Background: The Instructional Environment

At NYU, a traditional language lab equipped with audio cassette recording and playback equipment serves English-speaking students of other languages and students of English as a second language (ESL). The language lab is located in the Avery Fisher Center for Music & Media in NYU's Bobst Library. Bobst Library is the main library for the University, and is centrally located at NYU's main Washington Square Campus. The Media Center is open only 70 hours per week. Most language instruction courses require the use of extensive sets of audio cassettes, which are far too expensive for the students to buy (the textbook and workbook set, without the tapes, costs $80.00). One master copy of the entire tape set is purchased for the Media Center by the instructional department. According to agreements with publishers free duplication of the tapes for students is done by Media Center staff using a high-speed duplicator and tape stock provided by the student. Turn-around time is 48 hours and only one chapter may be duplicated at a time. The student also has the option of listening to the master tapes in the Language Lab. To use the tapes in

1907
the Media Center, the student has to compete with language students and others using extensive tape-based audio reserves.

3. New Web-based Models for Instruction

While "traditional" teacher-operated language lab operations have fallen into complete disuse, instructors still consider intensive audio and speaking practice highly effective. Instructors are already experimenting with web-based instructional models, using e-mail and listervs to enhance interactivity, and linking students to foreign language newspapers and information services. In addition to extending Media Center access off-site, the preparation of digital versions of audio materials will provide "raw materials" for instructors to create computer-based instruction and present it on class web pages without having to learn complex authoring programs. No proprietary software is necessary beyond the freely distributed RealPlayer, which works in conjunction with standard web browsers.

4. What Is Streaming Audio?

Good quality compressed digital audio over TCP/IP connections is now available. Low-cost encoding techniques and players that allow the listener to play audio (and video) while simultaneously downloading it. Using a process called buffering, the player downloads into the memory of the listener's computer a small portion of the sound before beginning playback. As the audio plays, the player continues to put some of the file in memory. Most streaming audio files do not require that special software be loaded on the host web server. Because the project requires archived audio be served to more than one listener at a time, RealNetworks Easy Start server software was installed on a Dell 6200 dual 200MHz server running Windows NT with Microsoft Information Internet (IIS) Web server.

5. A Procedure for Producing Streamed Files from Audio Cassettes

Each chapter of the text is accompanied by an audio cassette of about 30 minutes. In the test phase, the analog audio cassette was digitized using SoundEdit 16 V.2 (with the free RealAudio plugin) on an Apple Power Macintosh 9500 with 32MB of RAM and a 2GB hard drive. Files were initially digitized at 44KHz and a sample size of 16 bits. "Master" SoundEdit files require 5MB of disk space for each minute sampled, resulting in a file size of 148MB for a 26-minute chapter. When this master file was converted to RealAudio at 8Kbps (suitable for 14.4bps modems), the resulting compressed streaming file was reduced to 851K (a 10:1 ratio).
The Impact of Electronic Publishing

Henryette H. Katharina Roth
Computer-Chemistry-Center
University of Erlangen
91052 Erlangen, Germany
E-mail: roth@organik.uni-erlangen.de

Introduction

The number of pages published each year is steadily increasing. The American Chemical Society, for example, published 135 pages in one journal in 1900. By 1935, pages had increased to 4,500 in three journals. In 1995, ACS published 125,000 typeset pages of research and 80,000 pages of supporting information. The number of journals had increased to 24.

With Springer, in comparison, since its foundation in 1842, the number of journal titles published has grown to 34 in chemistry out of a total of over 400. By the year 2000, all journals of the international Springer publishing group will be available online, in addition to their printed versions. Right now, 200 (27 in chemistry) are online and 1,000 libraries are registered users of the new Internet information service LINK. [LINK]

History

The idea of an information highway is not new. In 1937 H.G. Wells [Wells 1994] promoted the concept of a "world brain" based on a "permanent world encyclopaedia" as a social good through which universal access to all of human knowledge is given. It was not until the 1990s and the advent of the World Wide Web that a system with many of the attributes of Wells' "world brain" came into being. The web makes available linked and indexed interactive multimedia documents so that it emulates the printed publication medium but also goes beyond it in offering sound, video and interactivity.

The Internet and the World Wide Web both typify technologies that came into being through serendipity rather than design in that the informations and aspirations of their originators had little relation to what they have become. The beginning of the Internet was the ARPANET with 23 computers connected in 1971. At the beginning of 1988 some 28 thousand computers were connected through the Internet. The number has grown to over 16 million in 1997 and an end of the expansion is not in sight.

The World Wide Web was conceived by Tim Berners-Lee in March 1989 as a "hypertext project" to organize documents at CERN in an information retrieval system. The design involved: a simple hypertext markup language that authors could enter through a word processor; distributed servers running on machines anywhere on the network; and access through any terminal, even line mode browsers. The web today still conforms to this basis model. However, major usage only began to grow with the February 1993 release of Mosaic for X-Windows. The growth rate of overall Internet traffic is some 100% a year. Web traffic, when last accurately measurable in 1994, was growing at some 1,000% a year.

Science Publishing

General

As already mentioned, the number of pages and title published is increasing constantly. At the same time the quantity of research continues to expand, therefore publication times of printed journals are not able to keep pace with the advances of science. In a world of rapid communication the scientist is slowed down by long publication times.

On the other hand science journals are part of the permanent, scientific record. Only quality science that
passes the critical review of experts in the field and falls within the scope of the journals' coverage should be published. The peer review process of a manuscript is time consuming, but necessary to guarantee the high level of a scientific journal. Like the refereeing, a number of steps had to be passed during the publication process to prevent errors from being introduced in the final publication. The solution at hand to achieve short publication times in a high quality scientific publication is to use electronic technologies in every step of the publication process.

Electronic publication also offer the possibility to publish information enhanced papers. Supplementary material like 3D coordinates, videos, spectral data etc. can be linked directly to the paper. Electronic journals that are available via the World Wide Web can be accessed from almost every computer all over the world. The scientist does not have to go to the library, but can retrieve the information directly from his desk in the lab.

Journal of Molecular Modeling

The Journal of Molecular Modeling [Clark 1996] has started as an idea at the Fall ACS National Meeting in 1994. In the beginning, not being aware of the World Wide Web, it was planned to distribute the articles as wordprocessor files via FTP. To guarantee longevity of the published material a CD-ROM and print version should be issued once a year.

When the project started in Spring 1995 with the publication of four articles, the WWW had become common knowledge. With this new hypermedia system an electronic journal could be presented in a way we never dreamed of. The limitations of the HTM language became clear when we tried to format our first article. Greek letter and mathematical formulae could only be introduced through tiny little images. Tables could not be typeset and page numbering was not available. The last one was the point of trouble. Being the first fully electronic journal in chemistry the abstract services were willing to include the Journal of Molecular Modeling as long as it could be cited just like a printed journal. The solution was to publish the articles in PDF-format. This makes the journal in the beginning more "book-like", but has the advantage that Greek letter, mathematical and chemical formulae can be included, pages are numbered and the manuscript is save in a format that cannot be easily tempered with. Authors and readers have the guarantee that the publication remains unchanged.

The Journal of Molecular Modeling has been developing over the years and still is. The primer aim is to be a good scientific publication, therefore every article must pass through all steps of a thorough publication process to control quality. Every manuscript is reviewed by at least two referees, experts in their field. The paper is revised by the author and after resubmission corrected by our copy editor. The layout of the corrected article is done by the desk editor, who will send the galley proof back to the author. After transfer of the authors' corrections to the original the paper is ready to be published. In principle this procedure is the same for printed and electronic journals. The difference is in the implementation: Papers are submitted and refereed electronically. The galley proof also is send back to the authors via email. Since an electronic journal must not adhere to a fixed publication schedule, papers are published as soon as they are proofread by the authors and double checked by the production department. Abstracting of papers published in an electronic journal is extremely fast. Abstracting services can either copy the graphical abstracts to their own server or link directly to the journals pages.

The first volume of the Journal of Molecular Modeling had 201 typeset pages, some of them showing color graphics, and the only multimedia component used were 3D structures provided in PDB- or XYZ-format. The number of pages has increased to 477 in 1996. Authors made widely use of color graphics. In addition to 3D structures multimedia material like VRML-scenes and video sequences were incorporated. In 1997 we expect to publish some 800 pages. Three new features are launched this year.

For the first time, the 1997 edition of the Journal of Molecular Modeling will feature enhanced abstracts, these are short (up to 6 slides) HTML-slide shows outlining the contents of the full paper that convey the message of the paper as effectively as possible.

The implementation of electronic technologies in every step of the publication process did cut down the publication times considerably. However, for urgent communications of up to three pages we will issue the Journal of Molecular Modeling Communications that are intended to provide unprecedentedly short publication times of less than 20 days.

Invited reviews of unlimited length will be presented as Journal of Molecular Modeling Reviews and Open Discussions. Reviews will be available for three months after the publication date for email comments from other researchers and replies from the authors. This discussion will then become part of the final published
version of the review.
The Journal of Molecular Modeling is always in development to adapt to the needs of authors and the wishes of readers. We cannot build up today the framework for tomorrows publishing. In theory there are much more multimedia applications that could be incorporated in an electronic science publication. The question that always arises is, does it help the author to present the results and does it lead to a better understanding? The aim of the Journal of Molecular Modeling is to communicate chemistry in a sophisticated way, not to make chemistry publishing to a new science of its own.

Simulations for Learning: An Inquiry-Based Approach to Biology

Laurie F. Ruberg
Center for Educational Technologies, Wheeling Jesuit University USA
email: lruberg@cotf.edu

Introduction

BioBLAST® is a multimedia curriculum supplement for high school biology classes. In the BioBLAST scenario, students use simulations based on USA National Aeronautics and Space Administration (NASA) life sciences research data to develop and test their own designs for a biological life-support system that could support humans in space. The primary goal of the BioBLAST program is to get students involved in critical analysis and problem solving processes associated with scientific inquiry. The interactive adventure/simulation framework includes computer-based tools and resources, telecommunications events, and hands-on experiments that are all presented within a graphically rich QuickTime™ Virtual Reality (QTVR) interface. Figure 1 provides an illustration of the three-dimensional lunar base model used in the QTVR user interface to the interactive simulations. The software is designed to draw students into a futuristic, problem-solving scenario in which teams of students are sent to a simulated lunar research facility. There, students use graphical simulation tools and resources to prepare for their mission goal: to design and test a model for a plant-based life-support system that can support a crew of six for three years.

Features of Simulations

The laboratory-based Plant Production [Figure 2], Human Requirements, and Resource Recycling simulators enable students to perform investigations not possible in real time or within the facilities of a high school lab. In addition, the interactive, simulation/modeling tools give students hands-on experience with the technology tools that scientists use to collect, analyze, and display complex sets of data. The three lab-based simulations are designed to accompany each of the three research strands within the BLiSS (Bioregenerative Life Support System) problem that students will address. A fourth simulation called BaBS (Build a BLiSS Simulator) [Figure 2] is used to pull all three topical areas together to construct an idealized model of plant-based life-support system. Students refer to the research database provided within the main simulator to generate their numeric entries regarding crop growth, human diet, energy requirements, resource recycling parameters, the number and gender of crew members, and duration of the test. All four of these simulations utilize NASA data and make it easy for students to export the database and the results of their simulation runs. Students are encouraged to further analyze their results in a spreadsheet program. Through the process of selecting and testing features to include in their simulation run, students apply, synthesize, and expand their understanding of such principles as: (1) how energy flows through living systems; (2) the role of plants in recycling air and water cycle for human use; (3) how various environmental factors affect the rate of photosynthesis; and (4) why photosynthesis and cellular respiration form a continuous cycle. As prescribed in the National Science Education Standards (NSES) [NSTA, 1996], student work with the simulations leads up to a design model that the student must explain and defend in a written report and/or verbal presentation. The final BaBS run, analysis, and report is one of the culminating activities in BioBLAST.

Teacher Involvement

Early on in the development of this program, high school science teachers representing a variety of cultural and socio-economic communities and geographic regions of the United States were selected to participate in the design, testing, and evaluation of this software. Two primary criteria were used to select teachers to join the extended design team: (1) access to the computer technology required to run the software; and (2) demonstration of a clear desire to use an inquiry-based approach that emphasizes problem-based learning. This study describes how early involvement of teachers in the design, development, and formative evaluation process helped identify the goals for teaching and learning that the simulations in this software most effectively address. Teachers used the initial list of goals that we designed this software to address as a planning document.

1912
Based on teacher reports regarding the process of integrating the simulations and related materials, student use and analysis of outcomes of the BioBLAST simulations fulfill the NSES [NSTA, 1996] through activities that ask students to: (1) Trace energy transformation and/or apply the principles of mass/energy conservation to physical and biological systems; (2) Relate the effect of light and other factors on various aspects of plant life and growth, including photosynthesis and respiration, germination, and tropisms; (3) Predict the effect on an ecosystem due to a given or proposed environmental change; (4) Formulate an experimental design to test a given hypothesis; and, (5) Relate the effects of biotic and abiotic factors to animal life including growth, reproduction, and behavior.

Figure 1. This screen capture shows the graphical interface for one of the BioBLAST simulators.

Figure 2. This screen capture illustrates the dynamic graphing available in the BioBLAST simulators.

Summary of Results
The formative evaluation of the BioBLAST software included data from pre- post-tests, student reports, teacher observations, and student work. Teachers developed unique ways to integrate this program into their curriculum that suited their school curriculum and course offerings. BioBLAST has been incorporated into introductory, general and advanced biology, advanced technology, student research electives, and math classes. Teachers reported that they had to change their teaching style to integrate this program and found that students needed the following skill-building activities prior to beginning the computer simulations: (a) cooperative learning and team building activities; (b) introduction to the use of spreadsheets for organizing and analyzing data; (c) concept mapping to tie together concepts and connect ideas; (d) building and interpreting graphs to represent data; and (e) conversion to and use of metric units of measure. Further analysis of pre- and post-tests will show whether our selection of ninth grade as the target population for BioBLAST is consistent with the findings of [Friedler & McFarlane 1997] and [Burkam, Lee, & Smerdon 1997] who determined that data logging and analysis can significantly improve student graphing and interpretation skills if conducted prior to age 16. Analysis of student portfolios provide descriptive indicators of student motivation and effort and, as [Hickey 1997] suggests, will provide ways to document teacher reports of increased student motivation and effort associated with the interactive media tools and approach to teaching that encourages inquiry-based learning.

Introducing a Media Production Course into the Middle School: Don’t Reinvent the Wheel

Stephanie M. Rusnak
NASA/MU-SPIN Center for Network Resources and Training
South Carolina State University
P.O. Box 7296, Orangeburg, SC 29117
rusnak@eejust.scsu.edu

As schools continue to add classes involving multimedia integration, teachers without production training are being asked to implement these courses. Usually an innovative instructor covering a traditional subject area will be asked to take on this new challenge. In other cases, a risk-taking teacher may volunteer to teach the new class. In either circumstance, teachers are left with the challenge of implementing a new course covering a subject area where there are few curriculum guides, few sample lesson plans, and even fewer teacher training materials.

One middle school near Charleston, South Carolina, successfully implemented such a class. Not wanting other teachers to "reinvent the wheel", the instructor created an online compilation of her teaching objectives, lesson plans, hand-outs, and resources called The Media Production Homepage. The web site contains practical information for a teacher with limited resources and limited training. Educators from across the globe have visited the web site that receives approximately 140 hits a month and have responded positively. From the Media Awareness Network in Ottawa, Ontario, Cathy Wing asked for permission to adapt the lessons for use in Canadian schools. Mark Dobbins, a member of the Education faculty at the University of Melbourne commented, "Your site is terrific! I can see many teachers wanting to try out your course. And you have supplied them with just about everything they would need. Thanks for putting such a wonderful resource in the public domain for teachers everywhere." Linda Cossel, a K-12 teacher from Michigan said, "I do a daily, live, morning news broadcast for our junior high school, or actually the kids do it. I stand around and pray. It is wonderful and the most stress I have ever endured. Anyway, I love your site and am in the process of reading every word. Five stars!"

The nine week middle school course taught students how to create short animations, write news articles, and how to take a broadcast news topic from idea to video. Students worked in teams to produce a segment of a final news show that was broadcast throughout the school.

The course was implemented with a very limited budget. Basic materials needed to follow the online lesson plans include a videocamcorder, tripod, copystand, microphone, typical classroom supplies such as scissors, tape, construction paper, computer running desktop publishing software, laser printer, TV, and two VCRs for editing.

The course ran for nine weeks. It began with an ice breaker on day one and the initiation of a collaborating partnership with an overseas classroom on day two. For the following three weeks, students worked on animations. Next, for one and a half weeks, articles for the school newspaper were created. Students then spent two to four weeks on video production. They wrote T-scripts, created sets and props, and then videotaped their segments. The Media Production Homepage gives several suggestions of how to fill any remaining time. The teacher may want to provide instruction on the Internet, spend more time collaborating with the partner school, teach a unit on advertising, or utilize Tom Snyder’s One Computer Classroom Kit, Violence in the Media.

Handouts for the class included a letter to parents telling them about the new course, Animation Guidelines, Steps in Creating a Newspaper, Formula for a Well-Written News Article, TV News Evaluation, What Are We Doing? Worksheet to help students with their video production planning, and an Occupations Related Worksheet to give students a chance to research careers related to media production.

By viewing the curriculum materials from a successful hands-on middle school course, teachers of media production will have an easier task of adapting the class to meet the needs of their schools. The Media Production Homepage, authored by Stephanie Rusnak, is located on the World Wide Web at www.geocities.com/Hollywood/Hills/1902.
Abstract: We want to promote teachers' collective work on the World Wide Web, through the definition of the architecture of a standardized network system for the integration of the operating cycles of the learning process. The integrated system is composed of an authoring tool (Tela) for the design of instructional material to be used on the Internet, of a distributed data base management system (Component Warehouse) and of a fruition module (Büxis). In this paper we will describe our current research work on that part of the integrated system which is used to create and modify the lessons: the Tela authoring tool. We will also describe the way chosen to represent the learning architectures thus tailored.

Introduction

The ideation of an integrated system and the development of its prototype are the most important phases through which we want to promote teachers' collective work on the World Wide Web. Our main objectives are:

- to define the architecture of a standardized network system for the integration of the operating cycles of the learning process
- to define how to store and use didactic components
- to define how to elaborate a training course dealing with the corresponding theoretical and practical approaches for teachers.

The integrated system is composed of an authoring tool (Tela) for the design of instructional material to be used on the Internet, of a distributed data base management system (Component Warehouse) and of a fruition module (Büxis). The system will be tested by a small group of secondary schools (25) in the first phase of our project. Its main characteristics are related to:

- the "ideation space" which will consent teachers to organize in a structured way the conceptual nodes they want to elaborate;
- the "filling of nodes", which will be processed by either a querying activity to the common data base or by the personal edition of content;
- a serie of guidelines, based on the instructional system design principles. The guidelines will orientate the design of material and the selection of media for knowledge representation;
- the navigational strategies through a new browser, called Büxis. We focus on a new mechanism for the visualization and the access of specific concepts integrated in a large cognitive map.

In this paper we will describe our current research work on that part of the integrated system which is used to create and modify the lessons: the Tela authoring tool. We will also describe the way chosen to represent the learning architectures thus tailored.

We will develop the system prototype according to the following actions:

- automating the identified methodology for Instructional System Design (ISD);
- implementing Tela's advanced GUI;
- structuring the Component Warehouse using a distributed OODBMS;
- defining syntax and extension of the Lesson Document as a SGML application;
- developing the Büxis navigator that offers the neccessary browsing and visualization tools.

The Learning Architecture
Concepts pertaining a particular topic, which is investigated in one or more lessons, are represented through a map of the corresponding cognitive area. This map consists in a hybrid structure with peculiarities of a tree as well as of a non-oriented graph, where every single concept, idea or task constitutes a node (labelled with a title).

In particular, ascendent and descendent links (associative connections) among concepts are represented with a hierarchical structure (tree), while referential links constitute further non-oriented archs among the nodes of the previously constructed tree.

First of all, the tree is designed and secondly, the learning architecture is completed with the referential links, thus generating a graph (reticulate structure) which is the final result seen by the user, who, however, still keeps traces of the underlying tree structure. The latter allows the use of implicit different Levels of Detail (LoDs) while visualizing the didactic material. On the underlying learning architecture, the teacher tailors the various lessons using instructional design techniques. In the graph, which represents the map, the lessons are shown as groups of nodes of different colours.

Every node of the map contains some material describing the concept dealt with in the node or, for instance, the development of a proposed exercise. This material may consist of one or more mediatic representations, for instance a concept may be better described with written text and an image. Generally, a node should not contain more than one element being represented with the same medium (for example two images). However, when this is necessary, it is better to further structure the map inserting two other subnodes under the main one, each of them containing an image. Still, the support of representations similar to each other may be useful when describing a concept, as in the case of a node describing a tree by showing two pictures of it.

In this way, the distribution of concepts is always organized in the graph whereas at a node level they are only codified. This makes it easier for the user to choose between verbal or non-verbal encoding depending on the topic being described. Finally, it is better not to leave a node empty (i.e. when structuring a topic in various subnodes): every node should contain at least an overview of the topics dealt with in the subnodes in order to facilitate the use of LoDs.

The Authoring Tool Tela

The system includes activities based on the conceptualization and development of learning architectures for teaching, distributing, accessing and differential processing of knowledge. All this will involve three specific, interdependent phases. The first one is concerned with the whole of the procedures defining and structuring didactic material. The second one regards the planning of the teaching strategies and the last one sees the development of the material, that is the attribution of contents to the nodes previously described. The latter activity becomes effective through the sorting of the media operating by means of a search system in the Component Warehouse.

Tela is new in its introduction of a set of techno-pedagogical functions which can place the user within a mixed environment, so that he/she can be guided by some principles of the pedagogical design but is not forced to follow its sequential organization. The user, moreover, is able to edit or create material from within the system itself. The idea of recalling information components in various formats from the Component Warehouse created for the project implies that it is possible to start operations of total or partial construction as well as to collect didactic activities carried out by the other participants to the project.

Connecting Educational WWW Pages With Curriculum Materials

Tago Sarapuu, Kristjan Adojaan & Triin Marandi.
Science Didactics Department, University of Tartu, 40 Lai St., Tartu, EE2400 Estonia.

Abstract: The main goal of the present investigation was to evaluate the relevant method of teaching in computerized science classes. Furthermore, we tried to estimate the impact of computerized biology lessons on students' motivation and their attitudes to the problems of environment protection and Estonian nature. The teaching method developed in our department was fully supported by the expert group of science teachers. The analysis of students' worksheets and questionnaires refers to the suitability of the relevant methodology to enhance students' ability to analyze and synthesize. The questionnaires revealed students' increased interest in school biology.

Estonia is currently undertaking reforms in its educational system. The implementation of the new State Curriculum in Estonian schools began in autumn 1997. The reform is taking into account Estonian aim of integrating into structures of European Union. Estonian educational reform covers pre-school education in kindergartens, general basic schools, upper-secondary general schools and vocational education. Following from the curriculum, different subjects are integrated by common themes. "Informatics and Infotechnology" is one these.

At the present time about 200 out of 350 secondary schools in Estonia have their own computer classes with the direct or dial-up Internet connection. Therefore at first we were interested in how our science teachers had used computers in their everyday activities. 85 science teachers of different secondary schools filled out questionnaires about their previous experiences, opinions and suggestions in using computers for teaching their own subject.

It appears that only 6% of teachers use computer every day and 37% of them have never used it. The most common areas of using computers are the following: typing texts (54%), various Internet services (31%), playing games (16%), creating databases together with statistical analyses (8%), and using educational software (8%). Nobody has used computers in teaching science.

One may ask whether Estonian teachers don't like to teach science in computer class. Our Department conducted several computerized biology lessons in different secondary schools. Teachers of those schools had an opportunity to observe these lessons. We were interested in their opinions. Nearly half of the teachers were willing to teach science using computers and only 4% of them declared that by no means. The students who participated in the lesson also liked it. More than 64% of students found that it would be nice to have more such kind of lessons. They also mentioned that the biology lesson carried out in computer class increased their interest in school biology.

Another problem is lack of educational software, in particular, in Estonian. Our students are not ready to use software in English or in other languages, except in Estonian. Of course, in some subjects, for example, in teaching languages the software is immediately applicable. In other subjects, the computer programs can be translated. But in the field of natural sciences every country must compile its own original educational software introducing their own unique nature.

Therefore our department has started the project "Estonian Plants and Animals". As the result of two-year project we will create Web materials applicable in teaching various themes of school biology, integrated science and environmental study according to the new Estonian State Curriculum. The materials consist of two distinguishable parts - the database about 500 most common species of Estonian plants and animals, and appropriate computerized educational tasks for both basic and secondary school students. All the opportunities of multimedia will be accounted for - texts, visuals and sound. "Estonian Vertebrates" (http://sunsite.ee/animals/) and "Estonian Plants" (http://sunsite.ee/tained/) available on Internet are the first examples of this project. These WWW materials are applicable in several out-of-class activities, for example, in writing and compiling students' research papers, reports, essays, etc. Computerized educational tasks composed on the basis of "Estonian Plants and Animals" enable students to learn the particular themes independently to develop their memory,
comprehend, analyze and apply the facts. Various tests added to the package will provide teachers with necessary feedback of students' knowledge and abilities.

On the other hand, it is impossible to create the computerized tasks satisfying all the teachers' needs and adaptable to all the appropriate themes in curriculum. Therefore, we have also compiled various students' worksheets. They can be used without any changes or might serve as examples for teachers to work out theirs own ones. It is essential to compile the worksheets not only for finding and memorizing facts, but also for developing students' higher order thinking skills.

According to the methodology developed for computerized biology class the first 10 minutes at the beginning of the lesson students should get acquainted with the new software. It is essential for both beginners and advanced users of computers - it speeds up work later on. A special printed instruction for students about the principles of layout and help information together with simple tasks was compiled.

Next, after the introductory part of the lesson students had 35 minutes to work independently to fill out the printed worksheets [Adojaan & Sarapuu, 1997]. Since the purpose of the educational tasks was to develop students' higher order thinking skills, the worksheets were composed not only for finding, memorizing and reproducing facts. Students had to find information on different WWW pages of "Estonian Vertebrates" or "Estonian Plants", to analyze, synthesize, make conclusions and find plausible reasons in order to fill out worksheets. Two versions of worksheets with different tasks were used in the pilot lessons. Solving both tasks was connected with all the categories of thinking: knowledge, comprehension, application, analysis, synthesis and evaluation [Bloom et al., 1956]. In case of all the tasks students' abilities to analyze, synthesize and evaluate were connected with acquiring knowledge and comprehending the presented material. Students' ability to find electronic information was also of interest.

Three teachers conducted nine pilot lessons in the computer classes of different schools. 27 basic school students of the ninth grade and 59 secondary school students of the 10th - 12th forms participated in these lessons. Immediately after the lesson students filled out questionnaires about their previous experiences in using computers, ways of using and interests. Students were asked to evaluate the software, worksheets and to express their opinions of possible application of the program in the biology lessons and its relevance to everyday life. Both formative and summative methods of evaluation were used [e.g. Thornton & Phillips, 1997]. Another aim of "Estonian Plants and Animals" is to motivate students to become more interested in school-biology, Estonian nature and the problems of environment protection. 19% of students claimed that it made them be more interested in biology lessons and 35% of students thought that "Estonian Vertebrates" together with the educational tasks made them be more interested in Estonian nature and its protection. Increased interest in these areas is the greatest success in the educational software and methodology.

Teachers of pilot schools formed an expert group. They were interviewed about the educational content of "Estonian Vertebrates" and "Estonian Plants" together with teaching method used in the pilot lessons. Almost all the teachers fully agreed the teaching methodology used in computerized biology lesson. Every educational database with understandable vocabulary is applicable with additional printed worksheets to promote students' knowledge, comprehension, analysis, synthesis and evaluation. Therefore, the relevant method of teaching science in computer class developed in our Department is applicable not only with "Estonian Plants and Animals" but with any electronic database consisting of appropriate information.

Evaluating Impact of Video and Web-Based Distance Learning Courses

Wilhelmina Savenye
Division of Psychology in Education, PO Box 870611
Arizona State University, Tempe, Arizona USA 85287-0611

Universities and colleges are increasingly delivering courses via various modes of distance delivery. This paper briefly describes the results of evaluations conducted on two types of courses which used distance learning methods. In one evaluation an outcomes-based education course for preservice teachers was adapted for television delivery. One section of this course also included a three-week computer-based self-instructional module to teach development of competency-based instruction, and students had access to an "electronic forum."

The other evaluation was conducted to determine the impact of a set of a prototype World-Wide Web-based tutorials for two university engineering courses. This evaluation is currently being completed and full results will be included in the presentation.

The presentation will compare both the evaluation methods and results in these two types of evaluations of two types of distance learning courses.

Introduction to the Evaluation of the Televised Course with Computer-Based Module

The Televised Course: First Course Offering, Fall, 1996

During the fall semester of 1996 a two-credit course, "Learning and Motivation," was taught for the first time via television. Forty-five on-campus students enrolled in one section of the course which was taught in a specially-equipped video classroom. Four students enrolled in the off-campus version of the course. (Another 160 students enrolled in other sections of the course.)

As did students in the other sections, the television-section students met for one hour once a week for the class lecture, followed by another hour of discussion section taught by a graduate-student discussion leader. All 49 television students (45 on campus, four off-campus) participated in the one-hour video lecture, taught by the first author. Then students were divided into three small discussion sections. Sixteen students in one of these, taught by the second author, participated in the televised discussion section, with twelve on-campus and four off-campus.

Both instructors taught the video course using an available graphics pad as well as computer graphics. The class was designed to be broadcast via cable to off-campus students enrolled in their homes or dorms and at various educational and employment
sites in the metropolitan area. The classroom was equipped for live two-way audio interaction. On the instructor's podium was a telephone which rang when an off-campus student called in with a question or comment. The video classroom was equipped with microphones, which campus students activated with a button when they wished to ask or respond to questions or make comments.

This semester, however, the four off-campus students enrolled in the course did not subscribe to the cable company, and chose to make copies of the class sessions and pick up materials when they came to campus for other classes later in the week. They watched the tapes at times convenient to them, and instead of using the telephone system to interact with the classes live, used either the electronic forum, email or phone to contact the instructors at other times. These four students were told they would not have the benefit, therefore, of live classroom interaction, but would need to be more active in interacting at times outside of class. They indicated they understood this, but felt it was worthwhile for the convenience of not coming to campus, and/or watching tapes at other times. (Off-campus students were required to come to campus three times during the semester to complete exams.)

**The Learning and Motivation Course**

The Learning and Motivation course has been taught for over nine years at this university. Over 200 students per semester enroll in the course and we are told students consider it one of their more relevant and enjoyable courses.

The course was initially developed over several years by James D. Klein as an outcomes-based course. We have made changes in the course and in 1996 chose this course for televised delivery, primarily because of its systematically designed, objectives-based nature and relevance for students.

The course is divided into 11 units in three topic areas, namely: applying learning theory in the classroom, developing competency-based instruction, and motivating students. During the first eight weeks of the course this semester students learned about learning theories, how to classify learning outcomes and the conditions for learning. During the next three weeks students worked on their own to complete the self-instructional computer program about developing competency-based instruction. During the last part of the course, students met together again, reviewed the elements of effective instruction and learned about motivation.

Students earned up to 200 points in the course by completing a midterm and final exam, the course computer project, in-class activities and section assignments.

**Method**

**Data Sources**

*Mid-Semester Formative Evaluation Survey.* Students completed a mid-semester survey to assess their attitudes toward the course and television delivery, as well as to
enable the instructors to make improvements in the course. The survey consisted of 25 questions. Students were asked the name of their discussion leader and whether and how they had used the class videotapes. Then they responded to eight forced-choice items on which they rated aspects of the televised lecture section. Following this, students answered 12 items rating their discussion section (one of which was televised, two of which were not.) Finally they answered three open-ended questions about the course.

Electronic Forum Logs. About mid-semester students in the television sections of the course were offered the opportunity to communicate with their classmates and all four instructors through an electronic forum somewhat like an electronic bulletin board. Students were told this represented a new aspect of the course that we hoped would work well for them and, if so, that we'd be incorporating in all other sections of the course. As an incentive students were offered up to seven extra-credit points for using the system. They could earn the maximum points by writing at least one original entry about a critical issue in education, replying to another person's entry, and writing one comment about any aspect of the TV delivery of the course.

The system kept a log of all participants' entries. Students' entries were analyzed for frequency and content of participation and results will be presented below.

End-of-Semester Formative Evaluation Survey. As is customary in the course, a brief end-of-semester survey was administered to all students. Students were asked the same questions as on the mid-semester survey, and were also asked questions about their overall rating of the course compared with others, their opinions about the self-instructional, computer-based unit, and whether or not they would again take a course via television. (Highlights of the results of this survey only will be included in the presentation.)

Course Performance. Students could earn a total of 200 points in the course. Mean numbers of points students earned were compared by section.

Results

Mid-Semester Formative Evaluation Survey

The results will be presented by section. Thirty-three of the forty-five on-campus students and three of the four off-campus students rated the televised lecture section of the course. Twelve on-campus and three off-campus students rated the televised discussion section of the course. For comparison purposes ten and eleven students respectively rated their non-televised discussion sections taught by the two other discussion leaders.

Results are summarized on a copy of the student survey in Table 1 and will be discussed in detail in the presentation. Key results were that the audio system was problematic for both in-class and remote students, and that students even in the classroom felt somewhat hampered in interacting in class due to the television system.
Electronic Forum Logs

Sixy-one entries were made in the electronic forum during the final six weeks of the course. Forty entries were made by students, while 21 were made by the two TV instructors. Only nine (18%) of the 49 students used the electronic forum. Four students made three entries each about an issue in education, a reply and a comment about the televised course delivery. These four students made their entries consecutively, thus participating the minimum amount to earn all the extra credit points. Three students made one entry each; each of these chose to describe their view of a critical issue in education.

Two students conducted undirected interactive discussion, beyond what was required to earn points; these two students made seven and five entries, respectively. The first student was an off-campus student taking the course via videotape. This student was the first to begin the discussion on the forum with an entry about a critical issue. This student followed by asking three questions about course delivery and made two entries communicating with the instructors. The second student who participated more than was required was an on-campus student who used the forum for longer discussions with fellow students and the instructors. This student made only one entry commenting about the course, but made four entries which commented about issues in education and replied to other students’ entries.

End-of-Semester Formative Evaluation Survey

A brief summary of key results will be presented. Most students rated the course highly when compared with other education and general college courses. Most said they would take another television course. Most said that we should retain the computer-based unit of instruction, however that it should allow students to go back and to print out screens. Some also suggested it should be supplemented with written material, or produced in both Macintosh and PC formats.

Course Performance

Students could earn a total of 200 points in the course. The mean overall course grade for the 213 students across all eleven sections of the course was 178.75. The mean score for the 16 students in the completely televised section was 182.93, including the mean score of 182.96 for the twelve on-campus students and 182.85 for the four who took the course via tape. Five students in this section, four on-campus and one off-campus, earned some extra-credit points by participating in the electronic forum.

Scores were 181.1 and 178.23 for the 24 students who saw the televised lecture, but participated in the non-televised discussion sections. Four students in the first section earned extra credit points, while no students in the last section chose to participate in the electronic forum to earn bonus points. Thus scores across sections did not differ greatly.
Discussion Regarding the Televised Course

Modifications to the audio system are being suggested. In addition, future versions of the course will encourage students to interact with off-campus students who are enrolled via cable, thus taking the course come "alive." In future courses, we intend to foster increased student interaction within the class by using brief motivational exercises early in the semester to get students presenting to their colleagues informally from the start of the course.

Course grades did not differ greatly among televised and non-televised sections of the course. This would be expected in that most of television students participated in the on-campus video classroom. It may be that the slightly higher scores could be attributed to the fact that the television lectures included better visuals, such as full-color PowerPoint graphics, than did the overhead-equipped regular lectures. Also students in the three television sections could choose to earn extra credit points by taking part in the electronic forum.

However, the television sections of the course were also smaller than the regular class sections, as they usually are for our evening sections. They ranged from 11 to 16 students compared with 18 to 27 for the day sections. Students in the surveys also indicated that they enjoyed taking the evening, television class because it was smaller than the day class, with 49 students in lecture, compared with 164 in the day lecture.

Finally, we have noticed a pattern in past years in course grades per discussion leader by section. Each instructor teaches each topic three times, usually beginning with the day classes and ending with the evening section, so evening section grades have tended to be higher.

We have concluded that the fact that scores did not differ greatly bodes well for at least on-campus students in televised classes. This is consistent with results of earlier evaluations of televised classes at this university. It is hoped that in the future increased numbers of students will enroll in distance learning versions of this course. Grades will be continue to be examined to monitor the performance of on- and off-campus students.

The Evaluation of the Web-Based Engineering Tutorials

The Web-Based Modules: Pilot Course Use, Fall, 1997

During the fall semester of 1997 a team of engineering professors and students received a grant to develop four prototype tutorials for graduate education in semiconductor processing and manufacturing. Each tutorial was designed specifically for each course to provide an interactive self-paced and very visual learning environment. An education professor assisted each development team in improving the effectiveness of these prototype tutorials as part of the process of developing an expanded set of tutorials for the following year.
During the latter part of the fall semester, the impact of the first two tutorials was assessed in graduate courses in the engineering program. These tutorials were for an electrical engineering course and a chemical engineering course.

The results of these evaluations are currently being evaluated. The proposed presentation will describe the methods and results of the formative evaluation study conducted to determine the impact of these prototype web-based tutorials.

Method

A short survey, based on those used in our previous evaluations of distance-learning courses and multimedia programs, was developed. The survey consisted of 21 items, with most being forced-choice, followed by three open-ended items. The survey items required students to provide us their perceptions in such areas as the value the tutorial added to the course, whether they'd used such web-based tutorials in other courses, how easily they were able to use the tutorials and their features, opinions about the design of the tutorials, their least-liked and most-liked features, and their suggestions for future iterations of the tutorials.

Nineteen students evaluated the CHE, chemical engineering tutorial and 56 students evaluated the EEE, electrical engineering tutorials. The students were either upper-division undergraduates or graduate students.

Results

Most students had not encountered web-based tutorials before, with 84% in the EEE course and 95% in the CHE course indicating they had not used such materials before. Students in the EEE course rated their tutorial more highly, with 89% indicating that the tutorial added value to their course, compared with 63% of the CHE students who said their tutorial added value. Similarly, 91% of the EEE students said more tutorials like this would help students learn. On this question, the CHE students were also positive, with 89% of the them agreeing that more tutorials like this would help students learn.

Students' responses to the question regarding where they accessed the tutorial provides insight into other attitudes toward the materials. Most of the EEE students (71%) accessed the tutorials from university computing sites, at which the computers were already set up with such necessary software as Shockwave. In contrast, only 28% of the CHE students accessed their tutorial from university sites, with one-third each indicating they used the materials at their home or their job. Using the tutorials at these other locations proved problematic for some students. Half of the EEE students, who mostly used the materials at the university, said they did not have to download Shockwave, while 23% said they had to download Shockwave and it did not work. Of the CHE students, 81% said they had to download Shockwave and it worked, but took a long time.
Students' open-ended comments about the course amplified and explained the previous results. For example, many students in the CHE course indicated they felt the graphics and animations helped them learn and they liked them. However, students described many problems downloading Shockwave preparatory to viewing the animations. They also indicated that there were some bugs in the program, so they could not view all pieces and that they would have preferred more textual explanations of the graphics.

Students who used the EEE tutorial wrote such comments as that they were "revolutionary," and helpful, especially for exams. Many of these students said they wished there were more tutorials or tutorials to accompany every topic in the course. They, too, described some problems with downloading fonts and Shockwave. These students were very sophisticated in their critique of the design of the tutorial. They suggested adding, for instance, more examples, more solutions and hints for solving problem sets, enhanced color contrast between text and background, less busy screens, a "page down" feature instead of scrolling, an index, added sound, and enhanced navigational aids.

(This paper provides a summary of results. Complete results will be included in the presentation.)

Conclusion

The presentation will conclude first with suggestions for adapting a course for televised delivery. Suggestions include ways to enhance the interactions of students and instructors, improve the systematic nature of the course, and use the visual power of the television medium.

Next will be discussed suggestions from the evaluation of the web-based engineering tutorials for improving the effectiveness of such tutorials.

Finally, the presentation will include a discussion comparing the methods used in the two sets of studies, as well as recommendations for evaluations of various types of single and mixed-mode distance learning systems.
Most studies regarding learning strategies are based on information from learning strategy questionnaires. One disadvantage of the questionnaire method is that it is not possible to conclude what learners actually do in a given learning situation. A study by Artelt and Schellhas [see Artelt & Schellhas 1996] shows that considerable discrepancies can occur between the strategies which learners report using and the strategies they actually use in a specific learning context. The presented study therefore emphasizes the need for analyzing the use of learning strategies in action.

Learning strategies are the result of the interplay between the cognitive competence and the situated experiences of a person. Furthermore, learning strategies are used to reach learning goals. We choose hypermedia learning/studying environments as a research context for analyzing learning strategies in action because they allow us to examine how students go about reaching a specific learning goal (in the sense of the constructivism view: self-regulated and self-determinated learning and exploring, so called "free learning"). By analyzing what contents they choose to learn, how they proceed and why they made particular choices, we can observe from multiple indicators how students structure the learning process (self-regulation) and construct a new knowledge entity.

In this study, 50 10th grade students studied a learning unit in History about the First World War in order to draw a personal conclusion. They were guided by a content question which was given to them at the beginning of the hypermedia session. Students were given considerable freedom in defining the task in their own terms and exploring the learning environment at their own pace with their specific questions in mind.

While studying the hypermedia materials, all learner-computer interactions were recorded in a computer log-file. This protocol thus contains data about reading-times, chosen cards, navigational data, etc. At the end of each session, the trace was displayed step-by-step. With the help of this display, students were interviewed about their intentions, goals, their thoughts and the strategies they employed while moving through and exploring the hypermedia learning environment.

Data were thus collected with three different methods: a) questionnaire data was collected concerning learning strategies, cognitive abilities, motivation (general and process-specific), anxiety, attitudes towards computers, school subject preferences etc., b) behavioral data was gathered concerning navigational and content choices in form of a computer log-file, and c) qualitative interviews were conducted about learners’ thoughts and intentions during the hypermedia learning session.

The main research interest was focused on the use of individual learning strategies, specifically, the use of deep and surface learning strategies and the use of metacognitive aspects of learning strategies such as resource management. We found that students who preferred surface strategies did not structure information in an elaborated knowledge system. They were not interested in getting further information for a deeper understanding of the subject. On the behavioral data level, we found a rather sequential orientation in using the hypermedia material. Also, students with a surface-strategy orientation were more extrinsically motivated and more affected by test anxiety than students with a deep-strategy orientation. On the other hand, students with a deep-strategy orientation showed more nonsequential or linked processing and more frequent use of content
maps indicating better metacognitive resource management in the behavioral data. Navigational behavior could be interpreted mostly in terms of self-regulated learning.

It could be shown, that learning strategies and exploratory styles (linear or nonlinear navigational patterns) were relatively independent factors in the learning process. In pursuing learning goals, the exploratory mode is controlled by some other factors, e.g. motivation, prior knowledge or cognitive style preferences. A lot of students who had a rich prior knowledge base regarding the History topic, preferred a more direct (or linear) way of information seeking. The interviews which were conducted after the session, showed that these students had a deep-strategy orientation although the trace of the behavioral record showed more surface-strategies indications (e.g. linear proceedings). This fact shows that qualitative interview data are necessary to reach valid conclusions about behavioral learning strategy data.

We also compared learning questionnaire data with behavioral data gathered in actual learning situations. The results indicate significant gender effects in attitudes towards the computer. Generally, students who are more familiar with computers rated the task more positively. Our findings suggest also, that the learning strategies identified for learning with traditional texts are also manifested in hypermedia environments. Furthermore, we found that students approach a task in very different ways, depending on prior knowledge, abilities, motivation and learning style. The implications of our findings are discussed with regard to improving the design of hypermedia learning environments.

Internet-Based Telelearning: Architectural Support and Experiences

Alexander Schill, Katrin Franze, Olaf Neumann
Department of Computer Science, Dresden University of Technology, Germany
Tel.: +49 351 463 8261, Fax: +49 351 463 8251

1. Introduction

With the evolution of Internet services and distributed multimedia technology new tele-education facilities become feasible. This enables numerous new opportunities for students and universities: Courses can be designed in a more interactive way, lectures of specialists from abroad can be integrated into a regular curriculum, solutions to exercises can be submitted and be corrected online, and interdisciplinary work can be stimulated.

This paper first presents experiences with a teleteaching project between the Universities of Technology of Saxony, Germany, in Dresden and Freiberg. To enable flexible teleteaching support, three major scenarios are being implemented: (1) Broadcast of lectures: First, lectures can be broadcast online or batch-oriented to remote locations via the Internet. In addition to the audio and video of the lecturer, the teaching materials are displayed via shared applications. Internet tools such as mbone, and wb (whiteboard) serve as an experimental basis. (2) Interactive exercises: Secondly, exercises can be accessed via World Wide Web in an asynchronous way, and solutions can be sent back by the students (also from dormitories) via HTML forms, recently also augmented with animations based on Java applets. Some exercises can be corrected automatically using solution masks (e.g. for multiple choice questions), but most are corrected interactively. Feedback is given to the students by MIME (Multipurpose Internet Mail Extension) mail. (3) CSCW (Computer Supported Cooperative Work) in small groups: Thirdly, we offer seminars to small groups of students. The students cooperate performing special exercises, for example designing web pages for a virtual company.

2. Java Based Teleteaching Kit (JaTeK)

Based on our experiences gathered in our previous project, an integrated infrastructure based on Java has been developed recently for more systematic development and more runtime support of such scenarios. In this part, the paper presents the major characteristics of this „Java Based Teleteaching Kit“ (JaTeK).

The usage of the programming language Java makes it easy to develop platform independent software that is able to run with various Internet browsers. The installation effort of such a system may be kept quite low. Java enhances the functionality of the Internet in such a way that makes it possible to use this language for such complex teaching scenarios as the ones listed above that mostly can be supported by the JaTeK system: (1) Creation of online teaching material: JaTeK offers utilities for structuring the teaching material in chapters and subchapters, inserting the lecturing material into these chapters, creation of interactive exercises, and for glossaries etc. (2) Offering teaching material: JaTeK supports teaching material in various forms such as scripts, video and audio sequences, simulations animations, and links to important literature etc. They are structured into various chapters and subchapters and combined with hyperlinks. (3) Online interactive exercises: Students have the possibility to access exercises in an asynchronous way. Solutions can be sent back via E-Mail, HTML forms, and recently also augmented with Java Applets depending on the representation of the exercise. (4) Workgroup support: The system offers the possibility to work in groups over larger distances by using such functionalities like e-mail, and newsgroups that are used for asynchronous communication, and chat, audio and video conferencing, and whiteboard for synchronous communication. (5) Evaluation of the teaching process: The system offers two major viewpoints: the evaluation of teaching material by logging and monitoring various access data and the evaluation by gathering data from questionnaires.
3. Architectural Aspects

JaTeK combines three main modules that interact with each other and realize the mentioned features of the system: JaTeK as the core module implements integration of multimedia lecturing material, user administration, management of user groups, and several auxiliary tools. This module consists of two modes: the student's mode is for learning using the lecturing material, and with the tutor's mode it is possible to edit this lecturing material. JaWoS (Java Based Workgroup Support) offers various multimedia-based CSCW tools for interaction within small learning groups. Finally, Javal (Java-based Evaluation) implements tools and techniques for evaluating learning success, especially with respect to online exercises. The architecture of JaTeK represents a Client/Server architecture, e.g. as the basis component serves a JaTeK server that interacts with JaWoS servers, the Javal server, and all JaTeK clients running in the context of a browser on the student's or tutor's side. On data request from a client the JaTeK server connects to a database, retrieves the according material objects, and extracts the requested data. In the database all lecturing material and glossary items are saved as well as all exercise parameters.

4. Conclusions

In summary, it is obvious that today's multimedia facilities, network infrastructures and Internet services already enable rather sophisticated, interdisciplinary teleteaching scenarios. In particular, we often discovered that didactic questions and issues of presentation and user interaction are as challenging as the basic technological problems. The results of a questionnaire-based evaluation have shown that the acceptance under the students for such a Java based teleteaching system is quite high. This is mainly based on the independance of time and location of studying. We also recognized the important potential of user interaction within exercises and practical online courses: The system gives students the possibility of interactive exercises in form of special Java applets. These exercises allow students to solve problems by playing different situations (experiments) or trying sample solutions (online exercises). In this case the solutions are automatically corrected online. It has shown that the availability of interactivity intensely increases the learning achievements of the students. The presentation of the lecturing material also crucially affects learning motivation. So we became aware of the importance of layouting the user interface, of colors, fonts, font sizes, and structuring texts. Especially the student's remarks in the free-form sections of this questionnaire caused us to set more sensitive store by those points during the realisation of the user interface.

Our further work will concentrate on the realization of more interactivity in exercises and on tools that support the user interaction within working groups. Moreover the evaluation of the JaTeK system and the presentation of lecturing material will continue being an important area in our work.

1. Introduction

The number of medical CD-ROM releases such as electronic databases, computer based training and multimedia systems, textbooks and conference proceedings is continuously growing. Therefore these media should be considered important information sources besides traditional library services [Graham 95, Schatz 97]. They are especially important for students in Health sciences and for the continuing education of Health professionals [Barnett 95, Klar 92, Schulz 97a]. An outstanding added value of electronic media is the independence from time and space through on-line access. But only a minor part of these publications (mostly literature databases) are really designed for on-line access or multi-user operation on the basis of terminal emulation or client-server architecture. Besides HTML and JAVA™ based Internet-resident free publications that will not be discussed in this paper, virtually all commercial medical multimedia programs are developed for stand-alone microcomputer (today chiefly Windows™-PC) usage. A possible network installation – if ever planned – generally requires time-consuming client installation and maintenance and is mostly restricted to one platform architecture.

2. Methods

In the Freiburg University Hospital with more than 3500 PCs connected to the local network we installed hundreds of different PC software titles on a high-performance Netware™ file server, called INFOSERVER [Schulz 97b, Schulz 98]. In order to use it, only once a Windows™ based client must be installed. This menu client cares for the necessary modifications to the local configuration, the mounting of server volumes and the license metering, as agreed with publishers. This unorthodox approach of keeping all program and library files on the server and avoiding local registration and installation of the programs was possible with more than 90% of all acquired software titles. The rest was installed on a central Citrix Winframe™ server [Schulz 98] with sessions delivered to the end users via the ICA protocol. INFOSERVER is however limited to the University Hospital’s network with a homogenous PC / Windows™ platform basis. Due to the great demand for medical programs from outside this subnet access to medical software will be provided within the campus network in near future. As here different platforms (PC, UNIX, MAC, OS/2) must be supported, we decided to migrate totally to the new Windows NT terminal server technology that makes Windows NT sessions exportable through the network using platform independent JAVA clients. This campus-wide implementation of INFOSERVER, called INFOSERVER+, will be based on the technology [Winterer 98] developed at the Freiburg Computing Center. INFOBASE+ uses the NTrigue™ server technology and the Keoke™ Java Clients. It is already routinely used for the platform independent distribution of Windows™ and DOSTM based databases.

3. Results

The present situation is complicated by the purchase of the NTrigue™ technology by Citrix Systems Inc. and the licensing of the WinFrame™ multi-user technology by Microsoft. We will therefore wait for a definite solution in this process before putting the INFOSERVER+ project into practise.
Besides the routine experience with WinFrame within the running INFOSERVER project, we performed test installation of medical multimedia CD-ROMs in the INFOBASE+ environment. The results are promising, but multimedia performance is still a week point, due to the limitations of network bandwidth and the performance of the JAVA clients. Sound is not yet supported. Printing on local printers can be realized by the transfer of PostScript files to the user. The following table shows a first comparison between the two approaches:

<table>
<thead>

4. Conclusion

The personal computer paradigm that may be outlined by "one CD-ROM, one program, one user, one machine" must be considered obsolete in corporate and campus networks, where a user-friendly on-line access to all electronic media should be taken for granted. We demonstrated the feasibility of delivering Windows based CD-ROM titles from remote application servers to multiple platforms. Compared to the traditional LAN approach with shared file systems the new terminal server technology seems to be more promising because clients are platform independent, there is no interference with the local machine and the file system is more protected against unauthorized access. Without any doubt, distributed client/server solutions might be preferable, but nothing indicates that commercial multimedia publishers will adopt this technology in near future. We expect that the present deficiencies in NTT™ terminal server technology will be overcome due to future improvements in bandwidth and JAVA performance.

Professional Taxonomies and Instructional in Information Systems:
Linking Educational Practice to Student Goals

Don Sheridan
Director, Management Teaching Technology Unit
School of Business and Economics
The University of Auckland
Private Bag 92019
Auckland, New Zealand
Email: d.sheridan@auckland.ac.nz

1. Introduction

The University of Auckland with an enrolment of 25 000 students shares with other tertiary educational institutions the vision of providing life-long learning for its students while attempting to deal with the current restraints on budget and a lack of progress toward optimal use of technology in teaching and learning. The Dearing Report (Dearing 1997), a comprehensive, 1700 page document laying out the situation of tertiary educational institutions in the United Kingdom, has been carefully examined here and its recommendations for expenditures on resource base learning (RBL) and increased use of technology noted with optimism.

The School of Commerce at the University of Auckland has developed a computer-supported learning system (CSL) that is now in its third year of operation and delivers browser-based assessments and other learning materials to more than 10,000 students in business, and the sciences. On a weekly basis CSL generates many thousand unique practice sessions and quizzes, sends out hundreds of diagnostic email messages and at times is processing more than 300 transactions per second. We have been asking ourselves how we can use technology like CSL to forward our goal to provide life-long learning.

The model curriculum for information systems, IS97[Davis, et al, 1997], is the culmination of more than twenty years of work by world experts and could be adapted to represent our student's goals, our curriculum, the model curriculum and the IS profession.

This paper will report on our research efforts to make IS97 a live link to courses of study, and papers (a single class). Our initial work using Apple's Project X (Hot Sauce) and its attendant graphical representation will be compared with a conventional database solution using Access an implementation of IS97 in Hyperwave™ and a consideration of Th!nkmap™ as an alternative method of representing the taxonomy.

2. Bodies of Knowledge

The body of knowledge (BoK) for information systems, IS97, is made up of 209 knowledge elements classified under 3 topics and 27 subtopics. The depth of knowledge expected of a student for each knowledge element is stated using a system similar to Blooms Taxonomy of Educational Objectives (Bloom 1956). The depth of knowledge varies with the course level and course content. Aggregations of knowledge elements form learning goals and learning units. Learning units are grouped to form 11 separate courses that make up the model curriculum.

Thirty-five Diploma in Business students (first year MBA equivalents with a mean of five years IT experience) were surveyed to determine what value they might ascribe to a body of knowledge in IT. The results were a very positive endorsement of a BoK to assist them in bench marking their courses of study with current job descriptions, the goals of professional IT organisations, and their current personal skills and knowledge in their profession.
One hundred seventy first year business undergraduates were surveyed to determine the value they might place on accessing a BoK in IT. This group strongly endorsed using a BoK to ascertain the relevance of course content and examination questions, as well as for planning their course of study and assisting them in comparing the university's offerings with a professional association's recommendation for a course of study.

Both student groups perceived a long-term advantage to having a personal BoK, and access to a BoK based upon the university's IT curriculum and a BoK maintained by practicing professionals. Given these various taxonomies an alumnus could determine what developments in the field indicated a need for professional upgrading by comparing their BoK with the university's BoK. Universities that maintained links with their alumni could proactively identify areas where short courses could be of benefit to former students. Practitioners who had developed niche specialisations or who received corporate training could build new knowledge elements into their BoK.

3. CSL + BoK

The computer supported learning system (CSL) used at Auckland University is based upon a database of more than 200 tables and 800 attributes. Access is via an Internet browser whether at home, work or at the university. CSL delivers active pages generated by MS ASP + COM objects from an SQL database engine mounted on an NT Server (Sequent NTX 2000). All students enrolled in the university are automatically loaded into CSL and have access through a universal ID and PIN, the same used for telephony services. CSL is used by a number of faculties and departments to provide access to teaching resources, on-line assessments with diagnostic feedback and course marks. Many academics use just the Gradebook feature since it can be loaded by tutors marking at home while on the Internet, or batch loaded from OMR sources.

IS97 has been converted to an MS Access environment and links to the CSL SQL database (questions, reference texts, and courses of study) explored. Portions of IS97 have been created in Hyperwave to exploit its multi-collection hierarchy. The greatest challenge is the representation of the inter-relationships among knowledge elements whether within a single course, a curriculum or the professional taxonomy. To this end Thinkmap and other graphical representations of a networked database appear to have potential.

Thinkmap has attracted our attention in particular since it allows one to visualise complex interdependent information without carrying with it the overhead of a major quantitative compute engine. Being able to evaluate the data from multiple perspectives and use standard SQL is a substantial advantage for us. Since Thinkmap maplets are Java applets that interface directly with the data in real time, navigating the curriculum results in the display changing dynamically.

This paper will report on the status of our research into providing a visualisation of the model curriculum, IS97, in the context of a computer-supported learning environment that contains an institutional curriculum complete with student achievement data.

Dynamic Generation of Customised Documents

D.B. Skillicorn, H. Yan and X. Yu
Department of Computing and Information Science
Queen’s University, Kingston, Canada
skill@qucis.queensu.ca

1 The Customising Problem

In many training and education applications of hypermedia, it is desirable to present material at different levels, and in different styles, matched to the learning styles of users [Skillicorn 1996]. Doing this by explicitly preparing multiple versions of the content is tedious, and creates consistency problems.

We present an approach, based on a two-stage filter, that allows a single copy of each document element to be maintained. The first stage is a generative filter. It uses both inclusion and automatic generation to transform a base document into a version that includes many different optional pieces. The second stage is a selective filter. It makes a choice from among the many different presentations implied by the document constructed by the generative filter, delivering the one selected by the user at that moment. The advantage of using a two-stage process is that the boundary between generation and selection need not be statically defined. Moreover, users select the presentation they desire dynamically for each page, and they can therefore adjust it based on their understanding at the moment of encountering the material.

2 Two-Stage Filtering

An important requirement for practical construction of courseware is that there should only be one copy of each element. For example, program code is often included in the courseware for programming courses. The easiest way to check that it has been correctly written is to compile it. Existing systems typically require the program to be embedded in an HTML page, from which it is clumsy to extract it for compilation. Two presentations of the same content pitched at different levels may contain substantial common text. It is hard in existing systems to avoid replicating this text.

The first stage of the filtering process is a generative filter which provides a general inclusion mechanism, and automatically generates semantically-placed tags.

Existing systems take two different approaches to tagging, neither of which is completely satisfactory. Closed systems, such as Hyperwave [Kappe et al. 1993][Maurer 1996], keep documents under their control, removing tags to separate linkbases whenever documents are created or edited. This makes it possible to be clever about which links are rendered, checking, for example, if the destination exists. However, documents can only be created or edited in ways sanctioned by the hypermedia system, which is restrictive. Open systems, such as Microcosm [Davis et al. 1993], permit users to control their own documents. However, it is then impossible to be sure that linkbases are consistent with documents.

The best of both of these approaches can be achieved for tags that can be generated semantically, that is whose positions can be inferred each time the document is served. There is no need for linkbases, and hence no need for the filter to know if the document has been altered since it was last served. A tag at the beginning of each document informs the generative filter which operations it should apply to the document.

Some of the semantic tagging possibilities that we have investigated are:

Automatic linking to glossaries. It is common, in presenting technical material, to provide definitions of terms, by making each occurrence of the term an anchor to a definition. Inserting all of these anchors manually is extremely cumbersome. The generative filter inserts such links automatically. A list of appropriate words, URLs of definition files, and priority levels for each one are provided to the filter separately. As the generative filter processes each page, it inserts an anchor around each occurrence of a word on the list, labels it with a priority, and links the anchor to the appropriate definition file.

Automatic Table of Contents. Especially in large documents it is useful to have a means of getting an overview. The generative filter produces tables of contents automatically by looking through the document for text enclosed in header tags, copying it into a hierarchically nested list at the beginning of the document, and making it a source anchor, pointing to the occurrence of the header within the document.
The second stage of the filtering process is a selective filter. In the present implementation, this uses a simple linear threshold to remove elements from the document it receives from the generative filter. Any element of a document can be optionally labelled with a priority. Each user defines the current priority threshold, and the selective filter removes elements whose priorities are below the current threshold (and their descendants) before serving the document.

There are two distinct types of priority attribute that may be included in any structure tag. Both allow the structure to be assigned a priority between 1 and 10, where 1 represents the most detailed information and 10 the least. The priorities differ in what they imply about structures that fall below the threshold. Content priority structures are removed from the document entirely (together with any substructure they contain) if their priority is below the current threshold. Tag priority structures have their tags removed but the content between them remains in the document.

For example, glossary words can be labelled with priorities in different ways.

The first occurrence has high priority, and subsequent ones have low priority. Using a high threshold means seeing definitions only once.

The first occurrence has high priority, and subsequent ones have priorities that steadily decrease. Using a high threshold means seeing the first few occurrences of the definition.

The first occurrence has high priority, and subsequent ones have priorities that begin low, but increase steadily with distance in the text, cyclically. Using a high threshold means seeing the definition at equally-spaced intervals in the document.

The selective filter inserts a set of buttons in each page that it serves. Clicking these buttons generates URLs that are intercepted by the selective filter and interpreted as requests to change the current priority threshold. Of course, structures without priority tags are always displayed.

3 Discussion

We have achieved the goal of only having one occurrence of each distinct element, which can be included wherever appropriate. This significantly reduce the overhead of generating courseware. Much of the structure that is pedagogically useful, but tedious to insert by hand, is inserted automatically. Such structure is inserted independently of other changes to documents, so that courseware can be freely altered without requiring subsequent consistency checking.

Decoupling the process into two stages gives more flexibility. It is possible, for example, to experiment with generation techniques that are overly verbose, because the downstream effects can be removed by the subsequent filter. For example, generating all-to-all links between occurrences of a key term produces too much information to be useful in the majority of cases. Our system makes it possible to tag forward links with one priority and backward links with another, so that users may see some or all of the possible connections, and alter their view depending on the results for a particular document.

A linear ordering of thresholds means that we can customise documents on a continuum from novice to expert. We cannot yet customise for different learning styles. This is not technically difficult given our approach. It is possible that structures, all of whose substructures have been filtered out, will still be rendered even though they are ‘empty’. There is no easy solution to this. For example, it would be easy to detect a list all of whose elements had been filtered. It is much less easy to detect the paragraph preceding the list which contains only a simple introductory sentence (“Some examples are:”) - and in this case removing the list but leaving the paragraph is arguably worse than leaving the empty list.

From Video-Conferencing to the Cybercafé: Membership, Performance and Online Learning

Dr. Marshall Soules, Coordinator Media Studies, Malaspina University-College
Nanaimo, British Columbia, Canada
soules@mala.bc.ca

In the Spring 1996 semester, Malaspina University-College offered its first distance education courses using video-conferencing technology. Four courses were offered to participants in Nanaimo, on Vancouver Island, and a satellite campus in Powell River on the British Columbia mainland. We employed switched-56, compressed video-conferencing technology (PictureTel PCS 100 from Adcom) in a Windows environment. The compressed video and audio signals posed on-going challenges for instructors and course participants when it came to such subtleties of communication as facial expression, body language and gestures, and a sense of timing in discussions. These challenges were compounded by occasional instability in the application sharing software (LiveShare), and instructors began to build redundancy into their methods of delivery. I learned to use web-based methods to provide lecture notes, resources, demonstrations, and a discussion forum for both remote and local course participants. This was especially important for the remote students, who expressed their desire to be given as rich an educational experience as the students in the source classroom.

The four courses were extensively evaluated by Norm Dolan, an external evaluator, in Interactive Television Course Delivery (1996), and the results were summarized in my Enhancing Capacity with Video Conferencing (Soules 1996). One of the significant conclusions of our research is the importance of establishing a sense of membership for participants in distance courses. Evaluation made it abundantly clear what common sense might lead us to expect: that students in the remote site “appear to have greater difficulty establishing a strong sense of membership in the experience, than do students in the host site” (Dolan 1996). What might not be as obvious is the discovery that student satisfaction and success are highly dependent on this sense of membership, or engagement by the learner in the educational process. Our research found, for example, that unlike the membership construct, the technology itself does not lead to high satisfaction rates: once the purpose of establishing clear and reliable communication has been met, further efforts to develop more sophisticated systems are not likely to result in more student satisfaction. Similarly, once basic student support services have been provided, more elaborate administrative functions do not significantly increase student satisfaction or success.

After considerable discussion between instructors, project coordinators, and the evaluation team, we formulated the following broad parameters designed to promote membership in distance learning, especially as it relates to video-conferencing technology (Soules 1996):

1. Course materials should be prepared to take into account not only the constraints and characteristics of the medium, but also to engage students successfully at the remote site. The level of structure and preparation required for distance delivery generally exceed that required in face-to-face settings where the instructor can rely on spontaneous interaction to enhance the learner’s degree of engagement.

2. Learners should be able to communicate easily and reliably with the instructor and the students at the other site. The instructor should take active measures to communicate personally with each student and subsequently to confirm the communication with the student. We established guidelines, or protocols of communication, which tended to formalize interactions until all course participants, including the instructors, found that the guidelines actually contributed to greater confidence and spontaneity.

3. The instructor should develop a learning environment in which individual students develop a sense of working cooperatively with peers in a meaningful activity. Engaging students in the active use of the medium of delivery will help them overcome their reticence and increase their confidence.
Besides our discoveries showing the important correlation of membership with student satisfaction and success, as instructors we found ourselves in a new performance medium: the distance education "classroom." I use the word "performance" here advisedly because the presence and demands of the technology tend to shift the instructor's focus toward delivery concerns and an acute awareness of the needs of the audience. The confidence we may have in addressing and reaching our audience in the traditional classroom is de-centered in distance delivery. Our presence is mediated by the human-technology interface which provides a new kind of performance medium, and not necessarily the stage we are used to.

Since the original video conferencing project, I have continuously offered web-based, online courses in Media Studies and Computer-Mediated Communication (see http://www.mala.bc.ca/~soules/). In the delivery and content of these courses, I continue to explore the performative aspects of participation in this learning environment, and how performance relates to membership. In Protocols of Improvisation and Online Communication (available online at http://www.mala.bc.ca/~soules/improv1.htm), I describe how the particular performance style associated with improvisation has many points of reference to online learning. Following Laurel's analysis in Computers as Theater (Laurel 1992), I suggest that the human-computer interface is not only essentially dramatic, but also requires a considerable degree of improvisation for its successful negotiation. A study of cross-cultural practices shows that the play of improvisation occurs within a matrix of constraints, or limitations, and these limitations can be considered "protocols of improvisation" (Soules 1997).

In the design and delivery of my online courses, I encourage learners to explore the medium of interaction by researching its history and writing about it as a medium of communication. Assignments have precise parameters regarding method of presentation, but they require learners to solve problems that they help formulate. Students are encouraged to learn computing applications from one another as well as from me. I have had most success in promoting membership, however, with a series of online journals featuring the writing of course participants. It has been extremely gratifying to see the improvements in writing quality when students write for one another, and for publication on the WWW. The traditional one-to-one writing relationship between student and instructor is redefined to become one-to-many, and this shift in broadcast model has, in my experience, a profound effect on the performance of learners in online communication.

In June 1997, my proposal for the Cybercafé Project at Malaspina University-College was funded to provide an alternative model of support for students and community members wishing to learn about computing, especially online applications. Unlike conventional computer labs in many post-secondary institutions, the Cybercafé encourages interaction between participants, experimentation in the learning process, and the networking of expertise in a "learning community." We use drop-in fees to regulate access to one of the institution's networked computer labs. Student facilitators are available to help users with their computing questions, to suggest alternate resources, and to foster the development of a non-hierarchical, stimulating, and safe learning community. The Cybercafé Project attempts, in short, to model constructivist learning principles.

The Cybercafé Project provides more than an alternate model of support for educational technology—something learners need when they begin to go online to accomplish their instructional goals; it also reflects on such institutional protocols as access to labs and the policies used to regulate them. This project attempts to address the interrelated issues of membership and performance in the context of computer-mediated instruction and online learning.

An Instructional Design Framework for System Dynamics Based Learning Environments

J. Michael Spector, University of Bergen

Abstract: System dynamics provides a powerful framework for the development of highly interactive learning environments for complex domains [Forrester 85; Sterman 88]. There is significant potential for improved learning in and about complex systems using system dynamics due to the ability to represent complexity in a visual form, to link that representation to visual and quantitative behavioral descriptions of complex systems, and to engage learners in the re-design of the underlying model based on a process of hypothesis formulation, experimentation, and validation.

Traditionally, system dynamics based learning environments have been called management flight simulators and contain three types of learning activities: preparatory tutorials and explanations, interactions with the simulation, and debriefing sessions [Richmond 93; Sterman 88]. The basic idea contained in this structure implies a particular approach to learning with some elements drawn from a constructivist perspective and some from an instructivist perspective. The designers of these learning environments are not generally aware of having adopted a particular learning theory or design perspective, yet they are inclined to make strong claims about potential learning outcomes [Sterman 88]. The evidence is mostly anecdotal, however. The learning effectiveness of these environments is not well documented nor well established [Mandinach & Cline 94]. As a consequence, there is not a well established methodology to guide design and implementation.

There are two missing links in the design of effective system dynamics learning environments: a firm and explicit foundation in learning theory, and a tight coupling of that theoretical perspective with the disciplined practice of instructional design. These deficiencies have resulted in the following kinds of problems: (1) inadequate attention given to preliminary learning and to learning transfer activities; (2) high variability in the preliminary learning environment, during the group interactions, and in the transfer activities; (3) lack of integration of the various learning activities; (4) inaccessibility of the underlying model without sufficient elaboration; and/or (5) inadequate preparation for the complexity of the underlying when provided.

The hypothesis of this research stream is that learning in complex and dynamic domains can be facilitated by the adoption of a version of cognitive apprenticeship [Collins, Brown, & Newman 89] which integrates a sociohistorical perspective [Spector 1994]. This emphasis on cognitive apprenticeship in a collaborative learning environment, implies an instructional design framework well suited for the management of complexity. Specifically, a process of graduated complexity consistent with elaboration theory [Reigeluth 83] is useful in developing an overall macro-level sequence to help learners come to grips with the various kinds of complexity in these domains and systems.

In addition, the design model provides computer-based preliminary tutorials to eliminate the variability of human tutors as we explore the learning effects associated with various versions of the interactive simulation experience. Some versions include an elaboration scheme which gradually elaborates a single case in increasing levels of complexity, focusing first on selected model components and the manipulation of a single variable and later on the entire model and its re-construction according to alternative conceptualizations. An alternative line of elaboration introduces many different cases before proceeding on to more demanding forms of interaction. Within these major sequences, we have placed versions which support small group collaborations and others which engage learners in isolated learning experiences.
The primary change within the system dynamics based portion of the learning environment is that learners are allowed to see the underlying model as they reason about the behavior of the system and its responses to various changes in variables. Because these models are depicted visually, learners are provided early scaffolding with regard to the various feedback loops and delays in the system. With the simpler cases, it happens that identification of the dominating feedback loops and associated delays is crucial in formulating reasonable decision policies.

As learners become more sophisticated in their reasoning, the notion of learner immersion is introduced. Immersion in these environments comes about by having learners play various decision-making roles, eventually empowering learners to re-design key portions of the complex system. For example, a particular decision policy with regard to hunting in a predator-prey model may alter the nature of a feedback loop or it may introduce an entirely new feedback loop. Small groups are formed within classes, sometimes at a distance, since these environments can be deployed in internet settings. The small group interactions between simulation runs appear to be crucial to learning effectiveness in these environments. When learners are denied opportunities to discuss the simulation results, they report significantly more difficulty in formulating explanations for the observed results and they do not score as well on simple posttest exercises.

Teaching Web Site Design + Development on the Web
Creating an Educational Paradigm to Empower Student Centered Learning Utilizing the WWW

Cary Staples
Department of Art
University of Tennessee, Knoxville
1715 Volunteer Blvd.
Knoxville, Tennessee, USA
staples@utk.edu

There are several difficulties to be overcome in preparing to teach a class about the Web, utilizing the Web. First is the changibility of the Web itself. Class preparation requires prior planning, however, by the time the instructor gets to a specific unit, that information may have changed. Second is the student's expectation of a "class" and their role as a "student". Finally, the role of the teacher or instructor is different. The instructor can no longer be responsible to be the technical "expert". There are simply too many different sets of knowledge required. It is equally inappropriate to ask an instructor to learn the material one week ahead of the class; this creates a very tense situation.

The solution to dealing with these issues is to change the expectations and definitions of a "student", a "teacher" and a "class". We created a class where the students became their own teachers, I call them learners, and the instructor directed, or facilitated, the individual research. The learners entered the class understanding that the answers today may not be the answers tomorrow. Each learner was helped to set up an individual system for seeking out and discovering innovations in hardware and software. Learners were then required to bring that information to the class. To teach the class with the idea that the teacher had all of the answers, indeed to allude to the notion that there was a "right" answer, would have been dishonest. The result of this process was that the students entered the experience expecting things to change rather than becoming upset by change. In addition, when the students left the class they were prepared to continue learning without the instructor.

At the onset the Web is very effective at helping to dispel the traditional teacher/student paradigm. The Web allows each student to develop a different "answer" to a common question. This creates a unique situation for discussions and insights about content and the effect of presentation on the interpretation or meaning of information.

To begin, we created a Web site to serve as a template to teach the class. The site was divided into conceptual and concrete information areas. The first area of the site housed concrete information: a class list, links to student pages, tutorials and the resources section which contained links to other resource sites. The second area housed the conceptual component including discussion topics, class feedback and a critic forum for outsider input.

Some of the issues that we addressed in the design of the teaching site include:
- the information presentation. Information was organized to be helpful to non web literate students and to build upon their previous educational experiences. We hoped this would build confidence.
- the site design itself. We thought the design needed to reflect good design practices without being "over" designed. The site was engineered to load fast. The primary screen allows the user to choose from a site outline and this outline is available from any point in the site. This was to prevent the user from getting lost and frustrated.
- the tutorials were designed to be printed and bound as a resource, not to be read on screen.

From the beginning the class had two diverse goals. For learners interested in becoming proficient in Web design, the class would introduce them to the skills that they needed to develop and expose them to the design issues that related to communication on the Web. For learners interested in becoming literate about the Web, but not interested in production issues, the class would provide them with
insight about the possibilities and limitations as they related to Web design, as well as give them a vocabulary and a frame of reference to work with Web designers.

For this project we encouraged the learners to address issues that would be relevant to the study of design and professional designers. We created the problem of how to encourage visual designers (practicing print professionals) to work on the Web. Because the Web is such a dynamic media, many designers have not had the concentrated time necessary to become literate about Web design restrictions. And when they do, the restrictions change. In the process of learning to design for the Web, the students created a site that attempted to educate professional designers about design for the Web. The site became a documentation of the creative process as it relates to design.

The site outline existed at the beginning of the class and acted as a template for the actual research. We broke the experience of learning about the Web into three levels. First we asked the learners to redesign an existing site. Second, we asked the learners to design a Web site for an existing data set not currently represented on the web. Learners were asked to research existing music sites as well as the recording artist(s) and design a site that created a visual experience that paralleled the music experience. Finally we gave the learners a conceptual design problem about legibility. This created a discussion about typographic issues and information visualization on the Web.

Several of the issues that we hoped to encounter included:

Even though the learners were working in an entirely new medium, they were still able to apply the design principles that they had learned in previous classes.

Several of the learners made major errors as they were working and their classmates supported them and helped them to recover.

The learners were willing to try to find their own answers to programming questions before asking the instructors.

The learners gained respect for their ability to learn on their own and saw the value in developing a working style that included constant learning.

Several unexpected issues that we encountered included:

The learners gained respect for the complexities involved in getting a design project to print and became more willing to view the production process as creative.

The learners gained confidence in their own ability to teach and relate to professionals, in addition to respect for the place they can occupy in the design community.

Due to this professional insight, the learners gained respect for the accomplishments of the practicing designers.

Class projects were critiqued in a traditional classroom manner. Critique insights were posted to allow visitors access to the designer thought process. Projects include a site map in addition to a design brief. This was meant to help visitors see the difference between intention and reality. Concluding insights were also posted to allow viewers to understand the analysis aspect of the design process. Outside reviewers were invited to critique the student work and offer additional observations. We hope, in the future, critiques will be able to be carried out on line in a more dynamic environment.

Another feature that was built into each “project” on the site was a timer that would disclose the amount of time each designer has spent creating that particular site. This will help practicing designers, as well as prospective clients, estimate the amount of time necessary to generate a project.

The tutorials were lectured about in class and general programming concepts were addressed. The learners were expected to post their work and check the site and their e.mail for information and feedback. While this class was not designed to occur entirely on the Web, that is the obvious next step. The dynamic discussion that occurred during the critiques was very informative and never could have been pre determined. If this were to become a totally electronic class, a system to facilitate the face to face dynamic of the critique would need to be incorporated.
By changing the role of the teacher from information giver to learning facilitator two things happen. First, the responsibility of having to know all of the information is removed from the instructor and second, the students learn how to learn as opposed to learning “the” information.
Multimedia-Based Environmental Science Education: From Local Use to Broad Dissemination

Multimedia-Based Environmental Science Education in a Planetarium

In the last 30 years, the image of the whole earth as seen from outer space has served as a cross-cultural symbol for the uniqueness and fragility of our home planet. Based on this image of our home planet, the planetarium in Freiburg is currently developing multimedia shows about global environmental issues. The pilot project aims to convey scientific information that fascinate and hopefully provoke interest and a fresh perspective on environmental issues. Particularly suitable environmental education topics are those of global scale, which are based on solar-terrestrial relations. Some examples include the ozone layer and its depletion, the greenhouse effect and global warming, the role of the sun’s radiation in the development of life on earth, and modern uses of solar power.

As a setting for science education, communication and entertainment, a planetarium has many advantages:

- It is an unusual and fascinating place to visit [Marshall, 1997].
- With a plethora of special video and audio effects, including the projection of a bigger-than-life starry night, planetaria shows are both deeply moving and highly informative.
- People expect science education in a planetarium and are, therefore, more willing to be exposed to science.

Creative, well-designed multimedia presentations (in a planetarium) grasp audience interest, thereby easing the learning process, and providing motivation for further learning [Apel 1997; Grasel and Mandl 1997; Weidenmann 1995]. A survey study indicates that environmental multimedia shows at the Freiburg planetarium sparked audience interest in the topics that extended beyond the show. Unfortunately, planetaria only reach a limited, mostly-local audience. It would be beneficial if the time-consuming intermediary steps in the production of a multimedia show could be re-used to impact a broader audience. At the Freiburg planetarium we explored the various means of disseminating information broadly with little additional manpower. Two productions have provided the thematic content and the media for (i) two article series, (ii) four radio broadcasts, (iii) a CD-ROM, and (iv) an internet presentation. The following discussions describe the four types of media in terms of the ease and effectiveness with which they re-use multimedia material originally created for the planetarium shows.

Authoring Systems in Science Education: a User’s Perspective

The Radio Broadcast

Broadcasts that directly incorporate the shows soundtrack with minor editing have been successful. The advantages of a radio show are: (i) little technology involved, (ii) minimal production time, (iii) a potentially wide audience. The disadvantages are: (i) particularly complex issues are difficult to convey as visual aids are missing, (ii) people need to listen closely if they want to follow the show, (iii) lengthy radio shows are difficult to place into the broadcasting system.

The Article Series

Only minor revisions are necessary to create free-standing text from the script of a planetarium show, and graphics from the show can be directly imported to complement the text. However, video clips and computer animations need to be replaced with stills. Advantages are the ease of production and the wide use and availability of print. However, placing articles on environmental science written for a lay audience is difficult.
Electronic Publishing

This section compares a traditional style CD-ROM production, which uses the Windows 95 based authoring system Toolbook with a Whiteboard authoring system called Authoring on the Fly [Bacher et al., 1997] that electronically records a lecture and its respective visual aids. Both authoring systems have the following features in common:

- They combine sound, text, pictures, video, and animation to convey information in a multicode and multimodal way.
- They require far more time and effort to produce than either an article series or a radio broadcast.
- They are less readily available to a potentially interested audience (computer technology is necessary).
- Given the up-front investment in computer technology, both are relatively expensive to access.

Traditional Style CD-ROM Production

Text and visual aids from two planetarium shows provided the CD-ROM material. The product was certainly the most appealing of all four dissemination types, yet:

- Adapting the text from linear storyboard to hypertext, reformatting the media material and the design of the CD-ROM itself were time consuming.
- The Editing and revisions necessary to produce the final version took up considerable time of the author.
- Close cooperation of collaborating content specialists and technical specialists was necessary, as the media designers who designed the CD-ROM had limited understanding of the content (as the case often is).

The advantages of a CD-ROM production are apparent:

- The final product is easy to use, well designed and appealing to students and lay audiences alike.
- The CD-ROM can be run on any Windows-based computer with a CD-ROM drive and a soundcard.
- Given all the color graphics, video clips, and computer animation, the CD-ROM is closer to the original multimedia presentation and, therefore, generates more of the original fascination.
- The contents of the CD-ROM can easily be placed on the internet.
- Like other types of electronic publishing, all charts, graphics, photographs, animations, and video-clips on the CD-ROM can be made available as teaching material.

Authoring on the Fly

Authoring on the fly (AoF) enables an educator to produce independently an electronic version of the work. The Whiteboard system has a range of advantages over the traditional style CD-ROM production:

- Little additional effort goes into preparation of the electronic presentation (a lecture held on a computer); production is therefore extremely fast.
- The author has total control over the product.
- Spoken words (the text) and visual aids are perfectly synchronized, even during scrolling.
- The recording can function as the backbone of a traditional style CD-ROM production: AoF-based presentations can be used to complement a traditional style CD-ROM by hyperlinking the presentation with written text and vice versa.

The AoF system is ideal to record a complex lecture for teleteaching, and unlike a CD-ROM production it requires almost no technical expertise. However, this authoring-on-the-fly system is still in the experimental stage and, therefore, not yet commercially available. So far, it requires a UNIX-system to operate and run (a Windows NT version is currently in preparation). The sheer size of a single AoF document (can be more than 100 Megabytes) makes internet transfer difficult at the moment. Still, from a user's perspective it is an extremely promising method for future science education.

Guidance and Personal Guides in Learning with Hypermedia

Robert Strzebkowski
Free University Berlin
Department of Media Research, Germany
E-Mail: strebi@zedat.fu-berlin.de

Abstract: The contents of many computer assisted multimedia learning environments realized on CD-ROM or the Internet is arranged in a hypermedia structure. It can be expected that particularly through the growth of Internet (WWW) based telelearning applications hypermedia becomes increasingly an important platform to deliver content and to be used as a cognitive tool. Hypermedia seems to be suitable for supporting the new constructivistic way of active and selfregulated learning. However, recent results of research in the hypermedia area have revealed some problems regarding to the use of hypermedia for learning purposes. In particular novices in the subject matter area who don't have adequate knowledge structures in that field as well as learners without advanced learning techniques have difficulties during the learning process with hypermedia. These problems are mainly known as 'loss of orientation', 'cognitive overload' and the lack of appropriate competence in dealing with hypermedia and for constructive selfdirected learning. This paper will discuss the use of 'personal guides' as a possible help and coach function to reduce the mentioned hypermedia problems.

Hypermedia as a constructive learning environment

Hypertext and hypermedia were originally created to handle large amounts of information in a flexible and dynamic way. Only later they were adapted for the use of computer based learning. The Internet and World Wide Web as the biggest hypermedia system today were not developed for learning purposes either, but for fast information exchange between the users. Several experiences and investigations have shown that hypermedia is more suitable to be used as an associative multimedia database or as a cognitive and learning tool than as course software with clear defined learning goals like computer based training or tutorial systems. Therefore hypermedia is an appropriate media and tool for supporting constructivistic learning environments. The possible activities in hypermedia environments could be browsing and searching for wanted information, collecting information, constructing own subdocuments or new hypermedia documents, exploring a topic from different points of view and learning from different authors in an associative web. The use of hypermedia learning environments is convenient if the subject matter is very broad and has no clear structure, like History, Medicine or Physics. The hypermedia program "THE WORLD FORMULA", which we have created at our research unit as an experimental platform is a physics program and deals with the topic of four basic forces, and with the attempt to describe these forces using only one mathematical formula. In the program are integrated the common hypertext functions like index, map, history function etc. and a notepad which is also a small cognitive tool and allows the students to gather text and pictures from the main program, modify the textes and to build an own small hyper-subdocument of this material.

What are the Problems of learning with hypermedia?

The experts in the particular subject matter are able to take advantage of direct and associative access to the information in hypermedia. They can enlarge and modify their knowledge base effectively. Many studies on learning with hypermedia report that novices - both in the subject matter area as well as in the use of hypermedia

1948
systems - have encountered manifold cognitive and ergonomic problems when using these systems for the first time. One of the central tasks during learning with a hypermedia system is the process of making a decision about the next step and the next action in the hypermedia environment. This decision-making process and the freedom of choice were seen in the early days of hypertext and hypermedia as an important pedagogical factor and advantage for an active and explorative learning process. Meanwhile numerous investigations have shown that this freedom of choice can also be an obstacle in such learning process. The reason is that the learner invests a lot of cognitive capacity for such strategic considerations instead of using it for the assimilation of new information. Conklin [Conklin 1987] subdivided these problems as Cognitive Overload and Disorientation. Cognitive Overload is the result of the three following aspects: the informational myopia, the serendipity effect and the context partition (dilution).

Learner control, learning strategies and hypermedia-Literacy

Hypermedia is a learning environment that is very strongly learner control oriented. The large extent of learner control requires a high level of self-regulation and metacognitive abilities in the learning process because the learner has to make decisions by himself during this process. Numerous studies have shown that students with a low level of metacognitive skills have more problems resolving problem oriented tasks and also in learning with hypermedia systems in general [Hammond 1993].The hypermedia tasks require a certain level of hypertext literacy. Therefore it is important for the user and in particular for novices to acquire learning strategies for hypermedia environments. There are prerequisites for learning with hypermedia:

- competence for effective use of hypermedia documents and environments (hypermedia literacy)
- competence for creative and constructive learning
- competence for selfregulated learning (effective learning techniques and metacognitive strategies)
- competence of content
- competence for team work in online environments

Tergan [Tergan, 1997] argue, that most students cannot use effective the complexity of hypermedia systems and need explicit modelling and scaffolding support as well as more experience in using hypertext-based technologies for constructive learning.

Personal Guide as a possible help for hypermedia-problems

In my research, I've chosen to examine the potential of personal guides to help reduce the above-mentioned problems in the hypertext and hypermedia learning environments and to enhance the motivation and acceptance by using such learning systems. One of the main functions is to support the user by building competences for effective use of the hypermedia program (e.g. effective use of the notepad as a cognitive tool) and for effective learning strategies. The guide is an anthropomorphic character as a help function. It can be called by the learner at any time in order to provide answers to a variety of questions. The guide can also carry out a variety of tasks, totally related to the learner's interests and approach of working his way through the hypermedia program. The main idea is to combine a trace, a database and content-support functions with a lot of different appearance forms of the guide. This way the user has the feeling of different, situation related reactions of the guide figure and the outward appearance does not repeat. There is no claim to make the guide an 'intelligent' one like an agent. However, it is interesting to see if the combination of the functions scope and the way of appearance form will give the user the impression, there is some form of 'intelligence' behind the guide.

These are the desirable and partly realized functions of the guide:

- a consultant who helps in the development of a learning strategy by giving tips and examples of efficient ways to use the program,
- a presenter who summarizes the highlights of the content, both of the program in general, and of the specific pages,
- a navigator who gives orientational aid to the learner as she or he works through the program, and provides glimpses of topics related to the current subject contained elsewhere in it

1949
- a coach who - after tracing and recording the learner's steps - proposes alternatives for how to proceed, and -
if the learner appears to be staying away from the chosen route - provides a gentle nudge to go back in the
right direction.

Evaluating Software Ease of Use based on Speed, Memory, Effort, Comfort

Jennifer D.E. Thomas, Ph.D.
Pace University, School of Computer Science and Information Systems
1 Pace Plaza, N.Y., N.Y. 10038, Email: thomas@pace.edu

INTRODUCTION

As training costs to companies increase, the issues surrounding evaluation of the various business software solutions available to them become more and more critical. The problem is that the basis on which to make this assessment is not straightforward. There are two main subjective approaches which may be used when trying to assess the effectiveness of various package design factors in achieving ease of use. These can be based on:

a) characteristics of the package - degree to which package has or does not have the characteristics considered essential (Doll and Torkzadeh, 1988; Davis, Bagozzi and Warshaw, 1989; Ives, Olson and Baroudi, 1983; Khalifa, 1990);
b) on general reactions to the package - degree to which users like or do not like the package (Scriven, 1990; Teng and Jamison, 1990; Roberts and Moran, 1983; Holcomb and Tharp, 1993; Ravden and Johnson, 1989).

In this paper, it is proposed that ease of use may be evaluated based on the support provided by features in a package for certain learning dimensions, namely, user performance speed, memory, effort and comfort.

BACKGROUND

In this paper, learning is viewed as the stages of transition required to achieve mastery learning and ease of use as relevant to the entire spectrum of usage, regardless of level of expertise. This view is adopted because it accounts for the fact that the learning of a package is, essentially, never complete. The user is usually at a mix of levels of expertise, depending on the mastery attained on the various functions. The user is always in a process of learning new functions or finding new and better ways of performing ones already learned, whereby the user may be novice in some functions, intermediate in others, and advanced in others. To classify ease of learning as being applicable to novice users exclusively and ease of use as applicable to expert users would, therefore, not take into account the user's knowledge of the current package as a whole, or of other packages. Ease of use, therefore, should be concerned with this 'harmony' which a package design creates for all user categories.

It is suggested that ease of use of a package will be determined by the extent to which it supports the learning dimensions of speed, memory, effort and comfort. A software package will be considered easy to use if it is able to reduce performance time (speed), reduce memory load or not require it because of the simplicity of operation or the nature of assistance provided (memory), reduce mental effort thereby reducing errors made (effort) and is deemed comfortable to use (comfort). Evidently, what contributes to reducing the strain imposed on memory and mental effort should also contribute to the psychological comfort felt when using the package, all of which, in turn, should contribute to reduced performance time. The speed with which the task is accomplished is also likely to affect the user's perceived comfort when using the package. The arguments for suggesting these components are supported by the Learning literature and the Human Factors literature. (Thomas, 1994).

The factors comprising ease of use and learning have found support in the varied views of different researchers on the concept. Roberts and Moran (1983) considered ease of use to be a function of speed and functionality, while Davis (1989) looked at it from the perspective of physical effort, mental effort and memory. This is similar to the Keystroke Level Model proposed by Card, Moran and Newell (1983) which is based on physical effort, mental effort, system response time and memory. Murphy (1990) looked at the effect of speed and effort on ease of learning, while Khalifa (1990) considered ease of use as a function of recall, recognition and cognitive complexity.
Studies which support consideration of these dimensions include Shneiderman (1982) whose studies of menu structures and message tones and specificity indicated that users' performance speed, memory and comfort levels were impacted by these factors. The well known studies by Miller (1956) which point to the human memory limitations suggest that the memory dimension is a critical one requiring support. Studies by Burns, et.al., (1986) and Gray, et. al. (1994) suggest that greater memory and mental stain will be tolerated if the outcome is sufficiently desirable. Waern (1985) found that users relied on memory rather than read unless the effort required to read was minimal. This has considerable import for the design of assistive material. Bigge (1982) identifies cognitive strain as being a block to learning and Todd and Benbasat (1991) found that strategies requiring the least effort were the ones most often adopted. Stephenson (1990) found that student's frustrations, that is, comfort with a statistical package lead to lowered perceptions of the package's value for the future.

Given this support, the notion of ease of use as a function of support for speed, memory, effort and comfort offered by various package features seems reasonable.

PROPOSED STUDY

A study is proposed wherein users will be asked to evaluate various software design features for ease of use based on their support for the dimensions identified as performance speed, memory, effort and comfort. It is suggested that this view of ease of use may provide a potential basis on which to make a multi-dimensional evaluation of packages. For instance, a package design which offers greater support of these dimensions is likely to be easier to use than one offering less support. Secondly, this approach may be valuable in pinpointing more clearly those areas of design in need of being rectified. A package feature rated low in user performance speed or effort may indicate deficiencies in the number of operations required to perform a task while a low rating on memory may indicate deficiencies in the assistance provided for the feature. A low rating in comfort may point to poor screen design, confusing wording, or unclear conceptual models.

CONCLUSION

In general, business software evaluation instruments which do exist, address only the degree of existence or non-existence of a particular design feature, and often includes ease of use and/or ease of learning as one on a list of attributes to be assessed. The evaluation is usually one-dimensional, and not based on the multiple underlying factors which promote learning and/or ease of use - memory, speed, effort, comfort, as is being advocated in this paper. It is hoped that this view of ease of use, and the study of it, will aid in deepening our understanding of the concept and to the development of appropriate instruments for measurement.

REFERENCES

One of the primary components of most nursing curricula is the inclusion of basic science courses in the first or second year of the program. Because these science courses are fact based, teaching methods tend towards the traditional lecture format. The problem with this approach is twofold. The passive learning environment tends to fosters memorization. As a result, students are left to synthesize concepts on their own. Not all students are motivated to do this nor does this come naturally to all students. In addition, even those students who are able to synthesize the material, will not have the opportunity to apply their learning until they graduate in two to three years. This calls into question how much will retained by that time.

To address the problems created by teaching basic science through the traditional approach, a course was redesigned around the use of an interactive multimedia program in combination with active learning strategies.

The multimedia program, which is based on real life clinical scenarios requires students to apply concepts and problem solve. The key feature of this process lies in the interactive nature of the technology. Fundamental to the problem solving exercises is the incorporation into the program of an easily accessible database of detailed information. Multimedia tools such as animation, video, audio, and images used to present the information, created a more inviting learning environment. In addition students were able to use the technology in accordance with their own preferred approach to learning. By using the multimedia program outside of the classroom, in class time was used to reinforce key concepts. This was accomplished through the use of varied active learning strategies and tools.

Anticipating that this would be an initial step towards implementing further change, a number of tools were developed to evaluate the impact of this approach on learning: 1. A questionnaire was used to determine the level of student satisfaction with the use of technology, 2. Interviews were conducted with individual students to explore the impact of the technology on their approach to learning and 3. A classroom observation tool was developed to assess the impact of the changes on the learning environment. This tool was used to monitor factors such as instructional method, teaching style and engagement of students. A key feature was the categorization of the interaction between the students and instructor.

It was felt that for the impact on the learning environment to be significant and permanent, further changes would need to be incorporated gradually over a number of years. Consequently it was difficult to draw concrete conclusions from the data gathered to date. However, it can be said that based on the results of the questionnaire, students had a high degree of satisfaction with the use of the technology. With respect to learning strategies, it appeared that the use of interactive multimedia technology fostered students to explore beyond the material that presented in class. This was based on individual interests and approaches to learning. The extent to which students made comments on the differences between using a textbook versus multimedia also seemed to have an impact on how they used the technology. Results from the classroom observation tool suggested that students were asking questions based on an understanding of the material, not just memorization of facts. Additional analysis of this ongoing research will be used to expand the use of multimedia in the further development of an active learning environment.

Building and Evaluating an Automatic Search Method for Pre-Answered Questions in an On-line Classroom

Yutaka Tsutsumi
Department of Business Administration and Information
Kyushu Teikyo Junior College, Japan
yutaka@kyu-teikyo.ac.jp

Kazuo Ushijima
Graduate School of Information Science and Electrical Engineering
Kyushu University, Japan
ushijima@csce.kyushu-u.ac.jp

Introduction
In on-line classrooms, i.e. "distance learning," questions from students to teachers are designed to be sent via e-mail. However, it takes a lot of time for teachers to write appropriate answers for each e-mail question. And very often, two or more e-mail questions are the same. Reading for the same questions many times, and writing the same answers many times becomes boring work for teachers who of course would like to process such work more efficiently.

We have been giving a lecture of computer literacy at Kyushu Teikyo Junior College. In this class, we have recommended students to ask questions via e-mail as in an on-line classroom. This report introduces our automatic search method for pre-answered questions and describes its evaluation in our classes.

Background
Our premise consists of pairing questions asked by students with the answers supplied by a teacher. These pairs are stored in a database called "Questions Database."

There are two current methods for reducing teachers' work in replying to students' questions. The first is by using a database system. Since it is so complex and difficult for students to use formal language like SQL as database access languages, a natural language interface for database systems are being developed. However,

Figure 1: Overall System
this approach still has the problem that students cannot write questions in normal, natural language.

The second method is a natural language processing approach, where we analyze question sentences, search for knowledge using a knowledge base, and then generate answers. This method has the following problems:

1. The knowledge base is required to be perfect and consistent. But building it is very difficult.
2. Domain specific knowledge is required. It means a knowledge base can be made only by a person who is familiar with the domain.

Both approaches do not suit our needs. Instead, we use a Similarity-based method of searching for sentences in a Question Database. This process is light.

**Similarity Based Search Method**

Figure 1 shows the overall system. Students can ask questions via e-mail whenever they have problems. The question will be sent to the similarity-based search system, and if the system finds a similar question in the pre-answered Questions Database, the student will receive the pair of both the question and the answer from the system. However, if the system cannot find such a similar question, then the e-mail will be forwarded to the teacher, who must read the question, and write an answer.

Figure 2 shows the flowchart of the similarity-based search system. The idea of this system is based on our previous research for syntax matching of natural language sentences [Sumita & Tsutsumi 88]. As shown, the process consists of two phases. First is Register and the second is Search. They share the morphological analysis, extraction of question sentence, extraction of main theme, and transformation to standard format. In the Japanese language, parts of speech for each word in a sentence can be determined by morphological analysis. After morphological analysis, the main theme of a question will be extracted by word-order patterns. Next, the main theme will be searched for in similar sentences in the Questions Database. If one or more sentences are found, they will be sent out. If nothing is found, a specified part in abstraction rule will be reduced to make it easier to search for similar sentences. The abstraction rule consists of six "primitive rules," such as the reduction of pronouns, changing the past tense to present tense, etc. We determined the rule order

in order to search for the most similar sentence by heuristics. Table 1 shows primitive rules and order to apply them.

**Experiment and Evaluation**

We experimented with our similarity-based search method in order to test this method in actual classes. We tested with 55 students, asking them to send a question via e-mail in actual class. Every question was searched for in the Questions Database. After searching, each question was stored into the Questions Database. When the search result found one or more question and answer pairs, we count it as a success.

Table 2 shows the experiment result. As shown in Table 2, it is clear that half or more of the students’ questions were automatically answered by our system. It is anticipated that teachers will be able to save considerable time by using our system.

Table 3 shows the reason of failure. As shown in Table 3, one third of the failures were morphological analysis.

**Advantages and Aspects**

In this section, we will discuss the advantages and the aspects of our approach.

1. **Preparation**
   Our system does not require any preparation unlike the AI based QA system which needs a large amount of the logical form of questions and answers.

2. **Easy-to-use**
   Students can ask a question via e-mail, which they can write in Japanese. It is very easy for them to use.

3. **Maintenance**
   Our system is almost maintenance free. If our system cannot find any similar sentences with a Database, it is automatically forwarded to a teacher, as well as stored into the database with the answer, as a new entry.
Morphological analysis
It is important that more powerful morphological analysis technology is developed, since e-mail includes spoken language expressions, miss-typed words, and long sentences.

Technique for asking a question
As described above, the ideal e-mail question consists of a situation description, a main theme, and a request to answer. We think it is important for students to describe these three parts firmly and simply, to communicate between their teacher by e-mail, as well as off-line.

Conclusion
We have described our similarity-based search method for e-mail questions. We believe that our system will help teachers answer more e-mail questions by students more efficiently. Additionally, by storing such e-mail questions into a Questions Database, teachers are provided with student feedback relating exactly to the point which they are having difficulty learning. In the future, we plan to develop a more powerful search method and on-line classroom environment, and we also plan to evaluate in actual on-line classroom.

1. Introduction

The project NeuroAssistant started at the University Hospital Tübingen in 1996. Its purpose is to establish new methods for storing, retrieving, visualizing and transferring complex medical knowledge gathered in many different clinics and research facilities throughout the world. The bilingual system, based on an object-oriented DBMS, is accessible via the Internet and is available at any time and place. The HTML user interface offers read access for all users and write access for authors with suitable privileges. Different access profiles for users and authors offer an appropriate way to present the required, interesting data. Figure 1 gives an example.

![Database entry of NeuroAssistant](image)

The facility to provide the data from distributed locations by different medical experts results in a new quality of work. Compared to books and journals there is no time delay in publishing both up-to-date knowledge and new research issues to all sites connected to the Internet. Furthermore, the use of various multimedia data offers completely new possibilities to present high sophisticated knowledge. One point of view we have to focus on is providing these data in an appropriate way and combined with comfortable information retrieval facilities.

2. Contents of NeuroAssistant and Target Group

The database contains medical knowledge of all theoretical (anatomy, embryology, physiology, neuroinformatics) and clinical aspects (neurologic diseases, methods of examination and therapy) of
neuroscience with numerous case reports and diagnostic images. For educational purposes a collection of treated cases and their follow up is offered, comprising all steps which led from diagnosis to treatment. A reference brain offers users the chance to interactively identify all anatomical structures with a suitable pointing device. Cross links allow fast access to related topics in the database. A fulltext search and some content based search engines, and a glossary tool are also available. To improve its educational capacities, all kind of contents are supported by multimedia objects like text, (animated) images, videos, Java Applets, sound, etc. Authors, in general medical experts, have the privilege to check in a new topic including all kind of multimedia objects by defining its context and specifying links to other items to thematically related entries. By following these links, a user may get further context information.

Typical users are physicians, medical students, technicians, or patients. Physicians can exchange their knowledge and can share access to anonymized data of already successfully treated patients. Students are offered insights into the clinical routine as well as a detailed description of basic sciences and the respective theoretical background. Finally, patients are able to obtain information about their therapy, which could facilitate the process of patient empowerment.

2. Platform

The DBMS ObjectStore (ODI, Burlington, USA) has been chosen for the platform of NeuroAssistant, because it is object-oriented and offers interfaces for C++ and Java. This is the technology required to traverse the complex medical data structures of the system. Furthermore the unique architecture provides database clustering, client caches with callback locking and high-performant virtual memory mapping. A special connectivity product integrates the database system with a WWW server by transferring the object requests to the multi-threaded database server and returning the objects. So-called ObjectManagers enable the integration of multi-media objects.

3. Database Design, Realization and User Interface

The conceptual database structure of NeuroAssistant was cooperatively developed by both physicians and computer scientists and consists of two base and 10 specialized classes. Two further classes are necessary for storing advanced user-specific data.

When accessing any database content via WWW, the HTML skeletons that define the graphical user interface are implicitly accessed. These skeletons consist of ordinary and extended HTML tags which contain the invocations of several queries. By requesting data, users transparently send a query via their web browser, our web server and a CGI script to the database service application (Fig.2). The service application which implements all existing query callback functions, executes the query and sends the obtained results in form of an HTML page back to the client. So far, we have implemented nearly 400 different skeletons for the web user interface and more than 90 different query callback functions that manage multiple tasks for navigating and editing the NeuroAssistant.

4. Future Works

At the moment, several physicians are working on further database contents. We also want focus on a more comfortable user interface with advanced information retrieval facilities. Furthermore, for educational purposes the development of an authoring tool for generating case based simulations of medical treatment methods is in progress. These case studies will be offered to medical students to support the training on patients treatment. In order to establish NeuroAssistant as an international education system more renowned experts have to be convinced to publish topics in their particular field. To manage this increasing number of authors, a more advanced mechanism of reviewing database entries is necessary to ensure a high standard of quality.
Towards An Advanced Multimedia Platform for Co-operative Work and Learning: The PLATINUM and MESH projects

Hermen J. van der Lugt, Elske Heeren
Telematica Instituut, P.O. Box 589, 7500 AN Enschede, the Netherlands
Phone: +31 53 4850485, Fax:+31 53 4850400,
E-mail: {VanderLugt, Heeren}@trc.nl

1. Intertwinement of developments in use and user, and in technology

Our aim is to develop innovative multimedia support for co-operative work and learning settings. We are well aware of the ‘technology stalemate’ that plays a role in this. On the one hand advanced technological developments require a clear demand from potential users. On the other hand, users have difficulty envisaging their potential use of novel, not-yet-existing technology, and thus cannot articulate this demand. The only way to speed up the development process, is to intervene and invest in either pulling user demands so that the required direction of technological developments becomes clear, or in pushing technology development so that users can develop their ideas and requirements. In the PLATINUM and MESH below, we have chosen to first invest in a collaborative effort of relevant parties in bringing technological development a step further.

user point of view, work and learning situations are very diverse in terms of task, duration, group, organisational contact, and culture. Likewise, the various groupware applications supporting these work and learning situations have to differ substantially in terms of functionality provided to the users. Moreover, the characteristics of user settings are likely to vary from one moment to another (e.g., switching between subtasks). Groupware should support multiple modes of Cupertino, ranging from users being closely coupled via video-conferencing applications to users working relatively independently on different sections of a document. Finally, various media should be supported, ranging from continuous media (e.g., 3D virtual reality, video and audio) to discrete media (e.g., text, graphics and pictures).

From the technology point of view the development of groupware applications involves many additional technical issues from distributed systems development and (broadband) telecommunication networks when compared to the development of single-user applications. Groupware applications requiring multimedia support for both synchronous and asynchronous collaboration are complex in design, difficult to develop, and hard to implement. Groupware systems that consist of independently developed groupware components provide a solution to these problems. The development of the groupware components should ideally be supported by a platform.

Where user and technology perspectives meet. A platform for component groupware allows users to make their own ‘pick and mix’ of functionality within the collaboration environment which with they are used to work. They can also add functionality which they require for a particular task, or which has become available newly, at will. Developing and pilot-testing such a platform for component groupware is an important part of the PLATINUM and MESH projects described below.

2. Two research projects

The PLATINUM project [Ouibrahim & Schot, 1995] was a co-operation between Lucent Technologies, the Telematica Instituut (formerly known as the Telematics Research Centre), the University of Twente and Deutsche Telekom and run from October 1994 through June 1996. It focused on the development of technology, applications as well as their (anticipated) use. On the applications level work focused on CSCW applications, in particular on desktop conferencing and co-authoring of multimedia documents. The MESH project (www.mesh.nl) is a two-year co-operation between Lucent Technologies, the Telematica Instituut, the University of Twente, KPN Research and SURFnet with several user organisations in higher education and
health care. The project started in November 1996 and is a follow-up of the LATINUM project. It focuses on the technology to requirements of the specific pilot settings. The overall architecture of the systems we have developed is depicted in [1]. The main mission for the users. In order to realise this, application developers should be able to easily develop new components that integrate with the existing platform and already existing components.

The main elements of the system are (from bottom to top, from technology to user applications):
- **Network services**: Research focused on the realisation of dynamically configurable multiparty multimedia conferences via ATM technology. This would allow for connections between multiple parties, providing support for several media, all under user-control (opposed to operator-control).
- The mediabuilder and call handling hide network-specific details for the application programmer. For example it provides facilities for the dynamic management of conferences, and enables stream support.
- The conference management component forms the overall user interface of the system. It enables the users to configure conferences (e.g., by means of a “conference wizard”).
- On top of the mediabuilder several groupware applications are developed. The key research issue is to demonstrate that application developers can indeed develop there own favourite component, being it video, audio, chat-facilities, shared whiteboards or others. The platform guarantees the interworking of the components. As innovative application we developed a collaborative compound document editing framework, CoCoDoc [ter Hofte & van der Lugt 1997], with an accompanying example application, called CoCoTree. The example application allows for collaboratively editing of the outline of a multimedia document.

The MESH project builds on the technology developed within PLATINUM, in order to achieve a user-demand pull movement. For this purpose, the PLATINUM/MESH platform is used in four pilot settings. Two of these are in higher education, involving teleco-operation among university teachers, and telelearning in student teams. The collaboration will be among faculty and students of the University of Twente and the Technical University of Delft, who are located at a 2.5-hour train trip from one another. The MESH platform will facilitate the development of a new inter-university course on multimedia (interface) design. The main argument to develop inter-university education is the knowledge and learning gains expected when faculty and students from different traditions and with different sorts of expertise work together.

Creating a Web-Enhanced Curriculum in German Studies

Donna C. Van Handle
Department of German Studies
Mount Holyoke College
So. Hadley, Massachusetts USA
E-mail: dvanhand@mtholyoke.edu

Abstract: This presentation will address both practical and theoretical issues involved in developing standards-based, web-enhanced courses for German studies. The presenter will speak about the instructional design of several course sites, the pedagogical strategies implemented there, as well as the benefits and occasional disadvantages to integrating web resources in a consistent way into foreign language instruction. The course web site for intensive elementary German will be especially highlighted during the presentation. Other course web sites currently in use or under development such as Intermediate German, Creation and Production of a German Play, and Political and Literary Cabaret in 20th Century Germany will also be discussed.

The German Studies Department at Mount Holyoke College recognized early on the value of the World Wide Web for language, culture and literature teaching. Since 1995 the department has been making a concerted effort to develop web-enhanced courses on all levels of instruction. Course web sites were created that linked students to timely, authentic materials in German that addressed social, political, historical, literary and cultural issues in the German-speaking countries. These web sites also included web exercises and access to asynchronous discussion fora.

The department’s effort was spurred on by the release of The Standards for Foreign Language Learning: Preparing for the 21st Century in November 1995. This document defines “content standards--what students should know and be able to do--in foreign language education in grades four, eight, and twelve” and is recognized on the national level as “a gauge for excellence, as states and local districts carry out their responsibilities for curriculum in the schools” [Standards 1996]. In reference to the use of technology in foreign language instruction, the standards document suggests that students “have access to a variety of technologies ranging from computer-assisted instruction to interactive video, CD-ROM, the Internet, electronic mail and the World Wide Web” as their use will help students develop and “strengthen linguistic skills, establish interaction with peers, and learn about contemporary culture and everyday life in the target country” [Standards 1996].

There is currently a push to develop national standards that include college-level foreign language instruction. In fact, the American Association of Teachers of German’s Student Standards Task Force is currently in the process of developing German-specific standards for K-16 students of German. Recognizing the need for instructors at the college-level to become familiar with the national standards so that entering students could continue to receive instruction consistent with the principles articulated in the standards document, the German studies department at Mount Holyoke College set about developing standards-based web sites for all courses. This effort was supported in part by grants from the Hewlett and Mellon Foundations recently received by the college. These grants not only increased student/faculty access to the World Wide Web (in campus computer labs, faculty offices and dormitories), but also provided funding for “student web technologists” who were hired by the department to assist with development of additional course web sites. This allowed for integration of the Web in an even more systematic way into the German studies curriculum.

In the intensive elementary German class at Mount Holyoke web resources were used extensively. The purpose in creating, designing, and implementing the course web site was to provide students in the class with links to a wealth of culturally authentic web resources related to the German-speaking countries. The idea was to provide students and the instructor with the least painful way of accessing sites linked to cultural topics and grammar explanations discussed in each chapter of the textbook. The course homepage features a table with links not only to sites in Germany, Switzerland, Austria, and the U.S., but also offers a link to a list of web exercises coordinated with the material covered in each chapter. Students were required to complete these exercises as regular homework assignments. To earn extra credit points, they had the option of e-mailing the instructor the URL of a site on the Web that they discovered and found interesting. The instructor then set up a separate page where the “student URLs” are listed. At the start of every class meeting the instructor displayed a site related to the chapter
As foreign language instructors begin to use the resources found on the World Wide Web more regularly in their teaching, they must reflect on how use of the Web has affected and changed teaching and learning in substantive ways. The Web itself is both a content provider and a delivery medium that offers nearly instantaneous access to the most current resources and experts in various disciplines. However, the Web is merely a tool. A tool does not teach, but assists students in the learning process. The key is to make this tool work effectively for the instructor and the students. Integration of the Web into instruction has the potential to impact positively on both the instructor's approach to teaching and on the learner's approach to learning because its use creates a community in which students are not afraid to take charge of their own learning. Using the Web in instruction encourages student interaction and collaboration. This interaction/collaboration can happen between classmates in or outside of the classroom, or between students and instructors at different schools or in different countries. Use of the Web should be encouraged so that students become engaged learners whose work with one another helps them perform real-life tasks and solve real-life problems.

The Web offers non-linear access to a wide variety of complicated and complex information. Students can also be introduced to many different ways of evaluating this information, especially when access to newsgroups and E-mail is integrated into the design of a web site. What the WWW does especially well is enhance already developed curricular goals--i.e., it helps instructors expand on what they have already been doing and offers students new perspectives on various topics. For instance, if students in a 4th semester German class are studying the history of the Berlin Wall, they can be alerted to the existence of a limited number of web sites in Germany that address this topic and/or can be asked to do a search to find other relevant sites. They can then explore these sites, most of which will be written in the target language, in order to ascertain the viewpoint or perspective of the site developers and others from the target culture. If students are normally asked to give oral presentations in a course, they should be encouraged to incorporate information found on relevant web sites into their reports. When given permission to surf the Web, students will often find sites that the instructor has overlooked. Thus, in effect the students become instructors themselves in an environment where cooperative learning is encouraged. Another activity that lends itself particularly well to use of web resources is pair investigative work. Students in a 4th or 5th semester German course could work in pairs to find information on the Web about a topic they are studying. Student interaction within the pair encourages cooperative learning and allows the instructor to act as a guide or facilitator of the activity, not as the sole information provider. After the pair has completed the research, both students could be asked to report in German on their findings--i.e., explain how they located the sites, what information is available on those sites, and how they have evaluated the information found there. Students who are writing theses or are engaged in independent study projects could do searches on the Web to locate information for their project. For instance, a student writing a thesis on the Stasi could do a web search to locate Joachim Gauck's address and the students. Integration of the Web into instruction has the potential to impact positively on both the teacher's approach to teaching and the students. Use of the Web should be encouraged so that students become engaged learners whose work with one another helps them perform real-life tasks and solve real-life problems.

As instructors begin to use the Web more and more frequently in instruction, their assessment methods will also have to change. Instructors may ask students to use the Web as a presentation tool. In this scenario other members of the class (the "audience") should be held responsible or accountable for what they have learned by listening to the presentation. For instance, they could be required to ask presenters at least one question to make sure that they have comprehended the material. Students could also work in pairs to create their own web exercises for the class. Pairs then exchange exercises and work together to complete them. This sort of discovery-oriented work calls for much more flexibility on the instructor's and learners' part since students drive or guide the instruction to a certain extent. They are working on complex, real-world tasks and should be encouraged to challenge information presented to them by a number of sources.

There are certainly disadvantages to using the WWW in instruction which should not be denied or ignored. For one thing anyone may publish his/her thoughts on the Web. Students will have to learn to look beyond the information presented and consider the source. Can this source be considered credible? Why or why not? It is a wonderful class activity to have small groups of students evaluate selected web sites with the goal of determining
which ones supply useful and valid information. This allows them to develop higher order thinking skills as they learn to discriminate between good and bad sources. If students in a course are considering use of certain web sites when preparing oral reports or papers, they should be asked to defend their decision to use the information gleaned from them. In this way they learn to take responsibility for the choices they make.

1. Introduction and Objectives

The aim of this paper is to seek the application of Information and Communication Technologies (ICTs) in the children training process within the region of Castilla y León. This Spanish region is mainly featured by its sparse population. Internet for Schools deals with the development of a support tool for children in rural areas. The main objective is the establishment of an “Educational Intranet” which will provide additional contents and more accessibility to those services traditionally located in urban areas.

The above signatories take part in a Research Work Group named Canalejas. The research of this interdisciplinary and inter-university group is focused on Educational Multimedia and Telematics Networks in an educational context, evaluating the possibilities and advantages of applying ICTs to the training process. Canalejas Work Group is formed by researchers from two different Universities (Valladolid and Salamanca), more precisely from the Telecommunication College and the Education College and from the Pedagogy College respectively. The collaboration carried out by these two teams is justified by the interdisciplinary character of the project. Due to the experiments and the nature of the research, the collaboration of professionals from the education and the telecommunication sectors is required, in order to assess the pedagogical and telematics developments respectively.
Internet for Schools consists on developing a pilot project about the possibilities of Internet in Primary and Secondary Schools [Verdú et al. 1997]. About 100 schools in Castilla-León will participate in this project. The actions to be undertaken are: Evaluating the use of Internet, focusing on the possibilities of ensuring equal opportunities of access; and giving occupational training for students, who will familiarise themselves with the use of ICTs.

2. Schools and the Information Society

Nowadays we are witnessing the evolution from the Industrial Society to the Information Society, where citizens will be able to use the advanced telecommunication services to improve the quality of their every-day life. With the emergence of the Information Society, everyone must upgrade their skills constantly and obtain new qualifications. In this way, education and training will play the main role. Distance Learning lets students get the best training, where they want and whenever they prefer, and they can always contact their teachers. The fact that all students can have the best teaching makes possible giving the same chances of training to everyone. Moreover, ICTs give students immediate access to universities, research centres, museums... and also provide new learning methods in which personal and group work is stimulated.

3. What does “Internet for Schools” offer?

The project has been recently initiated and among the services we are developing, can be mentioned the following ones:

1. With the Electronic Tutorial students can contact different teachers from different schools. These students can ask questions and discuss with the teachers.

2. University Guidance has the aim of informing last-year-Secondary-Education-students about the information about different careers. Not only students can know about where they can study one career or what it is about, but they can also contact university students, teachers or people who have taken a degree on that career, who will inform and talk to them about their own experiences. The contacts are made via e-mail.

Internet for Schools is implemented at the following Web site: http://www.intesc.cedetel.es.

4. Future services

First of all, we must analyse the consequences of introducing Internet in the Schools and identify and fulfil the needs of the primary and secondary school community.

Finally, an Intranet [Holtz 1996] will be created. The establishment of an educational Intranet will prepare children for intelligent use and management of information. Besides, the technology is accessible, cheap and easy-to-use, and can be easily addressed to Primary and Secondary Schools. We are trying to connect schools to the Network and lead teachers and students towards the Information Society, using innovative learning methods based on interactive information search and distributed working groups. And all of these, ensuring equal opportunities for all children.

Understanding the System: 
the Key to Sustained Task Competence?

Daniëlle Verstegen & Karel van den Bosch
Department of Training and Instruction
TNO Human Factors Research Institute
PO Box 23, 3769 ZG Soesterberg, the Netherlands
e-mail: Verstegen@tm.tno.nl, Vandenbosch@tm.tno.nl

Introduction

The operational power of civil and military organisations is becoming increasingly more determined by the competence of its personnel in acquiring and retaining skill in operating devices. One of the good properties of operating tasks is that they can be learned relatively quickly, even if the set of operations is complex (Kieras, 1990). Problematic is, however, that skill in procedural tasks deteriorates very rapidly during periods of no-practice (Christina and Bjork, 1991). Several training measures have been proposed to enhance skill retention (e.g. Hurlock and Montague, 1984), for example:
- Provide system insight: explain the structure of the task and the underlying system principles
- Mixed practice schedule: practise tasks in random order rather than one by one

The effects of these training design factors on skill retention have been studied separately, and in the context of different tasks. Moreover, their effects are not always clear (e.g. Koneske and Ellis, 1986).

Design

Subjects were soldiers of the Airborne troops of the Dutch Army (age: 18-25 years). Their educational level varied from lower vocational training to high school; Subjects were divided into 8 groups, matched on their scores on the subtest 'Technical Insight' of the Differential Aptitude Test (DAT). 94 subjects completed the learning phase (i.e. attained the criterion level of performance); 84 came back for the retention phase and reattained the criterion level.

Subjects learned to direct a simulated ship from one side of a lock to the other by mouse-clicking (simulated) controls on a computer monitor. The required sequence of actions depended upon the sailing direction of the ship and the water level in the lock. A total of four procedures were to be learned, each containing 14-17 steps.

The learning phase involved instruction, a written test (10 multiple choice questions) and training to criterion (three errorless performances of each task). Retention was measured after two months. Subjects retrained all tasks until criterion level and then completed a written test (25 multiple choice questions).

Three variables were manipulated:
1. Type of instruction: Subjects in the low system insight groups received only procedural explanations, i.e. a description and demonstration of the actions to be performed; subjects in the high system insight groups were shown how the task can be decomposed into five logical subtasks and they received additional information about the principles governing the lock’s behaviour and how these relate to the task procedures.
2. Training schedule: Subjects in the blocked training schedule groups trained one task to criterion and then continued with the next; for subjects in the mixed training schedule groups, trials of the four tasks were mixed.
3. Retention test schedule: Half of the subjects received a blocked retention test, and the other have a mixed
For both learning phase and retention test the following measures were obtained: number of trials needed to reach criterion, amount of time needed to reach criterion, number of errors in the first 12 trials (possible minimum to reach criterion level), score on the multiple choice test.

**Results and Discussion**

The results of the learning phase show that subjects in the high system insight groups (i.e. who had extra explanations about the structure of the task and the underlying system principles reached) the criterion level of performance with less trials and that they made less errors. The practice schedule had no significant influence on learning and there were no significant interaction effects between the two factors.

The results of the retention test after two months show no significant effects of type of instruction or practice schedule. There was a clear interaction between the practice schedule and the retention test schedule: subjects made less errors when they were tested in the same condition as they have practised. Especially the combination of minimal instruction, a blocked practice schedule and a mixed retention test seems unfortunate.

Strangely enough, the results of both written tests show no significant differences between high and low insight groups. A post-hoc analysis showed, however, that subjects who scored better on the first test immediately after the instruction, performed significantly better during the retention phase: they needed less trials to reattain the criterion level of performance during the retention test. These findings support the hypothesis that system understanding improves the retention of procedural skills. But they also make clear that the type of instruction was, in this case, not the main factor promoting system understanding.

Almost all subjects reported that they had some experiences with locks before the experiment. This background knowledge probably helped them to understand the function of the lock and the tasks of the operator. The results of this experiment suggest that explanations about the task structure and the underlying system principles are less important when trainees are already familiar with the system, even when they are not familiar with the operating tasks themselves.

Student Perceptions of Internet-Based Interactive Teaching and Learning in the Communication Arts

Errol Vieth
School of Contemporary Communication, Central Queensland University, Australia,
e.vieth@cqu.edu.au

Up to 1997 the film studies-oriented unit Screen Studies had been taught in the traditional way: a lecture of about one hour was followed immediately by a film screening, with a small group (approximately 15) of students meeting for tutorial sessions of one and a half hours during the same week. However, Central Queensland University (in the state of Queensland, Australia) is not a normal university in that it comprises five campuses in the geographical area of central Queensland and two campuses in the capital cities of Sydney and Melbourne. (The unit in question was not taught in those last two campuses in 1997.) Previously, lectures were delivered from one campus to the other campuses by videotape, recorded on the Monday and freighted to other campuses (Bundaberg, Gladstone, Mackay), where it was played for the students before their tutorial.

The rationale for the change to a computer-mediated course delivery and interaction derives from both negative and positive imperatives. On the negative side is the unique geographical dynamic of the central Queensland campuses, the forecasts for ever-diminishing funding relative to increasing student numbers, and the traditional rift between internal or on-campus students, and external or off-campus students in terms of access to resources, peers and lecturers. On the positive side is the potential for accessing information in ways that threaten to change the nature of a print-based library, the dismantling of geographical limitations to student communication and other features of learning that might be enhanced or generated by online learning and interaction.

One theory of Australian historiography postulates distance as the major influence on Australian history and further, argues that this tyranny of distance hindered western development in Australia [Blainey 1982]. The ‘delivery’ of ‘Education’ has been a major player in the conflict against that tyranny and the internet heralds a decisive victory in the war against the tyrant. Just as the telegraph wires disarticulated the delivery of news and information from the domain of geographical distance [Carey1989], the internet will liberate education.

In 1997 I trialed electronic delivery and interaction of Screen Studies via the internet, by placing ‘modules’ on the WWW that would replace traditional lectures [see Vieth 1997], coupled with four ISL (Interactive Student Learning) sessions during the semester, and electronic tutorials using e-mail that would bring together students from different campuses. ISL is simply videoconferenced lectures, where students from all campuses can interact via a videoconference link. While many examples of communication arts teaching material exist online, fewer examples of units taught interactively via the internet exist for communication arts units.

The students are generally communication and arts students not necessarily noted for interest in computing nor computers. All students at secondary schools in Queensland receive some training in computer literacy and incoming students at the university are briefly oriented to the WWW and email in the first week of their university life.

The study

In the fourth and twelfth week of the thirteen week teaching semester students were surveyed to gauge their responses to the unit in both its content and negotiation. Students were asked questions relating to their access to computing facilities, computer literacy, and orientation to computer skills; followed by questions relating to the film screenings, the ISL sessions, the WWW modules, electronic tutorials and general questions about their expectations. Questions were both quantitative and qualitative, although the qualitative seemed to be more useful for my purposes than the quantitative, because the students who did not reply to the survey might well have been those who failed through the computer-mediated nature of the interaction. Twenty-six students responded to the week twelve survey of a total of 52 remaining in the unit at the time. In this brief session I can only mention a few significant aspects of the results.
The survey shows that students have expectations about teaching and learning at tertiary level that impact strongly on their beliefs about the efficacy of teaching without face-to-face contact. For many students human interaction is a primary expectation of university life and for some this interaction is not only a pedagogy but a means of establishing social contact with others. This type of response is not determined by the students liking for the electronic mode of offering; indeed, students did comment on the value of the pedagogy in such a film studies unit. Yet there is an obvious paradox here in that it is not unusual for student attendance at lectures to decrease markedly during the course of the semester, and further, it is likely that those students who did not answer the survey would also be those who would stop attending lectures.

The mode of interaction also presents difficulties because the usual interpretation implicit in face-to-face communication is not available: that is, students are not able to 'know' the people they are responding to because they have no other medium of communication, such as sight and sound, through which to establish meaning. In addition, in one case a student complains that she has made 'no friends', linking this to her belief that the mode of offering is ineffective. One student iterates this sense of loss of visual and auditory identification, but then questions her need to attach an image to a response, asking whether such attachments 'mattered'. Some students realise that their expectations about the way education is practised is a learned expectation that might have no intrinsic basis, but for others face to face interaction is inseparable from education in the communication and the humanities while they believe that, in other disciplines of science and computing, such computer-mediated communication might be acceptable.

Related to the question of human and computer-mediated interaction is that of motivation. A common thread pervading the responses is that motivation and self-discipline to communicate and complete the tasks is a formidable hurdle. A student who failed the unit told me that she failed because she was not motivated to read her e-mail, respond and submit an electronic essay. Responding students also report a lack of incentive to read e-mail, a sense of being on one's own, a general lack of motivation, the need for motivation to complete the assignment requirements. One response was that face-to-face teaching and learning is 'forced learning' and is 'good', and that the computer-mediated pedagogy is not forced and is therefore not desirable. This response reveals more about the student's beliefs about education than the pedagogy itself.

Nevertheless, many students do both enjoy and approve of this different mode of teaching and learning. For this group motivation is not a problem and they enjoy the ability to choose their times of study and writing. Those who live up to 100km from the campus, or are otherwise employed at the times when lectures and tutorials are held, are very happy with the medium of interaction. Apprehension at the start of the teaching time is not unusual, but this apprehension sometimes turns into liking for the electronic tutorials and for the peer assessment that is an integral element of that mode of pedagogy. The lecture 'modules' on the WWW enable students to return to the text for re-reading; seen as an advantage over a lecture delivered orally, as is the enhanced research options the hypertext links provided. One student commented that it was more interesting than any other unit she had done.

The implication for distance learning in the communication arts units is marked and some responses note the increased potential for offering a full range of units on small campuses. Interestingly, some students find the computer-mediated mode of offering isolating while others experience the opposite. But the potential for the establishment of a 'tutorial dialectic' for off-campus students is one of the most potent elements of computer-mediated education.

Conclusion

Teaching and learning using computer-mediated communication might revolutionise the way we think about education. However, work needs to be done to establish, for students and educators, the validity of the pedagogy. At the same time, the need for face-to-face interaction in communication and arts disciplines as intrinsic to the learning process needs to be further researched to determine whether it is as important as students believe, and if it is, then some way of accommodating that requirement can be established while allowing for the broadening of possibilities computer-mediated teaching and learning offers.

1. Introduction

We are developing an educational software system to teach children (grades three to four) spatial orientation in two and three dimensional space. We understand the term 'spatial orientation' as the ability of a person to find physically and mentally one's way in two- and three-dimensional space [Maier, 1994]. Facilitating spatial orientation in two and three dimensional space is one important aspect of geometry in the mathematics curriculum of elementary schools in the state Nordrhein-Westphalia of Germany. Spatial orientation is an important ability for understanding, interpreting and developing the world in which the children live.

The current media-based approach (in Germany) of teaching spatial orientation typically involves pictures of a town depicted in a book. The used perspective projections of the three dimensional buildings awake an impression of their real three dimensional counterparts. Children are given tasks of navigation and orientation inside the town, using these perspective projections together with two dimensional city maps. They are also encouraged to accomplish the same tasks in the real world, using a map to navigate through their home towns.

2. The 'City Game'

Together with a research group at our University specializing in didactics of mathematics we are developing the 'City Game', a game to orient and navigate through a virtual city on a computer. The development of the 'City Game' is an interdisciplinary process between the didactics group and the computer science group.

To implement the 'City Game' we have chosen VRML 2.0, the Virtual Reality Modeling Language. The complex scenes of the city are modeled with Cosmo Worlds, a powerful editor (and free on Silicon Graphics workstations) to create VRML worlds. The 'City Game' consists of a realistic city structure and typical buildings and objects of a city. Animated objects such as a bus or a train enliven this virtual city.

Navigation through the city, along the streets, can be done interactively with various navigation help, e.g.

- a 2D-map (bird's view), which is showing the actual position of the user in the city and optionally displaying the covered way
- road signs and a hard-copy of the city map
- a wind rose for orientation with the four directions of the compass

Interactive navigation can be done by the standard mouse and direction buttons (forward, backward, left and right). It is implemented through viewpoint animation by automatically keeping the viewpoint at a fixed height.

One of our main interests in the City Game is the value it possesses for teaching children spatial orientation. The use of virtual reality to improve human abilities in the real world has been proven to be successful in other circumstances.

\[\text{http://vrml.org/Specifications/}\]
areas as well, such as the overcoming of phobias by training subjects in virtual reality [Strickland et al., 1997]. The main interest of the computer science group is to improve the requirements of teaching spatial orientation in virtual worlds.

A first informal study was performed to see reactions of children and adults by using the 'City Game'. Another goal was to determine what kind of features children use for orientation as compared to adults. The study included ten children (grade four) of an elementary school and ten students of the University of Paderborn. Each group consisted of five male and five female subjects. In this study subjects had to find their way from different initial positions to different target positions. Each trial should be performed with a different help or method, e.g. with the city map, with photos along the way to be found, with the wind rose or by backtracking a way that was shown before.

Before beginning the study each subject was shown a walk through the city and taught the use of the direction buttons. The subjects were asked "to think aloud" during performing their tasks. The comments were recorded by video and in written notes by the evaluator.

An unexpected result was that adults and children hardly used road signs and the city map for orientation in the virtual city. Their orientation occurred mainly through buildings with particular characteristics (e.g. function, size or color). An explanation may be the relative small number of streets and the great number of particular buildings. Also the experience with three-dimensional computer games might influence the behavior of the subjects. Mostly the navigation help of such games are objects and directions. The buildings used recurrently for orientation were the museum with a large dinosaur in front, the church, the city hall, and the school.

Differences between the children and the adults occurred when they were asked to remember objects of the virtual city after the study. The buildings mostly named by the children were (by decreasing frequencies): the museum with the dinosaur, school and church. In contrast to that the major buildings named by the adults were: grocery, petrol station and church, and museum. This indicates that children and adults use different objects for orientation dependent on subjective perception and the experience in daily life.

One important result was that subjects (both children and adults) often focused on the navigation tools (mouse and direction buttons) rather than on their tasks. Nevertheless the reactions of the subjects were very positive to the 'City Game', specifically to the structure of the city, the appearance of buildings and details. Some of the subjects suggested to populate the streets with people, who can be asked for directions.

Based on this preliminary study and the extensive development of the 'City Game' we are starting off a series of further tests of teaching spatial orientation in virtual environments. We are currently improving the navigation tools of the 'City Game' to develop a more intuitive navigation control to simulate a natural walk through the city. Formal studies based on more specific hypotheses will give us a deeper insight into the navigation feature used by children and adults in virtual and real environments.

Abstract: The process of constructing a set of three dimensional interactive web-based utopian communities has engaged two university professors in the challenge of mastering new technologies and operating within the limits of current hardware and software while maintaining their original vision. The authors invite participation and collaboration in the construction of MetaTopia.

Two teachers from different disciplines, one who knows nearly nothing about the construction of virtual worlds, the other who knows absolutely nothing, attempt to collaborate on the construction of an elaborate set of interactive utopian communities for the World Wide Web. Socrates would have said that such teachers are possessed of a divine madness. We lay claim to neither divinity or madness--though there may be those who argue the latter label is appropriate due to our lack of knowledge and experience with the practical processes of virtual world construction. One of us, then the other, sometimes dreams. These dreams sometimes manifest themselves as nightmares, reflecting our fears. At other times these dreams simply remind us of our hopes, our vision. This paper addresses our original reasons for conceptualizing a three-dimensional, web-based educational project, our observations during its initialization, and issues both encouragement and cautionary notes to others who would either undertake similar endeavors or choose to join us in ours.

The MetaTopia Project began with a vision. Through participation in the project and in collaboration with other participants students will learn about the central concepts, norms, customs, and traditions of utopian and dystopian communities (historical, literary, and operational) by becoming virtual members. Students will interact with one another and with the character population within each community. Students will also move among communities in order to examine the processes of social construction, as well as the individual-level and community-level social, political, and economic repercussions of community membership. As a long-term goal, we envision the creation of an over-arching community, a utopian virtual world called MetaTopia, where the insights gleaned from exploration of the smaller communities will be applied in the construction phase and then operationalized and revised in the later phases.

We turn now to the practical task of construction. Where to begin? It's like the story of the blind men who sought to identify some strange object in their path. The first, grabbing hold of the tail, thought the object was a vine. The second, stumbling into a leg, surmises he has found a tree. The third, upon encountering the trunk, insists he has discovered a massive python. None of the men can see the object in its entirety. They do not know that that which is before them is simply an elephant. MetaTopia is our elephant.

Web-site construction sometimes seems as if it has little to do with the world of ideas in which we have dwelt for a dozen years or so. The technology overwhelms us. The difficulties of loading other people's virtual worlds onto our computers overwhelms us. If the technology is so complicated that we can't use it (or so simple that it is comparable to reading a book or a journal article), then there is little motivation to continue its use. While we could hire an expert to build what we consider frustratingly complex, that would defeat our purpose. We are invested in the creative process and in the process of intellectual collaboration. Our inexperience also strengthens us. Our discomfort constantly reminds us that user-friendly designs will be important to our students.

Three-dimensional technology for the Web was, and still is, relatively new. We have searched and continue to search for ideas that are kindred. The virtual worlds which we have examined on the World Wide Web may share some ground with the worlds we are in the process of posting, but our work as we
envision it serves to fill in educational, technical, and aesthetic gaps. We were novices standing on the cutting edge of web-technology. Gathering information about software packages and comparing them was quite challenging. Our decisions were confounded by changes in vendor offerings and delays in funding. Our original plan was to produce a fully three-dimensional Plato’s Republic as the first component of MetaTopia. Instead, we began work on Charlotte Perkins Gilman’s Herland in flat text. It was only then that we realized that MetaTopia had become a monumental task. One with no end.

In the initial stages of development, students were asked to read utopian literary works, original texts, second-hand descriptions of life in community, and critical analyses. Student responses, accompanied by citations supporting each answer, to a series of questions will provide guidance as each community selected for inclusion is mapped. The first stage of the project included laying out flat text HTML for one community (with the expectation that this layout would serve as a map for more complex communities that would follow) and linking it together in two ways: 1) so that site visitors could follow a character through the website (allowing those more comfortable with linear thought processes to follow a path that was story-like) or 2) so that site visitors could follow a theme (allowing those more comfortable with a topic-oriented approach to move through the text). At all times during this early construction phase, we also kept in mind that we wanted site visitors to move among the communities with ease so as to foster comparison among them. We also kept in mind that visitors would vary in terms of their levels of sophistication and interest. For those who had, for example, some familiarity with the concept of utopia, we assumed that the theme-oriented path might hold more appeal. On the other hand, those who had little or no experience with the concept of utopia might need to be encouraged to continue their exploration by following a character with whom they could in some way hopefully identify.

It was precisely that, that there is no end to the task we have outlined for ourselves, that drew us initially to the task—and then in deeper and deeper into what seems a dangerous morass. Building utopian worlds, literary, historical, even contemporary, seems to be a thankless task. It was for them, we think. Why would it be any different for us? Those who have created utopian worlds, both those who have constructed their dreams on sheets of paper and those who have built them out of sweat and brick and stone, have had to endure not only the criticisms of their contemporaries, but are hounded still, even as they turn to dust in their graves. Unrealistic, say some. Unattainable, say others. Idealistic, charge still others. We, by undertaking this project, simply rejected these charges. Our engagement in this project should be read as an affirmation of the argument that heaven on earth can be created.

Our work is intended to serve as an operationalization of systems theory. The notion of interconnectedness, central to systems theory, remains a guiding force as we develop the sites. Students, like most academics, continue to live out their lives in one discipline, giving little thought to the relationships among them. By inviting students, or any site visitors for that matter, to examine utopian experiments, and to look for the commonalities, to examine what exists at the interstices, we may engage them in an exercise that has, ultimately, practical applications.

We believe that anytime anyone is engaged in a discussion about the proper goals of society, about the boundaries between personal behavior and the prohibitions of the group, about the rights, liberties, and duties of citizens, it is of benefit to the social compact. People who engage in such discussions are likely to be more active, more intellectually engaged. Simply being part of, and to some degree in control of, the process of exploration fosters the development of efficacy and power. This may be of relatively little value if confined forever to a virtual world—but if transferred someday to the real world, translated from attitude and belief to behavior, then heaven on earth is indeed possible. So, what was initially an intellectual exercise, a mindwalk of sorts, becomes a walk toward heaven which includes the body.

The single most problematic flaw in all utopian efforts, literary and otherwise, may be that the efforts at utopia building were conducted by single authors, or in the case of actual historical communities, by relatively small leadership cadres. Can one or a few people truly be expected to understand the functioning of an entire system, with all its constituent parts? Can one or a few be so omniscient? What if building utopia (not a utopia, which is what people have been attempting to do over the ages) takes the input of a large group? What if it takes us all? Utopia building in the virtual world is nothing short of the democratization of utopia building.

Towards Advanced Hypermedia: The Minimalistic Java Approach

Kai Warendorf
School of Applied Science, Nanyang Technological University, Singapore 639798
wdorf@acm.org

1 A Minimalistic Approach towards design of advanced Hypermedia

Development of a Java hypermedia application differs from WWW hypermedia development. Where most conventional WWW applications focus on the server, in advanced hypermedia development the focus is on the client application. In addition, development with Java is not based on existing components but will usually be implemented from the ground up. With Java, application design is more extensive. The object-oriented nature of Java encourages a fully object-oriented design.

We present the Minimalistic Java Approach (MJA) as a framework that links the advanced Internet hypermedia design process with implementation in Java. MJA does not intend to be a general hypermedia design methodology, since several extensively-used platform-independent methodologies already exist for hypermedia. Instead, MJA is result-driven and specifically aimed towards implementation. It is minimalistic because it does not rely on any specific development tool. All activities in MJA are based on a strong bottom-up and object-oriented approach to software engineering.

1.1 Consequences of Implementation in Java

Three aspects, specific for Java hypermedia, are addressed in MJA. They are the availability of development tools, the hypermedia authoring bottleneck, and integration with existing hypermedia:

1. Availability of tools and components: A large software library exists with freely available ‘plug-in’ extensions, languages and libraries for WWW browser and servers. In contrast, Java components and libraries for support of existing media formats are rare. This implies that only applications, which cannot be accommodated within the limits of conventional hypermedia development are worth the extra effort of custom hypermedia development.

2. The hypermedia authoring bottleneck: A second issue for hypermedia development is the central role of the authoring process. Without a supportive authoring environment, realization of a real world hypermedia application is laborious. This hypermedia authoring bottleneck [Nanard and Nanard 1995] is a major factor in the success or failure of new hypermedia architectures. Well-designed authoring tools or adaptation to existing hypermedia standards remove the bottleneck.

3. Integration with existing object-oriented hypermedia design: Among various hypermedia design methodologies, two were selected for MJA because both methodologies share language- and tool independence, as well as full object-orientation. The Extended Object-Relations Model (EORM) [Lange 1994] is based on the definition of a class hierarchy of semantically rich relationships. These linked classes allow designers to express the complex relations between hypermedia objects in fully object-oriented content. The objects are central in EORM because complex semantic information regarding hypermedia object relations can be stored in a single object. EORM’s relevance for Java based hypermedia design is to improve the conceptual shortcomings of most existing direct and non-semantic hypermedia link models.

The second hypermedia methodology in MJA is the Object Oriented Hypermedia Development Method (OOHDM) [Rossi et al. 1995]. It is a complete and graphically oriented methodology, specializing in hypermedia user interface definition. OOHDM applies graphical notation to define abstract data views, which express user interface dynamics in petri-nets. The communication between objects is expressed in configuration charts. With its graphical notation, OOHDM complements EORM, in particular for user interface specification.
1.2 The In- and Output of Java Hypermedia Design

MJA follows the waterfall model of software engineering, with seven development phases [Figure 1]. The top two layers display the design-input elements. The top input layer display is specific for Java; the second layer contains general design input. In seven phases, Java classes are defined, and after repeated refinements integrated in one prototype application. In MJA, Java source code has a role as a tool-independent design formalism. The language dependency of MJA promotes the direct implementation of abstract concepts from object-oriented modeling, closely integrated with the Java key technologies. The strong bottom-up approach, combined with prototyping and inclusion of two hypermedia design methodologies aims to overcome the incompleteness of abstract object-oriented software design, which are insufficient when used in isolation [Bryant and Evans 1994].

![Figure 1: The Minimalistic Java Approach (Italicised items are optional, depending on availability)](image-url)

2 Conclusion

We have introduced Java as a mature platform for advanced Internet hypermedia. With its platform independence, continuously increasing multimedia capabilities, and flexible distributed architecture, a hypermedia browser implemented with Java can eliminate various limitations of WWW hypermedia.

Acceptable Use Policies for Schools:
An Educational, Ethical, and Legal Analysis and Proposed Model

L. Dean Webb, Ph.D.
Professor of Educational Leadership and Policy Studies
Arizona State University
United States of America
webb@asu.edu

Martha McCarthy, Ph.D.
Chancellor Professor, Educational Leadership
Indiana University
United States of America
mccarthy@indiana.edu

The Internet offers a powerful new technology for the schools. However the promise the Internet offers for a free exchange of ideas and information is accompanied by concern for the potential online dangers to students being exposed to obscene material, sexual predators, material advocating or depicting violence to others, or racism. Media accounts of students accessing pornographic material or becoming victims of sexual predators have heightened parental concern about what their children are exposed to, a concern which is matched by educators' concern over school district liability [Marcus 1996]. The challenge for the schools is to provide Internet access to acceptable material, while denying access to unacceptable material in a manner that does not violate students' rights to privacy and freedom of expression.

The response of some schools to this challenge has been simply to not allow any Internet activity. Other schools have attempted to screen material through the use of blocking or rating software. Blocking software such as Cyber Patrol, Net Nanny, or InterGo block Internet sites that are known to contain pornography or violence or scan incoming text for specific words. Rating software, such as that produced by the Recreational Software Advisory Council or Safe Surf, are designed to permit or deny access to sites that based on their rating in specific areas [e.g., violence, sex, nudity, profanity, racism, gambling, etc.].

While blocking and rating systems can help protect students from objectionable online material, they are relatively new systems and their effectiveness depends heavily on the cooperation of the Web sites themselves [Truett, Scherlen, Tashner, & Lowe 1997]. Moreover, they require continuous updating and can be circumvented by expert users [Trotter 1996]. Another problem with the use of blockers is that in blocking certain potentially offensive words [e.g., "breast"], they block access to valuable information on many important topics [e.g., breast cancer] is also blocked [Trotter, et al. 1997].

Recognizing the limits of blocking and rating systems, as well as the fact that it is virtually impossible to prevent students from accessing materials whose existence can never be fully anticipated [Fishman & Pea 1994], many schools have adopted acceptable use policies (AUPs) as a strategy to ensure safe student use of the Internet. An AUP is a written agreement detailing the terms and conditions of Internet use. It also typically includes the penalties for violations of the policy [Laughon, Blacksburgh, & Hanson 1996]. Most school districts require that the student and a parent sign the agreement before Internet use is allowed. In addition to protecting students, AUPs intend to deter parental complaints and to reduce or remove the liability of the district resulting from any misuse by students [Sanchez 1996]. More importantly, acceptable use policies shift the focus from external control to students taking responsibility for their own behavior [Dyrli 1996].

While numerous schools have adopted acceptable use policies, too often these policies are internally inconsistent, lack clarity, and are illogical. For example, AUPs often include phrases which state that students shall not access "inappropriate" or "unacceptable" material without defining what these words mean. Such imprecision "shifts decision making away from students and toward administrators who decide after an incident..."
whether the policy was violated" [Trotter 1996, p. A13]. Another common phrase in AUPs states that students should not intentionally obtain copies of files or data that belong to someone else. On its face this statement would prohibit collaborative student projects--clearly not what its drafters intended [Kinnaman 1995].

This paper discusses the major educational, ethical, and legal issues related to AUPs, including liability, censorship, copyright protection, and students' privacy rights. It also presents the results of an analysis of AUPs from several dozen schools across the United States and Canada. Each policy was analyzed from an educational, ethical, and legal perspective. Based on this analysis, as well as a review of print and online literature, a model AUP is presented. The major components of the suggested model policy are: (1) an explanation of what the Internet is; (2) a statement that access is a privilege and not a right; (3) the process for governing local Internet system security, user accounts, and user privileges; (4) terms and conditions of use, including expected Network etiquette; (5) a specific explanation and reference to what is and what is not acceptable use; (6) the sanctions for violation of the policy; (7) a non-liability disclaimer of school responsibility or warranty for the services it is providing; and (8) student and parent signature.

1. Introduction

Constructivism seems to be the new paradigm in teaching. Most textbooks and older computer assisted learning (CAL) software are built upon behaviourism. New technologies and the increase of computational power of desktop PCs allow the implementation of this paradigm using highly interactive learning environments on desktop PCs. We implement CAL software on Windows based systems; our system is called Teach/Me.

2. User Interfaces for Learning Environments

In order to successfully implement such a learning environment, motivation of students has to be seen as one basic requirement. Providing different access methods and information retrieval features seems necessary to adjust to the different skills of users. The users of our courseware can be categorized into beginners, advanced students and experts. According to their experience in statistics and their familiarity with our software they have different expectations and needs.

Beginners want to get a quick and easy start and need short texts that explain the overall context of statistical methods and their application. They have to be motivated to start exploring the teachware. This can be achieved e.g. by applications using interactive graphics and sound.

Advanced students that already know how to use Teach/Me need to access more detailed information. To prevent users from getting lost in details it should be easy to change the level of detail, to zoom out, i.e. to look back to introductory chapters. Graphic and sound effects should still be used but less frequent than for beginners.

Experts are users that already know most of the contents of Teach/Me. They can use our program to study details or as a quick reference. A concise and powerful index and other retrieval features without any „cute“ graphics and sounds is the best choice to avoid annoying this group of users.

3. Implementation

3.1. Beginners

One basic problem for beginners in any field is the danger from getting overwhelmed by details. The student first has to structure his/her thoughts by building up a mental „landscape“ of the subject to learn. This conceptual clustering of [Hu 93], [Kremer and Gaines, 96] information is considered to be an efficient way to show students that are not familiar with statistics the basic structuring of and the relationships between chapters.

Each page of the underlying textbook is represented by a mountain in the landscape. The formation of the knowledge landscape is governed by two general rules: (1) fundamental chapters, explaining basic concepts, are visualized by high mountains, whereas more specific lessons are displayed by smaller mountains. (2) The placement of the mountains is done according to the similarity of the contents of the corresponding lessons. Since a great number of mountains may confuse and therefore demotivate beginners, the landscape can be flooded with water. The rising sealevel hides small mountains leaving only the fundamental texts visible.

Although students can explore the knowledge landscape on their own we also implemented what we call „guided tours“. Teachers may advise students to study regions in a given sequence. This is accomplished by an aircraft that follows the course set by the teacher. We found this feature most useful for beginners who do not know what texts they should read and where to start. Students that are used to reading printed textbooks can...
now use our aircraft to learn how to explore non-linear, non-hierarchical texts. 
For a large part of the text pages we have implemented small, highly interactive applets to support the understanding of mathematical concepts. Reading just the formulas and some text will never have the same positive learning effect as experimenting with the examples that illustrate the concepts. Further more Teach/Me features self adapting courses which configure themselves accordingly to the needs of the individual student.

3.2. Advanced Students

More advanced students may want to have access to more details, and more demanding methods. Therefore, the sealevel of the knowledge landscape can be lowered, uncovering more of the mountains which represent advanced material. Whenever a student is unsure about the context of a method, he they only has to look for bigger mountains, i.e. overview chapters.
Once a region has been explored students may want to mark this region. By placing light houses we allow them to set 3D bookmarks into the landscape. Those bookmarks can be preset by teachers but students may delete or edit existing light houses or add new ones.

3.3. Experts and Teachers

Students who already know most of Teach/Me's content and teachers who want to compile lectures and courses need ways to search the text efficiently. Therefore a full text search engine is provided which indexes the whole material of the textbook. In addition, we implemented the analogon of an index within the information landscape. All texts that contain the searched phrases will be marked by a user-specified texture.
We improved this feature by using the transparency of textures. Mountains representing texts which contain the search expression often or contain it in headlines or bold-face, will only be emphasized with the user-specified texture. If the texts does not fit so well to the search, the original texture of the mountain shines through.
Teachers may also want to use our interactive applications for demonstrations. We therefore strictly separated conceptual explanations and exploring texts from the interactive applications. All applications can be run in „teacher’s mode”, allowing full access to all parameters and modes.
Although the 3D information landscape is still useful for this group of users (e.g. texturing) we also provide a 2D overview map. This 2D representation allows the same basic interaction as in 3D; only the transparent texture mapping is not available.

4. Immersion and Future Tasks

The main task is to get people to like using our program. Games seem to attract people: productive, intelligent people often spend a lot of time playing adventure games. We hope to be able to fascinate users in a similar, though less brutal way by a more detailed, „nice“ 3D environment. Looking at animated objects, light houses, etc. does not directly help students with statistics but it keeps them interested in the subject.
Since computers are used for many tasks, users have the option to run a small program in the background. This program resembles the Tamagotchi [Chia 97]. Our little creature comes alive right after booting. Depending on its „annoyance“-setting it asks questions about statistics. Further investigation will show if adding small games that are not correlated to the learning task will increase the acceptance of our little creature. This approach seems a good way to keep people involved ; Whatever they are doing , they are led back to statistics by this creature.
In conclusion, we think that the combination of serious presentation of knowledge, and motivating visualization is a key issue in teaching . A user interface that can be adjusted to the user’s needs keeps students involved.

5. References

Abstract: Motivation of students has to be seen as a basic requirement for interactive learning environments. Ways to increase motivation can be seen not only in nice graphics but also in providing fast and easy access to any detail of the learning material, and in various kinds of user interfaces the user may choose from. We developed a networked learning and teaching system in the field of statistics ("Teach/Me - Data Analysis") which not only provides access in the way of a classical electronic textbook but also offers some new approaches, like knowledge landscapes, self-configuring courses, or embedded interactive applications. Teach/Me has been designed as an open system based on HTML and VRML, thus providing a framework for presenting material from any other subject, too.
CLear - A Cooperative Distributed Learning Environment

Martin Wessner, Jennifer Beck-Wilson & Hans-Rüdiger Pfister
Integrated Publications and Information Systems Institute (IPSI)
GMD - German National Research Center for Information Technology
Dolivostr. 15, D-64293 Darmstadt, Germany, E-Mail: {wessner, wilson, pfister}@darmstadt.gmd.de

1. Introduction

In today’s dynamic business world lifelong learning is a vital precondition of success. Often, the necessary knowledge to fulfill job requirements is not available from books, but is created in organizations and companies during the progress of the work. “The behaviors that define learning and the behaviors that define being productive are one and the same. Learning is not something that requires time out from being engaged in productive activity; learning is the heart of productive activity. To put it simply, learning is the new form of labor” [Zuboff 1988]. As a general goal, a method of utilizing this distributed knowledge, i.e. storing, retrieving, presenting and using it on the job, is required. A special challenge is the exploitation of the potential of cooperation in producing, comprehending and handling this information.

CLear (Cooperative Learning) is a prototype of a cooperative learning environment to support learning and training processes of groups including distributed remote learners. CLear is based on a hypermedia data model and supports a wide variety of learning situations, such as synchronous and asynchronous learning, co-located and distributed learners, and individual as well as a wide range of cooperative learning processes. Its architecture is flexible enough to extend learning processes to collaborative work or to integrated working and learning on the job. The objective of this paper is to report work-in-progress concerning several facets of the CLear approach: implementation and communication issues, psychological-educational issues such as methods and techniques of cooperative learning in virtual environments with a focus on training in companies, and learning/working interactions. In addition, the paper presents some preliminary concepts with respect to evaluation issues.

2. Theoretical Approach

Cooperative learning can be defined as the acquisition of knowledge and skills driven by a collaborative and interactive effort of a group of individuals, thereby gaining knowledge and competence not only by increasing individual competence, but also by obtaining social skills through permanent communication and immediate transfer of knowledge (see, for example [Bouton & Garth 1983]). The CLear approach is based on the metaphor of a virtual world and virtual rooms which are shared by an arbitrary number of persons. Each individual who participates in the learning process is an “inhabitant” of the virtual world and is associated with a virtual room, which provides functionalities to store and use hypermedia documents. Other virtual rooms such as auditoriums, group working rooms, public rooms for non-work related communication, and special rooms for trainers currently exist and users can easily create new rooms as needed. In addition, users can have different roles, e.g. trainer, learner, tutor, and different rooms may indicate these role assignments. As in the “real world”, individuals can move freely throughout this virtual world, visiting and cooperating with other inhabitants. This general model can be adapted to fit the specific type of learning/training task and the individual characteristics of the learners. Constraints such as access rights for different rooms, documents or other resources, and the provision of specific functions (e.g. help features) can be implemented according to user requirements.

3. Features of CLear

CLear is based on previous work at GMD-IPSI in the field of cooperative work and learning. Specifically, CLear builds upon ideas of the DOLPHIN system [Streitz et al. 1994], but has extended DOLPHIN’s functionalities to meet the requirements of the virtual room metaphor. The prototype is implemented using the COAST framework...
[Schuckmann et al. 1996], which allows easy development of cooperative applications. CLear provides functionalities for
- synchronous and asynchronous learning,
- remote and co-located learners/trainers,
- individual and cooperative group learning.

All learners are equipped with individual workstations which are networked and connected via audio/video communication channels. Each virtual room offers a shared workspace for the inhabitants. Co-located teams make use of (real) team rooms equipped with video projectors and an electronic whiteboard. This enables tele- as well as face-to-face communication. Individual self-study is supported by private virtual rooms which provide facilities to work on various hypermedia documents and access to databases. Synchronous presentations, demonstrations and discussions are supported by access to a common virtual auditorium (public whiteboard) and by functionalities that support parallel communication of a trainer to all or to a subset of learners. Synchronous cooperative learning is supported by virtual group rooms for special work and discussion groups. In all virtual rooms the documents may be shared, jointly edited and annotated by the participants.

4. Research Questions

The basic platform with its flexible role assignments and open access policy can be tailored to specific demands by putting constraints on the communication and document access features. In general, however, CLear aims at supporting small or medium sized groups of adult learners (e.g. departmental training groups) and focuses on a task-oriented learning style. We have begun to introduce modifications and/or restrictions of the general platform by adapting the following variables: individual access and communication rights, group structure (hierarchies, heterarchies), group size, content characteristics, instructional strategies, form of presentation.

Type and amount of necessary modifications to the general platform are derived from considerations about: content type (from motor skills to problem solving), content difficulty, content scope, individual differences in knowledge, individual differences in learning competence, amount of common knowledge in the group, cooperation capability of the group, time constraints.

5. Evaluation

Prototype evaluation, done in the winter semester 1997/98 at the Technical University of Darmstadt, focused on the handling and acceptance of the virtual room metaphor for cooperative learning. Results indicated that students found the system easy to use and generally accepted this metaphor. Furthermore, the evaluation provided us with invaluable input concerning the functionalities of the virtual room in relation to hypermedia documents.

1. Introduction

Traditionally, expert knowledge has been documented monolingually in printed form (typically linear texts) and trained in classroom environments. Progressive specialization, decreasing life-cycles of expert knowledge, and the growing decentralization of corporate knowledge in the wake of the globalization of industry and trade have made us painfully aware that the needed expertise is increasingly difficult to obtain or learn through the traditional forms of documentation and training.

Moreover, global communication among experts as well as between experts and non-experts, but also political developments such as the unification trends in Europe and the shortcomings of available automatic translation facilities have brought another need to the surface that can no longer be satisfied by an individual expert or traditional printed resources: the need for multilingual dissemination of expert knowledge.

As surveys have shown, the needs in institutional as well as industrial environments in terms of knowledge management (corporate intelligence) are manifold. They include

- to secure specific knowledge for the organization
- to centralize distributed knowledge to make it accessible
- to provide knowledge in multilingual and multimedia representations
- to organize knowledge in flexible ways (different types of ordering criteria)
- to make knowledge accessible for distant and on-the-job training
- to present knowledge to clients

The objective of this paper is to outline possible solutions for such demands as instantiated by the knowledge management system FILCOM 3.0. Three topics were considered particularly relevant in this context:

- how knowledge should be organized
- how a high degree of flexibility in representation can be obtained
- which features have proved valuable in the design of the tools and the knowledge bases so far implemented

2. Knowledge engineering

The conceptual design underlying FILCOM development rests on the assumption that different people may share knowledge and that such knowledge may be structured irrespective of any particular language. It was further assumed that expert knowledge consists of an inventory of atomic knowledge elements (conceptual units) which may be related in particular ways within a semantic network. The relations used in FILCOM are directional and labelled. Classifications are made with resort to "type-relations", extensions with resort to "topic relations", "part-whole relations" etc.

A special feature of the FILCOM knowledge management system is the potential for multiple classification. First, subordination can be made relative to different ordering criteria. For example, a particular product type may be classified into subtypes relative to size, type of production, type of ingredients, or else. This feature has
proved particularly helpful for non-experts to disentangle otherwise heterogeneous concept classes. Second, one particular knowledge element may be multiply associated with other knowledge elements. For example, "safety precautions with machine-based drilling procedures" may be classified as a subtype of "safety precautions with machines" or "safety precautions with milling". Moreover, it may desirable to classify this knowledge element as a relevant topic of discussion relative to "milling". The multiple connectivity is a characteristic feature of the conceptual network as developed by our group.

3. Knowledge representation

FILCOM allows a highly flexible display of knowledge to serve the needs of different user groups.

For the display of conceptual structures two alternatives are offered: hierarchical tree diagrams to provide macroscopic orientation within a given domain of knowledge, and conceptual networks to provide for microscopic orientation relative to a selected point (concept) of interest. Trees and networks are convertible.

Natural language representations can be freely appended to the elements of the knowledge base. Within-language representations include terms, definitional paraphrases, text passages or documents. One should note that one knowledge element may have more than one linguistic representation (e.g. synonyms), and that vice versa a particular language unit may represent more than one knowledge element (i.e. polysemy). Further language representations can be freely added, however, cross-linguistic representations are not directly associated among each other (for lack of 1 : 1 correspondence), but only via the knowledge base. It is only due to the knowledge-centred representations that a reliable multilinguality can be established.

Multimedia representations can also be freely appended to knowledge elements and displayed in parallel to language representations. In particular, multimedia facilities may be used for the purpose of displaying the pronunciation of words and text (sound files), the graphic display of objects (images), and the display of processes (videos, animations).

First experiences with users of the existing knowledge bases in industrial environments (e.g. metal processing, automation techniques, and food production technologies) suggest that there is no single type of representation that can be usefully applied generally or is generally preferred over others. For example, concepts of the abstract type seem to be most easily accessed through symbolic (verbal) representations, whereas concepts referring to real world objects are often most comfortably accessed in an analogue (visual or acoustic) representation. Moreover, individual learners may differ as to preferred representation. There is also evidence that exposure to multiple representations may have both, favourable or disfavourable effects on the process of perceptual intake, depending on the kind of display. Images with convertible cross-linguistic inserts have proved particularly effective to help learners overcome language barriers.

4. Where the system is bound to be intelligent

The amount of AI implemented in the current version of FILCOM is still modest. Among the AI-related features which users have found beneficial are the following:

- a multilingual dictionary can be dynamically generated from the knowledge base where the user can freely choose source and target language from the languages implemented and where they can define the scope of the output (selected domains of the knowledge base)
- translation of terms among languages can be automatically produced even where a dictionary does not yet exist
- documents for autonomous and distant (multilingual) learning of expert knowledge can be issued (on-line and off-line)

For further information about the scope of the application cf. the workgroup's homepage http://www.f-com.at

1. Introduction

Distributed learning systems on the Web have the potential and often the intention of reaching greater numbers of culturally diverse students. The key to success in the use of the Web across cultural boundaries lies in the appropriate design of on-line educational environments (Harasim, 1995; Henderson, 1996). Our own research (Henderson, Patching, & Putt, 1996; Wild, et al., 1997) has demonstrated that the Web is almost always chosen as a delivery medium for instruction primarily for its ubiquity and insignificant costs; however, it is not chosen for its instructional effectiveness; nor is it chosen as a medium particularly suited to carrying a range of information types for culturally diverse learners. In this context, creating systems for teaching and learning on the Web may well work to limit efficacy in learning, despite the Web’s ever-developing technical capacities to carry multimedia materials and information, and its growing provision for various levels of complexity in learner-material interactions. Indeed, while many learners might possess the basic information and navigational skills to contend with information access on the Web, instructional designers are yet to consider those aspects of this medium that determine its effectiveness for all learners, whatever their cultural characteristics. Henderson has determined, as late as 1996, ‘the relationship between cultural context and instructional design has received little attention in the educational technology and instructional design literature’ (Henderson, 1996 85). It seems apparent that the lack of research to target cultural issues in instructional design for distributed and interactive learning systems, such as those being placed on the Web by universities in ever-increasing numbers, is even more noticeable and is likely to have serious consequences, particularly for students as well as for universities.

This paper rationalises the need for further research into the use of Web sites as vehicles for flexible learning, especially for students of diverse cultural backgrounds. The presentation of the paper will also describe an original conceptual framework for conducting such research and demonstrate some of our early findings.

2. The influence of culture

The nature of the Web has attracted a great deal of rhetoric in favour of its potential to provide for a student-centred model of learning, where the learner is both intrinsically motivated and active in the learning environment (Becker & Dwyer, 1994). Certainly the Web, in terms of being a dynamic, extensive and extensible information base, provides for the ultimate in resource-rich learning. However, there is little guidance, and virtually no empirical research, to help determine the most appropriate ways of using the Web to stimulate effective learning. It is apparent, however, that instructional design for Web-based learning systems cannot, and does not, exist outside of a consideration of cultural influences—both the cultural influences operating on the authors and instructional designers of Web-based learning materials, and similarly, those influences that impact on the interpretation of such materials by learners.

Defining culture is a difficult proposition and many different classifications exist in relation to national culture. The most pervasive view appears to be that culture is a manifestation of ways in which an identifiable group adapts to its changing environment; that people often belong to more than a single cultural group, embodying a subset rather than a totality of a culture’s identifiable characteristics; and that they do not remain totally allegiant to their birth culture (Scheel & Branch, 1993).
There is also a clear consensus that culture must have a definite and very strong influence on the design and use of information, communication and learning systems, as well as on their management, despite the lack of identifiable research in these areas. In all areas of human activity, the behaviour of people is affected by the values and attitudes that they hold and the societal norms which surround them. When values are widely shared by a group of people, they are provided with a common mechanism by which they can share understandings and interpretations of their world. Culture, however, is more than just an abstraction, it also consists of a distinctive symbol system together with artefacts, that capture and codify the important and common experiences of a group. Distinctive significant symbolic meanings and values develop around information, its use and structuring in any cultural group. Also, at a practical level, when the act of instructional design translates this information into products or artefacts of learning, that artefact embodies cultural influences, such as the instructional designer's world view, their values, ideologies, culture, class and gender, and, their commitment to a particular design paradigm (Henderson, 1996).

These interacting cultural factors have a particular importance for the diffusion and efficacy in use, of information, communication and learning systems, such as the Web, and the products and materials of learning provided in those systems.

3. The need for investigation

Henderson describes three existing instructional design paradigms in static (ie. CD-ROM) multimedia products: (i) culturally unidimensional or exclusionary; (ii) inclusive; and, (iii) inverted (Henderson, 1996). For each of these paradigms, there is clear evidence they are either incomplete or problematic in terms of providing culturally appropriate instruction (Henderson, 1996 91). Also, work in progress by Wild and Henderson (Wild & Henderson, 1997) has begun to show that these same, unsatisfactory, paradigms also dominate in learning systems presently being provided on the Web by a range of educational and training institutions, and intended for use by culturally diverse students.

Thus, we presently have a situation where adverse cultural influences in the Web are present and are largely created unknowingly; and as a result, work to the detriment of large groups of culturally diverse learners who cannot identify with the instructional designs in Web-based systems of teaching and learning, originating as they do, in single cultural (usually 'western') identities. This problem, if uncorrected, is likely to become more evident as Web-based learning systems are increasingly put into place in the later 1990s and into the new millennium.

Situated Learning Environments: Theories and Perspectives

Douglas C. Williams
University of Texas at Austin, Department of Curriculum & Instruction, USA, dcw@mail.utexas.edu

1. Introduction

Today's society demands that individuals be capable of problem-solving, learning new tasks, and adjusting to change. Many schools have come under criticism for failing to develop in students the ability to apply knowledge in diverse contexts.

Authentic or situated learning environments have been proposed as a possible solution to these problems. Advancements in technology offer the possibility for the economical implementation of such learning systems. Problem-based learning, an instructional strategy which emphasizes problem-solving in situated contexts, exemplifies situated learning. Therefore problem-based learning will be used to explore the theories and perspectives that can benefit students working in authentic/situated learning environments.

2. Background

2.1 Situated Cognition

A problem that has been receiving increased attention is the failure of students to transfer what they have learned in school to everyday situations. One can argue that information becomes knowledge in its application. Therefore schools must emphasize knowledge in action (e.g. activity). The application of knowledge requires the consideration of context since activity takes much of its meaning from the situation. The context and activity that individuals engage in are impacted by the culture that embodies it. Therefore, understanding is a result of activity, context, and culture [McLellan 1993]. This view is embodied in theories of situated cognition.

Situated cognition grew out of research which explored the manner in which people reason and solve problems in everyday life. In dealing with everyday events, individuals reason with intuition which is developed through experience in specific contexts [Choi & Hannafin 1995]. The context and the activities in which students engage are an integral part of what is learned [Brown, Collins, & Duguid 1989].

2.2 Problem-based Learning: An Example of Situated Cognition

Problem-based learning (PBL) embodies many of the elements of situated cognition though it grew out of a different research tradition. PBL is a type of case-based learning which places emphasis on solving authentic problems in authentic contexts. PBL was developed in the 1950’s for medical education. Today PBL can be found in business schools, schools of education, architecture, law, engineering, social work, middle schools, and high schools [Barrows 1996].

Three implementations of problem-based learning are of particular interest since each emphasizes different design features. The Cognition and Technology Group at Vanderbilt developed anchored instruction where video-based scenarios “anchor” instruction in authentic problem-solving tasks. Roger Schank at the Institute for the Learning Sciences, utilizes computer simulations to embed learning in authentic problem-solving activities called goal-based scenarios. Cognitive flexibility theory, developed by Rand Spiro, emphasizes learning from multiple perspectives in ill-structured domains. Each of these implementations emphasize different elements of authentic learning environments and situated cognition.
The Cognition and Technology Group at Vanderbilt developed an implementation of problem-based learning which is called anchored instruction. Anchored instruction is an approach to instructional design whereby learning is situated or “anchored” in authentic problem rich environments [Cognition and Technology Group 1992]. The problem is set in a “macrocontext” which creates an environment for shared exploration by the teacher and students. By providing these elements, anchored instruction helps create authentic learning situations in the traditional classroom.

A Goal-Based Scenario is a problem that lies in the student’s area of interest that presents a goal to be accomplished [Schank, Fano, Jona, & Bell 1993]. From Schank’s perspective, the learning of skills and processes provides students with meaning and value for education. A skill is something one knows how to do. The student feels empowered by learning the skill and society benefits from having a skilled work force. A process is a system of relationships. Processes should be taught by selecting a goal the students will achieve and the skills to be learned in the context of the process. Students will seek out relevant information that they need to acquire while learning the skills and processes.

Cognitive flexibility theory grew out of research on the learning of advanced concepts in ill-structured and complex domains [Spiro & Jehng 1990]. Ill-structured knowledge domains present unique problems for learning since the application of concepts varies from situation to situation. In other words, the high case-to-case variability prohibits the development of concepts which have broad application. In contrast, structured knowledge domains allow for the development of concepts which can be applied to many cases thereby facilitating learning.

In order to accommodate advanced learning, one must have cognitive flexibility. Cognitive flexibility is defined as the ability to restructure one’s knowledge in many ways, depending on the learning situation. The ability to restructure one’s knowledge facilitates the accommodation of the high variability found in ill-structured domains. The storing of knowledge in multiple representations in long-term memory and utilizing processes of schema assembly results in cognitive flexibility.

3. Conclusion

These implementations of problem-based learning provide insight into the benefits of instruction that embody elements of situated cognition. Anchored instruction, goal-based scenarios, and cognitive flexibility theory illustrate the efficacy of learning that is situated in authentic contexts and activities. But further research is needed to establish which tools and features can support student learning.

What Are They Learning with Technology?
The Situated Learning of Collaborative and Service Work with Information Technology Management

John Willinsky, Larry Wolfson, University of British Columbia, Vancouver, Canada, V6T 1Z4
and Vivian Forssman, Knowledge Architecture
john.willinsky@ubc.ca

Abstract
Students taking a new Information Technology Management (ITM) course in high schools are learning to deliver technical support, services and training to their schools and communities. This experience of service learning opens a new range of skills that can best be assessed by using a "situated learning " framework that moves the analysis of learning away from specific technical skills to a much broader range of contexts that include problem-solving, collaboration, reflection and communities of practice. The advantages of this focus, when it comes to assessing the learning that goes on when with the introduction of technology into education, includes school to work transition, authentic evaluation, and community engagement.

The Information Technology Management (ITM) program was initiated in 1994 by Knowledge Architecture Inc., a Vancouver company that was established by a University of British Columbia professor and IT industry professional to make a distinct social and technological contribution within Canada’s telecommunications, information and education infrastructure. In a very short period, the company worked with teachers and industry people to develop one of the first project-learning programs. Students are currently taking ITM courses in Quebec, Ontario and British Columbia.

The ITM program is designed to provide students with authentic problem-solving experiences, engaging with different communities of experts as they seek answers to technology challenges encountered while supporting users who need assistance with new technologies. It places the students in collaborative learning situations that develop their sense of accountability and responsibility. They are learning about the nature of work in today’s new economy, a workplace fueled by the development of new technologies, where business success is determined not by the ability to “build a better mousetrap”, but by exemplary service delivery to the customer or client. In British Columbia the services which students provide as part of the ITM program has been recognized as a valid form of accredited “work experience” required for graduation.

This paper describes how students using new information technologies to provide service to others can be said to be engaged in “situated learning” (Lave & Wenger 1991). The literature on situated learning, under which we group a number of related concepts such as cognitive apprenticeships and situated cognition, provides a framework for analyzing various qualities of learning that relate to how people acquire new skills and become members of communities of practice (Greeno, 1997). We find this emphasis on the situation of learning, and the social practices that support learning, to be particularly salient when assessing the value of students’ work with information technologies, especially when that work entails projects that support the technology needs of the school and community as an instance of “service learning” (Olszewski & Bussler, 1993). See Table 1 for how we have created a framework for analysis of learning, with research currently underway by Larry Wolfson documenting the learning achieved by students as observed by researcher, student, teacher, and “client.”

Students in the ITM program are supported by Studio A: Website as Worksip (http://www.knowarch.com). This website offers them a personalized workspace has at its center a project book which provides the student with the templates, tables and informational links needed for planning projects in close collaboration with other students. The project book encourages students to achieve a high degree of accountability to both the “client” and the teacher. They also have an electronic portfolio for placing materials to be evaluated by the teacher or for showing to prospective employers. The student’s project book includes a skills matrix for students to set goals and review progress in light of the course’s goals and assignments which also forms part of the project book. The student can also reach out through
the project book to a wide variety of telementors who have joined the ITM program to provide online help with technical and service questions, as well as career advice. After working in their project books, students can also take a stroll through the Studio A neighborhood which offers ITM students and teachers a chance to check out what others in the program are up to in the Student Showcase, visit the Cafe' for up the minute news and a chance to exchange opinions, seek or offer help, make conversation, use the ThinkTank for evaluating issues and policies in essays or reports, or look up Just-in-Time-Learning to help them build the know-how in Information Technology they need for projects.

What do the students actually do in an ITM course? Laurane Parris who teaches the program in B.C. writes that, "with this emphasis on helping people manage, ITM students offer services ranging from providing on-the-spot relief to such calls as 'Help, the printer's jammed!' or 'How do I send e-mail?' They also get deeply involved in more complex, longer term projects such as...

- Building a school home page that will go up this year on the Web.
- Creating animations in 3-D to run on the hall monitors displaying school/community events.
- Participating in the planning, configuring and installation of a LAN at the nearby elementary school.
- Developing a hypercard stack on peer counselors to guide students.
- Implementing a FirstClass Server as the school's e-mail system and bulletin board.
- Assembling a demonstration computer in a clear plastic case.
- Implementing a web server to create and maintain web pages for non-profit groups in the community.
- Planning a web radio station for the broadcasting class to run.
- Establishing a production center for desktop publishing and multi-media presentations in the school.

Collaborative Learning: Integrating Student-Created CD-ROMs Into The Teaching of Local/Georgia History

Dr. Mary Ellen Wilson, Division of Social Science

Professor Troy V. Sullivan, Division of Business Administration

Middle Georgia College, 1100 Second Street, SE, Cochran, GA, 31014-1599, USA

1. Introduction

For a number of years college and university teachers have been encouraged strongly to adopt computer-based technology into their curricula in order to alter favorably the learning environment and the education process. Many of the faculty, in various disciplines, have awaited eagerly the opportunity to embrace the latest of these innovations and have been more circumscribed by the lack of enabling equipment/software than by their lack of computer-related knowledge or skills. In this paper we wish to present our plans and findings for incorporating the employment of student-created CD-ROMs into the teaching of a single course: Local and Georgia History.

This Local/Georgia History team teaching project was intended to empower students to author the content of a compact disc (CD) through networked interactive multimedia as part of the course requirements. It was anticipated that students would perhaps learn more by doing and become increasingly motivated because of participatory learning [Lennon & Maurer, 1994] and [Laurillard, 1993]. Our secondary objective was to use this successful project as an interactive multimedia model which might be replicated in or at least transferred to similar college-level courses. It was also planned that the student CD-ROMs would be used for assessment purposes.

With the combined course offering, students were assigned a family history project which would comprise a significant portion of the course grade for Local/Georgia History. At the beginning of the quarter, students were directed to bring in old and new family photographs, excerpts from diaries, legal documents, letters, newspaper clippings, etc., to scan into a computer. Furthermore, students were instructed in the methods of researching and writing a family history narrative. Student progress was monitored at intervals during the quarter. Selected contents of the student-created CD-ROMs will become part of the course content and its multimedia presentations as semesters progress. The Local/Georgia History course CD-ROM files will then be dynamic and divided into segments covering such topics as buildings of architectural significance, political events, modes of transportation, landscapes (forests, rivers, streams, farm land, etc.), scenes from area towns, industry, social gatherings, and hunting.

2. Classroom Methods

To provide students with the necessary computer skills in order to produce successfully a compact disc, Professor Troy V. Sullivan instructed our dual enrolled students in the use of Novell networked personal computers using NetWare (100 bit high speed network) supported by a Compaq Prolinea server using the Windows 95 operating system in his Introduction to Computers course (CIS 100). Students were taught also how to use the World Wide Web via the Internet accessed by Netscape Navigator 4.0 software to download text, graphics, video and sound to aid their creations/recordings. These students also used Corel WordPerfect 7 application software as their primary means of text input. WordPerfect topics covered in class included graphics, text boxes, templates, textart, and, of course, word processing for preparation of the family history narratives. They were also instructed in the manner one may employ that software while preparing term papers with appropriate documentation. Also included in the CIS 100 course was Corel Quattro Pro 7 applications so that students might create personalized graphs and charts. The students were further instructed in the use of a Hewlett-Packard (HP) ScanJet high-resolution scanner using HP PaperPort software and, to explain certain parts of assignments, he used a ceiling-mounted Sharp LCD color projector in the microcomputer laboratory. They employed Corel WordPerfect 7
software as their word processor and the HP ScanJet scanner to input pictures and other text into their document files stored on the instructor's LS 120 disks until ready to prepare their compact discs. Easy-CD Pro for Windows 95 authoring software recording to a Pinnacle Micro RCD 4X4 CD-ROM driver was used to create the individual CD's. Easy-CD Pro would prepare the discs for writing by first testing the speed of the CD and then copying the selected files. Approximate creating times ranged from 15 to 35 minutes, therefore, we found that creation time can be a problem associated with large classes. We also discovered that students not having LS 120 disk drives (or comparable) and/or individual CD-ROM drivers within their workstations created unnecessary delays during creation/recordings.

3. Conclusions

It is the intention of the participants in this project to adopt, on an ongoing basis, present and future-emerging computer-based and interactive multimedia technologies that are increasingly being embraced for academic instruction and active learning. For example, the writers intend to seek grant funds in order to equip at least the laboratory in which the Introduction to Computers course is taught with what is known as LS type drives in order that our students creating CD-ROMs will have the capacity necessary to receive photographs from scanner input. The planned structured student use of the Internet and the World Wide Web for online data retrieval and peer collaboration, as well as the development of a CD-ROM, will be part of the requirements of Local/Georgia History and will be added to the existing integration of PowerPoint assisted lectures.

It was comforting to discover that, during the quarter in which we discussed and used the CD-ROM technology, these students demonstrated a hands-on knowledge of computers and their uses which should aid them in the future in many facets of their education and employment careers—which is, after all, what we within the profession are all about.

It is not the purpose of this history instructor to replace the lecture with courseware, however, the infusion of these and other techniques of today's computer-assisted learning into the regular presentation of academic content is beginning to alter significantly the technical learning environment while calling for the development within our institutions of a new infrastructure for "lecturing technology" in the "electronic classroom" [Brennecke, Schwolle & Selke, 1997] and, [Lennon & Maurer, 1994].

1. Can a Computer Program Replace the Traditional Way of Learning Morphological Hematology?

The examination of blood films is a frequent task in medicine. Physicians and laboratory technicians must be capable to perform it. The best way to learn this task is with microscopes for two or more viewers or with mounted video cameras and monitors which allow students and teachers to discuss all the characteristics of the various blood cell types. This procedure is time consuming for teachers and requires an expensive infrastructure. Additionally, the teachers and the technical equipment are often not available when needed. Therefore, scheduling of both human and technical resources is essential.

This unsatisfying situation triggered the idea for a computer based learning program which would be a valid alternative to the traditional setting. To overcome the restrictions of time and place for its many other advantages [Friedmann 1 1996], we decided to put our a „digital“ Hematology tutor on the World Wide Web. To express this idea of freedom, the name „HemoSurf“ was given to the program.

2. What Shall Students Learn with HemoSurf?

The objectives for our web based learning program are:
1. To give learners reliable competence in interpreting blood and normal bone marrow films.
2. To link theoretical knowledge of hematological and other diseases to their morphological manifestation in the blood film.

3. What are the Educational Principles of HemoSurf?

Interpreting blood and bone marrow films relies much on pattern recognition. Therefore, HemoSurf is based on a collection of over 1500 images taken with a 3CCD video camera mounted on a microscope and digitised with a framegrabber card. These images can be accessed in different ways and with different intentions. Going through levels of increasing complexity and always receiving feedback (see figure 1), the student becomes capable of performing white blood cell counts and recognising qualitative alterations of blood films. Like in reality, the user must finally differentiate 100 blood cells. At the end, he can compare his results with the correct ones and review the misinterpreted cells. A comparison of the different cell types and the different blood films is possible throughout the program (see figure 1). A gallery of blood films allows the opposite approach by looking up the blood films of different hematological diseases. The morphological appearance serves as trigger to acquire theoretical knowledge which is provided with context specific links to a hypertext (see figure 1).

4. How is HemoSurf Accepted by Learners and Teachers?
HemoSurf is integrated in the first clinical year at the medical school of the University of Bern. Students prepare with HemoSurf for the practical courses in Morphological Hematology. Teachers report an astonishing increase of competence of the students making the practical courses a lively and rewarding experience for all participants. Nevertheless, nobody wants to give up to learn with the microscope because the quality of the electronic images is still not as good as in reality and lacks the 3D feeling when moving up and down the blood film.

Figure 1: In a series of images of blood films with numbered cells the learner must identify each cell by choosing a name from a popup menu (left). Feedback is given immediately. A window for comparison of the different cell types is always accessible (right). Another window provides theoretical knowledge when needed.

5. What Brings the Future?

The experiences so far encourage us to continue the further development of HemoSurf. An important new feature will be the introduction of clinical cases. Emphasis will be put on the demonstration of the course of a disease. The strength of HemoSurf lies in its image related interactivity. It will be a challenge to apply this didactical approach to other image based areas of Medicine like Radiology or Dermatology. These learning resources will contribute to the vision of a Virtual Clinical Campus and hopefully be so-called "killer applications" [Friedmann 1996]. Another idea is to use HemoSurf or similar learning programs for computer based examinations. Right now, this form of examinations is not accepted by the faculty.

6. Are There Other Websites Like HemoSurf?

There is quite a number of hematological websites. Most of them only allow browsing through an image collection without any form of interactivity. Unfortunately, the quality of their images is often mediocre and only one image per disease is shown which is insufficient to develop pattern recognition. Many sites offer clinical cases which are very useful to learn Clinical Hematology. A good list of links to educational hematological sites can be found at MedPharm of the University of Torino (http://www.medfarm.unito.it/education/hemato.html)

Technology Enhanced Instruction: A Model That Improves Science Learning And Teaching

Janice E. J. Woodrow and Jolie A. Mayer-Smith, Department of Curriculum Studies, University of British Columbia, Canada, Janice.Woodrow@ubc.ca, mayersmi@unixg.ubc.ca

Erminia G. Pedretti, Ontario Institute of Studies in Education of the University of Toronto, Canada, E_Pedretti@tednet.oise.utoronto.ca

"What students are gaining is the opportunity to see a different instructional style, one that is perhaps more in line with what they’ll be facing out in the real world, not only just in college and university but what they have to do in real jobs. They have to cooperate with one another, have to work independently, have to set goals, have to evaluate themselves. I think that is one of the major strengths of the TESSI program." L. Dukowski, Principal, Poppy Secondary School, Langley, B. C.

1. Purpose

This paper describes the Technology Enhanced Secondary Science Instruction (TESSI) Project which developed and tested a pedagogical model which has enhanced student learning by systematically and successfully integrating technology with instruction and classroom learning. The underlying research questions are: What happens when technology is integrated into science classrooms? What is the impact on student learning and teacher instruction?

2. The TESSI Model

The context for this study is the Technology Enhanced Secondary Science Instruction (TESSI) project [Woodrow, Mayer-Smith, & Pedretti, 1996]. The TESSI project was founded on the premise that if Technology Enhanced Instruction (TEI) were to become an essential part of science classrooms, technology applications must not be supplemental to the educational process but must be fully integrated into courses and programs. Initiated in 1992 in two Physics classrooms, and now expanded to ten science classrooms spanning grades 9-12, the TESSI project combines the educational opportunities provided by classroom-based, multimedia technologies with student-centered teaching strategies that encourage students to access and use knowledge rather than to accept scientific information delivered through traditional, transmissive modes. Student learning is variably paced, individualized, collaborative, and mastery-based. The longitudinal nature of the study, coupled with the consistent use of technology by both students and teachers, provided the opportunity to develop a variety of strategies for implementing technology into science classrooms—the TESSI model, and to reflect upon the impact of these strategies. Fundamental to the TESSI model is the availability of a variety of technologies within the classroom itself: technology is used as an enabling tool to enhance teaching and learning, neither as a substitute for the teacher nor as an "add-on" to the curriculum.

The physical resources of TESSI classrooms and the TESSI pedagogical model facilitate a non-traditional model of student learning. The curriculum is presented through a combination of technology-based activities, small-group instruction, one-on-one interactions, and hands-on activities. TESSI students are active participants in the learning process: they assume much of the responsibility for the depth and rate of their learning. Their learning is guided by a set of interactive Study Guides specifically designed for the process. Students work in small groups on interactive laserdiscs and CD-ROMs, computer simulations, MBL and multimedia activities, and, when necessary or desirable, with more traditional formats including texts, labs,
demonstrations, problem sets, and field work. TESSI also incorporates interactive, computer-based testing to enable both the student and the teacher to quickly identify learning difficulties.

3. Outcomes

"As administrators, we have all heard about the benefits of technology. TESSI is the first program that I have seen where the benefits are actually being realized." (C. Gesy, Principal, Brookswood Secondary School, Langley, B. C., Canada)

After six years of operation, the results of the TESSI project support claims that learning can be enhanced through the thoughtful implementation of Technology Enhanced Instruction. Students showed evidence of conceptual change in how they viewed their role and that of their teacher in the science classroom. They regarded themselves as directing and monitoring their own learning, and saw their teacher as a "helper" in that process. Attitudes towards assessment changed as assessment came to be regarded as a means of monitoring and enhancing learning rather than as an "obstacle to be overcome." Students demonstrated increased goal setting and time management skills. Enrollment in, and successful completion of the senior science courses has increased significantly.

The classroom ratio of students to computers in TESSI classrooms of 3:1 naturally results in students working in groups with the technology. Such grouping encourages dialogue among the students. These conversations help students link verbal representations of concepts with the pictorial representations viewed on the screen. Grouping also promotes task collaboration within the context of computer-supported learning. It is not an uncommon sight to see several TESSI students at a simulation, discussing how the physical variables interact or what will happen when a variable is changed.

The implementation of TEI acted as a catalyst for change from teacher-centered to student-centered instruction. TESSI teachers experienced a conceptual shift in how they viewed their role in the science classroom. They saw their roles as changing from that of "transmitter" to that of "facilitator." Mastery-based learning was promoted through the teacher's ability to diagnose specific learning problems, provide additional learning materials, and retest individual students with a minimal expenditure of classroom time. Assessment of students was more frequent and more focused on specific curricular objectives. Both formative and summative assessment procedures have been implemented. The use of technology also permitted the introduction of alternative activities, adjusted to individual student learning styles.

4. Conclusion

TESSI has illustrated how technology can be successfully integrated into daily classroom practice. The TESSI model is a means whereby teachers may be guided to quickly achieve TEI learning benefits such as deeper learning, skills backed with understanding, higher scientific literacy, skills in working with knowledge, communication skills and group problem-solving skills. The TESSI model has achieved these benefits in the two Physics classrooms consistently over a six year period and is in the process of realizing the same benefits in the General Science, Chemistry and Biology classrooms. The model has been particularly successful in attracting women students to Physics and helping the "average" student to achieve success in Physics. A fundamental goal of the TESSI project is to disseminate, as widely as possible, the results of its program of research to enable teachers to quickly and effectively implement technology enhanced instructional practices in their own classrooms. Accordingly, TESSI has developed a multilevel program of professional development that includes: the TESSI Professional Development Project designed to train selected teachers throughout the province to implement the TESSI model and establish TEI Professional Development Centers; the Mexico-based, Enseñanza de la Física con Tecnología project (EFIT - Teaching Physics with Technology) designed to contribute to the educational development of Mexico through the application of new technologies; and the development of a CD-ROM designed to introduce teachers to the use of technology in their classrooms.

Abstract: Fetal Echo Expert System, an Artificial Intelligence (AI) program was created to combine textbooks, an atlas of ultrasound images, and an expert system to form a single resource for reference and education. It was designed to teach physicians and medical students to detect congenital heart diseases in fetus. The expert system guides the user through the whole ultrasound study, asks relevant questions, and supports the process of detection of congenital abnormalities and making diagnoses. The image library contains over 500 different images and video clips related to different heart abnormalities, and ultrasound techniques.

INTRODUCTION

In the United States about 100 babies are born every day with congenital heart diseases. In many, perhaps even most cases, existence of an abnormality surprises the mother as well as the doctor taking care of her during the pregnancy. It is a common opinion between doctors that routine ultrasound evaluation of fetal hearts (Echocardiography) during the pregnancy does not decrease mortality caused by congenital heart diseases. Unfortunately this is partially true. The main reason for such situation is a paradox: the detection of congenital heart diseases depends on non-cardiologists. It is the responsibility of obstetricians and primary-care physicians to detect abnormalities. Today’s modern ultrasound machines provide enough power and capabilities to obtain good images of the heart, but still more important than equipment is keen observation and understanding of fetal cardiac abnormalities [Huhta et al. 1991]. Most physicians are not properly trained to detect abnormalities. Obtaining good images of a fetal heart is also non-trivial; so in reality, in many cases untrained physicians are supposed to detect abnormalities while analyzing poor images. It simply cannot work, and unless defects are severe, they remain undetected. On the other hand cases that are diagnosed are usually so severe that even early detection does not promise any help. But the situation is not hopeless. Today’s computer technologies can be utilized to support a process of making diagnoses and improve detectability of congenital heart diseases. The goal of this project is not to convert obstetricians into cardiologists, but to use computers to teach them how to detect abnormalities.

METHODS

In this multidisciplinary project linking biophysics, cardiology, obstetrics and clinical informatics, we developed tools supporting effective detection of congenital heart abnormalities by non-cardiologists. For that purpose multimedia program Fetal Echo Expert System has been created. This program includes a step-by-step tutorial, a library of congenital heart diseases, graphic images, digitized echocardiograms, and an expert system [Giaratano et all 1994] that can support the process of detection of congenital heart abnormalities. The block diagram of this program is shown in figure 1. Expert systems are a software technology that has been successfully applied to development of systems that model information processing tasks [Cios et al 1990]. The design of rule-based expert systems involves a process of interaction between a domain expert and a knowledge engineer who formalizes the expert’s knowledge as inference rules and encodes it in the computer. Since human experts vary in skill and experience, and they often do not know what knowledge they actually used in solving their problems, the process of building of an expert system requires enormous amount of effort and is rather time consuming. Despite of difficulties in creating of
such systems they have several advantages: 1. The expertise is permanent. Unlike human experts who may retire, quit or die, the expert system will last indefinitely. 2. The knowledge of multiple experts can be made to work simultaneously. 3. The expert system can explain in detail the reasoning that led to the conclusion. Knowledge that is attributed to intelligent entities more often has the form of uncertain beliefs rather than crisp, indisputable facts. A consideration in the development of an expert system is the ability to deal with uncertainties as they occur when conclusions are only partially confirmed by a piece of evidence. One way of logically manipulating uncertain propositions is to use one of the models of uncertainty. Traditionally subjective estimates of probability and Bayesian processing have been used to specify and propagate uncertainty through an inference network. One disadvantage of this approach is that it requires the assessment of a large number of conditional possibilities and is subject to combinatorial problems in the inferencing procedure. Another means of logically manipulating uncertain propositions is to use the Dempster-Shafer [Dempster 1968] [Shafer 1976] theory of evidence implemented as support logical programming by Baldwin [Baldwin et all 1986] and successfully implemented in building of expert systems. This algorithm has also been implemented in this program.

RESULTS AND DISCUSSION
Fetal Echo Expert System is designed to guide a physician or a student through the data obtained from ultrasound examination. It is assumed that user can view the study that is stored on magnetic tape at the same time as he/she is using the program. The questions asked by the program are divided into twelve groups that correspond to the different views of a heart and different techniques used. Every time one set of questions is answered, the user may click on the “Make Diagnosis” button and obtain a suggested diagnosis based on the data entered. The program will also search the library and display pictures corresponding to the data entered. It is possible to change the information supplied to the program and observe how it affects diagnoses. Fetal Echo Expert System was already presented at two major medical conferences: American College of Cardiology meeting in Orlando [Wróblewski et al 1996] and Radiological Society of North America in Chicago [Wróblewski et al 1996a] and was very well received by specialists.

ACKNOWLEDGMENTS
We wish to thank Dr. Jack Rychik and Dr. Bogdan Kaluzewski for helpful discussions.

Development and Evaluation of Japanese CALL System for Scientific and Technical Writing on WWW

Jie Chi YANG, Kanji AKAHORI
Department of Human System Science of Graduate School of Decision Science and Technology
Tokyo Institute of Technology, JAPAN
Email: yang@cradle.titech.ac.jp, akahori@cradle.titech.ac.jp

1. Introduction

The purpose of this study is to develop and evaluate a Japanese writing CALL (computer assisted language learning) system using NLP (natural language processing) techniques. This system could be used for supporting the writing of scientific and technical Japanese on WWW (World Wide Web) browser for the Japanese language learner.

2. Japanese Writing CALL System

In a previous study, the authors developed and evaluated a Japanese writing CALL system for learning of Japanese passive voice on WWW browser. The system was development using NLP techniques. Therefore, the learner can use this system by freely keying simple Japanese sentences.

To examine the error types in writing of Japanese passive voice by the foreign students, the authors conducted a survey. From the results, the authors classified the error types of Japanese passive voice into 12 categories, 65 kinds and 228 errors. The system uses NLP tools such morpheme analyzer and syntax analyzer. Then error analysis and feedback processing components were added to the system. This system thus enables the learner to key-in sentence freely, can detect the errors in typed sentence and gives adequate feedback messages back to the learner.

The system consists of the interface (i.e., WWW browser), the sentence analysis system, the feedback system, the dictionary, and the grammar/rules. The sentence analysis system includes morpheme analyzer, syntax analyzer, and error analyzer. The learner can freely type Japanese sentence in either kanji or kana of Japanese language, as this is the usual input method of most Japanese word processors. The present system analyzes a typed Japanese sentence in the morpheme analyzer and the dependency of the sentence is checked by the case grammar. Afterwards, the type of error is detected by applying the rules of error analysis. The feedback system includes the feedback messages generator, knowledge database, and a list of all learning histories during the operation of the system. At this stage, adequate feedback messages are given to the learner according to the type of error and relative information received as output from the sentence analysis component.

Furthermore, the authors propose a mechanism of self-correction that allows the learner to correct the typed sentence herself/himself and allows her/him to detect any error made. The self-correction implies that when the error analyzer detects the error, there will be no answer given back to the learner, but instead, the feedback messages according to the typed sentence will be shown. The learner can either read the feedback messages and correct the typed sentence instantly or she/he can refer to some grammar items about her/his error and correct the sentence later. This mechanism can be considered as a supplement to the prediction of the system and as an improvement in the effectiveness of current CALL systems.

Finally, the authors conducted an experiment to evaluate the usefulness of the system. 22 Japanese language learners participated in this experiment. The purpose of the evaluation is to examine the method of sentence input and feedback. Thus the experiment is designed to compare two different systems with different input method and feedback method. As a result of the evaluation, the method of freely input sentence and the feedback corresponding to the typed sentence is preferred to the method of multiple selection and feedback that just displays the correct answer.
3. Work in Progress

The authors are now going to enrich the system from the current simple sentence level to scientific and technical Japanese sentences level. One of the important and the basic factor to write the text sentences in a foreign language is enough vocabulary and grammatical knowledge. However, the amount of vocabulary and grammatical knowledge is not enough for writing sentences of the foreign language. The reason for this is that the grammatical rules are provided to arrange the structure of single sentence correctly at a time and the tie method of joining sentences is not taught. Especially, the tie method of joining sentences is important in writing scientific and technical sentences.

Foreign student has already experienced the composition writing by using the mother tongue, therefore, the purpose of this study is not to support the act of writing but to support the tie method of joining sentences. This tie method of joining sentences, can be described as conjunction or connection of joining sentences, is an important criterion for writing texts as per researches of cohesion or discourse structure [Yokobayashi and Shimomura, 1988; Kuno, 1978; Halliday and Hasan, 1976].

The method of this study is shown as follows:

1. Targeted sentences are “Text sentences of scientific and technical Japanese.”
2. This study empirically clarifies the structure of “Text sentences of scientific and technical Japanese” by considering the finding of other related researches.
3. Sentences collected from the investigation are extracted and classified to some structural patterns. If possible, the rules are extracted.
4. To give support to the composition writing, the extracted rules are implement in the system. The EDR concept dictionary and the EDR corpus are used to generate the resemblance degree and the examples automatically. As a result, a more flexible composition support system will be expected. However, before that how to employ the electronic dictionary to the system is to be examined and problems arising from this has to be solved.
5. Then the foreign student would use the above-mentioned system and the evaluation study for the effectiveness of the system will be conducted.

AN OBSERVATIONAL STUDY ON EXAMINING LEARNERS’ THINKING PROCESS IN LEARNING AND WRITING K-LOG PROGRAM

Kai-hing Yeung
The Hong Kong Institute of Education, Hong Kong SAR
e-mail: khyeung@ets.ied.edu.hk

Introduction

Programming languages are essentially programs that require their operators to define and solve their own problems within specific constraint of the language and general constraint of a computer. Hence, learning to use the programming language itself is a form of problem-solving. It is claimed that learning to program leads to the acquisition and transfer of important heuristics and metacognitive skills. Recent research in cognitive psychology has revealed that learning to solve problems requires the integrated application of three categories of abilities [De Corte et al., 1990]: (1) Flexible application of domain-specific knowledge base, involving concepts, rules, principles, formulas and algorithm; (2) Heuristic methods; and (3) Metacognitive skills. Polya (1957) developed four categories of heuristics. They are: (1) Understanding the problem; (2) Devising a plan; (3) Carrying out the plan; and (4) Looking back [Polya, 1957]. In views of these claims, this observational study tries to (1) find out how the learner learn a new programming language - K-Log; (2) study the thinking process of the learner; and (3) analyze the student’s strategy employed in the problem-solving task, especially on transferring skill from programming to other domain, Chemistry in this exercise.

The study

A Secondary four student was chosen to be the subject of this observational study. He has to complete a worksheet in an hour. The worksheet was divided into three parts. The first two parts are mainly concerned with the learning of K-Log programming language while the last part is concerned with a problem-solving activity. During the first thirty minutes, the student was introduced to the K-Log environment (an expert shell similar to Prolog) and the basic syntax in K-Log - the “object relation object” syntax, and also the ways to generate advice by the computer. After the student has explored with the program Doctor, part of the program listing was given to the student in order to help him in completing part B of the worksheet. The final part of the worksheet asked the student to write a K-Log program, similar to the program Doctor, which gives advice on the structure of any chemical substances in the periodic table.

Data collection and analysis

For the first two parts of the exercise, the data was mainly collected by observation. Since the two sessions were basically concerned with the learning aspect, the interaction between the observer and the student was high. The observer can post questions to the student at some stages of the session when he observed that the student was in confusion. The interaction between the observer and the student was recorded as an source of information for examining the learning process. For the last part of the exercise, the “think aloud protocol” was employed. The learner’s thinking process is recorded for protocol analysis. However, the “think aloud protocol” is a method which is new to the student. He often forgot to speak out what he was thinking about during the observational exercise. The observer had to remind him from time to time to “think aloud”. As a result, the data collected by this method is somehow affected because the student might just speak out the product of his mental process instead of the process itself. During the process, special attention was paid to any problem-solving skills shown by the student. For example, whether all four categories of heuristics, as suggested by [Polya, 1957], was applied or not. In addition, in solving the problem, the student himself not only has the knowledge on K-Log programming, but also knowledge of chemistry. Therefore, the transfer of the student’s skill would also be examined.
Findings

Mayer has identified four kinds of knowledge involved in computer programming [Mayer, 1985 & Mayer, 1992]. Syntactic knowledge refers to lexical units and rules for combining lexical units. Semantic knowledge refers to the actions that are carried out by the computing system for a given instruction or set of instructions. Schematic knowledge refers to knowledge of types of subroutines, such as knowing several different looping structures. Strategic knowledge refers to knowledge of how to plan and monitor the construction of a program such as breaking a program into modules. In the first two parts of the exercise, it concentrates mainly on the learning of syntactic and semantic knowledge of K-Log programming. During the learning process, it is evident that the student did use some kind of strategy in helping himself to understand how the computer program works— the semantic knowledge. He has a hypothesis in his mind, and then put it into test. Since this exercise focuses only on a limited number of commands used in K-Log programming, the student can learn the syntactic knowledge without any difficulty. From the last part of the exercise, it was observed that the student had followed a strategy which was similar to what is described as the four categories of heuristics by Polya [Polya, 1957]. From the protocol analysis, it was discovered that the obstacle encountered by the student was that he could not transfer his knowledge in the program Doctor into the new problem in chemistry. The main factor that hindered such transfer is that the student cannot map the syndromes and diagnosis in program Doctor to the physical properties and type of structure in the new task. With the aid of the hints given by the observer, the student can finally complete the program and solve the problem with minor changes of the program.

Conclusion

A major challenge in teaching of computer programming is to ensure that learners actually learn high-level problem-solving skills—such as how to design an efficient program— in addition to low level syntactic skills—such as how to write grammatically correct commands. However, research on learning to program has shown that learners often have difficulties in acquiring even low-level programming skills such as the syntax and semantics for individual statements, and rarely progress to the high-level skills such as programming design [duBoulay & O'Shea, 1981]. With reference to the chain-of-cognitive-changes theory, learners can learn to apply high-level planning strategies to programming only if they master lower level syntactic skills specific to the programming language [Mayer & Fay, 1987].

From this observational study, the findings are in line with the above research result. The learner required very clear hints for them to arrive at the solution. The hints given to learners are actually guide him through the problem-solving process and help him to re-organize their knowledge on K-Log language. The transfer of problem-solving skill from programming to other domain cannot be assumed. It is concluded that explicit teaching of the problem-solving skill and acquisition of sufficient language skills are the two factors which determine whether learning programming can promote high-level problem-solving skills.

Hypermedia's Effect on Declarative, Procedural and Conditional Knowledge Acquisition: An Ongoing Study

Zahide Yildirim
Science Education Department, Middle East Technical University, Turkey
zahidey@rorqual.cc.metu.edu.tr

Background

The major purpose of this study is to compare hypermedia with traditional instruction in terms of declarative, procedural and conditional knowledge acquisition and retention in a specific subject area, and students’ attitudes toward the units in the subject area.

The significance of hypermedia for learning and its motivational effect is stressed in many studies. Its power comes from organization of information for effective learning. According to Jonassen and Grabinger [1990], learning is reorganization of knowledge structures. These structures are arranged in a network of interrelated concepts known as semantic networks. These networks describe what a learner knows and provide the foundations for learning new ideas, that is expanding the learner’s semantic networks. This is the richest conceptual model of learning from hypermedia. To Neuman et al. [1995], hypermedia leads to independent and synthetic thinking, provides freedom to construct personal knowledge, enhances and expands understanding. There are many studies that support Jonassen and Grabinger’s and Neuman et al.’s views about learning and hypermedia’s effects on learning.

Although many research studies have investigated hypermedia’s contribution to learning, hypermedia’s effect on different types of knowledge, namely declarative, conditional and procedural, has rarely been studied. According to Jonassen [1991], hypertext systems provide sophisticated tools to integrate cognitive learning principles into practice in the instructional design and development field, and to help us reduce the dissonance between the declarative and procedural knowledge. Smith and Ragan [1993] and Schunk [1996] explain declarative knowledge as facts, beliefs, opinions, generalizations, theories, hypotheses, and attitudes; procedural knowledge as knowledge of how to perform cognitive activities; and conditional knowledge as understanding when and why to employ forms of declarative and procedural knowledge. Schunk [1996] states that the distinction between these three types of knowledge is important in terms of their implications for teaching and learning. Deficiencies in different types of knowledge not only hinder learning, but also produce low self-efficacy. Hence, discovering what type of knowledge is deficient is necessary for planning remedial instruction. In that perspective, the question of how hypermedia contributes to different types of knowledge acquisition still remains to be answered.

Methods and Data Sources

A pre-test/post-test experimental design will be used in this study. The subjects of the study will include 40 9th grade Biology students of a public high school in Ankara, Turkey. These subjects will be assigned to experimental and control groups by using matched-pair technique and asked to respond to an achievement test and an attitude scale as pre-tests to measure their achievement level in the selected units (human’s circulatory and excretory systems) in terms of different types of knowledge acquisition, and attitudes toward the units. Experimental group will be given an introductory session on how to use hypermedia. Then, the control group will receive traditional instruction while the experimental group will study using the hypermedia developed by the researcher. At the end of the five-week treatment, the same achievement test and attitude scale mentioned above will be given to students again as the post-tests. Two months after the experiment, the
achievement test will be given to both groups for the third time to measure retention of knowledge of different types.

The hypermedia designed by the researcher for this study included video episodes, still images and text, and employed instructional system development (ISD) and conceptual linking approaches. At the beginning of the ISD process, needs assessment was conducted to determine what students need to be able to do when they have completed the two units. Then, the instructional goals of the two units were determined. In the light of instructional goals, learning tasks, sub-tasks and procedural steps were described in details. Different types of knowledge that each task required were determined, and the semantic relationships between tasks were identified. In the program, a deductive approach was followed as instructional strategy. Interrelated concepts with general ideas were presented initially and followed by specific points. Finally, concept mapping and story boarding were done. Front Page Editor 2.0. was used in developing the hypermedia.

Data Collection Instruments

Two types of data collection instruments will be used in this study. First, an achievement test was designed to measure different types of knowledge acquisition in Biology. The test has three sections. The first section measures the declarative knowledge acquisition, the second section the procedural knowledge acquisition, and the last section the conditional knowledge acquisition in the selected two units. This test will be applied as the pre-test and the post-test. Based on the framework instructional goals of the units, different types of knowledge were determined and a table of specifications was constructed. The initial achievement test was developed by considering these knowledge types in the form of multiple choice questions and then, submitted to subject matter experts in the field to establish content validity. The initial test developed was piloted with a group of 25 students to assess for clarity, consistency, the time required, and item difficulty for each question. The second instrument to be used in the study is an attitude scale designed to collect data about students' attitudes toward the experimented units. It was piloted with a group of 25 students to check the clarity of the questions, internal consistency of items, and the time required to fill it out.

Significance of the Study

Although many studies have been carried out to test the effectiveness of hypermedia on students' achievement, hypermedia's impact on different types of knowledge, namely declarative, conditional and procedural, acquisition has little been examined. This study aims to offer useful knowledge to practitioners in terms of how hypermedia may influence different types and level of knowledge acquisition and retention. In the literature, it is stated that hypermedia is more appropriate for large knowledge bases. Knowledge bases can be large enough for using hypermedia, but it may not be appropriate for the types of knowledge those knowledge bases include. Results of this study may help practitioners examine the appropriateness of the knowledge bases for hypermedia from different perspectives, and apply hypermedia more effectively based on types of knowledge they teach.

DIFFUSION OF COMPUTER-NETWORKED TECHNOLOGY INTO SCHOOLS: A Study of Offering A Web-related Training Course to In-service Teachers and Students

Shwu-ching Young
Center for General Education & Center for Teacher Education
National Tsing Hua University, Taiwan 30043
scy@cge.nthu.edu.tw

BACKGROUND. At the launch of Taiwan's National Information Infrastructure (NII) project in 1994, the Ministry of Education made a commitment to bringing telecommunications and computer technology into the classroom at various academic levels over the following six years. To adapt to this technological innovation in education, the Ministry of Education has made a great investment each year to help junior and senior high schools, and elementary schools establish computer classrooms or laboratories equipped with multimedia computers with CD-ROM capability and a modem, or other related equipment. Furthermore, to get teachers and students involved in using the modern technology for their benefit and convenience, certain projects were promoted by the Ministry of Education. The "E-mail (TANet) to Middle and Primary Schools" project, for example, was initiated in 1994. Additionally, the National Science Council of Taiwan has sponsored more than 50 computer-assisted learning research projects each year [Chan 1996]. Significant results obtained from the research projects which were initially conducted at the college level, were anticipated to be extended to and applied at the junior and high schools and elementary school levels.

PURPOSE & PARTICIPANTS. The intent of this training project is to cultivate "seed" trainees (mentor trainees) recruited from both teachers and students, who are expected to disseminate the information learned and to promote the diffusion of innovative computing technology in instructional and learning settings on campus after the training. This study aims to investigate how a web-related training course is conducted in a natural educational setting. The purpose of the research is to understand and interpret how learners of diverse backgrounds and disciplines interact with each other and learn about web-related information and techniques and what they will be able to do with their new knowledge after the course. Therefore, it would also be worthwhile to conduct an in-depth study of their interactions in a learning setting and to explore the results that the intensive training yield.

THEORETICAL FRAMEWORK. The theoretical underpinnings are constructivism [Jonassen 1996; Duffy & Jonassen 1992; Cole 1992] and situated learning [Young 1997a; Brown & Duguid 1993; Brown, Collins, & Duguid 1989]; both theories are used to examine the way learners construct their knowledge through the training course. There are a variety of factors which might influence the way learners effectively interact with each other and the learning materials, including their background knowledge, attitudes, personal previous experiences with computers, interests, anxiety, and motivations [Young 1997; Young 1996]. In order to gain a comprehensive and in-depth understanding of the process of how the learners learn, how a training program is conducted, and what happens afterwards, a qualitative research methodology is adopted in this study. Within postpositivist paradigms, this study is described as interpretive and descriptive in nature.

RESEARCH QUESTIONS. Three sets of research questions addressed in this study are:
1. How do learners, defined as in-service teachers and students, having various backgrounds, disciplines and ages, interact with the computing technology, construct knowledge, and learn about the readings and software in the process of intensive training?
2. Are the in-service teachers and students able to interact with each other effectively while they are learning the new technology together? Does each group feel comfortable in studying and...
working with the other group? Or do teachers feel intimidated by the possibility that students might be more fluent in computer operation and in computer literacy acquisition? How do learners perceive the courseware and the web-related technology presented in this intensive training?

3. Are trainees able to fulfill their roles as expected to disseminate the information learned and further carry out their mission after this training? Who have the potential in so doing and what factors account for these individuals’ success in promoting networked learning and instruction or integrating the computing technology into their daily life?

**METHODOLOGY.** The design of this study is emergent in nature [Patton 1990; Lincoln & Guba 1985]. Basically, this is a long-term study that is conducted in two phases: the intensive web-related training, and then follow-up interviews and observations in classroom settings. The study site is the high school campus and the computer laboratories where the training program is held. The intensive training is conducted in seven sessions, three and half hours per session, on a weekly basis within the first semester of 1997. A questionnaire is used to gather subjects’ demographic data, computer experiences. In the study the researcher is the primary instrument for data collection and analysis. Ethnographic observations, therefore, are conducted throughout the training program, reflexive notes and field notes are made immediately after each session. In addition, a journal entry in the form of an open-ended questionnaire is given to each participant at the end of each session to investigate subjects’ perception of the learning activities and comprehension of the readings. In the second semester, a follow-up in-depth structured interview is given to all participants on a one-to-one basis to gather information concerning their dissemination and integration of web-related information and techniques in their learning and teaching settings.

Importantly, several methods such as prolonged engagement, persistent observation, triangulation and thick description, peer debriefing, and member check are used to establish trustworthiness and to legitimate the research project. Reflexive subjectivity on the part of the researcher will continue throughout the process of data collection and analysis.

**CONCLUSION.** The qualitative study is currently in progress. It is hoped that the results of the study will provide insights into how intensive web-related training should be conducted and what factors account for the successful integration of innovative computing technology into junior and senior high school settings. A model of conducting a successful training project based on the research data will be induced. Finally, suggestions for future training projects and suggestions for further research will be indicated for instruction and course design.

instructional program on interactive writing. Ph. D. dissertation. The Ohio State University.
Abstract: The progress in the development of new media, recommends to reflect upon pedagogical concepts on traditional fields of education. Our group, consisting of pedagogical and technical members, developed for a central part of road safety education - cycling - a two level pedagogical concept, based on multimedia and virtual reality as new learning media.

1 Introduction

48209 children had an accident while participating in road traffic during 1996 in Germany [VdTÜV 1997]. For 1997 it is estimated that numbers had not changed very much. Many accidents are caused by behaviour of the children. Today's traffic volume is so high that small mistakes very often lead to severe accidents. Here children are always the looser part.

In most European countries children are trained in school to participate in road traffic. The high numbers of accidents indicates, that traditional forms of training are no longer suitable to decrease accidents substantially. Additional forms of education have to be found.

Virtual reality (VR) is a promising learning method to be applied in this field for the following reasons:
1. Children are learning by doing and repetition. Training environments must therefore provide multiple channels of information (visual, acoustic, haptic) and must be available with little effort. This can be provided by VR
2. Training is especially necessary for critical and dangerous situations, without harming the child. This is not possible with conventional training schemes. It can be done using VR-based scenarios and VR-based training environments.
3. Virtual Reality training can also be used to learn basic qualifications, like estimating the velocity of approaching cars or detecting the direction of movement.
4. The training progress can be measured in this environments, thus training schemes can be evaluated very effectively.

2 Problems of traditional road safety education

Road safety education attempts to decrease number of children been involved in an accident since decades. In Germany the latest concept for the preparation of children to road traffic consist of abstract learning traffic rules in co-operation with the police, one exam to acquire a “cycling-licence” and a test-tour in real traffic.

Anyhow many dangerous situations can’t be tested by this tour in real traffic, because risk is to high.
Besides, these useful elements of road safety education are not integrated up with each other. Therefore it is difficult to decide, if the child is able to transfer knowledge learned in lessons to knowledge useful in real situations.

3 Solving Problems by Multimedia and VR

In our project "cyberbike", multimedia and virtual reality are used to form two levels in learning process. The "cyberbike" consists of a ROad Safety Educational MulitMedia Software (ROSE-MMS), which will be distributed on CD-Rom (DVD) and a ROSE - Virtual Reality Environment (ROSE-VRE), which may later be multiplied for an extended distribution.

The ROSE-MMS will prepare children to the usage of the ROSE-VRE, to standardise the starting point of the children and to amplify training effect by changing the learning medium. In this way the "cyberbike" is able to contribute essentially to tie together single components of road safety education and to ease the judgement the qualification of a child to participate in road traffic. The "cyberbike" addresses children at the age of 8 to 12 years.
4 Pedagogical Concept

Traffic is a complicated process of different events with a high intensity of optical and acoustic information, which must be assimilated very quickly. Traffic is designed for adults but not for children, with their visual, acoustic, emotional, intellectual and kinetic abilities [Warwitz 1994; Spitta 1997]. For example: The viewpoint of a child is smaller than of an adult, the perspective perception isn’t fully developed. The perception is selective, and the child does filter important stimuli only up to a point. Children learn by doing. Children have got problems to co-ordinate two different movements in parallel. A child acts emotionally [see Warwitz 1994]. In a virtual reality learning environment these special quality of abilities can be respected and deficits can be trained individually.

To respect emotional aspects of the child, a scenario has been developed. A story based training concept deals with children of different social groups, which provides to every child one character to identify with. To amplify learning progress, the scenario of the ROSE-MMS will be adapted to the ROSE-VRE. In this way children know geographical space in which they will move using the ROSE-VRE.

The ROSE-MMS will impart knowledge about appropriate behaviour in traffic and traffic signs. Therefore in the scenario recur dangerous situations, which causes accidents in real traffic repeatedly (turn off left, gateways, get in lane). But the ROSE-MMS not simply teaches traffic regulations, instead explains traffic signs, traffic regulations and last but not least wrong behaviour of other people. Road safety education in this project as a part of social and ecological education too [Spitta 1997].

The ROSE-MMS motivates the child to practice kinetic exercises, which are important for cycling. The ROSE-VRE doesn’t claim to replace exercises of cycling on a real bicycle in road safety education. Kinetic aspects would be large-scaled or even impossible to simulate in a VR environment at least in the first phase of this project. They should be learned by riding a real bike like done before.

The ROSE-VRE is the missing element in road safety education, which allows the child to transfer knowledge learned in theoretical exercises to knowledge which is practicable in real traffic.

Figure 3 shows how the “cyberbike” may be integrated into traditional road safety education. Further by using a ROSE-VRE for training, it is possible to record training lessons, to analyse and to consider them together with a trainer afterwards. In this way individual training for single children is possible.
5 Technical Concept

In the field of road safety education a widespread exploitation of the virtual reality training station is recommended. Every child should get the chance to be prepared to road traffic by this advanced training technology. Therefore the virtual reality environment has to be build at reasonable costs, and should be flexible in setup. To serve these issues we developed an very modular software and hardware architecture for the ROSE-VRE, based on object oriented client/server technologies.

The ROSE-VRE consists of one bicycle, fitted out with sensors, as the input interface. As output devices serves multiple stereoscopic projection screens, an acoustic 3D sound server and the break at the back wheel of the bicycle as a force feedback.

The functionality of various input and output devices of the VR environment will be encapsulated in objects, which have specified interfaces. In a Client/Server like paradigm the input and output devices will be implemented as servers, whose services can be demanded by an VR application as a client [Fig. 4]. For the communication of the single components, Common Object Request Broker Architecture (CORBA) has been used as a standard for communication of Objects over a network.

![Diagram of ROSE-VRE architecture](image)

Figure 4: Soft-, Hardware architecture of the ROSE-VRE

By this concept the various I/O Devices can be arranged easily to fit pedagogical needs. Because of the simple integration of various I/O devices, more than one possible configuration of the ROSE-VRE can be tested easily. Because of the specified interfaces, application software can be developed independently from the present hardware. The ROSE-VRE becomes in this way very scaleable. Hardware components which are currently too expensive for a widespread exploitation, may be at the end of the project at reachable prices to be integrated to the VR-environment without any changes to the software of the ROSE-VRE.

Abstract: This study investigates first-year faculty (n = 11) and students (n = 619) at a public liberal arts college and their: (a) expectations toward using the academic network, (b) background computing experiences, and (c) attitudes toward the academic networked environment. Using a combination of qualitative and quantitative methods, this study provides insight potentially beneficial to many colleges and universities as it directly impacts many programmatic decisions (i.e., computer proficiency requirements, technology training, service and support). Notable findings include interesting similarities in faculty/student expectations, toward their own use as well as the use by each other, of the academic network and highly pronounced differences in expectations warranting further research. Several types of background computing experiences are compared with faculty possessing significantly more experience in some areas while other areas are interestingly non-significant. Significant (and desirable) reductions in self-based attitudinal concerns and concomitant increases in other-based concerns were also found.
The present alterations in medical education emphasize the authenticity of cases for problem based learning. By those cases future physicians should be enabled to apply their knowledge and skills more effectively to handle real clinical problems. Therefore our objective was to offer realistically designed medical learning cases, provided by the CASUS authoring system, in an interactive way by the WWW platform.

The ProMediWeb client and server applications are developed by the Java programming language. The data of the medical learning cases is stored in a relational database and can be accessed via Hypertext Transport Protocol (HTTP) and Java Database Connectivity (JDBC). Because of the interactive design of our learning system the students are encouraged to communicate over the Internet to become actively involved.

First sample cases are already available. Pre-use and post-use HTML questionnaires and a user and interaction database on our WWW-server allow an evaluation of learning behavior and acceptance. The use of the cases will be useful for all medical students and physicians in continuing medical education.

Telecommunications is becoming increasingly popular as a delivery of instruction to students unable to attend traditional classes. Since this delivery vehicle can cost several thousands of dollars to implement a major question is whether students, accustomed to traveling to classes would accept a less personal modality offering. This study attempted to answer this question by offering several courses using a combination of traditional and distributed modalities. The data for this study was collected from seven courses offered at a major metropolitan university. Graduate students either met on campus or at a distant site connected to campus via a T1 telephone line providing real time audio/video communication with the instructor.

A pretest/posttest design was used to collect the data. Results showed that effectiveness was dependent on the degree of comfort student felt with the instructor and the technology. Students who were more technology sophisticated were more forgiving of technical problems.
A Prototype of a Stand-by System for Secondary School Mathematics

Johanna Berewinkel, Manfred Knott, Guido Körwers, Torsten Müller, Peter Schmidt

Institut für Informatik, Universität Bonn, Germany

email: {berewink/knott/koerwers/muellert/peter}@uran.informatik.uni-bonn.de

The goal of the project is to develop a stand-by system which is able to support students during their whole secondary school education when they work at mathematics on their own [Schmidt 1997]. Therefore the organization of the system reflects the typical mathematical activities and working situations of the students. The main structural elements of the stand-by system are the mathematical objects (the problem types, concepts, theorems, procedures, and subfields), several main functions (solve, exercise, discussion, represent, learn, diagnose), and some typical working situations of the students.

The prototype which will be demonstrated (in English language) is the first version of a coherent stand-by system and it will integrate the shells for some of the main functions (solve, exercise, and learn), a tool to process a semantic net, the actual subsystems of formula manipulation and of graphics, and some knowledge bases in the context of word problems which lead to linear equations or systems of linear equations. The programs are constructed in such a way that the use of additional languages is possible. The programming language is Java.

Jordi Llabrés
Departament of Psychology, University of the Balearic Islands, Spain, dpsjlb0@ps.uib.es

Mateu Servera
Departament of Psychology, University of the Balearic Islands, Spain, dpsmsb4@ps.uib.es

Since the program was addressed to disabled people working at the island the plants and tools showed up are the most typical from the region. The fact that most of the potential users cannot read has prevented us from making use of text. The program has been divided into three sections: plants, tools and tasks. The user can move from one section to another just clicking once the mouse. The section devoted to tasks is the main axis of the program: nine very frequent gardening tasks are included. The most important steps have been selected from each task. The user may watch an illustrative fixed picture and listen to a brief description step by step. The plants section offers some relevant information of about fifty plants. At the tools section the user may watch some movies to learn how thirty of the most commonly used tools work.
An Infrastructure for Collaboratively Building and Using Multimedial Corpora in the Humaniora

In recent years the Max-Planck-Institute for Psycholinguistics has build up considerable experience developing software tools for creation and analysis of multimedia corpora for spoken language and accompanying gestures.

In the CAVA (Computer Assisted Video Analysis) project a client-server system for annotation and analysis of digital video movies was realized [Brugman & Kita 1995]. Components are:
- MediaTagger client application, a sophisticated Macintosh based annotation tool. It handles media data and added text data in a closely synchronized way.
- A relational database to store annotation text and media references.
- A graphical query builder tool for generation of complex time related queries.

The CAVA project has reached it's final stages. To overcome CAVA's limitations (it is platform specific, uses a proprietary corpus format, offers no streaming media, allows no Internet access) the EUDICO (European Distributed Corpora) project was started [Brugman & Wittenburg 1997]. As proof-of-concept a prototype using Internet technology was finished successfully.

Planning, Designing and Implementing a Technology Training Center for Foreign Language Teachers

Reinhold Bubser
Department of Modern Languages
University of Northern Iowa
Cedar Falls, IA 50614-0504
USA
reinhold.bubser@uni.edu

To train foreign language teachers for today and tomorrow, the Department of Modern Languages initiated the design of a new computer-based training laboratory in which prospective elementary and secondary teachers, and faculty in foreign language and culture studies can gain expertise in the area of TELL (Technology Enhanced Language Learning). In planning, designing, and implementing the TTC lab facility, the foremost concern was to provide foreign language teachers with up-to-date hardware, software and authorware. My presentation addresses key issues related to the development of faculty expertise in TELL, to the selection of hardware, to criteria for a foreign language software clearinghouse, to the challenges involved in the various phases of planning, designing, and implementation of the TTC. If the imperative in teacher education of today is to train (prospective) teachers in the appropriate use of the current technology and to fuse current technology with sound pedagogical paradigms, a TTC is a necessary step in that direction.
Using Multimedia and Hypermedia in a Teacher Education Program

rarice@bsuvc.bsu.edu

The Graduate School of Education at Portland State University offers a variety of courses and programs to meet the needs of both pre-service and inservice teachers in the Portland metropolitan area. Schools in Oregon are committed to hiring teachers who know how to effectively integrate newer technologies into their teaching and learning. To better prepare students, and model effective teaching, we are using multimedia and hypermedia in various courses and student teaching experiences. This demonstration describes the “genealogy” of the Graduate Teacher Education Program as it has moved to teach students to use the World Wide Web, multimedia and hypermedia into their coursework and teaching. Examples of courses and projects created by students and faculty in the program will also be shared.
Quantum physics is extremely hard to teach in high school as there are only few experiments that can be shown and the students don’t meet the mathematical prerequisites that are needed for a quantum mechanical treatment of quantum physics. Consequently many students don’t understand quantum physical phenomena and a deterministic view of the world persists.

Therefore the software package Alea simulates experiments which cannot be done at school and illustrates mathematical connections which are otherwise hard to show.

Alea covers most of the quantum physical themes that are taught at high school: e.g. electron diffraction, the uncertainty relation, the Schroedinger equation, potential wells ... . It consists of fourteen components some of which allow the student to conduct experiments by himself others offer animations or simulations. All components have information pages for the students and a didactic manual which gives hints for the teachers.
TOON Into EDUCATION!

Yvonne Channel
Computer Animator
Pitsco
USA
ychannel@pitsco.com

Technology has become the essential tool for today's teachers. Animation is an especially appropriate tool for teaching a concept or for illustrating that which the eye cannot see. Disciplines in which animation is vital include the biological and the physical sciences. Animation can also demonstrate the application of technology in a classroom setting.

Since the learning styles of students are varied and additive, Pitsco uses a variety of formats to present material. Some students are readers, some are hands-on performers. Some students learn best aurally and others visually. The use of animation in conjunction with text, audio, and hands-on projects to explain and illustrate concepts is the key to reading and engaging more students. Animation is the crucial element in helping students learn.
Much of the literature on the flexible delivery of learning products for vocational education and training clients is based upon assumptions that these diverse clients already possesses the personal characteristics and technology readiness skills necessary to benefit from flexible delivery and on-line learning of these products.

The paper describes research which tests these assumptions.

Results, based upon the questionnaire responses of six hundred para-professional, skilled and semi-skilled clients, show that the Australian vocational education and training clients are in the lowest category of distance learning readiness when compared with international norms (Guglielmino, 1991). Results also show a lack of confidence in using various forms of communication for learning and that the majority of respondents either had no experience of the internet or were not confident in using it for learning. Noticeable percentages of respondents also reported that they did not find computers or the internet useful as an aid to their learning.
Internet Database Access:
Scaleability of Projects through Shared Database Creation and Use

Nancy Gadzuk Drexler, Edcentic, USA, drexler@meol.mass.edu
Cecilia Lenk, Lenk & Associates, USA, clenk@webivore.com
Amara Cohen, Lenk & Associates, USA, acohen@webivore.com

The Internet contains excellent collections of scientific data compiled by and for professionals in the field. These data, on earthquakes, weather, fossils, whales, astronomy, etc., have great potential to get children excited about learning and doing science. However, most of the databases are presented in formats that make little sense to children.

Grand Central Science, a National Science Foundation-funded project, addresses the accessibility and scaleability of these databases. GCScience is a centralized web locale for students to do and learn science by accessing and analyzing real scientific data from existing and newly created online databases. Students find and use information through GCScience’s easy-to-use graphical queries for these database systems. Students choose the way they want to display their results — as graphs, maps, tables, spreadsheets, etc. Students also can participate in the scientific process by publishing the results of their analyses at GCScience, and can seek supplementary material through web libraries.
Introducing Students to Online Distance Education

Philip Duchastel, Nova Southeastern University, Fort Lauderdale, USA
Mark Bullen, University of British Columbia, Vancouver, Canada
Rik Hall, University of New Brunswick, Fredericton, Canada

This presentation discusses the merits and difficulties of a flexible online course that serves as a springboard for students into the world of online learning. We developed the course in response to an evident need for guidance on the part of students who were undertaking graduate level study in a flexible advanced degree program. Our experiences in designing this course will be useful to those who are setting up online distance education programs or who feel more learning support is needed by their distance learners.

Teaching Using Online Technologies: A Review of Approaches to Staff Training within Australian Universities

Allan Ellis & Meg O'Reilly
aellis@scu.edu.au moreilly@scu.edu.au
Southern Cross University, Australia
http://www.scu.edu.au

Roger Debreceny
rogerd@netbox.com
Nanyang Technological University, Singapore
http://www.ntu.edu.sg

Academic Staff Development Units (or equivalents) were set up in most Australian universities by the end of 1970s with a common charter of institutional research and advice on improvement of teaching.

These units are now under pressure to respond to an environment which has seen a rapid growth in the demand for the provision of online teaching and course delivery. While individual institutions have reported isolated activities aimed at assisting staff, there is no comprehensive national picture of how this issue of staff development is being addressed.

This poster reports on a national Web-based survey of the 1997 activities within Australian universities. Results show the most common form of delivery is still traditional classroom presentations and demonstrations and half day tutorials with relatively low use of online teaching strategies. In terms of the content of the training, highest priorities are: designing web pages, course authoring systems and pedagogical issues in designing online courses. Attendance tends to be from a cross-section of academic levels with individual institutional profiles determining the level of representation across discipline areas.
Microeconomics in Internet - an Internet based learning environment

Birgit Feldmann-Pempe
Media project (research assistant)
Fachhochschule Altmark i. G.
Am Dom 13
39576 Stendal
Germany
Email: birgit.pempe@stendal.fh-magdeburg.de

Stephan Ressel
Media project (research assistant)

Germany
Email: stephan.ressel@stendal.fh-magdeburg.de

Summary

Permanent learning and training of individuals and organizations will be the key for competitiveness in an increasingly globalized market. Information and communication technologies are becoming more wide-spread. Both individuals and companies trying to understand and to apply the contents of business administration will have to update their knowledge constantly. Presently nothing like an online-learning system for microeconomics in Germany exists. Learning microeconomics is important for the understanding of economic comprehension. It is a decision-making tool that has a wide variety of applications. So far there are not enough suitable computer-based solutions for facilitating the learning of microeconomics.

Approach:

1. Development of an interactive, multimedia, modular online-learning environment for the Internet for low bandwidth with the content “microeconomics” for the European market.
2. Accompanying evaluation about the added value of the use of new media in learning and training.

During the whole development user groups will interact with the suppliers.
The quantity and quality of computer based course materials created in the last few years has been impressive. Managing and delivering these resources in a systematic and productive way has become the problem. The features of an ideal computer managed learning environment to resolve this problem will be outlined. In delivering economics courses at Mount Royal College we have used computer managed learning (CML) for over a decade with some 20,000 students. The lessons gained from this experience in conjunction with new software with the ability to incorporate all of the latest computer based multimedia will be provide an illustration of one approach to solving this problem.
Summary and Keyword Extracting Environment
for Mailing-list Review: A Trial

Satoru FUJITANI
Graduated School of Decision Science and Technology, Tokyo Institute of Technology, Japan
e-mail: mike@cradle.titech.ac.jp

Kanji AKAHORI
The Center for Research and Development of Educational Technology,
Tokyo Institute of Technology, Japan
e-mail: akahori@cradle.titech.ac.jp

Compared with other methods of traditional learning environment, the network-based collaborative system is difficult to provide real-time analysis and feedback by the teacher when the number of learners increases. Therefore, the teacher is not able to facilitate the process of learning effectively, as the latest statuses of the learners are not available.

So the authors envisaged the purpose of this study as the trial of keyword extracting from the series of e-mail in the mailing-list. Japanese natural language processing technology has been employed for the appropriate keyword extraction from the articles belonging to the same topic with which the group deals.

This extraction procedure is an extension of the WWW mailing-list reference environment with the additional feature of substituting the Hiragana character (simplified cursive script from Chinese characters) to the Chinese character of article. The result shows that the error rate is quite low for practical usage of this transformation.
Act on Line – Design of Distance Learning Integrated Environments for Teachers and Students

Act On-line is an academic research project that aims at the development of instructional design of interactive environments of learning through the use of Internet/WWW resources.

Its main goal is to develop educational projects to meet the emergent demands for continuous cultural and professional enhancement. Simultaneously, it researches how distance learning occurs through interface instructional drawing, emphasizing the use of interactive tools destined to active, autonomous and cooperative learning. The project of courses for the University internal and external public, arises from an interaction between teachers who produce content and the project development team that supplies technological and pedagogical consulting, including interface frames models and models of activities for students. WWW environments have been structured for the internal public, combining activities started in the classroom with Internet research.
Multimedia helps people communicate and learn quicker and more easily. The incorporation of multimedia into the Internet via the World Wide Web has made it possible for many more individuals to experience the power of multimedia. It is also the contributing factor for the popularity of the Internet today. Predictions have been made that this trend will continue in the future.

This demonstration deals with the multimedia applications and tools that can be used with a connection to the Internet. The main types of Internet-related multimedia applications include: computer conferencing, videoconferencing, and virtual reality. Some of the types of Internet-related multimedia tools that will be demonstrated and explained are as follows: Adobe Acrobat, Progressive Network's RealPlayer, ASAP WebShow, and Macromedia Shockwave.
Our work sets out a theoretically and empirically based description of a teaching strategy and a flexible knowledge representation for intelligent tutoring systems (ITSs) in the context of a system called ASSA (Adaptive System of Student Assessment) designed to assess pupils who show low performance in solving simple word problems of addition and subtraction. The paper describes an assessing planner able to take decisions in order to achieve two goals: Traversing the domain and maintaining the student’s personal learning characteristics and optimal motivational state. During assessing further student’s characteristics are diagnosed, for example preferences in context, learning strengths, effort and confidence. ASSA’s aim is to adapt its performance to the diagnosed student’s characteristics and encourage him to interact with it accordingly to his strengths. The assessment process provides the student’s cognitive profile as output, accomplished with pedagogical information about the student’s individual motivational characteristics.
Multimedia, Multi-campus and the Teaching of Health Informatics: The Lived Experience

Diane Goldsworthy, Faculty of Arts, Health & Science. University of Central Queensland, Rockhampton, Queensland, Australia. 4702 d.goldsworthy@cqu.edu.au

Health Informatics, is a multi-campus first year health science (nursing), undergraduate unit. Teaching utilises information technology as multi-media, with computer applications, software presentation, email, mailing lists and the worldwide web. Evaluation revealed positive student outcomes included increased competency and confidence using information technology. However, students encountered problems trying to apply concepts and principles of information technology as health informatics to health care. Consequently, the unit will be split in two modules. Module One - Information Technology will be introduced in year one. The focus will be on acquiring expertise in information technology skills with references to health care as health informatics, incorporated. Module Two - Health Informatics will be taught in the third year, following the students' clinical practice Health Informatics will be reviewed, using student exposure in the clinical experiences to its application in health care, as a learning medium.
Situation of Continuing Education Today

The challenges of achieving higher productivity and skills level, and of providing on-going support to learners at every level of work, will place increasing demands on the capacity of financial institutions to educate and train large numbers of employees. Lean management, reduced hierarchies, and overall staff numbers, moving decisions and responsibilities to lower levels make it more difficult for employees to leave the job for additional education and training.

Dynamic and constant changes in technology and new products of an internationalised financial market as well as new regulations and fundamental changes in the economic sector require that education evolves into life-long learning. Information delivery and education are becoming essential services that need to be made available on demand. Traditional means of education are not adequate to meet the needs of the banking staff for life-long learning.

The cost for training great numbers of staff can be reduced by using new technologies instead of traditional classroom education. Although multimedia learning environments may incur higher start-up costs the investment will pay off from about 100 participants onwards.

New Trends and Projects

To accommodate the trends outlined above, Bankakademie will add more on-demand educational services and streamline its production of educational material in order to react more quickly on the demands of our customers. This includes consultation for analysing the demand, planning and evaluation of the educational needs.

Learning to Learn

Many of our students have been working for quite a while before signing up for a course with Bankakademie. Bankakademie and CogniCom, Munich, are developing a multimedia program to help people refresh up their learning skills and strategies. Users are introduced to the workings of the human brain and to different learning strategies. Different scenarios and strategies are proposed for the different aims of the users (e.g. preparation for examinations). Our surveys show that a majority of our students have access to computers with CD-ROM drives (60%), and are willing to buy it (55%).

Multimedia Networks

Hyperwave and Bankakademie jointly developed an WWW-based multimedia database capable of holding all documents that are created during a course into one unified system. This includes preparational materials (handouts, literature), the material created in class (slides, sound/video of the presentation, students' notes) and all (electronic) notes and discussions created after class. This system is based on the Hyperwave Information Server. It can be accessed from any computer connected to the Internet or the corporate Intranet. All documents can be customized and annotated by students and trainers, access rights provide the necessary privacy.

Online Certification

CertiFire is a database system for the management of questions, tasks and examinations developed by Bankakademie. Every questions can be associated to different projects and groups, allowing to tailor the grading of the answer to the group or project selected. Questions can be arranged as self-tests, tests and real examinations. These can be conducted on paper, on the students' computer, or over the
Internet/Intranet. On examination, the user can request additional hints and information to every question. These hints may contain pointers back into the multimedia database and thus help the students to compensate for discovered deficits.
Implications for Virtual Reality in Natural Resource Recreation Management Curricula

Jeff Hill, Bob Buerger, and Jim Herstine
Dept. of Health, Physical Education, and Recreation
University of North Carolina at Wilmington, USA
hillj@uncwil.edu

Since 1992, researchers at the University of North Carolina at Wilmington have been gathering data in multiple media formats concerning physical impacts due to recreation on Masonboro Island, a pristine barrier island off the coast of Wilmington, North Carolina, USA. The data have been integrated into a hypermedia database and are now being used by both managers of the island, as well as researchers. More recently, the hypermedia database was also used by students in a Coastal Natural Resources Recreation Management course in developing coastal management plans. One primary limitation which emerged from utilization of the hypermedia database in both academic and professional settings was the static media itself (e.g., photographs, drawings). To address this limitation, navigable virtual reality images of Masonboro Island have been integrated into the hypermedia database utilizing Apple Computer’s QuickTime VR system.
Hypermedia Authoring as Learning Tool: an Approach from the University of Rijeka (Croatia)

Natasa Hoic-Bozic
University of Rijeka, School of Education, Department of Computer Science
Omladinska 14, HR-51000 Rijeka, Croatia
E-mail: natasa.hoic@ri.tel.hr

The project presents an attempt in preparing the senior students of Computer Science at the University of Rijeka School of Education not only to learn hypermedia and search the World Wide Web, but also that they themselves create their own seminar papers. The idea that rooted this study is that change in content, but in methods as well, have to be obtained in today's contemporary education in order to prepare the students for the information age. In this project students with no prior experience with Internet and hypermedia were introduced to elementary hypermedia concept and how to design WWW hypermedia applications using HTML. Introducing hypermedia by allowing the students to design and build their own hypermedia application was very motivating to them. We hope that those students, as future teachers, will know how to implement and use both hypermedia technologies and the independent study method in schools.
Hypertext Learning Environments as Model Activity Systems: A Pilot Study

Sven Horsmann, Institut für Didaktik der Mathematik, sven.horsmann@post.uni-bielefeld.de
Giselher Redeker, Fakultät für Pädagogik, giselher.redeker@post.uni-bielefeld.de
Falk Seeger, Institut für Didaktik der Mathematik, fseeger@post.uni-bielefeld.de

Universität Bielefeld, Germany

The poster presents findings from a pilot implementation of CSILE (Computer Supported Intentional Learning Environment) developed at the Ontario Institute for Studies in Education (cf., e.g., Scardamalia et al. 1994) in a Grade 10 computer class. The aim of the study was to identify changes and contradictions within the activity setting following the implementation of CSILE as a "model activity system" (Cole 1996). Looking at how communication operates in CSILE and how it is related to ordinary oral communication, we could identify typical changes and problems on different levels:

- physical and technical frame factors
- CSILE as a tool for cooperative communication
- CSILE-windows and features
- teacher and student roles
- products and objects of the activity setting, especially as regards form and content of the notes.

On the basis of the findings conclusions are drawn for future classroom applications.

HyperMeasure: A Video-intensive, Case-based Hypermedia Teacher Development Tool

Jeffrey K. Horvath
Andersen Consulting Education
jeffrey.k.horvath@ac.com

Abstract: Recently, there has been much optimism about the promise of hypermedia in case-based teacher education programs. Despite such optimism, however, there has been little evidence of how people learn with case-base hypermedia learning tools. This presentation describes the design and assessment of one such tool. First, I describe the learner-centric design of a hypermedia teaching tool (HyperMeasure). Second, I describe an empirical test which determined that pre-service teachers can learn about the growth and development of children's understanding of measure. I conclude with a discussion of the importance of design cycles in the development of educational software.
This session is related to the Information Sharing Special Interest Group session. The issues we are looking at are:

- Time to share information.
- Sharing "quality information" which will increase productivity.
- Common indexing systems.
- Common value systems.
- Standards.
- Technology.

Currently we are using email and exploring listservers and collaborative workspaces as means of sharing information with each other. We have been sharing information using informal profiles of each other's interests and reviewing information that relates to the Special Interest Group. David Ibsen has been working on a pilot project to develop a semiformal structure for information sharing and Irene Langner had been exploring the use of collaborative workspaces. Others in the SIG have reviewed their work and provided quality feedback.
An ITS Authoring Tool
with Automatic Generation of Courseware Knowledge

Kayo Ikeda, Minoru Kiyama, Satomi Ishiuchi, Shigeyoshi Izuka, Masahiko Tsujimoto, and Yoshimi Fukuhara
NTT Information and Communication Systems Laboratories
3-9-11, Midori-Cho, Musashino-Shi, Tokyo, Japan
kayo@isl.ntt.co.jp

Our laboratory has been carrying out research and development on an Authoring Tool for CALAT (a Computer Aided Learning and Authoring environment for Tele-education), an intelligent tutoring system (ITS). To facilitate wide-spread use of CALAT, the system must provide a variety of content, therefore an authoring tool must allow easy courseware creation. Our Visual Authoring Tool of CALAT supports almost all aspects of courseware creation, including design, input of design data, testing and evaluation. The tool includes Automatic Generation of Courseware Knowledge which is mainly composed of learning goals, scenario, exercises and their relationship information. This Automatic generation produces courseware from a part of Courseware Knowledge. After this process, we expect that courseware author rearrange their courseware to refining. By repetition of these way, it is promoted spiral-type's rapid development of courseware. We will demonstrate both the Visual Authoring Tool and the Automatic Generation of Courseware Knowledge.
The purpose of this poster session will be to articulate and reflect upon selected educational research Web projects with which we have been involved. The poster will demonstrate selected design features of Web sites such as the National Infrastructure for Education Web site (National Center for Supercomputing Applications at the University of Illinois), "Smart Web" for the Scientists-in-Action Project (Learning Technology Center, Vanderbilt University), artNtec Project (U.S. Army Construction Engineering Research Laboratory), Cognition, Technology, and Complex Systems Project, the Knowledge Mediator Project, and the Learning and Performance Support Laboratory Web site (University of Georgia). The poster will cover issues such as design processes, concept development, user interfaces, user feedback, content organization, platforms, implementation, and team work. Overall, we hope that the educational research design approaches we have been working on may stimulate interesting interactions with Ed-Media 98 participants related to ways to better design and utilize Web educational resources for students, teachers, researchers, and the general public interested in education.
Partnering in Technology Integration: South Texas Style

Aileen S. Johnson, Reading Department, University of Texas Brownsville, USA, ajohnson@utb1.utb.edu
Paula Parson, Reading Department, University of Texas Brownsville, USA, pparson@utb1.utb.edu
Norman Binder, Social Sciences Department, University of Texas Brownsville, USA, binder@utb1.utb.edu
Mary Jean Garcia, Librarian, Oliveira Middle School, Brownsville ISD, USA, mjgarcia@tenet.edu

The role of universities in preservice and inservice training of teachers is vital. Successful integration of technology to improve teaching and learning depends on the capacity of the university faculty to model and support public school teachers as they become familiar with, and comfortable in, using multimedia technology to enhance their instructional programs. This paper describes a model for partnering between a regional university and 17 area secondary schools that reflects ongoing support from the development of competitive grant proposals through the implementation and dissemination phases of the Technology Infrastructure Fund projects. This process involved four distinct phases: 1) developing a vision, 2) building computer literacy skills, 3) linking curricular objectives to technology, telecommunications and multimedia, and 4) designing and implementing technology-enriched courses. The scope and sequence of training and dissemination activities, together with examples of printed materials and products will be shared.
The WWW cannot guarantee learning. The design of WBI must take into account visualization, goal orientation, motivation, and structure so the design enhances the educational opportunities of the learners. By allowing learners to set goals and reflect on the content, the learners’ attention is focused and they understand the interrelatedness of ideas. Multiple media provide the learner with rich and realistic contexts for multichannel learning. Motivation is increased when learners are in control of navigation and encounter realistic examples. The structure is enhanced through simplicity so the interconnectedness of ideas is clear. Instructional design must translate design issues and learning theories into plans for web-based environments. Through the development of ThermoNet (instructional web site), we can determine the following: impact of visualization on learning and retention, importance of setting goals for learning, optimal navigational device to enhance students’ learning, and benefits of utilizing the web as a research medium.
Using The Wisconsin Sequence Analysis Package for DNA and Protein Analysis

Dr. Brigitte Kisters-Woike, Dr. Budi Tunggal, Volker Winkelmann
University of Cologne, Germany
Institute of Genetics, Institute of Biochemistry, Regional Computing Center
Email: gcg-kurs@uni-koeln.de

A WWW Based Tutorial

The computer analysis of DNA and protein sequence data is an important technique in molecular biology and molecular medicine. The Wisconsin Sequence Analysis Package of the Genetics Computing Group (GCG), Madison, USA, is one of the major tools for the computer analysis of genetic data.

We have developed a WWW based tutorial for people who have to become familiar with the GCG program suite. The course aims at students, who need an appropriate preparation before attending experimental courses in molecular biology and at scientists, who need a 'living cookbook' for their work on the bench. Our tutorial provides the possibility of a linear path to learn to access the programs as well as the fast access to a specific program which is actually needed.

Standard WWW browsers have the advantage to provide for each scientist or student at the same time on-line access to the program suite, his or her sequence data and access to the tutorial.

Figure 1: sample pages from the tutorial - starting page (left) and lecture page for program fetch (right)
Space for Learning and Teaching Exploration

Regan Knapp
Office of Instructional Technology
University of Michigan
brk@umich.edu

Tricia Jones
Office of Instructional Technology
University of Michigan
triciaj@umich.edu

Space for Learning and Teaching Exploration (SLATE) was developed at the University of Michigan through a collaboration between the School of Education and the Office of Instructional Technology. It is a combination of custom software and existing applications, designed around a rich set of multimedia data that U-M Professor Deborah Ball collected during a year's teaching in a third grade mathematics classroom. In this environment, mathematics education students observe a common classroom, complete multimedia research and writing assignments, and — in the process — learn to think about new ways of teaching mathematics.

Approximately 30 days of classroom interaction are represented with multiple media types, including classroom video, full-text transcripts, children's notebooks, and the teacher's journal. SLATE supports browsing of all media types, multimedia authoring, and full-text searching of the transcripts and teacher's journals. The transcripts are linked paragraph by paragraph directly to the video clips. SLATE is used on a Macintosh, and the search engine runs under UNIX and is accessed via the Internet.
A Bon Port/Ficelle: Designing and developing a multimedia language activity CD

Hélène Knoerr,
Second Language Institute, University of Ottawa, Ontario.
hknoerr@uottawa.ca

Alysse Weinberg
Second Language Institute, University of Ottawa, Ontario.
weinberg@uottawa.ca

After writing our new French language textbook A Bon Port (Prentice Hall, 1998), we began to develop a companion CD-ROM using the Ficelle authoring system. This CD-ROM will allow students to do independent work and receive immediate feedback about their progress.

The program originated not from a computer programmer but from language teachers who submitted a list of requirements to meet the needs of their students. The A bon port CD-Rom has:
- activities that complement the textbook rather than an electronic repetition of the textbook;
- truly interactive, communicative activities;
- a user-friendly browser-like interface;
- activities at different levels to accommodate a wide range of proficiencies;
- generic feedback reflecting in-depth error analysis;
- an end-of-activity scoresheet showing number of trials, and number of right and wrong answers;
- culture and grammar links.

Lessons in the A bon port CD-Rom may include:
- fill-in-the-blanks type questions to be used with text or graphics;
- multiple choice questions using either words or boxes to click;
- lesson sound files to play or the recording and playback of the student’s voice;
- pictures and photographs;
- capability to play video .avi files;
- coloured and highlighted text;
- “hotkey” glossary words.

The CD-Rom will be piloted in a number of French classes in September 1998.
Engineering Educational Environments for Tomorrow:
Quality, Virtuality and Reality

M. S. Vijay Kumar Ed D
Director of Academic Computing
Massachusetts Institute of Technology
vkumar@mit.edu
http://web.mit.edu/vkumar/www/

The vision proposed by MIT's Council on Educational Technology points to exciting ideas for combining the capabilities of new technology with the commitment and skills needed to achieve ambitious educational goals.

The educational activities and environments proposed - from Virtual Reality for freshman Calculus and animated sequences for teaching electromagnetism to visualization-intensive collaboratories for biomedical research and a Virtual Design Studio for architects - suggest the possibilities of a re-invented campus and a new sense of place.

Moving from the rhetoric of the rich, technology enabled educational vision to the reality of implementation will entail some interesting and challenging transition issues:

- Building an architecture of systems and services that supports experimentation without disrupting production.

- Making high performance available on highly available environments.

- Retaining the strengths of MIT's current distributed computing environment, Athena, while adding new capabilities and functionality to support a high-performance, media-rich, distributed educational technology.
The Pros and Cons of RealVideo

Dr. Eva Fung-kuen LAI
Independent Learning Centre, The Chinese University of Hong Kong, Shatin, N.T.
Tel: 852-2609-8759 Fax: 852-2603-5798 Email: fungkuenlaw@cuhk.edu.hk

Pros: Using web interface as the overall container, RealVideo can show a combination of video, audio and text and thus can be used to provide interactive self-access language learning materials to students through the campus network. For off-campus students, there is also the flexibility to deliver just the audio component over the Internet. When technology improves, the video content can be delivered as well.

As many students are already familiar with World Wide Web, they will find the interface user-friendly and do not have to spend time and energy over the technology, thus focusing more attention on the language learning process. Also, RealVideo can be used for authoring complicated interactive learning programmes.

Cons: The web interface is not particularly strong in synchronizing different objects. But now RealVideo has the functionality to allow webpages to synchronize with the video. Nonetheless, the authoring tool for this is not simple enough for everyone to use.

Email:nhoic@alf.tel.hr

In the ongoing research which final goal is to develop a model of university staff development, we consider the “new collegialism” approach as appropriate basis for using computer-mediated communication in the improvement of higher education teaching. This approach is participant oriented, opened, responsive and innovative, promotes networking and teamworking, welcomes change, facilitates active learning, has opened access and explicit quality criteria, and empowers the participants [Harvey & Knight, 1996]. We believe that computer mediated communication will open the process of continuous improvement of teaching and learning at the universities, primarily from the bottom-up direction. From 203 teachers who participated in our study, 108 of them want to start communication. Computer mediated communication we intend to use in our model will include: establishing news group: “What’s new in academia?”; establishing mailing list; establishing Web-pages where teaching materials, teaching “tips”, information about activities will be exposed, and establishing e-mail consultancy.

The Development and Analysis of the Effectiveness of a Multimedia Introduction to Plant Secondary Metabolism.

Michael B. Looney, M.Sc. Candidate, Department of Plant Science, University of British Columbia, Canada.

Dr. Brian E. Ellis, Professor and Head, Department of Plant Science, University of British Columbia, Canada.

This demonstration/poster will describe the development of a multimedia introduction to plant secondary metabolism and report the results of the effectiveness of the application.

For the uninitiated encountering most of the current literature in plant secondary metabolism is somewhat daunting. Since secondary metabolism is a visual and dynamic field, and since computer-based multimedia allows one to visualize dynamic phenomena that is not well represented on paper, it was anticipated that an accessible multimedia application may hold some potential for bridging the gap between the neophyte and the literature.
Introduction

Finland is one of the leading countries in Internet technologies. Universities have pioneered in the creation of Internet services which have proved to be of great benefit both to the students and teachers. This year, 1998, the various services of Finnish open universities have been brought together on the same WWW-pages. Internet technologies create new possibilities for studying and learning, including, naturally, the possibilities to search information, to compare different courses and get guidance from tutors.
Education Through Transcription Using Personal Computers

Misa Manabe
Kurosaki Municipal Junior High School of Kitakyushu, Japan
E-mail: i-ris@alphatec.or.jp

Abstract: In this research a multimedia software package was developed to improve students' Kana (the Japanese syllabary) writing with respect to the shapes of the letters and the proper use of the brush in their calligraphy lessons at junior high school level. This software 'Internet Shodo' was produced using HTML and it is now on the Web. Students can learn how to write each letter by carefully watching the QuickTime movie with sound explanation on it. Considering the research results this software was very effective in improving the students' writing ability and motivating them to evaluate their calligraphy works over and over again checking in detail the order of the strokes, the required change of ink thickness and the necessary height of each letter, etc. The students found that the software had increased their interest toward writing the letters properly and also changed their attitude more in favor of daily improvement of their syllabary writing. Further research is now developing to facilitate international Shodo collaborations between schools in Japan and the UK.

Flexible and Open Hypermedia Authoring Tools Need Courseware Modularity

Joaquim Arnaldo Martins, Joaquim Sousa Pinto, Hélder Zagalo
University of Aveiro & INESC, 3810 Aveiro, Portugal
Tel: +351-34-370500 fax: +351-34-370545 email: jam@ua.pt

This poster/demo describes an Hypermedia Document Composer (HDC)\(^1\) which can also be used to play documents in several collaborative education and training scenarios and that is being extended to support collaborative composition of hypermedia documents\(^2\). The HDC uses the overhead and transparencies metaphor to build the hypermedia nodes and to hold multimedia objects through the use of OLE technology which allows the composition of very flexible hypermedia documents supporting any type of multimedia OLE objects produced by MS-Windows applications (word, excel, video, audio, etc.) [PINTO et al, 1995]. This open architecture allows the easy integration of existing documents as well as new ones regarding they are produced by OLE/ActiveX applications. In modern authoring tools this flexibility is very important to allow the teacher/students to deal with and to build dynamic teaching/learning situations by reusing the several components and modules to handle with different pedagogical scenarios in more appropriate ways. The key to this flexibility and modularity is a centralised resource center which stores the multimedia objects, the hypermedia structures defining the documents, public annotations, OLE/ActiveX servers to support specific teaching/learning modules[SANTOS et al. 96] and mechanisms to support the related organisational issues [MARTINS & PINTO 96]. In “composition mode” a HDC user connects to the resource center, through ODBC, and browses it to find the multimedia objects or modules already stored to insert into the hypermedia document or adds new objects. All these operations to compose the hypermedia document are done graphically by direct manipulation. The possibility to support multimedia annotations (public and private) is also very important, because users can add their comments to the hypermedia documents. All public annotations are stored in the resource center, allowing user mobility. Public annotations are visible by every user while private annotations are visible only by their authors.

The Resource Center (multimedia database) is a key feature of this hypermedia composer since, we believe, the resources to build flexible courseware are a fundamental issue for an open teaching and learning environment. We need very flexible courseware modules, with low granularity, so that they can be reused to build dynamically several teaching and pedagogical scenarios which isn’t possible with long, static and linear courseware. In this way the HDC acts like a courseware resource center dynamic front end allowing the reutilization of objects in different contexts which are the hypermedia structures (new object) that hold a new hypermedia document.

A New Two-year Program in Multimedia at Utah Valley State College

Ralph T. Merrill
Multimedia Communication Technology Department
Utah Valley State College
United States of America
merrilra@uvsc.edu

Ruediger K. R. Lehnardt
Foreign Languages Department
Utah Valley State College
United States of America
lehnarru@uvsc.edu

The new two-year associate of applied science degree program in Multimedia Communication Technology is the only stand-alone multimedia program in Utah. Its curriculum was developed with considerable input from industrial multimedia consultants. This program is now completing its third year and its popularity with the students is growing rapidly. The program has two tracks to allow the students to choose an area of multimedia specialty. One track is multimedia technical support, the other track is multimedia design and production.

The multimedia courses are offered both during the day and evening. Because of this program, UVSC is gaining a reputation as being the multimedia learning site in Utah. Multimedia oriented industry in Utah is recognizing the importance of this new program and is commencing recruitment of the students. The program is also serving residents of the local community as an alternative new and rewarding career path. A unique and solid relationship with high schools in Utah has been established; their students, who are excited about multimedia, are looking to UVSC as the place in Utah to further their education in this blossoming field.
A Multimedia Installation as Critical Environment of Experience
–Tendencies of Change in Everyday Communication –

Müller, Petra arts and education KUNSTKOMM.T! Waltgeristraße 50 32049 Herford Germany
Email: petra.mueller@uni-bielefeld.de

Adolfs, Michelle arts and education KUNSTKOMM.T! Waltgeristraße 50 32049 Herford Germany
Email: michelle.adolfs@post.uni-bielefeld.de

As artists and educationalists we have developed an interactive multimedia installation which presents a room of experience and exploration. It deals with a vision of telecommunication in the future. Our view: By means of the dissemination of multimedia abilities in communication the everyday communication will change. In our artificial room of conversation the variety of effects of a simulated part of everyday conversation is to be experienced. At a laid table conversation partners are to be chosen at the touch of a button. Talking heads are projected at the face of a doll. Those Partners of conversation are present in the shape of the figure in a visual, auditive and physical way, but they are not real. The boundation to the effect on communication on the environment, on the interpretation of the user and his ascription of roles are to be experienced. The question of the impression of communication-reality is emphasised.
Internet Training for Teachers Using Content Area Earth Systems Science

Gerald ("Jerry") E. Nelson, Ph.D. Chair, Physical Sciences/Mathematics, Casper College
Professor of geology and Geography, Casper College
Adjunct Professor, University of Wyoming, Department of Geography
Adjunct Professor, Montana State University, Extended Studies
gnelson@acad.cc.whecn.edu

Susan R. Nelson, M.S.
Professor of Mathematics, Casper College
snelson@acad.cc.whecn.edu

Our approach to teacher training is to offer a web-based, on-line graduate class ("Internet-Based Earth Systems Science Instruction for K-14 Teachers") limited to in-service teachers. Project activities are used as the content vehicle by which teachers can gain practice and experience on how to use the internet in their own classroom. As the teacher participants work through activities, they are required to develop their own extensions of the materials that are most appropriate for their classroom and situation. The ultimate objective is to inspire them to see the possibilities and to give them a framework in which to expand their knowledge of an important content area, earth systems science, and the internet medium. Teachers report using the internet more in their classroom and in a more significant ways. Content-based activities encourage teachers to gain experience with the internet medium.
"Minds on Science" vs. "Hands on Science" - Lab Science in an Internet Class

Gerald ("Jerry") E. Nelson, Ph.D. Chair, Physical Sciences/Mathematics, Casper College
Professor of Geology and Geography, Casper College
Adjunct Professor, University of Wyoming, Department of Geography
Adjunct Professor, Montana State University, Extended Studies
gnelson@acad.cc.whecn.edu

I refer to laboratory science on the internet as "minds on" to distinguish it from traditional physical geography "hands-on" laboratory offerings revolving around paper maps, globes, aerial photographs, weather and climate data, soil samples and so on. Probably more than most sciences, these tools and topics are well represented on the internet. Rethinking what "laboratory" actually means, interpreting it in a "minds on" way rather than just "hands on" frees the teacher to make use of the richness of images and data available on-line. My Earth systems Science (http://www.math.montana.edu/~nmp/opening.html ) class for the Network Montana Project at Montana State University, and my Physical Geography (http://wind.cc.whecn.edu/~gnelson/physgeog/IntroG.html ) class at Casper College are attempts to put this philosophy into action. These projects demonstrates that "minds on" science activities on the internet can supplement and perhaps supplant traditional laboratory science activities.
This project helped high school students develop computer literacy and skills through the use of a constructivist teaching strategy, the development of a CD-ROM supplement for a high school yearbook. Because of a wide applicability for other computer uses, students used a combination of Microsoft PowerPoint and HTML to develop the contents of the CD-ROM. Contents included an introductory page with buttons for sports, student organizations, school events, and class pictures. Included were video clips of football and basketball highlights, a scene from a school play, students with musical talents, and interviews with students, staff, and teachers. The students were highly motivated! They learned PowerPoint, HTML, graphics, the making of a CD-ROM (etc.), and developed high rapport with each other and their teachers. Special thanks goes to the Corporation for Public Broadcasting (CPB), Ernest L. Boyer Next Step Grant, for providing the opportunity for this project.
Electronic Hypertext Reports Teach Content, Skills, and Teamwork

Melvin L. Northup, Biology Department, Grand Valley State University, USA, northupm@gvsu.edu

Having science students create hypertext multimedia reports by groups provided stimulation and encouraged teamwork while helping students learn new information and skills. Each group identified a question to be investigated, designed and conducted experiments, collected data, and made interpretations. As work progressed, a camcorder and a 35mm camera were used to document the project. Video images were captured, photographs were scanned, and voice clips were recorded for use in the final hypertext reports. Computer generated spreadsheets and figures were inserted. Final reports were presented to the class. Each student was involved with all phases of the project, using as many of their five senses as possible. The constant peer-review inherent to collaboration was more effective motivation than evaluation by the instructor. The creation of hypertext multimedia products instead of typed linear text reports fostered improved writing by many of the students because it introduced flexibility into their thought process.
Interactive Electronic Problem Based Learning (iePBL): An Internet based Application for Clinical Medical Education in the PBL Case Format

Francis S. Nuthalapaty, Northwestern University Medical School, Chicago, IL 60611 USA. E-Mail: fsnutty@nwu.edu

Jane Oh, Northwestern University Medical School, Chicago, IL 60611 USA. E-Mail: joh@nwu.edu

Christian Elsner, Carl Ludwig Institute for Physiology, Liebigstrasse 27, 04103 Leipzig, Germany. E-Mail: med93cwi@studserv.uni-leipzig.de

Michael Altman, MD, Northwestern University Medical School, Chicago, IL 60611 USA. E-Mail: maltman@nwu.edu

Project Description

Interactive Electronic Problem Based Learning (iePBL) incorporates the PBL case format into a multi-user computer-assisted information exchange. An Internet web-browser is used to provide platform-independent access to multiple users at remote locations.

Students are able to login to the iePBL web-page at a self-determined time. Case information is reviewed independently as it is progressively disclosed. During each session, the student enters his/her hypotheses and interpretation of information and identifies learning issues.

Individual user input is compiled by the iePBL web application for review by all users and the Faculty preceptor.

Students revisit the web-page at designated intervals for review of peer submissions and analysis of new case information. Students also order and interpret diagnostic tests. At each diagnostic decision point, the student is required to outline his/her medical reasoning and comment on other students’ ideas as desired.

The Faculty Preceptor plays an integral part in facilitating the iePBL discussion forum. He/she provides feedback to individuals and/or the group and asks pertinent questions to guide the learning session.

Attempts to incorporate computer technology and e-mail-function into PBL sessions have already been made with favorable results [Schor 1995] [Coulehan 1995]. iePBL’s new approach has several potential benefits in undergraduate medical education.

References

We demonstrate our WWW(World-Wide Web) based ITS(Intelligent Tutoring Systems) for guiding differential calculations[Okazaki et al. 1996]. It is a practice type ITS and you have access to the system from http://www.is.saga-u.ac.jp/ai/ai.html.

Its individualized tutoring mechanism is as follows. It dynamically generates individualized HTML documents in the phases of setting problems, guiding and summary of study. Hidden tags are used to embed user identifiers. Teaching module driven by CGI facility identifies student's error origin based on buggy model. We have grouped student's states of the identified error origin into 6 categories based on his/her score and frequency of the error origin. Teaching module generates guidance messages according to teaching paradigms which are assigned to each states.

Abstract: The Internet is being used more and more for the delivery of college coursework as millions of users go online. Although internet-delivered courses offer advantages to students such as convenience and increased access, a number of problems have resulted as well. One of these is the lack of a mechanism to provide demonstrations and short lectures in a format with which the student is familiar. In addition, courses that primarily use e-mail and web pages lack the interpersonal communication and visual imagery available in the classroom. With the advent of streaming media technologies, instructors can videotape short lectures, demonstrations, and other presentations, digitize and compress the video, and post the file on their course home pages. Students may then view these videos over the internet using a web browser and the appropriate plug-in. Our first experience with streaming video as part of an internet-delivered course was a qualified success. The current technology is adequate for the delivery of video and is relatively easy to use by both viewer and producer. There is no question that this technology will continue to improve and will become a major factor in the delivery of distance education materials. However, no matter how good the technology becomes, the emphasis will always be on the content and quality of the video production.
A multimedia educational software tool named *Virtual Class* has been developed. It offers interactive multimedia courses about various telecommunication services; and it is based on the use of telematics networks, what makes possible the interaction between teachers and pupils. *Virtual Class* is a server-client system, which uses the Internet protocols. The client side, along with the courses, is distributed in CD-ROM.

*Virtual Class* is the result of the coordinated action between diverse kind of specialists, mainly Pedagogues and Telecommunication Engineers.

*Virtual Class* is intended first of all for SME’s workers, although it will subsequently be extended to cover other segments. It has been evaluated while giving a course for SME’s workers in CEDETEL in September-October of 1997 and we will have the opportunity of evaluate it again in the first semester of 1998, this time in a course about Distance Learning for future teachers at the University of Salamanca.
Site-level Authoring, Revisited

Samuel A. Rebelsky
Department of Mathematics and Computer Science, Grinnell College, Grinnell, Iowa 50112
515-269-4410, rebelsky@math.grin.edu

In the early days of the World-Wide Web, most sites were small enough and the web was new enough that it was possible to create and maintain sites by hand. However, as the web has grown, so have individual sites and the effort required to maintain these sites. Site maintenance may require gardening to prune unneeded pages and links, redesigning pages or groups of pages, and even restructuring the whole site. Too often, effort that should be spent on global design or content issues is spent instead on repetitive details.

Fortunately, a number of systems have been developed to support authors, designers, and maintainers of larger information spaces. Academically-developed site-level authoring systems include ASML (the automated site markup language), CourseWeaver, Gentler, HtX, HyperWave, I-CARE, Siteview, Siteweaver, WebCT, and WebMapper.

This work describes the tasks of site-level design and summarizes the similarities and differences of these different tools as well as their applicability to different tasks.
Teaching And Learning Languages with the Internet: A Case Study

Uwe Richter,
Anglia Polytechnic University, Department of Languages,
Cambridge, Great Britain
e-mail: u.m.richter@anglia.ac.uk.

Introduction

The use of the Internet as source of a wide variety of information for academic studies is already well established. Some courses also use the Internet for distance and flexible learning e.g. by putting lecture notes and reading materials on a server or the Web. The novelty of this project is, that it goes beyond hyperlinked pages by using interactive HTML language exercises with direct feedback.

Over the last two years, the project on Teaching and Learning Languages with the Internet has resulted in the production of a number of courseware units and enabled me to explore the possibilities the Internet offers as authoring and learning environment. The main objective was to produce language learning courseware that include links to Internet sites as well as specific language learning exercises. Envisaged outcomes are models or templates of language learning exercises to support faster and more efficient courseware development in the future.

A sample unit can be visited on http://www.eon.anglia.ac.uk/CALL.

The Authoring Environment

General

HTML is an authoring language that is fairly easy to learn at least compared to other authoring tools. It could be compared to a word processor that needs to be programmed what to do such as font sizes, tables, etc.. However as with word processing more and more sophisticated editors make life a lot easier and authoring faster. However, because HTML is mainly an interface language anything involving computing such as learner progression or
performance in a courseware unit demands more complex computing skills depending whether the processing is client-\textsuperscript{1} or server-\textsuperscript{2}-based.

**Language Learning Exercises**

Many traditional language learning exercises can be produced using different HTML forms such as gap filling using text boxes, multiple choice using drop down menus, various matching exercises using text or check boxes and true/false exercises using radio buttons or icons.

By using frames the interface can be divided into different windows, whereby each window can be used for different activities and functions. In my courseware units for instance I used a small frame at the bottom of the screen for navigation but also for feedback. Additionally, HTML\textsuperscript{3} and the e-mail facilities of browsers open up the possibility for writing and conferencing tasks that are difficult to cater for in traditional language courseware. With these tasks learners can be asked to produce a summary, short essays or other types of texts, which they send to the tutor to give feedback. Furthermore conferencing facilities can be included which enable learners to communicate with each other on a topic, text, video or audio in the unit.

**Conclusion**

The Internet can open up new dimensions of language learning and teaching as it is possible to include text, image, audio as well as video with specific interactive learning tasks and relevant Internet links in a courseware unit, using only an Internet connected multimedia computer as equipment.

Authoring on the Internet is inexpensive and editing software is getting more and more sophisticated. The authoring environment is developing rapidly and is getting more powerful by the day, so that handy solutions for the current limitations of HTML could soon be found. However the effective application of courseware also depends on the speed it is delivered to the learner's computer. Computers, modems, servers and telecommunication lines are improving, but many factors are involved in the state of a particular network. It needs to be seen if the current state of

\textsuperscript{1} Cookies in Java Script can be used to store information on the hard disk of the client.
\textsuperscript{2} Computing expertise in a programming language such as PERL necessary
\textsuperscript{3} With text blocks and 'mailto' function
networks in particular areas (i.e. in education) can keep up with technological developments.

Canadian and Russian Universities on
Joint Design of the Distance Learning System in
Russian Teacher University

Irina Rozina, Rostov State Pedagogical Univ., Russia
Walter Epp, Lakehead Univ., Canada
rozina@rgpu.rnd.su, wepp@flash.lakeheadu.ca

This presentation sets the historical, philosophical and theoretical framework for the present and future needs of Russian education. The authors present the view that the deficiencies of contemporary Russian education can be addressed by a return to certain pre-revolutionary educational paradigms which parallel contemporary western thinking. An attempt is made to address the geographical and economic challenges which stand in the way of developing a distance education modal which will facilitate the organization and delivery of curriculum to meet the needs of modern Russia. To this end the Canadian experience, which has evolved through similar challenges to those of the North-Caucuses region, is described as a possible modal. The presentation concludes with a discussion of the first attempts at cooperation between Lakehead University in Canada and Rostov State University in Russia.

¹Projektgruppe Autodidakt, ZIBMT, Universität Ulm
²Abt. Innere Medizin II, Sektion Nephrologie, Universität Ulm

Correspondence: Dr. Claudia Scheuerer, Zentralinstitut für Biomedizinische Technik, Universität Ulm, Albert-Einstein-Allee 47, D-89081 Ulm; email: claudia.scheuerer@zibmt.uni-ulm.de

Introduction

The project group ‘Autodidakt’ and the division of nephrology at the University of Ulm are developing a case-based, interactive learning program. Representative diseases of the kidney are elaborated. Every case is designed according to a general structure: history, physical findings, laboratory, investigative results, diagnosis, treatment and prognoses. This program will offer for medical students an opportunity to train their understanding of diseases, and their ability for the treatment of patients. For this task the content of the program is subdivided into information-units. Interactive sequences, animation and a variety of clinical images and videos support the decision and learning process of medical students.

Aim

The program addresses advanced medical students and postgraduate physicians. It is intended to provide a learning tool, which trains especially the case-based decision during the medical treatment of patients with diseases of the kidney.

Concept

The case-based learning as opposed to the textbook learning has the advantage of simulating real situations of the daily clinical life. The student is confronted with a concrete situation and is asked to make decisions for the treatment of a patient. In the interaction with the program the student gets feedback on his decisions, and additionally he can gain advanced expert knowledge in a relevant field. Using the links, the student will be able to learn more about pathophysiology, differential diagnoses and discussion referring to the latest published results. In order not to confuse the student, additional information is presented in special windows, the so-called expert-windows. These windows are displayed, as if they were placed in front of the main layer. In the expert-windows the medical content is arranged in a systematic way. Additional pathways lead to knowledge-layers with more detailed information. Using the links, the student is able to determine the extend of knowledge of a special subject, he wants to learn.

For example: the virtual patient is suffering from diabetes mellitus. After the student has ordered a special bloodtest, the value of HbA1, he can recall the pathomechanism producing HbA1, which is named glycosilation of hemoglobin-molecules.

Whenever the pathomechanism is more impressive, an animation is shown. We have integrated 2D- and 3D-animations, sounds and videos.

The program will comprise 20 cases from all fields of nephrology.
Methodology

The program is produced for CD-ROM, running on the operating systems Windows95, WindowsNT and MacOS. For the development we use the authoring tool ‘macromedia director’ and other software for editing images, soundfiles and movies, such as ‘Adobe Photoshop’, ‘Adobe Illustrator’, ‘Adobe Premiere’, ‘Macromedia SoundEdit’, ‘Equilibrium DeBabelizer’, etc.

Evaluation

The evaluation of this program will be accomplished in two steps: The first step involves the user-tracking; it is performed by the program. User activities, such as the time spent on a single page, the type of button clicking, and the correctness of interactive answers are captured in a protocol file, and are used for evaluation. In the second step a questionnaire form is involved, which is given to the user in order to obtain information about the user’s subjective impression of handling, and his satisfaction with the program.

Conclusion

Performing this project at a university containing a major medical school has the advantage of easy access to professional discussions and advice by experts knowledgable in the most recent developments. Our program is designed to take advantage of this opportunity. Case-based learning combined with the ability to look up expert knowledge and to learn medical fundamentals in a single, electronic medium are the main advantages of this program. Multimedia elements, such as animations, support the appreciation of complex medical situations, and they can also add enjoyment to the learning process.

Information Technologies and Quality Management - An Integrative Strategy in the Design and Delivery of Postgraduate courses

Dr. Ravi C. Seethamraju, School of Quantitative Business Methods & Operations, University of Western Sydney Nepean, Australia, e.mail: r.seethamraju@uws.edu.au

Dr. Rakesh K. Agrawal, School of Quantitative Business Methods & Operations, University of Western Sydney Nepean, Australia, e.mail: r.agrawal@uws.edu.au

Nitya K. Karmakar, Faculty of Business, University of Western Sydney Hawkesbury, Australia, e.mail: n.karmakar@uws.edu.au

Abstract: Though, advanced technologies such as World Wide Web (WWW), Internet, e-mail, and interactive visual media are increasingly being used for distance education and for public relations or communications purposes, in normal day-to-day design and delivery of the courses in the context of on-campus education, its application appears to be minimal. Apart from its advantages in terms of the speed, convenience and interactivity, these technologies, are expected to supplement experiential learning strategies and meet to some extent, the different individual learning needs and learning styles. This paper explored the complementary nature of information technology to the on-campus face to face teaching mode of learning. By adopting quality management approach with its focus on continuous improvement and student as a customer, this paper argues, that a successful deployment of policies and procedures with regard to these information technologies lay foundations for continually improving education processes for life long continuous learning.
Geographic Information Systems (GIS) can serve as appropriate Media for creating convenient learning, presentation and exploring background for engineering and other branches of human activities. GIS belongs to new and fast growing direction of modern information technologies. They are integral systems, having important range of properties and facilities:

- 2D/3D raster and vector CAD-quality graphics editors;
- multi-layered presentation of spatially distributed objects, sensible to current scale factor;
- SQL graphics database subsystem;
- powerful interactive interpreter of visual structured program language;
- open systems architecture having DDE and OLE mechanisms;
- common GUI, web and paper publishing tools.

GIS can become attractive learning platform, capable to create structured space navigation media filled with objects from any territory distributed area, reflecting various engineering branches: architecture, water/power/gas distribution, telecommunications, transport systems etc.
The University of Central Florida (UCF) is aggressively developing distributed learning programs, particularly asynchronous learning networks (ALN), to meet the diverse needs of its growing student population. UCF has institutionalized distributed learning by developing the technical infrastructure, providing administrative support and leadership, systematic faculty development, and a plan for ongoing assessment of distributed learning.

UCF has formally recognized distributed learning as a strategic direction to increase access to educational opportunities for students within our service area and beyond. The university has chosen to employ ALN as a primary approach to address the challenges of a rapidly-growing student population, a shortage of classroom space, and the need to maintain quality--all within available resources.

Over the past two years, UCF has made significant investments in technology infrastructure, faculty and student support services, and organizational development to support both regular campus instruction and the ALN initiative.

Institutionalizing faculty development for ALN course instruction has provided cross discipline sharing of teaching techniques and has produced cohorts of faculty across all five colleges who continue to meet and discuss the teaching and learning process and evaluate their successes and failures. The faculty development process has evolved to a model ALN 'course' approach.

In an effort to determine the impact of online courses on both faculty and students, UCF began a pilot study in 1997 to examine teaching and learning in the ALN environment. This pilot study is focusing on five areas of investigation:

1. examining the demographics of students who enroll in ALN courses;
2. examining the perceptions of students who have enrolled in ALN courses;
3. determining the perceptions of faculty toward the experience of teaching in an ALN setting;
4. assessing student outcomes in ALN and traditional environments; and
5. identifying best practice ALN courses on the UCF campus.

To date, this pilot work has focused only on those courses that have been offered entirely in ALN mode with no face-to-face meetings beyond an orientation on the first day and perhaps a final examination. Data from ALN-enhanced format courses initiated in the fall of 1997 are currently being examined. We are expanding and enhancing this preliminary work to a scale that will support the necessary analyses to achieve program success, and to provide valuable information for dissemination to a broader audience.
One of the most often used nontrivial electronic measuring instruments in the experimental sciences and in engineering is the so-called "Lock-In" amplifier.

Since the instrument is difficult to understand and there is only little concise and comprehensible literature covering this topic, there is generally a lack of knowledge among the students, as well as the researchers, in the sciences and in engineering.

In order to remove this lack, and as an example of the feasibility and usefulness of technical, and even experimental, teaching on a university educational level via the "new" medium Internet, the Interactive Lock-In Simulation has been created.

Here, for the first time, a complete virtual experiment, which is now a fully acknowledged part of the Advanced Physics Lab of the University of Konstanz, is offered for worldwide access and use on the Internet via the URL http://fp.physik.uni-konstanz.de/Applets/LockIn/LI1.shtml.
The premise of this project is that while the student's ability to directly interact with faculty or to have class time for learning through mistake and repetition is diminishing, an interactive CD has the potential to provide much of that inquisitive experience. To this end we have developed lab books which include an interactive CD for use by students in the General Biology program at the University of Tennessee.

There are several advantages to working in a multimedia environment. First is the ability to utilize graphics, text and video to reinforce a specific concept. Second is the users ability to organize information in a way that is individually meaningful. We chose to present the information using three main outlines. The Directory includes a glossary which allows the student to choose a key word to launch their investigation. In addition we included a Laboratory Tutorial section and a Testing section.
Most schools are small and rural in the Canadian province of Newfoundland and Labrador and are far removed from the single local University. Digital intranets provide teachers in small, rural schools and pre-service teachers and their professors in the local Faculty of Education with new ways of teaching and learning from one another. In this process extended links between educational theory and practice are made possible and relations between schools on dispersed sites are strengthened. It is expected that as the Vista School District Intranet is expanded to accommodate further subjects and, with the likely growth of intranets in other school districts, a province-wide virtual school (which will include Memorial University of Newfoundland), will be created. The Digital Intranet project challenges the notion of geographic isolation as an educational consideration while increasing the role of the University as a mediator between local, national and international sources of learning.
The sentence parsing with automatic grammar tree building is embedded in the natural language learning system. Our developed approach to parsing bases on the relationship between the natural language comprehension and other psychic processes.

We have developed the interactive system. The student builds a sentence according to the dictionary defined by first. This sentence is analysed by parsing and the result is displayed. For correct sentence the grammar tree is presented and the functions of words are marked by different underlines. Otherwise there is not the connected tree.

The visualisation makes possible to perceive the sentence structure and its components as a whole. The students learn to analyse and generalise the information. The used approach allows to active the student's creative work.
DEVELOPMENT AND IMPLEMENTATION OF NP-ONE MULTIMEDIA LEARNING ARCHITECTURE

Abstract: NP-ONE, Ngee Ann Polytechnic's Optimum Nurturing Environment is a campus-wide initiative aims to inaugurate various state-of-the-art classrooms to develop our students' potential to their fullest ability. The Multimedia Learning Architecture (MLA) was conceived to support the development and implementation of innovative educational programmes. Our presentation will address how MLA is currently being implemented at the Polytechnic to deliver computerized tutoring and assessment to our students. The discussion will focus on how the architecture supports the delivery and development of component based learning objects.

The notion of OOI, Object Oriented Item is put forth for discussion and call for further study. OOI has been widely used for implementing innovative and pedagogically sound tutoring and assessment items in which learning process has been the focal point. The approach has opened up many forms of item, over the traditional multiple choice item, in which appropriate item response theory needs to be derived for item calibration.

Acknowledgements

The authors wish to thank the Principal of the Polytechnic, Mr. Khoo Chin Hean, in particularly, for his foresight and vision which lead to the actualization of the above.
LETS: A language educational tool for using closed captioned movies

Yutaka Tsutsumi
Department of Business Administration and Information
Kyushu Teikyo Junior College, Japan
yutaka@kyu-teikyo.ac.jp

Ryoji Matsuno
Prefectural University of Kumamoto, Japan
matsuno@pu-kumamoto.ac.jp

Planned Demonstration:

We plan to demonstrate an English conversation educational support system called LETS (A language educational tool for speaking-up), which makes use of video closed captioning. LETS consists of a CC extraction device, a CC decoder, a PC controlled laser disc player, and a program running on PC which allows users to a variety of searching for specific dialog. Participants will have the chance to operate LETS and can search for a dialog scene. And the demonstration will show how LETS assists English teachers to use movies in a classroom. We hope to encourage additional creative ideas for further enhancement of LETS. We also hope, through our conversation, to distribute our system to participants to experiment of LETS' effectiveness in actual ESL/EFL classes.

Problem:

Closed caption is a feature for English speaking deaf people to understand movies by reading English subtitles. Most of video tapes and laser discs sold in North America today have a encoded closed captioning. Closed caption in ESL/EFL has been used as supplemental material. English teachers showed students video movies without closed caption to practice their listening skills, and then would show the video again with closed caption to confirm their listening ability. This method is very effective in teaching natural, everyday English, as video movies have many variety of speech patterns of many different speakers.

However, one of the problems in using videos in the classroom is that we have to search for dialog that suits the needs of the class. It can be difficult to search for exact CC sentences.
in a video, and to stop the player at the exact location. Furthermore, there are requirements that teachers want to use a huge amount of scripts of movies.

Solution:

LETS makes use of video closed captioning. By using LETS, teachers can make a script database for each CC-encoded movies. Once the database is made, users can search and view a specific dialog scene. LETS allows users to search for dialog in many ways. Some of them are:

(1) Script Display function
Users can view the overall script of the target movie. Each sentence has film’s lapsed time and a link to the location on the laser disc. If a user clicks on a certain sentence, laser disc player plays back to the corresponding scene.

(2) Statistical Information
To select the movie for a class text, it is a great help that LETS provides statistical information of the target movie. This function gives the information of the total number of sentences, the total number of words, the total number of punctuation marks, and word lists of appeared order, alphabetical order, length order, and frequently-used order.

(3) Syntax Search function
Syntax search function is used for search for a sentence example of a class. Users can specify one or more words, LETS searches and shows the sentences including the words in such order.

(4) Minimal Word Pairs Search function
The minimal word pair means the pair of words which have a same pronunciation except one letter. For example, “fry” and “fly” are a minimal word pair. When students learn distinguish between two similar sounding letters like R-L, MWP will be a great help. This function search for MWP in the target movie.

Users of LETS can instantly playback to an exact dialog location on a laser disc in any of these specific and instant ways.

Significance of this Work:

Using LETS in a classroom has the following advantages:

(1) Without LETS, English teachers have to watch overall movies to search for appropriate sentences and note the position before class time. Using LETS, teachers can search for the text easily and can show certain scenes repeatedly and skip silent scenes. Therefore, the teachers can teach English in a class more efficiently.

(2) Closed captioned movie script includes a variety of syntax, everyday idioms, and sound-reduction-words. These are important elements in learning English, but hard to teach for one teacher in a classroom. LETS and video movies assist teachers to teach these elements as well as body languages and speech patterns of many different speakers which are also hard to teach without using movies.

(3) Additionally, LETS provides the functions for English conversation education, such as the Minimal Word Pairs Search function, Syntax Search function, etc.
Programmable Logic Devices (PLDs) are very complex devices that can be described using a lot of different non-excluding but related concepts. Usually, PLD education is based on the analysis of specific devices of several manufacturers, but this method is not suitable because it gives only a particular insight.

This work proposes an original method to accomplish PLD education supported by the use of hypermedia tools. The method is not restricted to PLDs but constitutes a general method for complex technologies education. This method comprises four stages. In the first one, a lot of representative different systems are chosen and analyzed. In the second stage all the common characteristics (basic concepts) are determined. The third stage comprises the definition of the particular characteristics (subconcepts). Finally, all the basic concepts and subconcepts are structured to obtain a descriptive model. This model combines the concepts in such a way that any commercial systems or device can be described from it.

The analysis of a lot of different PLDs led to the descriptive model shown in Figure 1 [MANDADO 96][ALVAREZ 95].

Although the PLDs descriptive model is very helpful, it can not be analyzed sequentially because it is frequently necessary to come back to previous concepts. This constrains turns hypertext into a very useful tool for PLDs analysis.

The principal advantage of hypertext documents is that they are non-linear documents that can link with other documents and software. At the same time they can be combined with powerful audio-visual resources to develop a hypermedia application [TERRY 94]. In the case of PLDs their great hardware complexity demands the use of a lot of graphic information for the better understanding of their architectures.

Taking into account all the above considerations, we developed a hypermedia application oriented to PLDs education. This application introduces the descriptive model of the technology (Figure 1), combining a lot of audio-visual resources to help students during the learning process.

Integrating Technology into the Curriculum: Strategies and Steps

Elaine Van Melle
Faculty of Education, Queens' University
Kingston, Ontario, Canada
6mepv@qlink.queensu.ca

Lewis Tomalty, PhD
Department of Microbiology and Immunology, Queens' University
Kingston, Ontario, Canada
tomalty@cliff.path.queensu.ca

It has been argued that technology should not be used to teach without first considering the teaching methods involved [Ehrmann 1995]. Carroll suggested further that to be effective, technology must be fully integrated into the curriculum planning process [Carroll 1997]. This poster session will outline the development and application of such an approach to the integration of a multimedia CD ROM and a presentation package into a first year nursing course. The technology was used to shift the focus of learning from memorizing abstract facts to the application of information in a real life context. The following five questions were used to guide this process: Why use technology? What technology should be used? How should the technology be applied? What outcomes are expected? Does the technology make a difference? The five questions will be used to incorporate suggestions for improvement and to make subsequent revisions to the curriculum. The process is iterative and continuous. Consequently it is anticipated that the full potential of the technology will unfold over a period of time.

Using the Teaching with Technology Instrument (TTI) to Assess Technology Staff Development Needs of Teachers in a School District

e-mail: neatkins@hotmail.com

The Teaching with Technology Instrument (TTI) was developed to assess teachers knowledge and classroom usage of technology. It was validated using 155 teachers, and contains forty-six items in three areas: writing and communication, information access and management, and construction and multimedia. Each question requires a Yes or No answer. The TTI was developed to assess the types of technology training a school needs to offer. The resulting printout consists of bar charts of the responses to each of the items. An administrator can turn the printout on its side, and see the school’s needs by interpreting the bar charts. By identifying all the items with a low percentage of Yes responses, you can identify areas that need targeted staff development activities. Using an instrument like the TTI will result in more appropriate staff development activities for teachers, and an increase in the effective integration of technology into our schools.

Recently teachers can be easy to get various CAI software, which are sold at bookstores or can be got from educational organizations. It is more effective for students to learn by both CAI and teacher's lecture at a same class. But it is not so simple to incorporate CAI software and a lecture in the same class. There are some problems as follows. As CAI system supports highly individual learning, there is a barrier of practical use at the class. The present technique of CAI is not so perfect and flexible as to add each teacher's necessary functions to a system. So we solve this problem by allowing teachers' customization. Main objectives of CAI incorporation in the class are to reduce the teacher's charge and increase the learner's learning effectiveness. We focus on the kanji compound CAI system for Japanese language.
Abstract: Computer-mediated communication offers the opportunity to teach outside the conventional settings of the classroom, the tutorial or the faculty office. But we know little about the social, linguistic, educational or emotional forms of relationship that are a consequence of virtual teaching. In this paper I will look at the use of First Class conferencing used to create a virtual culture among research students and as a vehicle for supervision/advising.
Delivering Laboratory Instruction Through Interactive Multimedia

The Marine Estuarine and Environmental Science (MEES) Program of the University System of Maryland is an interdisciplinary and inter-institutional graduate program. The program is designed to access educational and research expertise throughout the 14 Universities, Colleges, and Centers of the System. There are currently 270 students and 125 graduate faculty participating in the MEES Program distributed throughout the State of Maryland. An interactive video network is used extensively for delivering courses and holding committee meetings. Laboratories are important to MEES students because our science relies heavily upon observational, analytical, and numerical studies. To effectively deliver laboratory instruction, we have linked the internet, the web, email, video, and traditional computer-based training in modular format. Within this hybrid computer-based training system, each laboratory module emphasizes self-assessment, self-testing, application, and discussion. Except for a final examination or practical experience, the learning is enabled and mediated by computers.
A Collaborated Composing System for Musical Education Using Internet and MIDI Technologies

Kenzi Watanabe
Faculty of Systems Engineering, Wakayama University, Japan.
E-mail: watanabe@sys.wakayama-u.ac.jp

Musical composition is one of the most important theme in music education. A System based on Internet and MIDI technologies can support the theme. When each student belongs different schools, students can exchange their musical performance using this system.

In this system, two computers, one is called "sender" and the other is called "receiver," work collaboratively. When student performs musical instrument, the sender encodes the performance into MIDI data and transmits to the receiver through the Internet. The receiver receives the data and analyses them, then it plays musical instruments and writes scores.

We try to use the RTP [Schulzrinne et al. 1996] protocol within this system. Since the RTP is a UDP based protocol, it is suitable for real-time transmission. And more, the RTP has facilities to recover against above troubles.

Implications Derived from a Case Study of Teachers’ Understanding and Use of the Internet as It Relates to Curriculum Changes in a Middle School

Diane Beatrice Westfall
Moultrie Middle School
645 Coleman Blvd
Mt. Pleasant, South Carolina 29464, USA
westfalld@citadel.edu

We are in the midst of a technological revolution which is impacting education and society. The Internet has profoundly influenced how people communicate, access databases, and share information. Educators should view this revolution and its curriculum implications as important because the changes will affect the very nature of teaching.

In this inductive case study discoveries revealed how middle school teachers understood and used the Internet as it related to curriculum change. The research took place in a natural school setting so that from this, the teachers’ real-life, everyday experiences could provide insight into educational practices.

The data demonstrated that the power and hope of the Internet is its daunting ability to allow and facilitate collaborative efforts. These efforts are inherently dependent upon adequate funding of technical and support personnel, strategies pursued in learning about the Internet and technology, and integrating curriculum applications.
Immediate Feedback to Your Cloze Exercise

Fawn Whittaker
BYUH Language Center
Hawaii, USA
whittakf@byuh.edu

Abstract: A weekly grammar and vocabulary multiple-choice, cloze exercise WEB site with broadcast news transcript content provides advanced ESL students with immediate feedback regarding the correctness of their selections. NetForms produced by Maxum Development enables the response to bounce in fdml format from a cgi-based folder in the MAC server to the student within 5 seconds, depending upon connections and distance. Contextualized vocabulary and grammar are selected from a listing of all selected words or grammatical distractors in comprehensive multiple-choice format.

The Activity

Language Center director and staff at BYUH produce a weekly grammar and vocabulary, multiple-choice, cloze exercise WEB site with broadcast news transcript. Selected vocabulary words are chosen with a preference for commonly-used words nestled in matching contextual environment, offered in a multiple-choice listing of all selected words (usually 10-20) in the passage. Grammar study is also multiple-choice, cloze-based, with grammar selected according to the contextual offering and requests of the international student audience for a specific study, typically consisting of articles, clauses, conditionals, connectors, infinitives/past and present participles, direct/indirect speech, modals & auxiliaries, passivity, prepositions, singular/plurals, tag questions, verb forms, verb phrases, verb tenses, or word forms. The cgi-based (fdml) response provides advanced ESL students with immediate feedback as to the correctness of their selections.

Integrating Technology into the Foreign Language Teacher Education Program - A Model from the U.S.

Siegrun Wildner
Department of Modern Languages
University of Northern Iowa
Cedar Falls, IA 50614-0504
USA
BubserWildn@uni.edu

Even though researchers in second language acquisition have not yet fully explored the implications and ramification of using current technologies in the foreign language (FL) classroom, the integration of computer-based technologies into FL curricula shows promising new possibilities for global communication. As a consequence, foreign language departments such as ours should launch a curricular initiative to incorporate a new course into the existing curricula for its teacher education tracks in French, German, Russian, and Spanish.

Based on the changing paradigms in the U.S. educational system, recent research on the efficacy of technology in the FL classroom, general pedagogical concerns, and logistical feasibility, the presentation proposes a theoretical framework for a technology course and identifies crucial technology-related elements to be included in FL teacher preparation programs. Although this presentation introduces and elaborates on a course model geared towards the U.S. educational system, the underlying ideas and concepts are flexible allowing modifications for other cultural, linguistic, and instructional contexts, and the adaptation of emerging technologies.
CORPORATE PAPERS
DISTRIBUTED EDUCATION FRAMEWORKS

A Method for Structuring Distributed Education Development

IBM@ Canada Ltd., Pacific Development Centre, Burnaby, British Columbia, Canada.
Session #916, P: 604-293-5102, F: 604 473 5807, E: chamilto@ca.ibm.com

Abstract: As the competition for the education dollar increases, educational organizations are reinventing themselves in farther-reaching, more distributed ways. For many, the distributed education direction is both confusing and expensive. This paper summarizes a method, employed by IBM’s Pacific Development Centre, to help organizations grapple with rapidly changing education delivery environments. A distributed education framework is a tool used to structure ongoing and continuous development of distributed education solutions. A framework helps to structure the distributed education mission; such that both management and technical staff understand the strategy using simple models. Once created, a framework can be used to support technology selection, budgeting, and visioning efforts. Frameworks have proven to reduce the cost of development, and to increase the adoption of a common vision, and to reduce the number of products/tools evaluated in the development process.

1. INTRODUCTION

We are undergoing a technological revolution in the delivery of education. In this time of innovation, it is important that educators never lose focus on the processes at work in the education industry. To realize the potential of applied technology in education, we need to move beyond passive absorption of facts to fully engage students in complex and meaningful tasks linked to predefined learning outcomes.

A distributed education framework is a tool used to structure ongoing and continuous development of distributed education solutions. It links the technology available today with the goals and objectives of the learning organization—providing a common point of reference for future decision making or exploration.

The primary objectives of a distributed education framework are to:

- describe current and planned distributed education business as envisioned by the educational organization;
- incorporate available technology components with the educational constructs, process directives, and flexible course creation/delivery requirements;
- describe criteria, principles, and guidelines for selecting technology components within the framework;
- determine and document technology components and processes that are missing, without which the organization cannot effectively offer a distributed education delivery program; and
- provide a common point of reference for ongoing development efforts at both the technical and management levels of an organization.

As an education solution provider, the IBM Pacific Development Centre fields requests from a variety of organizations pursuing distributed education strategies. Most organizations find themselves asking questions such as:

- Is there a framework that an organization could use as a basis for discussion and development in the evolution of a distributed education vision?
- Which technology components should we evaluate now, and how are these technologies related to the education process as well as other technologies we have in place today?
- Are there technology infrastructure components which are common to all or most distributed delivery methods, and if so can this infrastructure be shared by multiple organizations?

These are exactly the types of questions being addressed by IBM’s Pacific Development Centre in cooperation with Universities, Colleges, Schools, and private organizations.
2. BACKGROUND

The framework development process has evolved from a number of internal IBM activities (such as the IBM Global Campus and our ongoing development efforts), as well as through consultation with various external clients.

What started out as a simple method used to categorize and compare the issues confronting organizations considering new education delivery systems, has now evolved into understanding and documenting the distributed education organization itself.

Initially, it was felt that IBM could help capture a current state “snapshot” and map it to a new environment, and a new organizational direction. However, in practice we found that most education environments were changing too rapidly, and detailed technology comparison and analysis was not always possible in the time available. We needed to be able to point various levels of an organization to a simplified model while simultaneously helping to build it. Furthermore, we needed to match overlapping efforts across organizations as there are plenty of opportunities to share and reapply skills, and products, within the Pacific Development Centre and across IBM globally.

One of the guiding principles of the Pacific Development Centre’s distributed education framework is that “technology-based learning should complement traditional instruction—not replace it.” Computer-assisted, self-directed, electronically-mediated learning may work for most students, but not all. Similarly, it will work for some institutions but not for others.

Pacific Development Centre education framework consultants work with academic institutions to understand where distributed learning is the most appropriate solution, what tools best meet the business model, and how new tools can best be integrated. This is an evolving process, which will continue to change with the dynamics of the education industry. Our experience has shown that this process of establishing a distributed education framework requires between forty to sixty days of effort to complete with contributions from most levels of an academic institution.

3. UNDERSTANDING DELIVERY HISTORY

With respect to distributed education frameworks, the adage “in order to understand where you are going you must know where you’ve been” rings true. To change any organization, we require an understanding of the business history of that organization: its successes, its failures, and the lessons learned through that discovery process. With the benefit of historical perspective, we can instruct others to follow a new path and encourage the growth required to shift from one paradigm to the next.

In spite of pessimists who suggest that education institutions rarely change, studies show that technology (a constantly changing variable), was introduced into pedagogy well over thirty years ago. A closer look at the history of education delivery systems often reveals a series of intriguing trial balloons and conservative yet evolutionary changes. Where new delivery models have been driven by economic or social backlash these changes have sometimes been radical, even ahead of their time, in some cases.

3.1 FRAMEWORK APPROACH

This framework methodology relies heavily on the recent education delivery history of an organization. We track where changes have occurred, how well those changes were adopted, and what shortcomings were observed. We begin our design of a new distributed education framework by assessing past delivery methods and how these delivery models can be conceptually described. This modeling effort shows us that there are distinct themes at work in every distributed education delivery process.

Two immediate observations can be made from the models described in this section: First, there are likely as many delivery models as there are institutions, making for a huge variety of distribution systems; and second, it is clear that although technology has significantly impacted delivery methods, the overall delivery philosophy remains much the same within an institution. We conclude through this analysis, that the principle objective of distributed education is not delivery of information (since technology could have altered that process over the period shown), but the creation of connected communities, where teachers, students, and peers can discuss, debate, and communicate information in an open manner.
For some organizations just considering a distributed education business, the models are much simpler and easier to discover. However, as we evaluate the way people learn, it is clear that it is the history and a culture of learning within that organization which most influences the learning model.

In the following example several models are shown which describe the delivery progression of one organization over the past ten years.

**Figure 1 - History and Progression (Common Models)**

4. **UNDERSTANDING THE BUSINESS DRIVERS**

The competition for the shrinking education dollar is fierce. Many education institutions are finding that their traditional market is smaller as students discover a plethora of global education options made available by emerging technology. The Internet and private Intranets are two technologies revolutionizing the education industry. The demand and opportunity for Internet based training have led some educational organizations to consider reinventing their entire delivery process, in preparation for the distributed future—partnering with technology companies, other institutions, and their students to help manage this transition.

Technology is clearly a driver in this revolution. Consider the following statistics to understand why education communities are scrambling for an Internet based technology infusion:

- A report by FIND/SVP and Grunwald Associates based on a survey of 2,000 households, reports that almost 10 million children are using the Internet. "This translates to 14 per cent of the approximately 70 million children under 18 in the U.S. Nearly half of the children currently access the Internet from school, and most of them use it for school or homework. "There will be a fundamental shift in the market in late 1998 and early 1999 when more children will go on-line at school than at home."  

- In Canada, 4.12 million adults now use the world-wide-web one or more times a week. That's 19.3 per cent of the population, a massive jump from 9.7 per cent in 1996. Use by men jumped 70 per cent, while women's use increased by 182 per cent in the same period. Canadians aged 18-34 doubled their use, while those venturing on-line tripled among the 45-and-older set.  

---

In British Columbia, statistics show that almost 7 in 10 people in this western Canadian province use a computer and of those, 72 per cent have been on the Internet. Half of all people in British Columbia have used the Internet at least once. Those on-line are likely to be young, have a steady job, have some higher education, and live in the city. Of those that are on-line, 80 per cent connect to surf the Web, 62 percent use it for e-mail, 32 per cent read discussion groups, and only 9 per cent can be found in chat rooms.\(^3\)

Along with increasing access demands, educational organizations are being pushed to deliver more efficient service, greater and more open access, more effective learning with greater education value and accountability. This is a nontrivial undertaking for any organization, and such drivers have the potential to consume nearly every available resource.

In order to reduce the confusion generated by these pressing demands, we focus the organization around business principles. Principles are attempts to translate technical alternatives into key ideas that can be effectively organized and evaluated. Principles can also be used as a "yardstick" to evaluate how closely a potential technology component meets the needs of the organization. In the following example we establish principles related to Pedagogy, System Functionality, and Technology for Company X.

4.1 PEDAGOGY PRINCIPLES

The following is an example of a pedagogy principle:

**Principle 1: Education Process First, Technology Second**

Technology projects, whether a research project or an application, must be grounded in the values of Company X. These values guide our education business—a business of providing distance education and distributed learning. It is therefore essential that selected technologies reflect our educational practice and processes first and the technology itself second in the delivery process.

4.2 FUNCTIONAL PRINCIPLES

The following is an example of a functional principle:

**Principle 2: Ease of Use and Delivery**

While the organization makes extensive use of technology, and through the effective application of technology has gained some market recognition, Company X is not a "technology organization". Therefore every attempt must be made to ensure technology is easy to use, apply, and support across the environment. To support this principle we must:

- Reduce the cost associated with maintaining a large and diverse group with specific technology skills. This will be done by creating a culture of technological literacy, skills to self-teach new technologies, and to make intelligent technology selection; and
- Apply technology, that improves educational or working experience, without complication. As such, the benefits of any technology must be weighed against any and all costs of the implementation, including training time, changes in productivity levels, user satisfaction, and quality of product.

4.3 TECHNOLOGY PRINCIPLES

The following is an example of a technology principle:

**Principle 3: Improve portability and scalability of Applications**

Company X will acquire and support applications that adhere to this technology framework. These applications will be portable, allowing for movement across heterogeneous computing platforms with little or no modifications. Client portability is a particular concern for both K-12 and Higher Education, where Mac OS, Windows95, and Windows 3.1 each hold a substantial market share. This concern has begun to be described as the "Single Window Design" where courses and services are made available through an industry-standard browser technology.

\(^3\) Angus Reid, 'The penetration of the Internet in British Columbia', study completed in December 1997, reported in February 1998, Emerge Online News Service.
5. DOCUMENTING THE FRAMEWORK

Once we understand current education delivery strategies and what processes need to be more effective, we can conceptualize a new delivery model for Company X, that combines the lessons learned with current organizational values. We attempt to determine the essential delivery components and how these components interrelate with our delivery process. The result is a conceptual model that conveys the spirit of the planning process, future direction, and the interrelationship of the people addressed in the model.

5.1 TYPICAL FRAMEWORK

A typical framework model will have at least six primary components depending on the organization and delivery drivers. The original IBM Global Campus Framework (Figure 2) created in 1996 combined ten major components, which has evolved into the six component model shown in Figure 3.

Figure 2 IBM Global Campus Framework

IBM Global Campus Framework

Figure 3 PDC Framework

Administration Environment

5.2 FRAMEWORK COMPONENTS

Each component must be clearly defined. The functional areas described in the PDC Framework closely reflect software/hardware developments in the education market. Of the five functional areas shown in this model, four—Content Development, Content Repository, Delivery, and Student Services—seem to appear in nearly every framework. These components have detailed descriptions and process relationships that are not described in this document due to space constraints.

Once a framework definition is established, it is important to communicate the direction as widely as possible. We have found that a collaborative web site works well for this activity and allows the most amount of feedback across the organization.

5.3 COMPONENT EXAMPLE

The following example describes some of the characteristics of a typical component. Application areas associated with this component are defined and linked to existing delivery processes. Each component contains specific application sets, which are then mapped to standards, products, and tools available in the current marketplace.

- Data Structure, Content Storage, Data Management, Rights Management, Search and Access, Content Synthesis, Digital Library.

5.4 REMAINING PROCESSES

With the completion of the framework model, the organization can begin the process of integrating the model into the working environment. We have been continually surprised by the number of applications for these simple models when used to convey education direction within an organization. For example, when we used a framework as part of an Intranet discussion database, we found that both management and the development community made use of the model quite quickly. Some users copied the first bitmap image into
their working papers, prior to making a funding request, to clearly describe what they were working on to management.

The framework consists of a number of parts other than the component model itself. Used as a project planning tool, the framework should see several other essential planning steps documented. Additional steps include:

- Mapping existing and proposed applications to the model;
- Establishing technology standards checklist by component;
- Establishing performance measures for business change;
- Listing technology and process gaps;
- Business model/case for deployment;
- Estimating the cost of development by component; and
- Testing and Integration planning.

Each of these activities can be as detailed as resources and time permit.

6. CONCLUSIONS

Having completed several framework strategies within our customer base, the Pacific Development Centre has drawn the following conclusions about the process. They are:

1. There are many confusing and often complex approaches for distributed education delivery in use across the education industry. In order to reduce confusion and risk, it is valuable to conceptualize the desired delivery process in the form of a framework, prior to embarking on a new delivery paradigm.

2. A method, which conceptualizes the distributed education mission in simple models, can help to translate the vision across an organization very quickly. The sooner everyone adopts the vision, the sooner the organization can stake its claim in our high competitive education marketplace.

3. A framework can reduce overall development cost for organizations attempting to implement an end-to-end distributed learning system. This is accomplished by focusing development effort on a common vision, by reducing the number of products and tools evaluated in the development process, and by early recognition of gaps and missing components.

4. Some components of the distributed education framework are common to most organizations. This presents a new partnership opportunity for similar organizations, where joint funding of a project can lead to wins for both parties.

5. All of us have something to learn, as well as something to teach. If only used as a common reference point, a framework allows us to demonstrate and possibly share common visions and skills. As current technology skills are often at a premium, organizations with similar reference points can quickly see the opportunity to share skills and experiences. This has both cost reduction and effectiveness benefits for the education organization.

6. Technology is a rapidly moving target. If the educational organization leads its distributed education mission with trial technology balloons, they risk losing the pedagogy in the medium. The full spectrum of education and training requires that we fully utilize the strengths of network computing, education processes, and the growing range of skills within the industry, to provide an effective distance learning solution. This development process must remain stable yet highly flexible, adapting to a rapidly changing education market and technology evolution. The framework method allows organizations to regularly revisit processes and functional components as technology opportunities present themselves.

PANEL PAPERS
Playing the MOOstage: Theatricality As/In Interactive Online Environments

Dr. Juli Burk, Department of Theatre and Dance, University of Hawaii, USA, burk@hawaii.edu

When Shakespeare wrote "All the world's a stage/ And all the men and women merely players" (As You Like It, circa 1600) he could hardly have known the stages human beings might inhabit at the end of the 20th century. Close to four hundred years after Shakespeare wrote those lines, the stages on which men and women play are no longer limited to physical platforms in large rooms or open air spaces. The advent of radio, film, and television brought stages for mass transmission of human players in action, and the development of networked computers added cyberstages as arenas on which women and men might play. One such powerful stage is the synchronous MOO environment, about which Shakespeare's descendant might write "All the MOO's a stage since all the men and women are player objects."

MOOspaces and interactions are inherently theatrical. Like a stage set, each room is designed and filled with objects intended to create an atmosphere that colors the interactions and possibilities within it, establishing a context for the action that occurs there. Like a theatre production, each interaction is comprised of a set of performed words and gestures that creates the character a player wishes to inhabit. Further, as the players define their characters through descriptions, moods, and entrance, exit and other messages, they inform their interactions with elements that create textual costumes. Defining MOO as a theatrical environment foregrounds the interactions in the space as collaborations: collaborations between the players and the characters they inhabit, between the participants and the environment, and between the participants themselves. In turn, viewing MOOspace as theatrical allows us to utilize MOO as a means to explore the nature of the interactions that take place there through what A.J. Austin called the performatve. This concept of a semiotic action that constitutes rather than expresses being is particularly effective in an environment where the central referent for an individual is the written speech displayed on the screen rather than the physical body generating the words. One educational benefit of the newly developing field of theatre production in MOO is that it provides an opportunity to examine instances of intentional performativity. Creating a performance in MOOspace illuminates the similarities between identity-formation (as opposed to expression) through speech, gesture and costume on a literal stage and the means utilized to do the same in social interaction on the MOO stage.

The many ways that theatre in MOO differs from production on traditional physical stages necessitate the creation of new conventions for performance. The means by which spectators perceive setting, costume, dialogue, plot, and character are primarily through reading text onscreen, although some MOOs do contain graphical elements. This locates the experience of MOO theatre somewhere between that of reading a novel and watching a traditional theatre production with one crucial difference. In few other situations does the spectator, by virtue of the environment, have the opportunity to interact directly with the performers and the performance space. Interaction between performer and audience is at the heart of the theatrical experience. Traditionally, a distinction is made between theatre and film because filmed performers cannot respond to any stimuli provided by their audiences. In the theater where audiences are generally separated from performers by their physical location in seats facing the stage and by the darkening of the auditorium, spectators' communication with performers is limited to laughing, clapping, or shouts of encouragement. The nature of MOO interaction extends the notion of communication between performer and audience. In MOO environments, a player's presence is made known by the action of typing to communicate. MOO spectators can log in and be completely passive during a performance, simply reading their screens, or use the emote command to laugh or clap--an experience analogous to that of a film or traditional theatre. But MOO provides a performance environment in which the separation of actors and audience is sharply reduced; those accustomed to the interactivity of MOO expect opportunities to directly participate in exchanges held there. Thus, in the traditional sense of an audience shaping a performance with reactions, MOO creates unique possibilities for collaboration between actors and spectators that directly affects the experience. A MOO is created not only by those who interact there, but by those who design, decorate, and program the room objects. The theatricality of these objects distinguishes MOOs from the literal enactment of daily life and establishes them as a stage set upon which players interact and the play, as such, occurs.
Cyphertextual MOOrauders: Reading with Others, Writing in Time

Dr. Cynthia Haynes, School of Arts & Humanities, University of Texas at Dallas, USA, cynthiah@utdallas.edu
Jan Rune Holmevik, Department of Humanistic Informatics, University of Bergen, Norway, jan.holmevik@hdb.uib.no

In recent years technology has enabled educational interactivity in exciting ways. Examples include hypertext, WWW, email discussion lists, newsgroups, chat rooms, IRC, and audio/video conferencing, among others. Clearly when texts are interactive, new modes of teaching and learning evolve. Interestingly, with respect to reading and writing, we often still perceive interaction in passive ways. That is, we often view interaction as one-sided or asynchronous, just one step beyond simple reading of a printed text. We interact with buttons or links on a webpage. We navigate through a hypertext. We send and receive asynchronous messages via email. MOOs are, however, enabling us to reconceive interactivity. The MOO's potentiality, i.e. its untapped time/space integration of interactivity and collaboration among individuals and the MOO environment itself, beckons.

In the MOO, the player (who is at once writer and reader at the same time) negotiates a number of modes of interactivity at the same time. That is, much like we understand multi-tasking in a computer environment, where we navigate between and among various windows and processes, MOO persona toggle between modes and roles. Part real-time, part asynchronous, from writer to reader to writer, actors are acting a part or emoting an action or feeling. Not only this, but MOO client programs (and some inMOO telnet gateways and interMOO communication channels) enable players to multi-task on a number of MOOs simultaneously (with the same number of inMOO modes of real-time and asynchronous activity going on in each MOO). Across domains and time, MOO players inter-act and inter-talk while at the same time paging players in other rooms, in other MOOs—all of which is interspersed with composing, programming, editing, mailing, and other multiactive, interpassive writing and reading with other multi-communicating players, bots, programs, and morpho-logical, cyphertextual beings.

Thus, our presentation aims to split open the question of interactivity by discussing synchronous publication in MOOs and how writers of texts 'published in MOOspace are writing 'in time'; and readers of texts in MOOspace are reading 'with others,' including the author(s)—a combination of reader, writer, and MOO environment that we call "cyphertexts." In addition, we consider the implications of redefining interactivity across a "working" model known as multi-tasking, carrying the reality of multi-active modes over into cyphertextual spaces in MOOs. As publishers of synchronous texts, and as authors of synchronous texts, we seek to unmask textual interactive marauders by rethinking the nature of interactive reading, writing, and publishing via the notion of cyphertext.
Collaborative Virtual Space: Pedagogy and the Presence of Others in MOOs

Dr. Beth Kolko, Department of English, University of Texas at Arlington, USA, bek@uta.edu

Educational technology has changed dramatically in recent years, and the use of networked technologies in particular has altered how we conceive of technology as a pedagogical tool. However, even today, with the Internet and the World Wide Web, technology only infrequently increases students' interaction with one another and with the instructor. This limitation with respect to educational technologies is perhaps best seen in distance education programs. Distance education has found many ways to make curricula flexible and to deliver material despite geographical and scheduling obstacles. However, many distance education technologies, such as compressed video and telephone bridges, allow primarily for interaction from the instructor to the student or the student to the instructor. Rarely do such technologies facilitate student-to-student interaction and collaboration. Courses based on the World Wide Web are striving to overcome these limitations, and with everything from CGI submission forms for questions to Web-chat, such classes are able to effectively bring interactivity back into the educational process. However, as distance education initiatives grapple with the challenge of providing a complete education to far-flung students, they find themselves facing the simple fact that it is easier to move a knowledge-based class (such as a programming course) over distance than a discussion-based class (such as a literature class).

Humanities disciplines base much classroom activity on the notion of interaction, and this is perhaps why humanities disciplines have been among the first to see the educational possibilities of the more interactive technologies available. In particular, MUDs—and their end-user programmable relation, MOOs—hold increasing appeal for teachers. MOOs are based on collaboration and interactivity; like any networked classroom equipped with synchronous communication software, a MOO creates an environment where participants create and contribute to multiple discussion threads. Computer-mediated-communication, whether on a LAN or across a WAN such as a MOO, allows for increased amounts and kinds of discourse, not to mention modes of collaboration.

Participating in a MOO is by definition a collaborative activity. Whether by writing with others through conversing and storytelling, or by manipulating the database through examining objects and exploring rooms that someone built and described in a previous visit to the virtual world, a MOO participant always and constantly confronts the presence of others. These synchronous and asynchronous collaborations with other participants are collaborations with other writers, and it is the importance of this textual "other" that stands to teach us so much about how users collaborate and interact effectively in MOOspace.

The pedagogical effectiveness of collaborative learning has been addressed for the past several decades. The text-based environment of the MOO urges us to consider such research in conjunction with the work done by writing theorists on the importance of writing and reading. That is, writing is a component of the process of self-definition, and writing theorists from a variety of perspectives have examined how composing allows the writer to work through and among versions of the self. This dynamic of "writing the self" becomes literalized in the MOO environment. Online, a participant decisively constructs a persona, and then moves that characterization of the self into interactions with others. This self is necessarily a social one; since the MOO is by definition a collaborative environment, writing in a MOO is necessarily a collaborative act, and MOOing is collaborative writing.

There are clearly more and less successful versions of MOO collaboration, most of which hinge on the kinds of interactions users have. As in any CMC exchange, MOOing can lead to a variety of educationally ineffective moments. This paper takes the position that narrative theory provides a useful way to consider the relationship between reader and writer, and thus MOOer and MOOer. The presence of others in printed text provides a departure point for considering how we might assess our responsibilities as writers in online environments. By theorizing the nature of collaboration and interaction online that is predicated on the presence of others, we can begin to understand how it is that users learn to MOO in productive ways, and, consequently, how we can best adapt such virtual worlds to educational uses. Particularly, as MOOs evolve into more graphical formats (and those MOOs with web interfaces are already text/graphic hybrids), a detailed theoretical understanding of interaction and collaboration in virtual space is necessary in order for the design of emerging virtual environments to be as pedagogically productive as possible.

2113
Abstract: The panel discussed the personal dynamics of global Internet partnerships. The presenters of this session served as facilitators for their students from Germany and Turkey who participated in eight-week worldwide communication Internet projects over the past few years. The application of global computer networks is breaking new ground in education, utilizing flexible learning techniques, and importing an international dimension to the classroom. This presentation concentrated on the development, organization, and assignments of the project. It also focused on the learning gains and reactions of the student participants.

Historical Overview

Over the past three years, the three presenters have been involved with the Cross-Cultural Explorations and Dialogue Project (CCED) organized by the University of Tartu in Estonia. CCED is an eight-week Internet-driven project involving university teams from around the world. Students involved in the project utilized new and innovative learning techniques as they corresponded via e-mail and Internet Relay Chat. This added a new dimension of reality to their communication as they interacted with peers and colleagues at universities in Peru, Estonia, Japan, Bulgaria, Spain, and other countries. Students overcame the barriers of time and distance limitations in learning as they expressed their opinions at will to others around the globe. The project additionally encouraged student autonomy by inviting student input throughout the duration of the project.

Panel Content

Objectives of CCED

The objectives of the CCED were to:
1. communicate with university students around the world;
2. promote participation in communication networks and foster international cooperation and understanding;
3. understand the fundamental characteristics and applications of electronic communications technology; and
4. collaborate as a team on problems, ideas, and issues, and then respond with a team consensus using the Internet.
Summary of the Project Syllabus

The project contained a series of assignments designed to help students explore their prejudices, cultural misunderstandings, stereotypes, and misconceptions. All students subscribed to a group mailing list where weekly assignments were posted. Students first discussed the assignment in their group and then presented the results of their discussion, views, or questions to the other groups via an e-mail message. Students were also given the opportunity to voice their individual response, or related concerns to others in the project via a separate open-discussion type mailing list. Students were challenged to respond to prejudices and misconceptions about themselves and also voice their conceptions of other cultures.

The culminating activity of the project was an on-line conference via Internet Relay Chat. Here students participated in a cultural simulation simultaneously. They were also given the opportunity to put into practice some of what they had discovered over the previous weeks of the project.

Learning Outcomes

Different methods of evaluation of this project were used. Students engaged in a debriefing session within their group. Here they were able to comment on what they learned from the communication experience and evaluate Internet learning. Debriefing helped students synthesize the knowledge gained during the project.

Another way of viewing the learning was the analysis of the comments of various participants in the project. Such analysis showed that students became more autonomous in their learning by offering topics for discussion and engaging in more natural and authentic conversation. They were also able to formulate conceptions of their own cultures which allowed them to more easily comprehend the similarities and differences of the other cultures involved in the project.

The project offered more than just a cultural awakening. It provided students with greater control and initiative in their language learning. As described in [Warschauer, et al. 1996] students were able to initiate conversations and discussions with other students any day or any hour resulting in increased student-to-student interactions. This resulted in greater student enthusiasm, motivation, and dedication to the project. The project evolved and took shape due to their efforts. It was a product of their creativity, not a pre-conceived curriculum or course syllabus. It provided an authentic forum for the interpretation and application of their new ideas.

These projects further provided a variety of other benefits: equal access to learning for all students, development of writing skills in their second language, new and better means of learning (the collective experience) increased cultural sensitivity, understanding of the commonality of the human experience, self-reflection, and the understanding of the fundamental characteristics and applications of electronic communications technology. See [Warschauer, et. al 1996] for further information on these findings.

Overview of Panel Topic

A variety of substantive issues confront education with respect to helping students learn increasingly complex knowledge mediated by various emerging and existing technologies. How can students acquire and maintain deep
understandings about difficult topics? How can a wider range of students be successful at learning? How can we better
prepare students to use and apply their acquired knowledge in new situations and contexts? How can we
appropriately evaluate enhanced technology mediated learning outcomes both for individual students and for large-
scale assessment purposes?

This panel will involve position statements and a discussion by researchers who have been investigating issues and
questions such as these. Broadly viewed, these varied research programs have explored such questions from a
constructivist framework in which new approaches for the design and use of learning environments have been
informed by current socio-cognitive learning theory and the creative utilization of the affordances of existing and
emerging technologies. A distinguishing aspect of these projects has been the delineation of ways technologies can
flexibly scaffold learners as they are involved in activities such as acquiring information; finding, conceptualizing,
and solving problems; communicating ideas and findings; and so on. Such scaffolds include tools for representing
models and ideas; reifying tacit knowledge of experts; interconnecting knowledge in multiple representations;
encouraging articulation and reflection; and supporting "expert-like" or "intelligent novice" approaches while students
conduct open-ended projects and inquiries.

This panel took the general format of discussing lessons learned by the participants who have extensive experience
with innovative approaches to designing and using educational technologies. During the first half of the session, each
panelist briefly discussed aspects of her or his research that informs perspectives related to questions above. Audience
questions and a discussion were conducted during the second half of the session.

Panel Position Statements

Considerations for Complex Learning

Heinz Mandl, University of Munich, Germany

There are a number of factors that must be considered for complex learning. First, there must be appropriate support
for complex learning. In accord with proponents of situated learning models (Cognition and Technology Group at
Vanderbilt, 1996), we plea for more attention towards developing appropriate means of instructional support for
situated learning environments. In principle, this support can take various forms: scaffolding provided by a teacher or
a more capable peer; preparing lesson with teacher presentation, etc.

Second, there is the need to prepare and motivate students for complex learning. Of course, the anchor problem has
to be carefully designed so that (most) students will regard it as interesting. This is not, however, sufficient. There
are many more aspects that have to be considered. One major obstacle in implementing effective situated forms of
learning is the lack of fit between examination demands and complex learning arrangements (Mandl, Gruber, &
Renkl, 1993; Renkl, Gruber, & Mandl, 1996). If passing exams primarily requires factual knowledge, why should
students be motivated to engage in complex forms of learning? Facts can best be learning by other methods. We
strongly believe that in order to motivate learners to actively engage in open learning environments it is necessary for
exams to call for the types of skills and knowledge that are fostered by situated forms of learning (e.g., application of
theoretical concepts to solve problems). The main point we want to make is that although using complex anchor
problems for learning may have some motivating potential there are many more important factors that determine the
students' engagement in instructional settings. Therefore, it is not adequate to regard complex learning anchors as
quasi-automatically engagement-inducing. The larger context has to be taken into account when learning
environments are designed that aim to induce fruitful learning activities.

Third, careful consideration must be made regarding the proportion of learning-relevant and learning-irrelevant
activities that are induced by complex learning environments. In complex learning environments, students are
usually expected to learn complex things. In order to do so, much cognitive capacity is required and, as a
consequence, learning processes are sensitive to distractions by task-irrelevant demands (Sweller, 1994).
Another important consideration is to not regard learning by problem-solving as the ideal and only way of learning applicable knowledge. For instance, learning by examples can be used to reduce cognitive load; it is not only an effective way of learning, but also a learning mode that is preferred by individual learners (VanLehn, 1996) and that is consistent with basic ideas of the situated learning models. There is some evidence that combining learning by problem solving and by examples is a rather promising approach (Renkl, in press; Van merrienboer & De Croock, 1992). The main point we want to stress is that learning by problem solving is not the best method of learning in all contexts. Other modes of learning should receive more attention in situated learning models.

**Environments for Social Constructivist Learning: Theoretical Rationale, Experiences, and Lessons**

Yam San Chee, National University of Singapore

Learning needs to be viewed and studied in a broader socio-cultural context if we are to acquire a deeper understanding of the dialectic processes at work in authentic learning situations. In the design of learning environments to support authentic learning, we argue, in principle, that two complementary elements are essential. First, there must be learning activities that provide a meaningful context for experientially grounded learning. These contexts may be real or virtual. Second, there must be the opportunity for meaning making discourse that takes place between members of a learning community. Such discourse will revolve around shared representations (text, images, animations, sounds, and digital movies) that serve as referents for meaning making.

In my position statement, I shall explain why the social constructivist perspective provides a superior and more complete approach to addressing the design of technology to support learning. I shall also trace the evolution of learning environments that we have developed in pursuit of the kind of learning we seek to achieve and evaluate the extent to which our goals have been achieved. The review should provide some useful lessons for ongoing design of learning environments.

**Scaffolding the Design Skills of students Through the Use of Web Tools and New Didactics**

Betty Collis, University of Twente, The Netherlands
Plon Verhagen, University of Twente, The Netherlands
Koos Winnips, University of Twente, The Netherlands

The process of becoming a designer of instructional media-products involves a complex mixture of implicit and explicit insight and knowledge. Some of this can be indicated in terms of objective criteria: How to handle multimedia files within Web-pages, what sorts of computer-related products teachers are most likely to use in the classroom, how to manage the lighting for a video production or a tele-learning session.

But there is a meta-level that is much more complicated. Partly this meta-level relates to insights into how particular learners learn and particular teachers teach, partly to individual creativity, and partly to metacognitive skills, self-regulation and the ability to work productively as a member of a team.

In design education measurement criteria for implicit skills are not available. With the absence of such criteria, how can students be scaffolded towards becoming an expert designer? How can novice design students be scaffolded in becoming an expert when the expert designer can not articulate what it is that makes an expert?

But nevertheless expert designers have developed a style in the creative use of explicit and implicit knowledge. They have a design style that characterizes a specific author.

When learning to become an expert designer explicit as well as implicit design skills should be addressed. Becoming a designer can be scaffolded with the help of design guidelines as they represent both explicit and implicit knowledge in designing. Explicit in that fixed rules of 'good practice' are given. Implicit in that the application of those rules is not fixed and dependent on the use of creative processes. An evolutionary approach is advocated to teach design skills.
By using examples of good and bad practice in applying guidelines the meaningfulness of guidelines will gradually increase. Critical thinking about expert applications of guidelines and application of guidelines in own products will eventually make guidelines more meaningful.

In this presentation research about the presentation of guidelines is presented. Different forms of scaffolding design skills are compared that should eventually lead to self-reliant authorship. The WWW site for our group is: http://www.to.utwente.nl/user/ism/winnips/eigen.htm.

*Scaffolding the Transformation of Meaning in Resource-Based Learning Environments (RBLEs)*

Michael J. Hannafin, The University of Georgia, U.S.A.

Resource-based Learning Environments (RBLE) represent a class of learning systems wherein a range of resources designed for vastly different purposes are used to support the transformation of meaning according to the needs and intents of individual users. The World Wide Web represents the most robust repository of such resources. Individual users access a wide range of resources, many of which were created to support particular functions, in an effort to address their unique learning goals. Collections of resources, in effect, are identified and analyzed to support the construction of meaning for which none may have been created initially.

How, or can, support be designed to scaffold the varied intents and needs of different individuals as they attempt to transform personal meaning from such resources? When usage intent is supplied, scaffolding can be closely linked to the domain under study. When the locus of intent and meaning are uniquely generated, however, scaffolding becomes problematic: the more user-centered the system, the more difficult to anticipate and provide useful scaffolds. The focus of this research involves the design and testing of different types of scaffolding (conceptual, procedural, metacognitive, and strategic) in support of RBLEs. Current progress and examples will be described and demonstrated.

*Cognitive Scaffolding in Technological Environments: Promoting Deep and Flexible Conceptual Understandings of Complex Knowledge*

Michael J. Jacobson, The University of Georgia, U.S.A.

Today globally distributed, network mediated hypermedia between potentially millions of computers via the Internet is not only possible, but also becoming increasingly the norm in thousands of classrooms. But the utilization of these technologies as part of learning environments must confront a central question: Can the affordances of sophisticated hypermedia and network mediated technologies improve student learning of complex knowledge? Unfortunately, a critical review of the current literature on learning with relatively open-ended technological environments, such as stand-alone and network-mediated hypermedia systems, suggests this is not often the case, particularly in domains that consist of complex and difficult to understand knowledge.

The focus of my position statement concerns a program of research that has explored how students can learn difficult scientific knowledge using case-based hypermedia learning with design features based on recent cognitive learning theory and research. In particular, two general design features of this system provide special types of cognitive scaffolding that are intended to promote conceptual change and deep conceptual understanding: (a) represent contextualized knowledge using cases and problems, and (b) reify the deep structure of knowledge with cognitive indexing, expert case-theme commentaries, and mental model visualizations. Also, specific hypermedia learning activities have been developed to take advantage of the affordances of the cognitive scaffolding provided by these design features, such as: cognitive preparation to seed new concepts and to promote conceptual change, knowledge transfer priming to show multiple dimensions of conceptual interconnectedness across cases, and on-line scaffolded problem solving tasks. Previous papers have reported on significant learning outcomes associated with the use of these design features and learning activities. In my panel presentation, I will briefly consider the theoretical and design implications of this research for technological learning environments, both stand alone and network distributed, that
are intended to help students deeply learn complex knowledge.

Abstract: An examination of the creation of an effective learning environment for a large undergraduate survey course in meteorology, based on constructivist learning theory. The project reflects conversion of an information transmission model of teaching to an active-student, knowledge-construction learning environment, without sacrifice of class size, utilizing technological innovations.

Introduction

Advancements in our understanding of human learning, shifts in societal requirements of education, and demands for increased economy of schooling have created considerable pressure for large changes in educational practices. These changes have begun with a major shift in instructional philosophy that grounds new and radically different theories of learning. The new theories create a strong challenge for educators to develop instructional materials and teaching strategies that reflect these theories. In this paper an on-going project based on the theory of constructivism is described. This project explores the creation of an effective learning environment for a large undergraduate survey course.

The project involves the conversion of a large meteorology course, in which the information transmission model of teaching was used, to an active-student, knowledge-construction learning environment without reduction of class size. To make this conversion, technological innovations have been used to encourage and support major advances in teaching and learning practices. This effort has required close collaboration among content experts, computer scientists, educational theorists and instructional developers. The challenges and issues encountered along with the educational materials that have been developed are discussed from three distinct perspectives: theoretical, practical, and technological.
2. Theoretical Basis

Constructivist theory holds that learners must construct an internal personal representation of knowledge. The richness and utility of this representation is dependent on the degree to which learners integrate new knowledge with their existing knowledge base. This integration demands the restructuring and change of existing knowledge. Since personal restructuring is required, knowledge cannot be transmitted. Rather, it must be constructed by an intellectually active learner striving to build a meaningful personal representation of experience. The constructivist learning setting is therefore rich and authentic since the context becomes part of the constructed knowledge and serves to enhance the utility of that knowledge, especially when applying it to new situations. In this setting, complexity of the topic is maintained to the greatest extent the learner's maturity permits. Complexity and authenticity maintain the structure of the material to be learned and inherently provide reasons for knowing. Collaborative learning, through which students can share views and strategies, and thus develop multiple perspectives, is encouraged in the constructivist environment. These multiple perspectives provide learners with flexibility and support in reorganizing their knowledge base and contribute to the toolkit of strategies for organizing new experiences. A major goal of constructivist learning is learning to learn, or metacognition, which prepares the learner for life-long learning. Thus, much of the teacher's efforts are directed toward developing skills and strategies for learning. Collaborative learning within a complex learning environment provides rich and varied opportunities for the developing and sharing of learning skills.

3. A Model for Class Management

The Iowa State University introductory meteorology class restructuring has been facilitated by World Wide Web server software (ClassNet, http://classnet.cc.iastate.edu/) which manages Internet class activities. This allows every student to be an active participant in learning activities with easy access to course materials, enhanced communication with the instructor and with other students, rapid feedback concerning assignment evaluations and exams and ready access to their private records of course performance. Although the course enrollment is in the 250-300 range, ClassNet software enables ease of constructing, distributing and evaluating assignments. The assignments involve authentic activities (forecasting), simulated learning environments (Java-based simulations) and more standard evaluations of content understanding (short answer responses).

The course goals have shifted from the learning of science content to also include learning how to learn science. The focus of the course is on the understanding of weather phenomena, and the primary vehicle for learning is an authentic activity where each student routinely predicts weather events and supports their prediction by identifying determining factors. This weather forecasting activity has been very successful in encouraging student participation and in promoting understanding in this course. The forecasts provide a continuing thread of meaningful discussion and motivation throughout the semester.

Part of the class time has been allotted to group assignments and discussions of their forecasting successes and failures. These have been well received by students. Class time is also used to engage students in discovery activities and to promote confidence in each student's capabilities to successfully engage in scientific reasoning. Various collaborative activities are used to draw each student into the construction of hypotheses for explaining observed scientific phenomena or processes. Lectures are used to provide explanations when students have explored, tested and questioned various factors that relate to central course concepts. To more closely integrate theory and application, Java-based Internet simulations were developed, integrated into the curriculum and tested. These have facilitated just-in-time student understanding of important meteorological concepts. The simulations were developed to enable students to explore key concepts that have historically been problematic. These simulations are microworlds in which the student chooses parameters in an attempt to cause specified weather phenomena to occur. Because the main focus of the course involves understanding weather phenomena and the primary activity is forecasting, the heaviest weight in the evaluation of course performance is an authentic assessment of forecasting skill. Each student may submit on the order of 100 forecasts during a semester, but only the best 30 are counted in the final grade. This encourages students to regularly participate in the forecast activity and gives them many opportunities to fail without penalty. The forecast activity is weighted as half of the student's course grade. The other activities (standard exams, use of simulations, standard assignments, group activities during class) make up the remaining evaluation items.
4. Materials Development

The lecture-textbook-objective-test method of instruction does not provide an environment in which learning to learn is adequately supported. Thus, new materials have been developed which require the learner to employ the tools of the discipline to wrestle with authentic tasks. Complex opportunities have been provided for learners to apply and test their developing knowledge and new instructional techniques have been employed to orchestrate this environment.

Materials development for the new learning environment do not rely on traditional instructional development models. The new materials could not be designed to teach the learner the course content, when the goal was to encourage the learner to explore, conjecture, and test ideas. The chosen solution was to develop problem-based simulations that pose scenarios and provide tools with which learners can explore, and that accurately reflect the results of specific learner’s actions. The materials have served to set the stage for further learning by revealing misconceptions, raising questions, activating relevant existing knowledge, and alerting the learner to the structure and utility of the material to be learned. They have also provided an authentic environment in which the learner can integrate and apply segments of knowledge acquired independently. A model for developing these materials was not initially well defined. The model that has evolved includes the targeting of difficult concepts, identifying reasons for the difficulty, and creating an environment for learner exploration of the relationships among the essential components. This environment incorporated tasks which enabled the learner to confront the important relationships, and that reflected the results of the learner's thinking. An exemplary environment is seen in Figure 1.

Figure 1. MountainSim, an adiabatic simulation.

5. MountainSim

The purpose of the MountainSim simulation (http://www.public.iastate.edu/~abc/java/mtnsim.html) is to permit students to construct an intuitive understanding of the relationships among temperature, vapor pressure, altitude and precipitation in mountainous terrain. The assignments in using the simulation are to cause cloud formation at a specific height on the windward side of the mountain and to produce a specified temperature differential between the windward base and the leeward base. To cause these effects, students can set the initial temperature and vapor pressure of a parcel of air as it approaches the base of a mountain. The simulation shows the air passing over the mountain, and if appropriate, rain and thunder are produced. Gauges and graphs reveal the critical data and a table of data from the student's runs are maintained. Other simulations have been developed to enable the students to explore concepts involving energy balance, radiation and advection.
6. Enabling Technology

In order to organize and manage the large class a web tool called ClassNet was developed (Van Gorp and Boysen, 1997). ClassNet provides a suite of tools for managing Web-based activities including registration, assignment design, automated evaluation, intra-class communication and grade reporting. Central to ClassNet's design is a growing framework of assignment types including tests consisting of multiple-choice, fill-in-the-blank, Likert, essay, option lists and list question types; surveys; weather forecasts; student evaluations and Java simulations. The assignment framework is extensible, allowing instructors to customize ClassNet to meet their individual class needs while still providing general administrative functionality. ClassNet assignments may also be used to track interactions with computer simulations for later replay by instructors or students. This has proven to be a very powerful utility for research relative to metacognitive and simulation design issues and simulation usage.

The current system supports thousands of students world-wide and is used for assignments such as forecast judging in meteorology, practice tests in geology, personality testing in psychology, simulation tracking in mathematics and student counseling practice in counselor education. Students may access ClassNet anytime from anywhere to take tests, view class progress and see current scores. ClassNet is also capable of reading scores for assignments administered outside ClassNet or for reading tests into ClassNet. The capabilities of ClassNet will be discussed and its use in the meteorology course described during the presentation.

7. Significance

The rewards from these efforts in meteorology are already being realized. This weather forecasting activity has been very successful in encouraging student participation and in promoting understanding in this course. The forecasts provide a continuing thread of meaningful discussion and motivation throughout the course and a context for course concepts.

ClassNet, which was developed to support this course, is serving over 130 other classes. The model for simulation development is being used in other disciplines. It is anticipated that the simulations will be useful via the Internet to other institutions including middle and secondary schools. The strategies for promoting science learning are being studied in an experimental teaching methods course by preservice teachers who are concurrently enrolled in the meteorology course.

This model of student-directed learning—combining information resources, microworlds, discussion, and authentic application—is very powerful and is expected to be a valuable model for distance education. It can remove student isolation through electronic discussion, keeping the discussion relevant and on-target through authentic forecasting and simulated activities. As a model for distance education it would replace the traditional practice of providing "access to information" by providing "access to understanding."

For access to these and other class materials see http://www.public.iastate.edu/~pals/homepage.html

ROUNDTABLE PAPERS
A Vision for Distance Education in the 21st Century

Nancy Gadzuk Drexler, Edcentric, USA, drexler@meol.mass.edu
Sheila L. Cassidy, Wexford, Inc. USA, scassidy@wxfrd.com

Abstract: This paper presents an emerging vision of distance education for the future. Critical issues, barriers, and facilitators for reaching that vision are raised, along with strategies for operationalizing this vision. Major areas for further research are addressed: equity and access; professional development; learning and the "best fit - best use" for distance education; cost factors; and dissemination. Policy implications are discussed.

Over the last decade, the advancement of technology and school reform efforts, as well as other factors, have paved the way for the rapid evolution of the field of distance education. Distance education has great potential to help shape the restructuring of education in the United States and throughout the world. It can work hand in hand with reform efforts to create learning opportunities for all learners, at any locale, at any time. Learning is not and need not be tied to specific places at specific times. Telecommunications is a vehicle for providing educational opportunities to meet the increasing needs of our diverse society for high quality, lifelong learning. We must develop a vision of distance education in the 21st century which supports high quality educational opportunities for all members of our society, and takes into consideration all the resources we need to accomplish our vision.

In March 1997, the U.S. Department of Education's Office of Educational Reform and Improvement brought together national leaders in the field of distance education and related industries in a Forum to begin to articulate a vision of distance education in the 21st century and outline strategies for operationalizing this vision. The presenters prepared a background paper tracing the evolution of distance education over the last decade to provide common background for the participants of this Distance Education Forum. The Forum itself provided an opportunity for participants to craft and articulate an emerging vision of distance education. Participants addressed critical issues, barriers, and facilitators for reaching that vision. Participants then issued a call to action, describing the essential building blocks needed to reach the vision they articulated. In our presentation at this 1998 World Conference Vision for Distance Education in the 21st Century, we synthesize the ideas that came out of the 1997 Forum, and add additional commentary to buttress and expand the ideas. The 1998 World Conference presentation will provide an opportunity for expanding the vision for distance education into a truly global vision through active discussion with an international audience.

The education reform movement has led to major changes in classroom roles and organization, with learners taking a far more active role in constructing their own learning than in the past. The vision for distance education moves the learning community beyond the classroom walls. Boundaries disappear, including those of geography, time, location of school, home, community, and work; age, language, culture. As these walls break down and learners become more in control of their own learning experiences, distance education becomes transformed into distributed learning. Distance education and new technologies offer unique opportunities for learner control and individualization. What learners need to know in the 21st century, and how they need to learn and use knowledge, changes.

Distance educators have several choices in addressing the role they might play in advancing educational reform for the future. First, they might ignore the reform movement and use new distance learning technologies to promote old ways of teaching and learning. Second, they might reflect the movement, and provide technological tools and information resources that support existing educational reform efforts. Finally, and most excitingly and appropriately, they might embrace the reform challenge and lead the way by encouraging teachers and students to learn new things in new ways and provide new models of distance education as catalysts for true educational change.

The presentation focuses on efforts to embrace the reform challenge. We describe strategies for using distributed education to support programs and services for diverse populations, as exemplified through a variety of multilingual, multicultural, distributed learning environments and communities. Several successful national and international distance education projects will be discussed, including the Global Networking Project — 1*EARN, “DeOrilla a Orilla”; Global Learning and Observations to Benefit the Environment (GLOBE); TEAMS Distributed Learning; MATHLINE®; and Hawaii Network for Education in Science and Technology (HINEST).

Forward-reaching distance education endeavors, like any educational undertaking, face both obstacles and facilitators in the implementation process. Some of these barriers include limited time and resources, lack of capacity, high operating costs, and the complex nature of serious, meaningful change. At the same time, there is public demand for cost-effective programs that address high standards for learning. If distance education can be accurately perceived as an important vehicle for equity of access and the achievement of high standards for all students, including life-long learners, it will thrive and prosper.
Our research agenda for the future needs to address these critical issues. How will teachers keep current when technologies change almost daily, when national borders and global economics change almost as rapidly? How and what should students learn so they can acquire the skills and knowledge to adapt to the ever-changing requirements of the labor market, the knowledge explosion, and global citizenship? How can we provide equitable access to both formal and informal educational opportunities when our population is so mobile and so many children may be isolated from these opportunities? We discuss five major areas for research to answer these questions: equity and access; professional development learning and the “best fit - best use” for distance education; cost factors; and dissemination.

Finally, we discuss some public policy implications and connectivity solutions in shaping the future of distance education, along with the role of government in funding and implementing effective distance education programs.
Introduction

Distance learning is here to stay and now we, as educators must find a way to successfully integrate it into pertinent curriculum. The idea of utilizing multiple delivery systems to best meet the needs of students touches on concerns of scheduling and learning styles as well as student outcomes. There are many types of class presentations available, traditional classroom settings, which may benefit from an occasional assignment posted on the web or student reference information posted for easy access; Synchronous distance learning can offer increased student access to instructional materials and interaction between classes. Asynchronous distance learning can benefit by allowing student more than one delivery style, to ensure all student learning styles are reached. This might mean using email in class, using a threaded discussion or real time chat, having students search for information on a specific topic or posting classroom materials on the web for students to access. These formats are not specific to distance education, but rather can be used to enhance the learning process in any setting by increasing the opportunity for student interaction, making their learning process a more active mechanism.

Instructional Considerations of Distance Education

There are many instructional issues encountered in distance education which instructors are not prepared for ahead of time. Instructors should be aware that even a class which they have taught for years will now require presentation changes and flexibility as well as intense classroom preparation. Things which should be considered are course preparation (the development of a course pack, electronic presentation of lecture material, class schedule); daily classroom preparation (adhering to your schedule, getting students involved, delivering and gathering papers); student interactions (keeping all classrooms interested, getting the students involved with each other); student evaluation (comparing classes and outcomes); student comments (student evaluations of the program or course); sending one class vs. sending a program (issues such as what to do about lab classes and some solutions used in the DMS program at TCC); class schedules and calendars (creating a calendar that works for everyone); and using the Internet to make access easier for students (how can the net make your job easier in a distance learning setting? What asynchronous delivery systems are available for your use?); Many programs, especially in technical fields, are also required to meet accreditation standards which must be considered and planned for. Good instruction can be achieved through a variety of methods and as educators we should set a standard of excellence for our students and communities.

Other issues affect the classroom but are administrative in nature and instructors have no input into them. Instructors in distance education programs should be aware of as many of the issues surrounding the delivery of distance education classes as possible and how they might affect classroom instruction. For example, many institutions do not offer remuneration for efforts put into developing distance education classes such as release time or additional pay for additional class sections. It is
important for educators to know not only what is out there for them to use, but what they should expect when they try something new.

Compressed video can be a very dynamic teaching modality and instruction will be more effective with careful planning by the instructor and institution. Using the knowledge gained through the experiences of others can be a very effective tool towards making the transition into a distance education classroom less traumatic for the instructor involved.

Integrating Multiple Delivery systems into the Classroom

Integrating multiple aspects of delivery systems into a class can help increase student learning by encouraging the development of critical thinking skills. Educators can use hypertext links to encourage students to collaborate as they learn about the technology they will be expected to be familiar with in the business community. There are many aspects of the Internet that can be brought into our classrooms. This paper will discuss e-mail and the use of the World Wide Web in the classroom.

Courses can use the Internet to gather general information, supplemental information, provide the bulk of course materials or the entire course. We need to plan carefully and choose how our classes can best be enhanced by these additions. Technology should never be added simply to add it; there must be an instructional plan and a desired outcome. Without careful planning classes appear haphazard and the addition of technology is treated like busy work by the students. The addition of the Internet in the classroom should be to increase student learning and interactivity.

E-mail can provide a easy, flexible link for the student and the instructor. It can allow the student access to instructor virtual office hours as well as providing a potential link to fellow classmates for collaborative interaction. On-line testing can, if monitored and designed correctly, provide a means of student assessment effective in distance education, both synchronous and asynchronous. It can also be used as an effective method of student review and continuing education. The last aspect of the Internet that I will discuss is the World Wide Web (WWW). The WWW offers students a tremendous amount of information to utilize. Students can use this information for research, collaboratively in class or with classmates. There are programs which can allow students to surf the web together and discuss findings simultaneously.

Students can be shown how to gather pertinent data from their area of interest off the WWW. They need, however, to be taught how to be selective in this process and how to effectively use search mechanisms. Students can gain a deeper insight into subjects which might offer an otherwise limited exposure to certain topics. Using the WWW as a common ground, instructors can post classroom materials for students to access at their convenience, assignments, tests and review materials. Several software packages can aid in this delivery system.

Advantages of Using the Internet in the Classroom

University of Washington Training Module, The Uses of the Web in Education, Available at: http://weber.u.washington.edu/~rells/workshops/design/uses.html

Sherry, L., Issues in Distance Learning, Available on Line: http://www.cudenver.edu/public/education/edschool/issues.html#abstract

Powwow. Available at: http://www.tribal.com/
As students turn to distance education as a means of attaining educational goals from institutions not in their immediate geographic location educators must find a means of making the required adjustments to provide that education. Distance education is appealing to students because it is student centered. Depending on the educational setting, it can allow a more self paced learning environment, both in time and place of learning.

E-mail can be a useful means of maintaining student interaction. Students need to feel a link to both the class and the instructor. Certainly phone calls and an occasional written note or personal visit are very effective methods of student communication, but e-mail can be convenient and cost effective in a distance setting. One thing to remember is that many student do not have previous training in electronic communication and must be given easy to understand instructions. Posting an e-mail link on the class home page can help make student access less stressful.

E-mail can also be a very effective tool for ensuring student feedback on a regular basis. This may include strategies such as journal entries and prompt questions from the instructor or interaction with other students. E-mail can be used as a means of getting students involved with their classmates. This can lead to more involved discussions in a chat format or threaded discussion format as educational patterns become more established. Certainly, in any distance education setting, e-mail is an imperative link between the instructor and the students.

The WWW can have many uses in a classroom, especially in a classroom which has a distance education component. It can be used to make the students at all sites feel they are part of the same classroom rather than isolated from each other. This can be accomplished by making all students go to the same WWW address to gather class information and assignments. It can be one on a more personal level by posting a picture of everyone in the class, so they can learn names and interact more easily with the other students.

Many class items can be posted on the WWW to give students increased access to instructional materials. Items which are appropriate to post on a classroom home page include course and instructor information (policies, office hours, textbook and course objectives), a means of class communication (an e-mail link), class assignments and tests (allow a means for electronic feedback or submission of classroom evaluation assignments), classroom materials (lecture notes or outlines and related web pages), demonstrations (to include audio, video or other graphics) and reference materials (be aware of distribution of copyrighted materials).

Students are often amazed when they realize the amount of information on the WWW related to their fields. By showing them how to do effective searching on the Internet, or providing them with specific links, the instructor can broaden the learners perspective, giving them a more global outlook to their education and their chosen field. In sending students out onto the Internet to learn about any field, it is imperative that instructors provide students with a guide for evaluating data they might find. Students often don't have the knowledge base required to make judgments on their own early in their education.

Strategies for Teaching at a Distance: A Series of Guides Prepared by Engineering Outreach at the University of Idaho, Available on Line: http://www.uidaho.edu/evo/dist2.html

Strategies for Teaching at a Distance: A Series of Guides Prepared by Engineering Outreach at the University of Idaho, Available on Line: http://www.uidaho.edu/evo/dist2.html

2130
and should be given some means of establishing the credibility of the information they encounter. The
WWW can also be used more effectively if students are given detailed, well planned assignments to
complete. This will ensure that they are less likely to deviate from their learning goals.

There are several programs which can help make posting classroom materials easier for the
instructor. Programs like Toolbook, QuizPlease, Web Course in a Box, PowerPoint and
Front Page all can provide Hypertext Mark-up Language (html) based instructional materials. Toolbook,
QuizPlease and Web Course in a Box are all programs which can allow instructors to post testing
materials on the WWW. Of the three, Toolbook and Web Course in a Box allow the integration of written
course materials, such as lecture or review materials whereas QuizPlease is truly a test generator. Of the
three programs, Toolbook is by far the most difficult to learn, but is extremely powerful and once
mastered can allow a great combination of online presentation of course materials and testing materials.
QuizPlease is extremely easy to use, utilizing a template format to allow the instructor to add questions,
graphics or sounds in a variety of testing formats. Web Course in a Box is also quite easy to use. Using a
template format it walks instructors through the process of posting a class on the Internet by setting up
the course syllabus and outlining the web site. All three programs allow testing, Web Course in a Box
does not have the capability to randomize test questions or electronically return test results to the
instructor.

PowerPoint documents can be converted into html format and posted on course pages.
Interactivity is limited and this is best used for the presentation of simple graphics, and written materials.
Front Page is a html editor and can be sued to design course materials for Internet posting or the
development of a threaded discussion for classroom use.

Often instructors find that no one program can meet all their needs. Instead each program should
be evaluated for classroom needs and used accordingly. I think that each program can be utilized to
some degree; PowerPoint to present written classroom materials, Web Course in a Box to develop a new
course and organize that course, Toolbook to present more complex course content (either on line or as
a stand alone presentation), QuizPlease to add on line testing and Front Page to add a threaded
discussion to classroom interaction. Practice and experimentation will decide which program best meets
the needs of each instructor and course based on network limitations, cost and flexibility.

Required Resources

In order to utilize the WWW in the classroom or as an alternate delivery system, students must
have Internet access. If they choose to take a class via this system it can be made a pre-requisite for
them to have this available. Many students take advantage of the computers available in their local
school or public libraries. If education is presented in a synchronous manner, students might have to
travel to a specific location at a specific time to receive instruction. In this case, two way video
conferencing equipment is required at both sites.

Limitations

Stevens, S., Using the Internet in the Classroom Available on Line: http://vbbuslnx1.tc.cc.va.us:80/~eci760/Class7/class7.htm
The greatest limitation to using the Internet for any learning is access. Certainly many institutions are requiring students to have a computer but the body of students served by community colleges generally cannot meet that requirement. Public and free access can often be found in public or school libraries. Instructors must remain very aware of copyright infringements and how they present class materials to students. Instructors must be very aware that anything they type is not private and might be viewed by many persons. They are a representative of their institution and therefore should act accordingly. This means that anything they post on the WWW should have a professional, easy to read appearance for easy use by all students. Poorly designed pages, or assignments which are not carefully planned might discourage students from pursuing other distance education opportunities in the future. Instructors should be cautious about the sound and video clips they choose. These can load very slowly and distract from student learning instead of enhancing the process.

Another limitation that is not always discussed is time. Preparing these course materials take time and instructors should be prepared for that. Generally even the most basic course materials must be altered for use in this setting. Instructional institutions are encouraging the developments of distance education courses, but often allow no compensation for the time and work involved in that process.

Extensions

Perhaps the most promising extension to adding the Internet into our classes is the increased student access and flexibility. Now we can offer students at least partial flexibility in certain classroom assignments. The WWW especially can offer this to students as more educators move to posting class materials for student access. Through careful planning and lesson planning, the WWW can also enhance critical thinking skills of students by encouraging student collaboration and analyzation of web sites and their content.

Summary

The Internet is an exciting addition to the classroom and is a challenge to all educators to meet learner needs. One way to meet learner needs is to make the educational process more flexible. We can do this by providing students a means of gathering classroom assignments, reaching the instructor for questioning or taking tests at their convenience. We can accomplish these goals by integrating the use of e-mail and the WWW into our classrooms. Even a "traditional" classroom setting can add these components in an effort to make the learning process more accessible for students.

E-mail and the Internet can also make distance education settings more effective in accomplishing student learning by increasing the opportunities for developing critical thinking skills and student access to instructional materials. In order to meet the needs of learners in these alternative educational settings, no one means of instructional delivery is effective. Instructors must explore all resource available to them and choose the ones most likely to meet the goals of their class. E-mail and programs such as Toolbook or QuizPlease are just a few examples of how learning on the Internet can be an effective learning tool.

Special Interest Groups PAPERS
Computers, sophisticated software, e-mail, and Internet access are the new tools of business and education in an evolving post-industrial society where information is power [Weins, 1993]. Those who have access to these new technologies have opportunities to compete in an aggressive marketplace. These technologies permeate virtually every field, and skill in using them is essential.

The rate of change in the information age carries with it major challenges for colleges and universities. Principle among those challenges is the problem of securing funding necessary to establish and maintain the technological infrastructure required to leverage these new technologies in the teaching/learning process [Division of Information Infrastructure, Dec. 1997]. They are also pivotal to the research, public service, and administration of higher education.

Is the key to funding campus technologies the implementation of a technology fee? Colleges and Universities devote massive funds and innumerable hours to integrating computers and the Internet into their curricula [Graves, 1994]. But with decreased funds and increased costs, budgets are strained with the pressure. The use of a student technology fees is an option.

Once a technology fee is in place, how is it implemented? Is used as a simple add-on to enhance current technology, or is it the technology used to transform the teaching/learning process, support challenging research, and aid in public service [Division of Information Infrastructure, Aug. 1997]? What role will students play in deciding how the fund is distributed and how will that presence be represented [Division of Information Infrastructure, Nov. 1997]? Will faculty resources be financed with technology fee funds?

At the University of Tennessee, Knoxville, the Educational and General budget, which is funded largely by state appropriations and student fees, support a number of basic computing and telecommunications services. Included among these services is access to central computing and server facilities, access to online documentation and computer based training courses, access to staffed and unstaffed student computer labs, a limited set of software at no charge, and access to student support services [Division of Information Infrastructure, Aug. 1997]. The state appropriations and basic student fees don’t begin to cover the breadth of need involved with implementing and supporting technology on a university campus.

In this case the student technology fee was established on a $12 per credit hour basis, with a $100 semester cap per student. This fee is in addition to a $140 activities fee, tuition, and fees associated with parking and housing. This student technology fee was designed to create an ongoing revenue of approximately $5,000,000 per year [Division of Information Infrastructure, Jan. 1997].

The revenues derived from the fund are placed in a separate account in the office of the Vice Chancellor of Information Infrastructure. It is distributed by the Vice Chancellor of Information Infrastructure with the
help of an advisory committee called the Technology Appropriation Board. The board represents members of the Student Government Association, the Graduate Student Association, Academic Affairs, and Information Infrastructure. There is also a Subcommittee, composed of five student members of the advisory committee and five additional students.

![Figure a: Technology Fee Breakdown FY 96-97 [Division of Information Infrastructure, Jan. 1997].](image)

The technology fee at UTK has been designated for several student related service, including [Division of Information Infrastructure, Aug. 1997];

1. Enhanced Network Access On- and Off-Campus
   The capacity and speed of the existing network has been increased to support electronic communication and access to information and will include connectivity for on-campus student housing and all academic departments, including additional ATM switches, T-1 lines, and ethernet connections. Of the 6,839 existing circuits, 5,745 will be upgraded, and approximately 8,972 will be added. All dorm rooms will have network capability, and when complete, the campus network will include 15,811 circuits. Commuter students have access to the campus infrastructure through a high speed modems or subsidized ISDN lines.

2. Enhanced Student Computing Labs
   Computing lab improvements include upgrading equipment on a three-year recurring basis, expanding hours of availability, and increasing the number of seats available. This year 26 labs were upgraded or built, more than 1,000 computers have been purchased since the fee was implemented last fall.

3. Enhanced Student Support Services
   The support line has been expanded to 40 hours per week. Ten hours per semester of statistical support will be made available to all students without charge, and subsequent hours will be charged at a reduced cost of $20 per hour. Additional instructor-based training courses for students have been added. Current classes available for students include; “The Life Preserver” an introduction to UTK Computing, classes on the Office ‘97 Suite applications of Word, Excel, and PowerPoint, a class on the Web and effective ways of gathering information, and classes offering assistance in utilizing computer software to produce a research paper.

4. Enhanced Software Distribution
   Licensing arrangements will be negotiated for additional software based on student needs. These packages will either be free or offered at a reduced cost. Currently Lotus SmartSuite and Notes are available at no cost to students. Software available at a reduced cost includes, Microsoft Office and SPSS.

5. Enhanced Instructional Technology
   One classroom per year will be equipped with 20 student network ports and a faculty computer station with display devices. An additional classroom per year will be equipped for computer-based faculty presentations. Training and support for faculty will be provided. This year 18 departments were given computer projection systems. In 1997, the ITC offered 116 sessions of 25 different courses related to integrating computer and multimedia technologies with instruction. Approximately 1,100 seats were filled by faculty, staff and graduate teaching assistants attending the courses, and post-session evaluations indicated that 99 percent of survey respondents rated the quality of the courses as "very good" or "excellent." Additionally, 57 faculty were awarded 1997 ITC Fellowships and Grants and worked in 27 teams to produce a variety of technology-enhanced course components.
It is obvious that technology is rapidly changing the ways that people conduct business and provide educational opportunities [Weins, 1993]. Students and faculty must try to remain abreast of the technology in order to maintain their competitiveness in the job market [Marcus, 1997]. If colleges and universities fail to provide the opportunity to learn these skills, they risk a decrease in student enrollment as students seek colleges better able to accommodate their needs. As computer technology becomes ensconced in our culture [Weins, 1993], it is in the best interest of colleges to consider the costs and benefits of providing access to technology and to budget accordingly so that they can continue to provide necessary services to students. In the case of UTK, the amount of fee-funded equipment, software and projects has been boosted by unexpected discounts and grants from computer manufacturers and other companies.

Despite the costs of implementing technology at a university like the University of Tennessee, Knoxville, the benefits gained have the potential to increase instructor creativity, increase student interest and learning, and create greater flexibility of instructional delivery.

OTHER PAPERS
A method of integrating (tele-)presentation and multimedia production

W. Hürst, R. Müller, Th. Ottmann
Institut für Informatik, Universität Freiburg
EMail: {huerst,rmueller,ottmann}@informatik.uni-freiburg.de

We explain a new method of integrating three apparently different activities, namely teaching in class, telepresentation, and production of instructional material for offline use into one single task. We call this method Authoring on the Fly and distinguish the three different phases of preprocessing, online delivery, and postprocessing. In the preprocessing phase the lecturer prepares slides as colored postscript files using one of his favorite tools, collects pictures and audio- or video-clips in one of the standard formats, prepares animations and simulations, and installs all this course-related material on his computer. In the online delivery phase, the material is presented and orally explained by the lecturer using an electronic whiteboard. The audio and video streams, the whiteboard actions stream, the animations and simulations, that is, all data streams generated during the lecture are then converted into a multimedia document, which can be linked together with other material and thus integrated into an open teaching and learning environment.

In this demo we demonstrate the method and explain all the various tools needed to successfully apply it. It will be shown how electronic whiteboards, the Mbone whiteboard wb and a more advanced whiteboard AOFwb, are used as presentational tools for teaching which allow the loading of slides, pictures, and the start and stop of animations and simulations. Using the multicast facility of wb, a lecture can be transmitted to remote locations via the internet. The two environments aofShell and AOFwb integrate the recording of the audio stream and all whiteboard actions, the seamless conversion into so called AOF documents, and the immediate replay of these AOF documents with the built-in viewer from the personal workstation's desktop.

By using examples from different areas like Computer Science, History, and Chemistry we explain
— how to prepare a lecture for telepresentation,
— the features of the integrated electronic whiteboards,
— the creation and handling of AOF documents,
— how to integrate AOF documents into teaching and learning environments such that they become accessible via standard internet browsers (both on Unix and WindowsNT platforms).

Demos as download packages are available under: http://ad.informatik.uni-freiburg.de/mmgroup.demos. Further information on Authoring on the Fly: http://ad.informatik.uni-freiburg.de/mmgroup.publications.
