This collection presents papers pertaining to the wide area of educational multimedia/hypermedia and telecommunications. The conference serves as a forum for the dissemination of information on the research, development, and applications in all areas of multimedia/hypermedia and telecommunications in education across all disciplines and levels. The papers cover a range of topics, including: instructional design; distance education; authoring; media in education; interactive learning environments; pedagogical issues; hypermedia systems; hypermedia applications; small dedicated applications; networked environments; courseware; educational media design; and computer supported cooperative work. This collection is a guide to what is happening in educational multimedia and hypermedia, now and in the future. This proceedings contains 485 short and full papers, reports of 6 panels, 23 tutorials and workshops, and 130 posters and demos. (DLS)
Proceedings of ED-MEDIA/ED-TELECOM 98

WORLD CONFERENCE ON EDUCATIONAL MULTIMEDIA AND HYPERMEDIA
& WORLD CONFERENCE ON EDUCATIONAL TELECOMMUNICATIONS

Freiburg, Germany; June 20-25, 1998
Preface

Welcome to ED-MEDIA/ED-TELECOM 98 in historic Freiburg, Germany. After two years in North America (Boston and Calgary), the conference is returning for its regular third year in Europe. The conference, a successor of the International Conference on Computers and Learning (ICCAL) which started in 1987, is already in its eleventh year. Over the last decade, ED-MEDIA/ED-TELECOM has become one of the top events of its kind in the world, thanks largely to the efforts of many volunteers.

Organized by the Association for the Advancement of Computing in Education (AACE), ED-MEDIA/ED-TELECOM retains many valued aspects of the earlier conferences, most importantly the truly international nature of its participants and its wide scope of coverage. Over the years, the conference has grown in sophistication, scope and number of participants, as has the technology that it presents, and this year's version will live up to this established trend. The following paragraph summarizing this year's statistics attests to this claim.

This year's conference received proposals for papers, panels, posters and demonstrations, and tutorials and workshops from 46 countries. After a careful review by the conference Program Committee (PC) whose members are listed on the following page, a total of 485 short and full papers, six panels, 23 tutorials and workshops, and 130 posters and demos were accepted. Although submissions arrived from all around the world, the following ten countries were the source of most submissions: USA, Germany, Australia, Canada, Japan, United Kingdom, Spain, Austria, The Netherlands, and France.

Based on preliminary inquiries and early registration, AACE expects around 1,000 attendees, a 35% increase over 1995 when the conference was last held in Europe (Graz, Austria). Both the number of submissions and the interest of potential participants confirm the growing importance of computer technology in education, and the popularity of ED-MEDIA/ED-TELECOM.

As co-chairs of the conference, we have done our best to ensure high quality of papers, tutorials, workshops, posters, demonstrations, panels, showcases and other events at this year's conference. This would not have been possible without the hard work of PC members from nearly twenty countries who reviewed more proposals than ever before. Separately, demos and posters were reviewed by Nick Scherbakov, panels by Peter Brusilovsky, and tutorials and workshops by Maria Teresa Molfino. Members of the PC and of the Steering Committee members also suggested and selected the keynote and invited speakers. The hard work of logistics was performed by the AACE team under the leadership of its Executive Director Gary Marks.

We acknowledge the hard work of the Local Executive Committee in Germany including Dieter Fellner (Technical University Braunschweig), Günter Müller, Eduard Bock, Frank Dal-Ri, Volker Krieger, Rainer Müller, Elisabeth Patschke, and most particularly Michael Sethe.

Finally, special thanks are extended to the conference local host, Albert-Ludwigs-Universität Freiburg, and to the local sponsors: University of Freiburg, State of Baden-Württemberg, Medien- und Filmgesellschaft Baden-Württemberg, Medienforum Freiburg, City of Freiburg, ASKnet GmbH Karlsruhe, and Eurographics Association.

A conference could not occur without presentations, and we are grateful to the hundreds of authors who submitted their thoughts, experiences, and hard work for presentation. Thank you one and all.

More than a year of preparation will soon be over and ED-MEDIA/ED-TELECOM 98 will be a memory. It is our hope that this memory will be refreshed each time you open this volume, seeking information and inspiration for your future work. We look forward to meeting you in Freiburg, and seeing you again next year at ED-MEDIA/ED-TELECOM 99 in Seattle, USA.

Thomas Ottmann, University of Freiburg, Germany
Ivan Tomek, Acadia University, Canada

Chairs of ED-MEDIA/ED-TELECOM Program Committee
Steering Committee

Chair: Ivan Tomek, Acadia Univ. (Canada)
Patricia Carlson, Rose-Hulman Univ. (USA)
Dieter Fellner, Univ. of Bonn (Germany)
Gary Marks, AACE (USA)
Hermann Maurer, Graz Univ. of Technology (Austria)
Thomas Reeves, Univ. of Georgia (USA)

1998 Local Executive Committee (Germany)

Chair: Thomas Ottmann, Univ. of Freiburg
Exhibits Chair: G. Müller, Univ. of Freiburg
Dieter Fellner, Univ. of Bonn
V. Krieger, Univ. of Freiburg
F. Dal-Ri, Univ. of Freiburg
M. Sethe, Univ. of Freiburg

1998 Program Committee

Program Co-Chair: Thomas Ottmann, Univ. of Freiburg (Germany)
Program Co-Chair: Ivan Tomek, Acadia Univ. (Canada)
Demos/Posters Chair: Nick Scherbakov, Graz Univ. of Technology (Austria)
Panels Chair: Peter Brusilovsky, Int'l Center of Sci. and Tech. Info. (Russia)
Tutorial/Workshop Chair: Maria Teresa Molfino, Consiglio Nazionale delle Ricerche (Italy)

Alan Amory, Univ. of Natal (South Africa)
Philip Barker, Univ. of Teesside (UK)
Alfred Benney, Fairfield Univ. (USA)
Michael Bieber, New Jersey Inst. of Technology (USA)
Solveig Bjornstad, Univ. of Bergen (Norway)
Jacqueline Bourdeau, Univ. of Quebec (Canada)
John Buford, Univ. of Massachusetts (USA)
Patricia Carlson, Rose-Hulman Inst. (USA)
Tak-Wai Chan, National Central Univ. (China/Taipei)
Ronald E. Clark, Embry-Riddle Aeronautical Univ. (USA)
Betty Collins, Univ. of Twente (The Netherlands)
Gordon Davies, Open Univ. (UK)
Christian Depover, Univ. de Mons-Hainaut (Belgium)
Mike Dobson, Open Univ. (UK)
Jorma Enkenberg, Univ. of Joensuu (Finland)
Richard Feifer, U.S. International Univ. (USA)
Kurt Feichtner, Massachussetts Institute of Technology (USA)
Otmar Foelsche, Dartmouth College (USA)
Yoshini Fukuhara, NTT Information & Communication Systems Laboratories (Japan)
Peter Gloor, Coopers and Lybrand (Switzerland)
Kent Gustafson, Univ. of Georgia (USA)
Gus Habermann, Massey Univ. (New Zealand)
Nick Hammond, Univ. of York (UK)
Michael J. Hannafin, Univ. of Georgia (USA)
John Hedberg, Univ. of Wollongong (Australia)
Rachelle Heller, George Washington Univ. (USA)
Lyn Henderson, James Cook Univ. (Australia)
Bill Hunter, Univ. of Calgary (Canada)
Ludwig Issing, Free Univ. of Berlin (Germany)
Piet Kommers, Univ. of Twente (The Netherlands)

Alison Young, UNITEC Institute of Technology (New Zealand)
Increase your students reading speed and comprehension with Kurzweil 3000 software. Kurzweil 3000’s multisensory approach to reading provides both visual and auditory feedback.

The Kurzweil 3000 reads aloud any printed textbook, magazine, or printed material. It gives students the advantage of highlighting and taking notes right on the computer. A dictionary, thesaurus, syllabification, and dual highlighting of printed text are additional tools for your students.

Students can now read the web. With the click of a button, Kurzweil 3000 will read aloud web pages opening a whole new world of research and learning for your students.

Your Students will:

Read with ease
Read with confidence
Read independently

... because everyone should have the opportunity to read.

For a free demo or more information call our toll free number or visit us on the web.

KEYNOTE PAPERS
AEIOU - The Development and Presentation of a Multimedia National Project

Hermann Maurer
Graz University of Technology, IICM, Schießstättgasse 4a, A-8010 Graz, Austria
hmaurer@iicm.edu

Abstract: The 5 letters AEIOU are found over the entrance of Austria's most famous gothic cathedral, St. Stephan's in Vienna. Nobody really knows what they stood for. Some say they stood for "Austria Erst In Orbe Ultima" (Latin) meaning something like "Austria will be the ultimate country in the world" or (German) "Allen Ernstes Ist Oesterreich Unersetzlich" meaning something like "All of the world belongs to Austria", and there are also some more modest interpretations! Be it as it be, Austria celebrated its millennium in 1996 and for this occasion the hypermedia group at Graz University of Technology was awarded a contract to prepare a multimedia presentation of Austria, again using AEIOU as acronym: this time the 5 letters stand for "Annotatable Electronic Interactive Austrian (in German Austria is called Oesterreich) Universal encyclopedia".

By end of 1996 a 4 G Byte presentation of Austria including a complete encyclopedia, hundreds of pieces of music, hundreds of historic movie-clips, thousands of historic, geographic and arts pictures, and much more was available on the Web (see http://www.aeiou.at ). To be able to structure and administrate such a huge amount of information new techniques involving the WWW based knowledge-management system Hyperwave (see http://www.hyperwave.com ) were necessary.

In this presentation, those techniques are presented. It is explained how AEIOU can be used as a treasure-cove for teaching and learning purposes. Continuing work and why it is necessary will also be discussed. AEIOU will be compared with some other similar undertakings. A good part of the demonstration will, however, be dedicated to a guided tour through some of the highlights of AEIOU, and this tour should be a feast for both eyes and ears.

Abstract: How can we integrate educational technology into the workflow? We will consider three activities: courseware and learning, virtual classroom and teaching, and virtual school and administering. Our own efforts to integrate into the workflow of users will be illustrated for each of these activities. Then the market will be broadly analyzed from the perspective of three types of providers: corporate educators, state educators, and brokers. A growing market is predicted for corporate education to employees and clients. One challenge is to implement the model of student learning that fits into the life style of the student and that allows the computer to monitor for quality.

1 Introduction

Virtual education realizes a new synergy among people and their information technology tools. Virtual education transcends boundaries – space, time, and organizational boundaries [Rada 1997]. What tools are being developed for this education and what audiences are best positioned to benefit from these tools? What organizations will take responsibility for what education? Some people predict the end of traditional, place-bound education [Noam 1995]. The more compelling argument is that new markets exist, and that a continual adjustment is needed so that certain, new technologies fit into the educational needs of certain students.

The next section of this document views the educational enterprise as divided into Learning and Courseware, Teaching and Classrooms, and Administering and Schools. From each of these three views, what is the model of the educational process and what tools are relevant? Our work in implementing models is used to illustrate the directions that we believe are most profitable. Next, the deliverers of virtual education are related to new market niches. Finally, the challenge to virtual education is posed as a dialectic that needs to be repeatedly resolved through the mapping of people, tools, and problems.

![Diagram](https://example.com/diagram.png)

Figure 1: This flowchart of part of a virtual classroom system shows the student’s submission of an answer and comments, each date stamped. The comment also assigns a score to the answer.
2 Learn, Teach, and Administer

For different learning tasks different interactivities are appropriate. The book printed on paper remains a valuable tool for certain learning purposes. Through courseware the computer supports learning tasks. At its simplest, courseware holds linked text that gives the student a different kind of flexibility with browsing. An intelligent tutoring system uses domain, pedagogy, and student models to simulate a 1-to-1 student-teacher interaction. These student, domain, and pedagogy models can help guide rich, multimedia interactions in the form of virtual realities. However, the cost of building intelligent, virtual reality tutoring systems is currently prohibitively high for most occasions. Adequate standards for the components of these intelligent, virtual reality tutors do not exist. The paucity of courseware standards interferes with the perpetuation of courseware [Rada and Schoening 1997].

Courseware may be used by a lone student or in the context of a classroom. In the classroom, students interact with other students and the teacher. The virtual classroom exists on the information superhighway. Groupware technologies are particularly apropos to the classroom. Groupware supports the activities of a group in synchronous or asynchronous mode. The simplest way to do this is to provide for online submission of exercise answers and electronic bulletin boards for discussion of those answers. Students may use a paper book for the core reading material. However, the computer can go beyond this relatively static role and can more directly manage student-student interactions [Fig. 1].

A classroom exists within a school. The virtual school is a type of virtual organization. To place a school onto the information superhighway, one needs a model of the school. This model must accommodate students, teachers, administrators, and more. Information systems are commercially available which implement a model of a school and which can be tailored to a particular school's needs. One of the impediments to progress is the idiosyncratic character of individual schools and the corresponding high cost of tailoring an information system to a particular school. With computer networks one could monitor many of the transactions within a school and automatically give feedback about the performance of people within the school.

3 Our Tool Building

For all three activities of learning, teaching, and administering we are building and maintaining educational technology that fits into the workflow of our users. Furthermore, the production of the tool itself can be semi-automated. Figure 2 illustrates how tool building must serve all the activities of delivering education.

We are developing a state-of-the-art, interactive, multimedia course for introductory economics. Students will be given clear instructional objectives that are supported by multimedia exposition. More importantly, students are repeatedly challenged to do exercises for which the courseware knows the correct answer and critiques incorrect answers of the student. The course covers introductory university economics, and part of our target audience is advanced placement, high school students because those students in their own high schools may not have an opportunity to take a course in economics other than through our courseware.

In our virtual classroom developments we have pioneered a quality control system that has students assess the work of other students. On a weekly basis students submit exercise answers and assess the work of three other students to whom they are assigned on a rotating basis by the computer [Fig. 3]. The computer not only monitors that all the assigned work is done in a timely manner and to a certain minimum standard of length...
but also performs quality control calculations on the numerical assessments that students make of one another. When several students grade another student, then the variance among the grades on the answer should not be great; otherwise, the students are asked to consult with one another via email and to reconsider their scoring. Likewise, the grades assigned by one student to the other students should significantly discriminate answers, and if a student fails to distribute scores in a discriminating way, then the student loses credit. The virtual classroom allows teachers to manage the submission of work and student-student interactions in ways that would be impractical without the computer support [Rada 1996]. In our many experiences with this method of semi-automated quality control the results are pedagogically sound. We are beginning to teach to engineers at factories of the Boeing Company using this method and operating exclusively over the web.

At the school level, we have started a Virtual Information Technology College within the Globewide Network Academy (GNA). GNA was established in 1993 as the first virtual educational organization in the world. Its basic operation is to catalog virtual-mode courses and to provide free access to anyone to this catalogue. The catalog lists about 15,000 courses and receives about 1,000 visits per day. The Virtual Information Technology College provides a filter onto the GNA catalog and is offering further educational services [see http://catalog.gnacademy.org/gnacademy/vitc/].

In addition to semi-automating the work of individual students, classes, and schools as above indicated, we are also attempting to semi-automate the work of organizations that develop the educational technology tools themselves. Figure 4 shows the courseware factory web site that is based on methods elaborated in earlier European Union projects [Rada 1995]. For developing its catalog, GNA operates totally in virtual mode with email programs reminding educational organizations about the maintenance of their catalog entries, editing programs supporting the collaborative authoring of GNA online documents, and so on.

4 Corporations, States, and Brokers

Schools are often sponsored by organizations that have some market to serve [Fig. 5]. One classification of the sponsors considers 1) companies that educate their employees or customers, 2) state-supported institutions that offer students in the state subsidized education, and 3) brokers that connect teachers and students. What are the market niches for the schools of these different sponsors?

Many large companies have education programs for their employees, and these employees constitute a captive audience for education mandated by the employer. In global companies, the costs of bringing employees together in one place may be prohibitive for education or training that can, however, be cost-
effectively delivered over a distance. When a course was taught on the Internet to employees in offices of one company distributed around the world, the timeliness of the topic and the low cost of participation more than offset the awkwardness of the technology [Rada 1997].

A company that sells a product has a captive audience for education. Furthermore, providing such education helps the customer use the product and thus improves customer loyalty. Novell Corporation develops computer network software and delivers education about networking. Some employers say that a new employee with an education certificate from Novell earns more than a new employee with a Master's degree in Business Administration. Educating customers is part of a broader mission of Novell to increase its market share [Novell 1995]:

Novell Education's mission is to drive global pervasive computing through quality education programs and products; its purpose is to increase literacy on Novell products and technologies and thereby foster Novell's success worldwide. Novell Education plays a critical role in providing true pervasive computing by building the infrastructure of support and literacy that is necessary to drive and sustain that vision.

In other words, Novell is educating its customers so as to better sell its networking products.

The state collects taxes to support education. State schools for children have captive audiences and are

Figure 5: The diagram on the left shows that Sponsors are associated with Virtual Schools that in turn bring Educators and Students together. The diagram on the right shows that People, Tools, and Problems are intimately linked to one another.
often physically very near to the houses of the children. The reasons for virtual education to children are less to do with transcending space and time barriers than to do with duplicating teacher expertise. State universities do not have a captive audience of students in the strict sense. However, the state university is able to offer reduced costs to students from the state. The state is in a strong position to finance virtual education initiatives that bring together state-supported, higher education schools to meet state-specified educational needs for working citizens of the state.

Education brokers link students and teachers. Brokers can take many forms. Publishers can take advantage of the information superhighway and become brokers that go directly from the authors of textbooks to the students who study from those textbooks. Professional societies may sponsor education functions for their members and be seen as highly credible.

5 Future

The uses to which information technology might be put over the next five years in education are many and varied. One principle will surely apply: when the technology fits smoothly into the life style of the intended users, then success is likely, and otherwise not. For instance, if the target audience has no computers but has to go to special facilities to use them, then some of the advantages of virtual education may be diminished. Likewise for teachers and administrators, if routine computer use is awkward, then the opportunities to have a virtual organization are limited.

One key to a successful virtual educational activity is that the participants are comfortable with information technology and are highly motivated. Accordingly, one discipline that is particularly ripe for virtual education is the information technology discipline itself. Where else could one be more assured that the teachers and students would be comfortable with the tools? Plus the demand for information technology education is great and growing! At least in the United States, the traditional, higher education organizations have fallen woefully behind in providing information technology education, and new, virtual-mode, education organizations are entering this marketplace.

The detailed shape of information technology thirty years hence is difficult to predict. Wireless computers the size of a credit card will receive data or multimedia information anywhere and anytime for some people. Artificial intelligence techniques will allow some roles in the organization to be performed by computers. New education marketplaces may rise in prominence over the next thirty years. More and more companies may want to educate customers in virtual mode to improve customer satisfaction. State-funded organizations have rather well defined audiences and boundaries. Companies with a product to sell have different constraints. Virtual education between company and customer could become increasingly the mode of continuing and life-long learning in thirty years.

6 Dialectics

Consider the mapping among tools, problems, and people from a dialectical perspective [Fig. 5]. If we say that a certain tool supports virtual education, then we mean that for certain people with certain educational needs that a certain tool can help. For other people or other educational needs the tool may well be inappropriate. At any point in time, we could develop an extensive set of maps for various combinations of people, tools, and problems. Now consider changes across time. For instance, a new tool appears. This new tool may be better for some combination of people and problems than the tool that they currently use. A tension arises between the established way of working and the new way that uses the new tool. After the tension is resolved, a peace prevails only so long as people, their problems, and their tools stay in harmony.

Bill Gates emphasizes the role of friction-free capitalism in the information age. The information highway may extend the electronic marketplace and make it the universal middleman [Gates, 1996]. For this low-friction, low-overhead scenario to attain, market information must be plentiful and transaction costs low. Perhaps for a consumer buying a radio such a friction-free market can exist. However, students usually want education in some organizational context. Marx would say that the state should provide all education [Fig. 6]. Another dimension of the virtual education dialectic appears. What organizations will most control virtual education?
In the open-market of the information superhighway, schools might re-assess their relationships with their students, teachers, and sponsors [Fig. 5]. Schools provide certification of one sort or another and can compete globally relative to their certification. The tension in competing globally may drive the adoption of new tools by some schools. Publishers may offer virtual education, and the competition between commercial publishers and state-financed, educational institutions is another change agent in the evolving map of virtual education.

Global companies with captive audiences of employees and customers may increasingly compete with one another through their sponsorship of virtual education. Global companies have different boundaries than those of any particular government but also have needs to perpetuate their own culture. To this end a company may collaborate with state-funded, higher education institutions to better prepare the company’s employees and customers to deal with the products and services of the company. This education may go beyond narrow training and may encompass combinations of theory and practice that will be relevant to the day-to-day experiences of the students. This growth in the breadth and depth of life-long, virtual mode education will drive the development and adoption of new technologies that address learning with courseware, teaching in the virtual classroom, and administering the virtual school.

In this talk, I will report about new ideas and concepts on extending the scope of human-computer interaction, collaboration and learning support not only from desktops to electronic meeting room or electronic classroom scenarios as we and other people did in the past but we will go beyond. While the ideas are based on the results of our past system developments (e.g., SEPIA and DOLPHIN) and their empirical evaluation in experimentally controlled studies, we take now a much more comprehensive perspective resulting in highly flexible and dynamic work and learning environments. This perspective is provided by the notion of "cooperative buildings" which addresses the issues of how to integrate information technology, new work and learning practices resulting from organisational innovation, and the physical architectural environment. Our approach incorporates also ideas from augmented reality and ubiquitous computing resulting in the view that the world around us is the interface to information and for collaboration.

In order to illustrate this perspective, we have developed i-LAND: an interactive landscape for creativity and innovation. i-LAND integrates several so-called "roomware" components into a combination of real, architectural as well as virtual, digital work environments for creative teams. By "roomware", we mean computer-augmented objects in rooms, like furniture, doors, walls, and others. The current realization of i-LAND covers an interactive electronic wall (DynaWall), an interactive table (InteracTable), two versions of computer-enhanced chairs (CommChairs). Furthermore, we developed "Passage", a mechanism for connecting information structures in the virtual information world with real world objects allowing also for physical transportation of digital information. More components are planned. In the following we describe the characteristics and the realization of the "roomware" components we have built so far.

**DynaWall**

The DynaWall is an interactive electronic wall, representing a touch-sensitive information device with a display size of 4.5 m wide and 1.1 m high and a resolution of about 3000 by 1000 pixels. Since the availability of display space is a crucial point of most visually-oriented tasks, the DynaWall enables groups to display and to interact with large information structures collaboratively in new ways. Two or more persons can either interact individually in parallel or they share the whole display space. The size of the DynaWall opens a new dimension in human-computer interaction, where, e.g., information objects can be picked up at one position and dropped elsewhere on the display (pick'n'drop), or thrown from one side to the opposite side, where dialog boxes have to appear in front of the current user(s), etc.

**InteracTable**

The InteracTable is the first in a series of information devices that investigates general shapes and orientations of interaction areas, e.g. round or oval displays. It has been designed for display, discussion, and annotation of information objects by a group of people sitting or standing around the table. Information objects displayed on the table can be rotated and shuffled across the surface in correspondence to different view perspectives. Manipulation is done by gestures using fingers or pens, annotations by voice and/or pen.

**CommChairs**

The CommChairs are a new type of furniture. There are two variants: one with integrated pen-based information devices and one with a docking facility for plugging in laptops. Each CommChair has an interface for wireless networks and an independent power supply for maximum mobility. The CommChairs enable people to make private annotations and to connect to shared workspaces, displayed on devices like the InteracTable or the
DynaWall. Localization of the CommChairs in a room, identification of the person in the chair, establishing network connections and shared information displays simply by moving CommChairs together is done automatically. This is based on sensoring devices in the room. Built-in audio and video communication facilities, leaving messages for other people sitting in that chair afterwards as well as tactile notification of incoming calls/information are further aspects to be investigated.

### Passage

Bridging the border between the real world and the digital, virtual world, Passage describes a mechanism for establishing relations between physical objects and virtual information structures. Within the framework of computer-augmented reality, so-called Passengers (Passage-Objects) enable people to have quick and direct access to a large amount of information and to "carry them around" in terms of physical representatives. Each Passenger has a physical and a virtual part. Passengers will be placed on so-called Bridges, making their virtual counter parts accessible.

i-LAND serves as a testbed for exploring new ideas on how to support a wide range of different group work and learning situations. This includes a special focus on the development of new computer-based creativity techniques. The design is based on an extensive requirements analysis and interview studies with creative teams in industry and large organizations. The development activities are complemented by evaluation studies to obtain early feedback from users to be used in the redesign process.

i-LAND is an example application of our vision of the Workspaces of the Future where work and learning have to be addressed in a common framework. At the same time, it is a testbed for developing new forms of human-computer interaction and computer-supported cooperative work and collaborative learning.

INVITED PAPERS
Reuse of Educational Resources through Telematic Means
(ARIADNE at HOME)

E. Duval
Departement Computerwetenschappen, Katholieke Universiteit Leuven, Leuven, Belgium
Erik.Duval@cs.kuleuven.ac.be

Introduction

In this invited presentation, I will present some of the results of our work on reuse of educational resources. Most of this work has been carried out in the framework of HOME (Hypermedia Object Management Environment).

Our basic aim with the development of HOME is to investigate [Hendrikx, Duval & Olivié, 1997; Hendrikx, Duval & Olivié, 1998; Duval, Hendrikx & Olivié, 1998]:

- the application of database technologies for hypermedia application development;
- hypermedia modeling, based on collections of hypermedia objects in object-oriented inheritance hierarchies,
- design and (semi-)automatic generation of hypermedia applications, based on conceptual design models similar to the Entity-Relationship model or more object-oriented variants thereof.

The main ideas behind HOME will be presented briefly, with an emphasis on the applications of HOME in the context of education and training (next section). The main focus will be on the ARIADNE project, where HOME has been used to set up a distributed Knowledge Pool System of reusable multimedia pedagogical documents (last section).

HOME

In general terms, our research focuses on maintainability of relatively large and highly structured applications. HOME acts as a framework for our research in this area, which is applied in several projects:

- A HOME-based research prototype has been developed on bibliographical information in the field of database and hypermedia research <http://www.cs.kuleuven.ac.be/~koenh/home/>. This prototype was the starting point for current developments on an Intranet based information management system for our Computer Science Department.
- AHM is a prototype implementation, based on HOME, of our approach for adaptive hypermedia courseware, in which a course is organized around concepts that are explained by documents. Links to concepts and documents are dynamically adapted to individual students [Pilar da Silva, Van Durm, Hendrikx, Duval & Olivié, 1997] <http://miro.cs.kuleuven.ac.be/ahm/>.
- DIGIT is a HOME-based system for the dissemination of information on the educational application of Information Technology <http://www.cs.kuleuven.ac.be/~koenh/digit/>.
- A nationally funded research project has just started in which HOME will be used to analyse and monitor social practices that determine the demand for mobility.
- HOME LITE is a personalized version of HOME that runs on low-end (e.g. portable) Personal Computers, with very limited system requirements. All information is stored in a light version of a commercially available database management system, and can be synchronised with a central server when the PC is reconnected to the network after stand-alone operation.

ARIADNE

ARIADNE is a European project where HOME is used as the underlying technology for a European Knowledge Pool System. At the core of the ARIADNE project is the idea of 'share-and-reuse' for the development of courses supported by telematic means [Forte, Wentland-Forte & Duval, 1997a; Forte, Wentland-Forte & Duval, 1997b]<http://ariadne.unil.ch/>. The Knowledge Pool System stores both the descriptions of educational resources and the resources themselves. As is customary in HOME, the Knowledge Pool System relies on a commercially available DataBase Management System for basic data management and query services. We are heavily involved in efforts to
standardize the metadata structure of the descriptions, both on a European and on a more global scale. These efforts are important as such a standard would lead to interoperability between Knowledge Pool System-like infrastructures and would allow publishers of educational resources to adhere to this standard and make their material more easily accessible.

An important characteristic of reusable educational components is that they should have no links to external material, as this jeopardizes reusability. If such links are included, then it becomes very difficult to ensure that the links will still be relevant at a later time, when a student consults the document. The link target may well have moved, changed or have been removed altogether. More importantly, a link to an external resource may be inappropriate in a different context, when the document is reused. Finally, a link to an external resource can easily lead to disorientation, as it blurs the boundaries of 'the course' and the vast reservoir of disparate information that the Web currently is. To ensure a critical mass of educational resources, the Knowledge Pool System needs to be deployed on a relatively large scale. Using the current Internet facilities, one central database suffers from limitations on bandwidth and Quality of Service. Therefore, a distributed database has been set up so that each local server handles a region of telematic influence. Material introduced at one local site proliferates to a national centre and from there to a central server in Leuven, Belgium. From the central site, descriptions are replicated to all local sites. Documents are replicated if allowed by the rights holder and if the local site has been configured to replicate the document. In order to maintain high quality content, it is necessary to have some kind of validation mechanism. We are mostly concerned with a consistent and clear description of the material. For the validation of these descriptions, we distinguish four levels of users, each with well-defined privileges to the Knowledge Pool. The Knowledge Pool System directly interfaces with a number of ARIADNE Core Tools that enable an end user to describe and insert new educational resources, to search for relevant material through queries on the descriptions, to define the structure of a course, and to automatically generate a Web site from the course structure and the content in the Knowledge Pool System.

Abstract: In 1996, Acadia University joined a small number of North American universities who embarked on a transition to a fully computerized campus. The adopted strategy was to equip each student and faculty member with a personal laptop computer, take advantage of computer technology in most courses, and provide ubiquitous access to the computer network everywhere on the campus.

In this presentation, we will describe the experience of campus computerization, talk about the logistic problems, impact on faculty and students, successes and disappointments, present video tapes showing the use of computer technology in our classrooms, and introduce some of the technical and education-related research that was stimulated by the project.

Introduction

Acadia University located in Wolfville, Nova Scotia, is a small, predominantly undergraduate, teaching-oriented university in Eastern Canada. Its full-time enrolment is about 3,500 undergraduate and some 100 MSc students, for a faculty of about 230. Student-faculty ratios are relatively low, class sizes typically 20 to 30 students, with only a few around 100. The corresponding size of classrooms, labs, and other teaching facilities is generally quite small too. With its small size and focus on teaching, Acadia University has always placed emphasis on instructional style and technology.

In 1996, Acadia University began the Acadia Advantage program (AA for short), an academic initiative that integrates the use of notebook computers into the undergraduate curriculum. Phase I of the program saw 370 students and 45 faculty piloting the initiative. In September 1997, all first-year, full-time undergraduate students and approximately 125 faculty entered the program. By the year 2000, all full-time undergraduate students and all faculty will be involved.

History

The original impulse for the creation of AA can be traced back to difficulties associated with maintaining information resources. During the late '80s Acadia University faced the problem shared by many other North American universities: How to continue providing students and faculty with the information and knowledge resources required to maintain a dynamic academic environment under the conditions of decreasing
public grants and increasing costs of purchase and storage of printed materials. At the same time, some faculty members felt that the traditional lecture format needed to be adopted to new technologies to prepare students better in critical areas of communication skills, problem solving, working in groups, entrepreneurial instincts and technological capabilities. In addition to these fundamental challenges, Acadia faced daunting costs in maintaining the traditional computing facilities that students and faculty had come to expect and to depend on.

In 1989, a report entitled The Global Library was prepared at Acadia University by the Director of the Computer Centre and the University Librarian. The document was approved by the Senate and the Board in 1991. Key among its more than 20 recommendations was the goal to provide access to the information highway at the user's preferred location on the campus. As Acadia moved to implement this strategy, it became increasingly clear that all of the objectives could be met through a single project. The first step in the project - identification of what was to become the Acadia Advantage Program - began in August 1995. Through the fall of 1995 and into early 1996, the initial concept was investigated, discussed, refined and developed. The final draft of the plan was presented to an open assembly and approved by the Senate and the Board of Governors in the spring of 1996.

Implementation

The key elements of the project included identification and study of similar projects in North America, identification of material and development needs, design and construction of new teaching facilities in support of the new technology, design of a program to support faculty development, and significant increase of the capacity of the existing campus wide intranet.

While the project was under development, various other universities started introducing “electronic” classrooms [Mühlhäuser 1996], [Shneiderman 1995] where each student has access to his or her computer, either a mobile notebook [Wake Forest, 1997] or a stationary computer (University of North Carolina). In these classrooms, computers are usually networked, allowing students to access Internet. At the same time, various organizations started developing integrated educational systems that provide numerous facilities including access to information about courses such as course descriptions, computerized course materials, discussion groups, chat rooms, on-line tests, etc.

During the summer of 1996, a new ATM backbone was installed beside the existing FDDI backbone. Fibre optic cable was extended to all buildings on campus, and copper wiring was provided to bring data to faculty offices and classrooms. Seven classrooms ranging in size from 30 to 100 were redesigned and provided with network connections to all seats. Each classroom was provided with full multimedia capabilities that are easily operated from an instructor console. Approximately 3000 sites on campus were wired including the library, public gathering areas, lounges, offices and other key locations. In the summer of 1997, 12 more classrooms and several laboratories were renovated, and by summer's end of 1998, 60% of all learning facilities will meet AA requirements.

At the time of this writing, each new AA student arriving at Acadia is provided with an IBM Thinkpad with 24 MB RAM, and 1.2 GB hard disk, a CD ROM drive, and software including Windows 95, Microsoft Office Suite. A host of discipline-specific programs is included individually to satisfy the needs of each department. Faculty and students make use of the computers in both synchronous and asynchronous ways, using them in a standalone or network connected fashion. The majority of courseware is either TCP/IP based or resides on individual laptops and students thus have 24-hour access to courseware material. The hardware/software configuration continuously evolves and selection of a new model with more RAM and disk space for the fall of 1998 is under way.

In terms of faculty development, Acadia faced a fundamental problem faced by all colleges and universities undertaking similar initiatives: What type of support will most successfully help faculty to prepare course material and master the new technical tools available to them for curricular innovation? Students involved in the program have high expectations about the use of the technology (they pay an extra amount in addition to already high tuition fees), and many faculty were rightly concerned with pedagogy and course content. Information on the effective use of computers in education is full of qualitative data, but little concrete information was available to help guide the process. It was clear that faculty should not be required to learn all there is to know about using personal computers, accessing the Web, developing courseware, adapting to new
modes of scientific data acquisition, or constructing on-line tutorial or testing programs. What was needed was a place where faculty could go to discuss possibilities and find help in implementing technology-based enhancements to instruction.

To address this need, the university created a central location to support faculty development, the Acadia Institute for Teaching and Technology or AITT, now better known as the 'Sandbox'. AITT is the primary on-campus site for technical support of computer-enhanced learning, research, development, and training. Quite naturally, AITT also came to play a crucial role in the selection and development of educational software. The first steps in the selection of appropriate software included evaluation of numerous commercial packages, as well as software developed at other institutions. Cost, installation, support, and maintenance issues were considered and in the end, a mixture of software with a shared core of applications augmented by discipline-specific applications adopted. Due to the perceived unsatisfactory quality or lack of match with course specific requirements, AITT undertook to develop a core application that would satisfy the shared needs of the faculty across all departments.

The largest Sandbox project in the area of software development to date has been the development of ACME - an Automated Courseware Management Environment [ACME]. ACME (Figure 1) is a Web-based course development package that has now been widely adopted by the faculty; at present, 150 faculty use it in over 450 courses and labs on-line. Its first version was developed over a short period of time, mainly by Acadia University Computer Science students under the leadership of the first author.

![Figure 1. A typical ACME course page providing access to course materials and other facilities.](image)

The main goal of ACME is to make courseware development and use as easy as possible for faculty and students with limited computer expertise. The package provides a directory of registered courses allowing authenticated users to access their personal combination of course materials. The tools provided include access to general course materials, access to the instructor and information relevant to the course provided by the instructor, a discussion group facility, and an on-line test tool.
The early experience with ACME has been positive as both the faculty and students enjoyed the opportunity to access a large amount of material within a fully integrated and easy to use system. Soon, however, users started presenting new demands, asking for additional features and for customization of existing features. This has been positive in correcting initial design shortcomings and helping to discover new possibilities, but it also created problems in that specific features are required only by small audiences and are not economically justifiable. Because of unsatisfied requirements and interest in exploring new directions, various faculty members started developing their own subsystems as their personal research projects. This initiative is currently supported in two ways – by a competitive university Teaching Innovation Fund which supports selected projects in the general area of innovative teaching endeavours (commonly AA-related), and through support provided by the Sandbox. Sandbox support for departmental AA-related activities has the form of allocating qualified students to individual departments for varying lengths of time during the summer, to help with the implementation of AA-based course materials.

Among the education technology-related research activities triggered by the AA initiative, the best known probably is the Digital Agora [Waters et al., 1998], a Web-based interdisciplinary project that aims at shifting the educational paradigm in social sciences from instructor-centered to student-centered (Figure 2). The project allows authorship of hypertext nodes and links (both shared and private), discussion groups, collaborative analysis, simulations such as economic forecasts and population growth, and graphical representations of complex issues using lateral maps built from a dictionary of shared annotated symbols. The project provides access to primary and secondary data, supports quizzes and evaluations, consensus negotiation, collaborative writing, online student newspaper, glossary, calendar, personal annotation, and additional features. The software has been initially used by Political Science students at Acadia University but its use has now grown beyond Acadia University and outside of university educational settings.

Since learning is a collaborative process and since computer networks invite collaboration but don’t provide sufficiently sophisticated tools to support it, faculty researched development of collaborative and interactive sharing of tools and collaborative virtual environments (CVEs). In particular, the second author of
this paper is involved in research on the following implementation techniques: servlets instead of CGI, RMI or Corba rather than sockets, Java instead of ad-hoc user-defined specialized servers (such as relay servers), and JDBC for persistent data. The cost of this approach is in the need for highly skilled programmers, but the benefits greatly outweigh the cost: The resulting software will be efficient, maintainable, portable and modifiable. The following projects are currently under investigation: (1) Virtual collaborative working environments [Hussey, 1998]; (2) Comparison of RMI and Corba for development of persistent shared workspaces; (3) Comparison of two implementations of Corba: IONA Orbix and Microsoft Con; (4) Integrated Java desktops; (5) Specialized Java servers for workspaces with shared applications; (6) Complete Corba-based educational systems; (7) Balancing the load for client/server systems; and (8) Design patterns and frameworks for access controls for shared workspaces.

In another project, a prototype MOO-based CVE called Jersey [Tomek et al. 1998] has been extended and used to teach three software development courses in which participants did not have to, and occasionally could not, work in the same physical locations (Figure 3). Clusters of virtual rooms including personal offices, document rooms, and meeting rooms were created to support projects, and software agents were implemented to perform tasks such as notification of project events to users who registered interest in them, meeting support, delivery of a weekly newsletter to subscribers, and asynchronous query support. A new version of this environment for use in much larger courses is under development.

Figure 3. Jersey main window with an output area, talk input field, and workspace on the left, and current room and selected object information on the right.
Conclusion

The Acadia Advantage program, one of the first North American attempts to bring computers into the hands of all students on a university campus, is now nearing the end of the second year of its existence. From a beginning pilot implementation restricted to a few departments and courses, the program has now become universal and all incoming students at Acadia University now obtain a laptop computer with their registration. The initiative required large investments of money and personal time, created internal controversies, and went from apprehension to enthusiasm and critical reappraisal.

In spite of inevitable problems, a large majority of participants consider the program a success. After the initial focus on the use of laptops in the classroom, many instructors have now realized that computer technology does not yet provide the same interactivity as more traditional forms of presentation. In the classroom, the computer has thus become a supplement, an additional tool providing access to large amount of live information and interactivity, instead of being the center of the lecture. More and more instructors are finding that a greater benefit can be derived from the ubiquity of the computer and direct students to use it outside the classroom – as an information accessor, as an interactive tool, and a learning partner with limited intelligence but great power.

The active involvement in exploration of new teaching technologies opened new research avenues for all Acadia University faculty. With continuous hands-on access to computers and with a large student population enjoying the same access, Acadia faculty has started exploring ways in which computer technology can be exploited in university education at a scale that was impossible until now.

From a very pragmatic point of view, perhaps even more important than its presence in the teaching process is the computer's continuous availability. As computer literacy is increasingly a prerequisite to success, employers value extensive experience with information technology, AA students with their 24-hour access to computers can claim this background, and employers appreciate it.

[AA] Acadia University 1997: "Acadia Advantage"
What are the requirements for information society? What kind of skills and knowledge is needed for our future generations to be able to be active and productive citizens? In many studies which relates to education and information society have two different kind of approaches to the requirements of the information society. Narrow interpretation of the skills needed in information society emphasize the need to train citizens how to use technical tools, computers, networks and other media tools which are the most visible part of information society. Campaigns like “Every school should be connected to the Internet before year 2000” and “Internet skills to every teacher” are often closely linked to this narrow interpretation.

Broad interpretation about information society concentrates more deep qualitative changes of the living conditions in information society. The rapid growth of the new society, its digital and global economy and development of media will deeply affect to the culture and skills which are needed in work. It is of course hard to exactly predict the changes but analysing the most advanced working environments and looking the results of future oriented research it is possible to find some trends of changes related to nature of the work and estimate the requirements of learning and education.

The research literature offers several review- and metastudies related to the learning results and Information and Communication Technology. The main result is that ICT and the other arrangements together with ICT in education have a small positive effect on learning. Closer look to those results and studies behind them shows that results from different studies are inconsistent and inadequate. Many of these studies have been done in United States which social situation as well as the role of male and female are quite different than many other countries. More national research is needed to understand better complex phenomena of ICT and learning.

A large research and evaluation project “ICT in Teaching and Learning” is in progress in Finland. The Future committee of the Finnish Parliament proposed this study and it is conducted and funded by SITRA (National Science Fund). More than 50 researchers are committed to provide information and results starting from early childhood up to the senior citizen activities related to ICT. More than 3000 students and thousand of teachers will part of the study and several case-studies related to ICT and education.
will be analyzed. The aim of the study is to have a broad view to the challenge of information society and look technology as cognitive and social tool. The influences of ICT will be evaluated macro, meso and micro levels in education.

Changing understanding of knowledge is the basic of evaluation-process;
* Technology also changes our understanding of knowledge
* The role of the knowledge is changing the society
* The structure of the society is becoming more networked
* The change of expertises is in progress
* The complexity of society is increasing

First results of the project will be presented, demonstrated and discussed in my presentation at ED-MEDIA 98.

AWARD PAPERS
Computer Games as a Learning Resource

Alan Amory, Kevin Naicker, Jackie Vincent and Claudia Adams
Biological Pedagogics Research Unit, Biology Department, University of Natal,
Durban 4041, South Africa. E-mail: amory@biology.und.ac.za

Abstract: Playing games is an important part of our social and mental development. The computer games industry has grown swiftly, notably on the Windows95 platform, over the past few years. The aims of this project were to: determine the types of games enjoyed by undergraduate Biology students; evaluate student opinions regarding computer games; develop a game (based on criteria identified by students); and assess the role that such a game could play in teaching students. Students evaluated four commercial games (Sim Isle, Red Alert, Zork Nemesis and Duke Nukem). Results suggest that they prefer 3D-adventure (Zork Nemesis, top-scorer) and strategy (Red Alert) games to other game-types ("shoot-em-up" or simulation). A 3D-adventure game on human evolution was designed, developed and used as part of a first-year Biology practical session. While student learnt equally from the game and the traditional practical material, they found playing the game more enjoyable. Games appear to motivate students intrinsically and represent one of the best uses of multimedia in education.

1. Introduction

Play, especially during early childhood, performs important roles in psychological, social and intellectual development, and could be defined as a voluntary activity that is intrinsically motivating, involves some level of activity (often physical) and may possess make-believe qualities [Rieber 1996a]. These attributes closely match those of modern educational theories where learning should be a self-motivated and rewarding activity.

The advent of advanced personal computer graphic systems has precipitated an explosion in game software. This million-dollar market produces many different kinds of games ranging from simulations through to first-person adventures. Here players are immersed into virtual worlds filled with stunning graphics, compelling, if not additive, story-lines, sound and video. However, many question the social consequences of this new form of entertainment.

Some authors [McKee 1992; Billen 1993] argue that games affect cognitive functions, motivation and remove the player from the "real world". But, games appear inherently to motivate users intrinsically by stimulating due curiosity [Thomas & Macredia 1994]. This may be due to the challenges and elements of fantasy [Malone 1980; 1981a,b]. Carroll [1982], Malone [1984] and Malone & Lepper [1987] argue that intrinsic motivation is also a result of the novelty and complexity of games.

Simulations games, in preference to other game-types, are often used in educational environments as students can be focussed on single goals, there is decreased competition between students and allows them to explore or experiment at their own pace [Roberts 1976]. However, such simulation games are based on the concept that students need to engage in real-world activities and fail to acknowledge that play is part of our everyday lives, it is not the opposite of work as is leisure [Blanchard & Cheska 1985], and appears to be a universally accepted mode of learning.

Games represent one way in which learners can be emersed into constructivist microworlds. Here, users do not study a particular domain but become part of the scenario, thus stimulating interest and motivation. Microworlds differ from simulations in that they present the user with a simple domain that can be reshaped by the user to explore complex ideas [Rieber 1996b]. Also, self-regulation is an important aspect of microworlds. Such learners appear to be intrinsically motivated [Malone & Lepper 1987], metacognitively active, behaviourally active and self-evaluating [Rieber 1996b]. Rieber believes games, rather than simulations, may provide a meaningful way to present microworlds to learners.

The aim of this project was to evaluate the role that games could play in education. The research was broken down into three phases: (1) Identification of attributes, or game characteristics, enjoyed by students; (2) Development of a game containing aspects of human evolution; and (3) Evaluation of this game in a teaching environment. This paper reports on the evaluation of four commercial games by biology students. Here, student opinions with regard to game attributes, including racism and sexism, were obtained using a questionnaire.
Students also ranked the games according to the enjoyment and were asked how such games could be used in education. A Myst-like game was developed that includes exploration of human evolution in a virtual setting. Students played the game prior to a practical session where they were presented with problems related to human evolution. Each phase of the project will be discussed separately.

2. Evaluation of Commercial Games by Biology Students

2.1. Introduction
The objective of this part of the study were to: (1) Determine the type of game enjoyed by the majority of our students; (2) Identify game elements, or attributes, appropriate for South African students; (3) Create awareness of the racists or sexists elements, if present, of games; and (4) Evaluate student opinion relating to the use of games in education.

2.2. Research Methodology
Outline: Four games, representing different types, were played by a small group (n=20) of first and second year Biology students. Each game was played for about one hour and for each game the student completed a questionnaire. In addition, students provided some demographic data.
Student Selection: All first and second year Biology students were invited to participate in the project. From these applications we selected a group of 20 students made up of an equal proportion of the different race groups and an equal number of male and female students.
Game Selection: Four games were selected and included Command and Conquer: Red Alert (strategy) by 3D Realms; Duke Nukem 3D ('shoot-em-up') by Westwood Studios; Sim Isle (simulation) by Maxis; and Zork Nemesis (adventure) by Activision. All games were played under the Windows 95 platform.
Questionnaire: The students answered question regarding to their computer experience and a series for each game. Computer literacy was assessed from questions on experience, how often students used computers and for what they used computers. In this section we also asked them to rate the four games. Questions on each game attempted to ascertain whether the game was captivating or addictive, presented challenges and/or contained racist or sexist elements. Also students identified attractive game properties and suggested how such a game could be used in education, what strategies they used to solve problems and if they acquired new knowledge and or skills. Two types of questions were used: ranking (1 to 4) and open-ended. The time spent on each game and the level, or stage reached, were also noted by each student.
Analysis: Ranking questions were calculated as the mean score out of four (maximum). To determine differences in responses by gender, or by race, the Kruskal-Wallis one-way Anova [SPSS] was used by grouping all the questions relating to each game (n=60).
2.3. Results and Discussion

Of the 20 students who participated in this part of the project, half were female, with an equal distribution among White, Black and Asian. The average age was 19 with most of them having very little computer experience and little exposure to playing computer games. Most students used computers for doing class assignments or for obtaining information. A few students did appear to spend some time playing games.

To determine the type of game elements most appreciated by the students we asked them to rate the games according to the fun aspect, sounds and graphics, type of game, game story and use of technology. Zork Nemesis scored the highest in all aspects, closely followed by Red Alert, Sim Isle, on the other hand, was rated poorly by the students [Fig.1].

As a number of different skills are required to play games, students were asked to assess the importance of some skills (logic, memory, visualization, and mathematics, reflexes and problem solving). The game that required the widest variety of skills was Zork Nemesis followed by Red Alert [Fig. 2]. Few of the games required mathematical skills, while reflexes were necessary in Duke Nukem and problem solving was rated highest for Zork Nemesis and Red Alert [Fig. 2].

Students were also asked whether the game was easy to play, addictive, too long, challenging, confusing, too difficult, illogical, difficult to play or manoeuvre and if their performance increased with continuous play. Except for Sim Isle, students were able to play the games successfully (see too easy and too difficult); found them addictive, challenging and not boring; were not totally confused; and found that practice makes perfect [Fig. 3].

![Figure 3. Evaluation of game play by students.](image)

Generally students appeared to enjoy Zork Nemesis and Red Alert the most, and did not enjoy playing the simulation game Sim Isle. The student ranking of the different games supports this conclusion (from best to worst: Zork Nemesis → Red Alert → Duke Nukem → Sim Isle).

Statistical analyses of student opinions according to gender, or to race, showed no differences. It appeared that males played the games longer than did the females and therefore completed more of each game.

Students were also asked two open-ended questions dealing with sexism and racism in the games. Only 15% of the total sample indicated that there was evidence of sexism in the games. For Zork Nemesis comments that there was "no character stereotyping" and that "the main character could have been female" was made by one student. Duke Nukem elicited the greatest response with four students making comments. The most evident response was that of degrading, pornographic portrayal of women (expressed by both male and female students). This game was also seen as being "male dominated with rough, violent behaviour". The theme of Red Alert was seen as some what male-orientated but did have both a male and a female in the leading role. No sexism was found in Sim Isle.

Few students commented on racism in the games. However, those that did, showed insight into the underlying cultures that are represented by these games. Duke Nukem was seen as the most racist ("all the
characters were white"; "villains always seem to be dark skinned than the main player or 'hero'"; "hero that wasn't white would be a welcome change"). In Sim Isle "agents were white .. making decisions about island" and "three out of 25 agents were non-white". Characterisation in Zork Nemesis was seem as appropriate "seeing someone of different colour would have made the game difficult to believe" as the game is based on "white's beliefs" and "wizards". Only one comment was made with respect to red Alert: do "not see any blacks or non-whites in the game".

Generally students enjoyed Zork Nemesis and Red Alert the most. The game requiring the greatest skill was Zork Nemesis. The game least liked was Sim Isle. There appears to be little different between how male and female students viewed the games and the responses according to race groups were similar. These result also suggest that simulation-type games are not appreciated by our students. Therefore, based on these results, we used the 3D-adventure genre to develop a game to solve particular educational needs.

3. Game Development

Outline: In consultation with departmental subject experts, a story line was developed based on the adventure-type game. The pilot game was authored to run on the student LAN (Windows 3.11), but is designed in such away that 3D-virtual worlds can be created for the Windows95 platform.

Technology: Graphics were created in 3D-Studio Max (Kinetics) and the game-engine in Delphi (Borland). When necessary, graphics were edited in Photoshop (Adobe). The game was created using tools that added navigation and other elements to each game page and created the game files. The game player was programmed to read and display these game files.

Basic Story: The player is sent to an island that has been evacuated because of a viral infection. Here, within a single museum-like building the player, wearing a biohazard suit, explores the different levels to discover clues and objects that will be used to create an anti-viral protein in the final episode of the game. In the pilot program only one such level has been built. In the helmet of the biohazard suit the ambient temperature and oxygen levels are also displayed. During game play the temperature changes, depending on the location of the player and the oxygen level decreases with time. Also, e-mail messages are sent to the player. The control panel, at the bottom allows the player access to e-mail messages and the collected objects. The basic design of the game interface in shown in Fig. 4.

![Figure 4. Interface of the game showing a view through the helmet of the biohazard suit.](image)

4. Use of Games in Education

4.1. Introduction

To evaluate the role that games can play in the teaching of Biology, a first year student practical session was redesign to include two elements: (1) Playing of the game; and (2) Practical work on problems relating to human evolution. To determine student knowledge a pre- and post-game test was used. Student attitudes with respect to this activity were obtained using a questionnaire.
4.2. Research Methodology

Outline: Before the start of the two practical sessions, Environmental Biology 1 students (n=58) were asked to complete a number of multiple-choice questions on the evolution of man. During the first practical session students played the game, developed by the research group, for a minimum of 2 hours. In the second session students were presented with a number of practical problems that they had to solve. Thereafter, the students answered the same multiple-choice questions.

Pre- and Post-game Tests: Here knowledge obtained from the game, practical handout and practical session was assessed. Individual students were scored on their success in answering the questions.

Questionnaire: Opinion relating to the use of a game to help in the teaching of human evolution was obtained from the students by means of a short questionnaire.

4.3. Results and Discussion

To assess the use of the game as a viable teaching method, students answered a number of multiple choice questions testing knowledge provided either by the game or during the practical. The mean and standard deviation for the pre-test was 44.13±12.27 and for the post-test 60.07±12.48. While not significantly different, student did perform better in the post-test. Test questions related to knowledge learnt from the practical material or game were separated and plotted as the difference in mean percent for each question (Fig 5). Students appeared to learn information equally from both forms of material (no significant difference between groups, t-statistic: 0.24).

![Figure 6. Rating of Zadarh aspects by students.](image)

![Figure 7. Assessment of skill required to play Zadarh by students.](image)

Game evaluation was by means of a questionnaire similar to that used for commercial games. Students were asked to rank Zadarh according to their impressions [Fig. 6] and skills required [Fig. 7]. Rating scores were similar to Red Alert but not as good as for Zork Nemesis (see Fig. 1 and 2).

Table 1. Student answers to the question: "What was your motivation to play the game?".

In addition, we asked them if the game improved their understanding of the course material, if it is a good
idea to include games in courses (3.2), if games made learning more fun, if they would prefer written material and if the game allowed them to explore and learn at their own pace. The scores, out of a maximum of 4 were 3.0, 3.2, 3.2, 2.4 and 3.1 respectively.

Two open ended question were asked. The first: "What do you think you learnt about human evolution while playing the game?" elicited a variety of answers with "Phylogenetic grouping and origination" and "Facilitated understanding" being the most popular. When asked what their motivation was in playing the game a number of answers were given [Tab. 1]. The majority of the student appear to be intrinsically motivated to play the game, except 20% who stated that they played the game is was a course requirement.

These results suggest that student enjoyed playing an educationally based game, appeared to be motivated by the "fun" aspects of computer technology and gained knowledge.

5. Conclusions

First and second year biology students appear to favour 3D-adventure (Zork Nemesis) and strategy games (Red Alert), were critical of the racism and pornographic elements in the first-person "shoot-em-up" Duke Nuken and found the simulation game Sim Isle unsatisfactory. The development of an adventure game by the research group was used to test the applicability of such technology in education. The pilot project on integrating information into an adventure type game was enjoyed by most students and they also learnt knowledge while playing.

Acknowledgements

We wish to acknowledge research grants from the University of Natal Research Fund and Foundation for Research Development, and to especially thank Mr Richard Devey for his help with the statistical analyses, Dr Rob Slotow and Professor John Cooke for their expert help, and Professor Pat Berjak for careful reading of the manuscript.

Abstract. Equitable computer collaborations in mixed gender teams have been a pressing issue for many years. While some have argued for creating single-gender teams or girls-only computer activities, our approach was different. The current study examines a three-month software design activity in which mixed teams of girls and boys [10-12 year olds] designed and implemented multimedia astronomy resources for younger students. In this context we assessed how students' levels of access to technology were impacted by gender differences at the project outset, and how these participation patterns changed throughout the project duration. We found that the documented positive change in girls' access was impacted by the configuration of social, physical, and cognitive "spaces" in the project environment. We discuss the implications of these results in regard to issues surrounding the development and maintenance of gender equity in computer use and further research.

As recent research has shown, the road toward becoming technologically literate and scientifically competent has been a "leaking pipeline" for girls and women in particular, from the elementary schools where girls feel disenfranchised in science and technology, to universities where fewer female students choose science and engineering majors [Camp 1997]. A variety of explanations have been offered for this trend, ranging from different attitudes toward computers [Shashaani 1994] and different levels of participation in computer and science courses [Chen 1985; Linn 1985], to cultural and social conditions found in the respective domains [Sadker & Sadker 1994] and different representations of women in media publications [Heller, et. al. 1994]. While each of these variables alone or in combination have an impact on situating girls' interactions with computers, we examined more closely girls' access to computer resources in classroom activities and collaborative groups. With the increasing use of computers in classrooms, there remains the issue of whether all students participate equally and receive equal benefits. We were particularly interested in identifying the kind of activities and support structures that can be used in helping girls break down barriers to technological access and expertise in a variety of mixed-gender settings.

Toward that end, we investigated students' activities and collaborations during a three-month long computer project. In this project mixed-gender teams of fifth and sixth graders used Logo Microworlds™ in their classroom to design multimedia encyclopedias about their astronomy unit for use by younger children. We paid particular attention to the status of girls in these mixed-gender teams—their status positions at the outset, the change most girls experienced in going from low status to high status designers, and the means by which these changes were accomplished. In examining this last factor, we outline several support structures which emerged over the course of two projects to address girls' needs. Finally, we conclude this paper with a discussion of the implications of our findings for developing gender equity in educational technology use.

Theoretical Background

Many girls are not receiving the same kinds of opportunities to become technologically skilled as boys are [e.g., Wellesley College Center for Research on Women 1994]. Boys develop alliances with computers largely due to their extensive out-of-school computer experiences. Boys are more likely to attend summer computer camps than
girls, more boys than girls have their own computers at home, boys play more video and computer games than girls do, and boys are more likely than girls to see themselves depicted as male main characters in these games [Sadker & Sadker 1994]. These factors relating to amount of experience with computers have a significant effect on students' attitudes and perceptions. In a survey of high school students, boys had higher ratings than girls on all of the following: perceived competence with computers, positive attitudes toward computers, and perceived utility value of computers [Shashaani 1994].

Gender differences also arise when boys and girls use computers in the school context, even though so-called 'equal opportunities' may be presented. Studies of computer use at school have found that when computers are used during class time, boys tend to dominate computer space [Sadker & Sadker 1984]. In observations of student dyads working on the same computer, boys were shown to use more aggressive tactics to gain control, such as grabbing the mouse and pulling it away from their partner. Girls used more 'non-contact' methods such as verbal requests [Inkpen, Booth, & Klawe 1991]. Boys also are more likely to initiate and maintain control of school computers during non-classroom hours such as lunch time and before or after school [Canada & Brusca 1991].

Studies have shown, however, that when girls have as much exposure or interactions with computers as boys do, gender differences tend to disappear [Linn 1985]. In learning situations in which children can work on computers at their own pace and engage with tasks according to their interests and styles, girls tend to be as proficient as boys in programming [Harel 1991; Kafai 1995]. Giving opportunities for access thus seems to be a crucial aspect in overcoming the widespread gender differences as well as finding computational activities that appeal to both genders [Spertus 1991]. Access, however, is often hard to come by---both in activities with computers and those without.

Even when computers are not involved, putting students in mixed-gender teams for collaborative work can result in very different experiences for boys and girls. Research shows that gender is often a strong predictor of status in heterogeneous groups; thus, girls' contributions to group work end up being less valued than boys' [Cohen, 1994]. These gendered interaction patterns sometimes have consequences for girls' ability to make the most out of collaborative work, as evidenced by subsequent knowledge assessments [Webb 1984]. Even when academic achievement is not affected by these differences in interaction, girls' self-esteem and interest in the subjects in question may suffer [Wilkinson, Lindow & Chaing 1985].

It appears that bringing together collaborative work situations with computer use amplifies some of the gender issues found in either situation alone. In attempting to ensure that girls will have the opportunities they need, some researchers and practitioners have taken the approach of providing "female only" environments. Whether this means pro-active technology intervention programs that are exclusively for girls [Martin & Heller 1994] or forming single-gender collaborative groups in after-school computer clubs [Wood 1996], the assumption in most cases is that girls will have a more positive experience in the absence of male computer users. While these programs represent important steps in introducing girls to technological activities, we find that eventually girls will have to learn how to negotiate access in mixed-gender settings. Our aim in this project was to find out how girls [and boys] might react to the challenge of working with programming technology in mixed-gender groups in a classroom setting. Based on the existing research, we anticipated that at the outset of the project girls would occupy lower-status positions in their groups; however, we hoped that through careful attention to addressing their needs in the project, girls' status would change.

Research Participants, Context, and Methods

The software project from which our gender study comes is based on the model of 'learning through design,' in which students simultaneously learn new information and design a relevant product reflecting their knowledge [Harel 1991; Harel & Papert 1990; Kafai 1995]. The project took place in an urban elementary school that functions as the laboratory school site for UCLA. The participating classroom was equipped with seven computers, one of each was set up as a workstation for the seven table clusters. Additional seven computers were in an adjacent room and were mostly used for related Internet searches.

An integrated class of 26 fifth and sixth grade students participated in this project. There were 10 girls and 16 boys of mixed ethnic background (19 Caucasian; 2 Hispanic; 3 African-American; 2 Asian) ranging between 10 and 12 years of age. With the exception of 10 students—8 had participated in another design project.
the previous year and 2 knew programming from home—none of the other students had any programming experience before the start of the project. All the students had used computers in school and were familiar with word-processing packages, graphics software, Grolier's Multimedia Encyclopedia™, and searches on the WWW.

Heterogeneous groups of 3 to 4 students each were arranged in seven teams according to the following criteria: one “experienced” designer who had participated in the previous design project, mixed gender, and different academic skill levels. Over the course of several months students created their own research questions about astronomy, researched these questions using various sources, and represented their findings in a group software product. Students worked 3-4 hours per week on the project for a period of 3 months spending 46 hours in total, of which 23 hours were dedicated to programming. Science instruction and programming time were combined. Groups were videotaped regularly and their activities were documented via fieldnotes on a daily basis.

Defining Status

In most previous studies of collaboration, groups of students are engaged in a single task such as solving a math problem or writing a story. In the learning through design environment, however, the final task of making a multimedia encyclopedia requires many different kinds of activities in order to be accomplished. Observations led to the conclusion that students' own conceptions of status in this more complex environment were based on what activities were most desirable and who had the most opportunity to do them. Activities were classified into the scheme in Table 1 via the first author's observations of student arguments over "who would get to do ___ today" and conversations with students about the desirability of certain activities.

For data analysis, students received status codes based on whether or not they typically engaged in high, medium, or low status activities. Fieldnotes and videotapes taken during two time periods were coded. The first time point [T1] was after the first 3 weeks of the project, and second time point [T2] was approximately two weeks before the end of the project. On each day during the two selected time periods, students' activities were catalogued and coded according to Table 1. For each instance a particular student was present in a set of fieldnotes or tape on a given day, he or she received a 3 for engaging in one of the high status activities in Table 1, a 2 for medium status, and a 1 for low status. Sets of notes and videotapes were then aggregated, and students received a single status score for the aforementioned two time segments. We then conducted multiple regression analyses to determine what factors predicted status at T1, predictive factors at T2, and change in status levels over time.

Results

Gender and Status

The factors of age, gender, previous design/programming experience, and academic achievement were analyzed via multiple regression for their predictive value for status at T1. Gender was the only significant factor [p < .001]. Statistical results confirmed what we had observed during student work time: a significant number of girls were engaged in low status activities which afforded little access to new technologies.

Students' status levels did not stay the same throughout the project. At T2 status was measured again and found to be not significantly correlated with status at T1 [Pearson correlation = .1880; p > .100]. Furthermore, the composite of leadership and gender was not significant as a predictor of status at T2 [p > .05]. Girls’ status, in particular, changed greatly from T1 to T2 [see figure 1]. While at the beginning of the project all but three girls had low-status group roles affording very little computer access, at time 2 the majority of girls were engaged in high status activities. Girls were seen taking more leadership roles in demo sessions and programming on the
computer more frequently. It appears that the software design project provided girls an opportunity to change the pattern typical of girls in mixed-gender teams of remaining low status throughout the duration of group projects.

Figure 1. Changes in Status Over Time for Each Gender

Give Girls Some Space

So how did these status changes for girls take place? Status changes began gradually occurring as features were added to the project to address girls’ emergent needs. We refer to the process of changing the classroom design studio to reflect diverse needs as “creating spaces” on the social and physical planes of the environment. Within these “spaces,” girls (and some boys as well) found contexts which were more compatible with their own ways of interacting, working, and thinking than they had encountered in the initial structure of the design environment. In this next section, we describe the “spaces” that were created, and we discuss how they emerged and their subsequent effects on girls’ attitudes and behavior in the design project.

Social Space

Early in the design project, the task of organizing and reporting on groups’ progress toward product completion was assumed by girls. This task required talking to everyone in the group about what activities they were engaged in and what their goals and plans were. Girls experienced frustration with this activity, due to the fact that many boys did not want to sit down and discuss anything if it took time away from programming. Girls were also concerned with resolving interpersonal problems within teams right away when they arose, whereas boys focused more on getting computer work finished and would keep right on working and ignore problems that came up, even to the extent of not listening to girls when they attempted to talk about these issues. After observing these interactions for several weeks, we saw a need for a specific “space” on the social plane of the design project which could be an appropriate time and place to air personal conflicts and frustrations in a safe and mediated environment.

Our solution was to create group meetings which were mediated by either the classroom teacher or a researcher. These meetings occurred about once every 10 days. Students were told that each person in the group would have a chance to say what was bothering them and then the whole group would address each issue. We found that while we had initially instituted the sessions to ensure that girls would be listened to by boys in airing
their complaints, boys also had many issues they needed to work out, but which they hadn't been addressing during computer work time. Issues the boys were upset about concerned Internet use for legitimate research versus "surfing" for fun, ownership and piracy of ideas, and accusations of "goofing off." All groups came to some resolutions through these discussions, and most boys and girls subsequently reported that there were less conflicts in their groups as a result of the meetings. Thus although the "social space" of group meeting time was initially created as a place to address girls' concerns, boys benefited from this development as well.

**Physical Space**

The majority of computer environments take the form of individually segregated workstations; this arrangement tends not to appeal to girls and their preferences for a work style characterized by more social networking [Canada & Brusca 1991]. In our design project the group stations were spread throughout the classroom, making it difficult for students in different teams to communicate with one another without leaving their seats. We found that when girls had opportunities to work at the classroom computer workstations, they often got much less accomplished than boys did in the same amount of time due to frequently showing off their new work to friends and getting up to view one another's screens. Thus the arrangement of physical space in the classroom seemed to be holding girls back--until they changed it.

The physical arrangement of the lab was such that computers were lined up in rows right next to each other along the walls, rather than being spread out. Girls began moving files back and forth from lab computers to group workstations via file sharing or floppy disks. Upon seeing how well this arrangement worked for those girls, coupled with the fact that most students had finished the research phase of their work, we opened up the lab for regular Microworlds use. Changes took place almost immediately. Rather than waiting to be told what to do by boys and whether or not they would be allowed to work in Microworlds for the day, instead many girls often grabbed their floppy disks and headed off to the lab with a long list of things they wanted to accomplish on their own.

Creating a new "space" on the physical plane of the design environment in which to do programming allowed individuals to work and help one another in the way they felt most comfortable. Most boys worked at their own individual stations, which were spread out across the classroom, and would call one another over for help with specific things. Many girls (and a few boys), on the other hand, worked collaboratively and used the space in the adjacent computer lab, so they could talk and give programming/design advice by glancing over at one another's screens while they were all working together. This arrangement seemed to encourage those involved to stay on-task longer and develop innovative ideas so they could be shared with the rest of the community. Thus the addition of another "space" in which to program allowed students of either gender to find a workplace which was compatible with their own preferences.

**Discussion**

In our analysis of results, we paid close attention to the various factors that helped girls change their status. In the following discussion we want to address several key issues in designing and implementing computer-based learning environments, consideration of which can help support girls and boys equally in their learning endeavors.

**Timing of Interventions**

One issue that needs to be addressed concerns the place and timing of interventions. Previous intervention models such as science and technology after-school programs and summer camps try to reach out to female student populations in high schools and colleges. These are important programs, but we hold that the timing of such interventions is too late, considering that girls form many beliefs about themselves and subject domains during the elementary school years. For that reason we propose to situate interventions much earlier in development, thus providing younger girls with opportunities to interact with advanced technologies and science in substantial ways. Furthermore, we find it important that girls are not only introduced to technology as consumers; hence our focus on students as producers of software artifacts such as multimedia resources or software games [Kafai 1995].
New Era, New Questions

Education is currently in the throes of a trend in project-based learning [Blumenfeld, et. al. 1991] for computer use to be integrated into long-term, multifaceted projects such as the one documented here. Computers no longer reside solely in a distant laboratory, with few if any ties to other classroom activities [Kafai 1995]. These new developments have staggering implications for the way we think about gender and computer use. If girls have little access to computer resources in these integrated classroom settings, they not only miss out on the opportunity to develop technological literacy, but they also risk missing out on learning other subject matters being mediated by computer use as well. Even when it appears that girls are spending an equal amount of time in front of the computer, advocates of gender equity still should not be entirely at ease. In our project, which was supposed to provide students with creative and innovative opportunities, girls’ initial computer work consisted mostly of word processing and consumer-based use of software encyclopedias. These results are cause for concern. We are reaching a point in gender and technology research where the issue may no longer be about if girls are using the computer but rather how are they using it. Results from our study confirm this, in that there was an initial division of labor where boys dominated all of the available ‘cutting edge’ technology such as the Internet and the programming software. Through creating new spaces in the environment to address girls needs, we found ways to alleviate male domination of technology and provide opportunities for girls to gain access. We would also argue that such measures are not only helpful but necessary to continue to address issues of gender equity in technology environments.

The Digital Lecture Board - A Teaching and Learning Tool for Remote Instruction in Higher Education

Werner Geyer, Wolfgang Effelsberg
Lehrstuhl für Praktische Informatik IV
University of Mannheim, Germany
{geyer, effelsberg}@pi4.informatik.uni-mannheim.de

Abstract: This paper presents a novel, integrated teaching and learning tool - called digital lecture board - which takes into account the requirements of synchronous, computer-based distance education. For almost two years, the Tele Teaching project Mannheim-Heidelberg has been using video conferencing tools for transmitting lectures and seminars. These tools prove to be insufficient for the purpose of teleteaching since they are not powerful enough to support team work, they are not flexible enough for the use of media, and are somewhat difficult to handle by non-experts. We discuss shortcomings of the existing tools and disclose features we had in mind while designing the digital lecture board. Embedded in a teaching and learning system, the digital lecture board even allows for asynchronous usage modes, for instance, the preparation of lectures. Moreover, we cover implementation issues of the current prototype.

1 Introduction

The advent of powerful hardware and advances in high speed networks enabled synchronous learning, with teachers and students being geographically distributed but connected via computer networks. Compared to traditional distance learning, this allows for a higher degree of interactivity and collaboration but still entails crucial drawbacks compared to the traditional classroom situation. Today’s synchronous learning systems are mainly based on video conferencing technology which provides audio, video, and joint editing of documents only, but does not take into account the specific requirements of teaching, for instance, controlling the course of instruction, raising hands, or reference pointing. A shared whiteboard for transmitting slides is often the core part of these systems but mostly also the bottleneck, since the teacher is forced to tailor his or her course to the limited features of the whiteboard software. The digital lecture board presented in this paper is a novel, integrated teaching and learning tool which is basically an extended whiteboard tailored to the needs of synchronous teleteaching.

2 Background

The development of the digital lecture board is based on the experience we gathered in the TeleTeaching project Mannheim-Heidelberg. The project aims at an improvement in the quality and the quantity of lectures by using multimedia technology and networks for the distribution of lectures and seminars. We have implemented three different instructional settings - as indicated in [Fig. 1] - which are characterized by their scope of distribution, interactivity, and individualization of the learning process.

In the Remote Lecture Room (RLR) scenario, audio/video-equipped lecture rooms are connected via a high speed network, and courses are exchanged synchronously and interactively between participating universities. Remote Interactive Seminars (RIS) are a more interactive type of instruction where small groups of participants are distributed across seminar rooms connected by a network. RIS focuses mainly on the co-operative, on-line construction and presentation of reports. Interactive Home Learning (IHL) copes with maximal geographical distribution of all class participants: Each student learns asynchronously as well as synchronously at home in front of his/her PC. Obviously, the IHL scenario makes the greatest demands on technology (e.g. low-
bandwidth transmission of video) and pedagogy (e.g. controlling the course of instruction and/or human interaction). For a description of pedagogical, organizational, and technical issues of the project refer to [Eckert et al. 97].

Figure 1: Instructional settings in the TeleTeaching project Mannheim-Heidelberg.

So far, we have been using the Internet and the MBone video conferencing tools vic (video conferencing tool), vat (visual audio tool), and wb (whiteboard) for remote lecturing [Macedonia & Brutzman 94]. Observations, surveys and interviews with the students and lecturers during the last two years indicate that these tools can provide satisfactory results if the lecturer adapts the layout of the lecture exactly to the limited features of these tools, but are far from optimal for teleteaching since they have not been designed for this purpose. This concerns specifically the whiteboard which can be considered to be a substitute for the traditional blackboard. Along with audio, the whiteboard is most important for conveying knowledge to distributed participants. In order to overcome the weaknesses of the whiteboard, we decided to develop the digital lecture board (dlb) which will better satisfy the needs of the instructional settings RLR, RIS, and IHL.

3 Design Considerations

In this Chapter, we present, in more detail, the shortcomings of the existing MBone tools [1], and we discuss the most important features which we had in mind while designing the dlb.

- **Integrated User Interface**: The MBone tools do not provide an integrated user interface. Teachers and students complained about many confusing windows and control panels which are not important for learning and teaching but make it more difficult to operate the tools. Since teleteaching at the university level should not be restricted to computer experts, we find it especially important that the dlb provides an easy-to-operate user interface which integrates also audio and video communication. Moreover, in order to allow the interface to adapt to different instructional settings, it should be configurable. RLR, for instance, mainly focuses on presentation of knowledge to passive receivers and, therefore, receivers do not want to see tool or page selecting options on their screens.

- **Media Usage and Handling**: The MBone whiteboard wb is very limited concerning the use and handling of media: only postscript and plain ASCII text are supported as external input formats, and later editing (besides move, copy and delete) of the built-in graphic and text objects is not possible. In addition, wb does not support joint editing of these objects. For instance, it is impossible for a distributed group to create a common text, or to modify objects created by different participants. Since media are very important for a modern instruction, the dlb should support a variety of media formats such as GIF, JPEG, MPEG, AVI, HTML, AIFF etc. as well as many built-in object types such as lines, rectangles, circles, freehand drawings, text etc. Technically, objects are required to be editable by every participant and the dlb should provide functions like select, cut, copy, paste, group, raise, lower etc. similar to a word or graphic

[1] The described shortcomings are not limited to the MBone video conferencing tools but concern also other systems like NetMeeting, CUSeeMe, ProShare, etc.
Workspace Paradigm: The shared workspace of wb is limited to a two-layer concept with a postscript slide in the background and drawings and text in the foreground. It is, for instance, not possible to render two different postscript slides onto a single page so that results of two distributed work groups may be compared. Moreover, wb adheres to the strict WYSIWIS (What You See Is What I See) paradigm. Thus, participants cannot have a private workspace where they can prepare materials, for instance, when doing on-line group work. Teleteaching software requires a more flexible workspace concept with multiple layers where arbitrary media objects (audio, video, images, animations, etc.) can be displayed, grouped, raised, lowered, etc. Single participants or small groups should be offered private workspaces (invisible to the rest of the whole group) in order to allow for modern types of instruction such as group work. The outcome of the group work can be transferred to the shared workspace so as to allow a wider discussion of the results.

Collaborative Services: Today’s teleteaching systems suffer a lack of communication channels compared to the traditional face-to-face instruction, since most systems support only audio, video, and joint editing of documents. Social protocols or rules control the human interaction and the course of instruction in a classroom. These mechanisms are difficult to reproduce in a remote situation and include, for instance, raising hands, giving rights to talk or to write on the blackboard, setting up work groups, and reference pointing. Collaborative services provide mechanisms to support the communication of persons through computers and to increase social awareness. Basic services such as floor control, session control, telepointers, or polling should be supported by the dlb. A detailed analysis of collaborative requirements in teleteaching indicates that the following situations should be supported by computer-based teaching and learning systems [Hilt & Geyer 97]:

- Joining a session at the beginning or later
- Leaving a session at the end or earlier
- Removing a participant from the session (e.g. by the moderator)
- Raising hands (signaling)
- Drawing back signals
- Removing signals by the moderator or teacher
- Selecting participants (with and without signal)
- Selective granting and removing of permissions (floors)
- Returning own permissions
- Pointing to shared instructional materials
- Creating, joining, and closing sub-groups (for group work)
- Private discussions and co-operation
- Nominating moderators for sub-groups
- Surveying sub-groups and participants (super user role of the moderator)
- Granting of permissions (floors) for work areas and materials to sub-groups
- Accessing work areas and materials without a moderator in order to enable internal group discussions

It is interesting to note that most of the computer-based tools for remote instruction are ignoring these types of interaction completely. In the dlb project, we attempt to build, and experiment with, electronic surrogates for social protocols.

Synchronized Recording and Playback of Sessions: The dlb should also provide the possibility to record a transmitted lecture or course which can then be stored on a server for playback. Students will then be able to retrieve the lecture in order to review certain topics or the complete lecture if they have missed it. Recording should include all transmitted data streams, i.e. audio, video, whiteboard actions & media, telepointers, etc. In order to achieve a synchronized recording, data has to be time-stamped. The data streams could then be recorded by existing systems like the VCRoD service (Video Conference Recording on Demand) [Holfelder 97]. These systems rely on the Real-Time Transport Protocol RTP for synchronized recording [Schulzrinne et al. 96]. The current release of the MBone whiteboard wb does not support the RTP standard.

Storage and Retrieval of Pages and Teaching Materials: Lectures or courses given with the computer need to be prepared in advance, i.e. producing slides, images, animations, etc. The preparation of materials with the MBone whiteboard is limited to a list of postscript files which can be imported by mouse click.
during a running session. In order to allow for a better preparation of on-line lectures and for saving results after a lecture, the dlb should support storage and retrieval of pages and objects in a structured, standardized file format such as SGML. Dlb documents would then be readable and modifiable by the human user or by other programs (e.g. a viewer software for lectures). Moreover, it would also be desirable for the dlb to have access to a multimedia database which stores teaching and learning materials of teachers and students. Such databases are also a research issue in our TeleTeaching project [Eckert et al 97].

- **Network Transmission**: Scaleable and efficient transmission of data to a group of participants is only possible using multicast. Since we rely on the Internet for remote lecturing, we need to employ the Multicast Backbone (MBone) for multicast data delivery, as do the MBone tools vic, vat, and wb. Basically, multicast IP is an unreliable, packet-oriented protocol. In contrast to audio and video data, lecturing materials need to be transmitted reliably. Following the ALF concept (Application Level Framing), wb implements reliability within the application [Floyd et al. 95]. We think that separating the reliability issue from the application is a more appropriate approach for our dlb since this eases implementation and also allows other applications to use reliable transport services. Another important issue is security. We believe the dlb should support encryption in order to allow private sessions and billing. Prior to joining a specific course, students would have to register in order to receive an access key.

4 **Usage Modes in a Teaching and Learning Environment**

A teaching and learning environment consisting of a full-featured dlb (according to [Design Considerations]) along with a recording facility (e.g. the VCRoD service), a multimedia database for teaching materials, a WWW server, a VCRoD editing tool, and a WWW dlb document viewer would allow for several synchronous and asynchronous usage modes [Fig. 2].

1. **Preparation/Pre-Authoring (asynchronous)**: Teachers and students use the dlb for the preparation of material for the synchronous teleteaching mode. They may access a multimedia database (MDB) or a local storage device (ls) for the retrieval of multimedia material needed for teaching and learning. The outcome of this mode is an off-line dlb document which can be, for instance, a complete presentation for RLR, a small report prepared by students for RIS, or a piece of group work for IHL. The dlb document can be stored locally (ls) or on the multimedia database (MDB).

2. **Transmission/Teleteaching (synchronous)**: The prepared dlb documents are used as a basis for synchronous teleteaching in the three instructional setting RLR, RIS, and IHL. The material is transmitted to the entire class. Teachers and students can then employ the advanced synchronous features of the dlb such as, for instance, reference pointing (telepointer), forming sub-groups (session control), annotating (drawing tools), controlling the course of instruction (floor control), on-the-fly development and import of
materials (drawing tools and access to Is or MDB), or discussions (audio and video). The result of this mode is on the one hand a modified dlb document which can be stored by both teachers and students in order to save results. On the other hand, the VCRoD service allows for the recording of the complete teleteaching session including all media streams (audio, video, telepointers, dlb actions, etc.).

3. Revision/Post-Authoring (asynchronous): Based on the materials obtained from the transmission mode (dlb document and VCRoD recording), a complete multimedia document, enriched with further multimedia components (e.g. animations), can be produced by using the dlb, a VCRoD editor, or further authoring tools. The multimedia document can be distributed off-line by CD-ROM or on-line via WWW. Obviously, the advantage of this approach for authoring is that production time is considerably reduced since material obtained from usage mode 1 and 2 is basically a spin-off of synchronous teleteaching [2]. In addition to the publishing issue, students may also use the modified dlb documents of usage mode 2 in order to produce individualized, annotated lecture notes with the dlb, e.g. for the preparation of exams.

4. Retrieval (asynchronous): A light-weight WWW dlb viewer can be employed for retrieving lecture notes (dlb documents) from a WWW server for the purpose of viewing and printing. Moreover, the VCRoD service offers students who missed the lecture or who want to review a certain difficult topic the possibility to playback recorded lectures (VCRoD recording) as originally captured. The VCRoD service supports random access, fast-forward and rewind to arbitrary parts of the lecture [Holfelder 97].

5. Implementation Issues

We have implemented a prototype of the dlb which fulfills most of the requirements mentioned in [Design Considerations]. Audio and Video are not integrated yet and a module for synchronized recording (VCRoD service) is in progress. Since the source code for the MBone whiteboard wb is not publicly available, we had to develop the dlb from scratch. To allow for a high degree of portability, we implemented the prototype in C++ and the Tcl/Tk scripting language [Ousterhout 94] and we took great care to reuse only components which are available on all major hardware/software platforms (e.g. ghostscript for rendering postscript pages). The current version has been successfully installed on the Unix systems AIX (IBM), IRIX (SGI), Solaris (SUN), and Linux (PC).

To satisfy the collaborative requirements of the dlb, we have developed a so-called collaborative services model (csm). The csm is implemented as a separated service application which can be accessed by multiple clients through a well-defined application programming interface. As indicated in [Design Considerations], collaborative services provide an electronic surrogate to compensate as far as possible for the lack of interpersonal communication channels. The csm implements enhanced floor control and session control mechanisms and policies. Floor control realizes concurrency control for interactive, synchronous cooperation between people by using the metaphor of a floor. A floor is basically a temporary permission to access and manipulate resources (e.g. a shared drawing area). Session control denotes the administration of multiple sessions with its participants and media. Session control increases social awareness in distributed work groups because members gain knowledge of each other and their status in the session. The csm keeps the collaboration state (the relationships between participants, floors, resources, and sessions) in a single object-oriented model. The model is replicated on each participant's workstation and held consistent by using an optimistic synchronization scheme. Applications using csm get either messages about the collaboration state or they can explicitly send queries to csm, e.g. to ask if the floor for drawing on the shared workspace is currently available. The csm supports the following features:
- Administration of participants, groups, sub-groups, and super-groups,
- management of resources and assignment to participants, groups, and sessions,
- participants with different roles and privileges (e.g. teacher, student, etc.), and
- different floor control policies (e.g. implicit control, explicit control, chair control, etc.).

For a more detailed description of the csm see [Hilt & Geyer 97].

[2] This procedure is very similar to the „Authoring on the Fly“ concept but differs in that our approach does not limit the recording to the teacher's actions [Bacher & Ottmann 96].
6 Related Work

Besides various existing video conferencing systems such as NetMeeting, CUSeeMe, ProShare etc., which provide audio/video transmission, application sharing and standard whiteboard features, we know of two approaches closely related to ours. The "Authoring on the Fly" (AOF) [Bacher & Ottmann 96] concept merges broadcasting of lectures with authoring of CBT software. With AOF, lectures are transmitted by means of an extended whiteboard to a number of receivers. Interactivity is limited to the audio and video channel, modifications to the transmitted material are not possible for receivers. Thus, collaborative types of instruction are not supported. The sender's (teacher's) media streams are recorded locally. The synchronized recording together with lecturer slides and additional media, such as animations, are then transformed to a CBT course which can be either published on a CD-ROM or accessed through the WWW. The Interactive Remote Instruction (IRI) system developed at Old Dominion University [Maly et al. 96] provides a very powerful, integrated teleteaching environment. The system can be used to view or make multimedia class presentations, to take notes in a multimedia notebook, and to interact via audio/video and shared tools. Furthermore, it provides class management and floor control. The system differs from ours in that IRI partly relies on analog transmission of NTSC video signals and that collaboration is limited to application sharing.

7 Conclusion

Experiences in the TeleTeaching project at the universities of Mannheim and Heidelberg indicate that standard video conferencing software is insufficient for the purpose of computer-based distance education. As a consequence, we decided to develop the digital lecture board (dlb), an integrated teleteaching tool, which takes into account the requirements of synchronous, remote instruction. The dlb supports multimedia presentations in RLR up to modern, collaborative types of instruction in RIS and IHL. As a part of a teaching and learning system, it allows for pre- and post-authoring of teaching and learning material. The current implementation presented in this paper already supports most of the envisaged features. In the upcoming semester, we intend to employ the dlb for a few trials in a distributed seminar for evaluation purposes. Future work will concentrate on the integration of audio and video communication in the dlb's user interface, and on extending dlb's media capabilities. Moreover, we also plan to work on integrating animation and simulation facilities.

Abstract: Multimedia allows for new forms and techniques of teaching. Modern educational material no longer only consists of text and some figures but also includes audio, video, animations and simulations. We decided to use Java in our distance learning projects because it becomes increasingly important in the World Wide Web. Although Java applets can easily be inserted into asynchronous material like hypertext pages, it provides no mechanisms to use it in synchronous scenarios. We therefore developed the Java Remote Control Tool with the help of which distributed Java applications and applets can be controlled and synchronized.

1 Introduction

During the last two years distance learning became an important application for the Internet. Since 1996 our institutes are exchanging complete lectures on regular terms by using the MBone technology (see Section 2). At the same time, several animations and simulations were developed and added to the educational material on our Web-servers. Because of its platform independency we decided to use Java for our animations and simulations. Furthermore, we wanted to put these applets into action during the teleteaching lectures. Since no means for distributing Java applets were provided in early 1997 we were forced to develop the Java Remote Control Tool which allows us to control and synchronize animations running on several distributed machines.

This paper is structured as follows: Section 2 gives an overview of the Tele-Teaching Project between the Universities of Heidelberg and Mannheim. Several scenarios that are to be implemented will be described shortly. Before explaining the architecture of the Remote Control Tool in Section 5, we briefly mention several projects related to our approach and discuss "Shared-X" as an alternative approach. Section 6 provides some example animations and simulations before the conclusion and outlook in Section 7 finish the paper.

2 The TeleTeaching Project between the Universities of Heidelberg and Mannheim

In January 1996 the universities of Mannheim and Heidelberg started a joint Tele-Teaching project. In this project, we planned to implement three different Tele-Teaching scenarios. The first scenario was the "Remote Lecture Room Scenario" in which whole lectures are transmitted via the Internet. The MBone tools (vic, vat and wb) [McCann and Jacobson, 1995] are used to transmit video, audio and postscript slides. The second scenario we have also explored actively is called the "Remote Interactive Seminar". During the winter-term 1996/97, a joint seminar on "Digital cash in the Internet" took place in Mannheim, Freiburg and Karlsruhe. Again, the MBone tools were used to transmit the talks. In contrast to the "Remote Lecture Room Scenario" the seminar was much more interactive and a discussion between the three sides took place after each talk. The organizational, pedagogical and technical aspects of the first two scenarios are discussed in more detail in [Eckert, Geyer, and Effelsberg, 1997]. The third scenario which has not been implemented yet is called the "Interactive Home-Learning Scenario". Here the target groups are typically students running Windows95 or Linux on their PC with an Internet connection via ISDN. This scenario has the most widespread distribution of members. It can be divided into two periods:

1. In the asynchronous period, production and consumption of the educational material take place at different times. The material is offered to the students on the World Wide Web. Aside from hypertext we concentrate on animations and simulations as new teaching technology. We already developed several Java applets for a physics and a computer science lecture. As a further add-on we plan to integrate several recorded and digitized audio and video shots which were added to the hypertext material.

2. In the synchronous learning period, production and consumption of the lectures take place at the same time. In this period, we plan to transmit lectures not only live to the remote lecture rooms but also live to the students at home. The required Internet connection will be based on ISDN. In this period we also want to
make use of the Java applets we developed during the asynchronous period. Therefore we developed the Java Remote Control which will be explained in the following section.

3 Related Work

The roots of our Java Remote Control Toolkit date back into the early days of 1997. Meanwhile several other projects pursue similar goals three of which shall be mentioned in this paper: S. Shirmohammadi and N.D. Georganas developed a Java-Enabled TeleCollaboration System (JETS)\(^1\) at the University of Ottawa. JETS is an API that supports the development of collaborative Applications. A similar project called Haberno was started at NCSA\(^2\). Haberno is a framework for sharing Java objects. Included, or planned, are networking facilities like routing, arbitration and synchronization mechanisms which are necessary to accomplish the sharing of state data and key events between collaborator's copies of a software tool. Javasoft started a research project named “Java Shared Data API (JSDA)\(^3\)” with the goal to provide an API for A Shared Data Multi-point Delivery Service for Java, JSDA concentrates on multipoint data delivery and provides services for multipoint communication among an arbitrary number of connected application entities. These approaches are designed to facilitate the development of shared application, e.g. shared word processors. On the other hand, our goal is the development of an API which allows synchronization of animations. Therefore these approaches do not exactly match the needs of our scenario.

4 Java versus alternative approaches

The problem of remotely controlling applications running on other computer systems had to be solved from the beginning of networked computing. However, with the advent of object oriented GUIs, the problem became much more difficult since programs became heavily interactive. Although some GUI systems are already originally designed to run across networks, e.g. X11, these solutions require large bandwidth which were not available in our Home-Learning scenario. (Experience shows that e.g. mouse movement in the X11-environment can consume up to 20KBit/s!)

One of the first multi-user remote GUI systems is a Shared-X environment \cite{Baldeschweiler1993}. Several people on different computers in a network can jointly use an X-application. As described above, running X across networks requires large bandwidth. Several research projects \cite{McCanne1996} have worked on restricting the current protocol to a low bandwidth version. Typical approaches to reduce the bandwidth are data-compression and delta-encoding (XRemote). A newer approach called Low Bandwidth X (LBX) uses short-circuiting, reencoding and motion event suppression mechanisms. Further information about LBX and shared-X can be obtained in \cite{Mauve1997}.

Only recently, Microsoft discovered the need for remotely and jointly controlling GUI applications. Their NetMeeting\(^4\) products might become a valuable tool for TeleTeaching and Teleworking scenarios.

However, all these solutions suffer from a crucial drawback. Most applications that are to be used jointly across a network were designed for local, single-user access. If they are to be used by a group of people, access restrictions and synchronization problems become an issue of great importance. Implementing different access levels for different GUI elements and advanced synchronization also require substantial changes to the original application. Furthermore these solutions are no longer platform independent, which is an important issue in case of the Home-Learning Scenario where Unix Workstations (at the class room) as well as Windows95 and Linux PCs (at the student's home) are used jointly.

5 The Java Remote Control Tool

In Section 2 we described the scenarios we want to enhance with shared animations and simulations. We therefore decided to implement the following functionality within the Java Remote Control Tool in order to accomplish the task:

1. The first basic functionalities needed are methods to exchange data between the distributed applets. Based on this core functionality, methods of higher abstraction level can be implemented.

\(^{[1]}\) Further information can be found at http://www.mcrlab.uottawa.ca/jets/ and \cite{Shirmohammadi1997}

\(^{[2]}\) Further information can be found at http://www.ncsa.uiuc.edu/SDG/Software/Habanero/

\(^{[3]}\) Further information can be found at http://www.javasoft.com/people/richb/jsda/

\(^{[4]}\) Further information on NetMeeting can be found at http://www.microsoft.com
2. To implement a shared application, we have to find ways to control several remote applets. Events must be caught and sent to the other participating applets. This must be accomplished through secure channels of communication because the loss of a single event will result in inconsistency of the distributed applets.

3. The next step after sharing of events will lead to floor control mechanisms in order to prevent contradictory events. It is necessary to decide who is in control of the shared application at a certain time: E.g. suppose two users want to move an object on a shared drawing canvas at the same time. In case of our synchronous learning scenarios, the control of the animations must reside by default at the teacher's side. He may give the floor to a student for a short period of time but he must have the ability to reclaim the floor whenever he wishes. Further issues of collaborative services in distributed learning environments are discussed in [Hilt and Geyer, 1997].

4. Unfortunately Java applets will run differently on different machines. E.g. the drawing of a line takes much longer on a PC than on a workstation. Therefore it is not sufficient to share events; rather synchronization mechanisms are a prerequisite in order to have the applets running consistently.

5. All these mechanisms must be designed in a way to allow the easy adaptation of already existing applications (e.g. animations and simulations).

We decided to insert this basic functionality into our API. Methods on a higher level of abstraction may be included at a later time.

5.1 Conceptual outline

According to the above outlined specifications, we decided for a solution that adds means for distributed control to the GUI of an existing applet. The main features are:

1. Different users sign up for participating interactively (e.g. automatically by invoking a web-page that contains the applet).
2. They then receive all GUI interaction commands via network which forces all the applets to behave coherently. (The applets will not run identically since processing speed on different machines might be different. Methods for synchronization will be explained below).
3. Floor control has to be implemented: If a user wants to control the applet, he can apply for being granted the control (e.g. by pressing a control button). A master program (on the server providing the applet) checks the request and eventually hands the floor control over to that user. The user who possessed the control before looses the control over the applet.

If the `apply for control`-button is placed in a separate window, the GUI of the applet need not be changed. This entirely conserves the web-pages' layout allowing for an easy migration towards distributed control. The web-server providing the applet's class code is in charge of distributing the GUI events among the applet instances and grants the different users the right for controlling the applet.

5.2 Technical outline

Since changing specifications is one of the biggest sources for software malfunction, the changes required to adapt existing applets should be as small as possible. This goal was met by a solution that in fact requires no changes in the applets at all. We defined a class DistributedControl that besides from its constructor only needs one method, the handleEvent method. Applets that are to be controlled distributively, will instantiate one object of that class and send every event to that object. Processing of that event will then take place in the DistributedControlWindow that will be explained in a moment. As a result of this minimal interface construction, it is even possible to introduce distributive control into classes for which no source code is available. This can be done by overriding handleEvent for that class, invoking DistributedControl.handleEvent and then calling super. On instantiating a DistributedControl object, a DistributedControlThread is started, the purpose of which is to hold contact to the control server via a socket connection. Another feature of the DistributedControl class is that if it is called as application, it will work as control server, i.e. it suffices to place the class files on the web-server and start DistributedControl there. Coordination of all the parties joining will then be handled automatically. This feature is achieved by additionally supplying a main method for DistributedControl.

The DistributedControlWindow acts as local control unit. At first, it blocks all GUI events for the applet by disabling its GUI. It then pops up a window with the 'get-control'-button and a status display. If the user presses the button, a request for floor control is sent to the server. The server then notifies the applet that holds the floor control to release the control. Finally the floor control is handed to the applet that applied for the control and its GUI elements are enabled.

A time-out mechanism is required to cope with network breakdowns. If the applet holding the floor control does not release it on request, the server will close that connection. Unlike in the normal case, events might be lost leaving this applet in a possibly non-coherent state. All other applets, however, remain coherent. But since the server logs all events of a session allowing for 'coming late to a lecture', a reconnect is always possible.
5.3 Synchronisation

Event handling has thoroughly changed between Java 1.0.2 and Java 1.1. During release time, we were working on a first version and were hence forced to re-implement the scheme described above. We used this chance to extend our concept towards synchronized distributed control as follows.

Many simulations not only rely on user input but also on random numbers to simulate effects. Together with different processing speeds on different platforms, this leads to diverging applet states. This need not be a principal problem. In fact, the model described above usually suffices completely. For the cases where identically running applets are required, we introduced a broadcast method that broadcasts objects e.g. random numbers, user input, GUI events. Instead of writing \( z=\text{Math.random()} \) we write \( z=(\text{Double})\text{distributedControl.broadcast(new Double(Math.random())} \). As one can see implementation has become easier due to RMI.

Synchronization is now also easily handled by inserting a \text{distributedControl.broadcast(null)}. Hence properly programmed applets i.e. applets that do not use local events or random numbers but only the broadcasted objects will now always run identically.

6 Examples

Now that we have described the Java-Remote-Control in the previous section, we will introduce some example animations and simulations. Throughout the lectures we make use of simulations. Students can now make hands-on experience during the lectures and explain their questions directly using the object. The following subsections illustrate this approach by giving three examples we developed. The examples can be retrieved from our world Wide Web Servers. The section will be rounded up by a short example of a shared application which can be controlled by the Java Remote Control Tool.

1. In the computational physics lecture, students can easily test different sets of parameters. This can amount to a feeling for the physics behind it.
2. The examples from the computer networks lecture are aimed to illustrate algorithms and protocols. Students can either view a pre-defined example for illustration, modify certain settings or create an entirely new sequence.

6.1 Simulation of AVL-Trees

An AVL-tree is an elementary data-structure usually introduced to students of computer science during the first basic courses. The basic concept is a height balanced binary tree. After each insertion or deletion of an element rotation-algorithms are used to rebalance the tree [Ottmann and Widmayer, 1993].

![Figure 1: The AVL Tree Simulation](image-url)

[1] In order to save bandwidth we had rather broadcast a Random object than the random numbers themselves. But this example is only for demonstration.
The applet concentrates on the visualization of the rotation operations. It supports two steps in the learning process of a student: In the first step the algorithms are explained in such a way that an example tree is build by the applet itself. In the second step, the student can freely build and change a tree by inserting and deleting elements. The applet animates the rotations after each insertion/deletion. While it is the goal of step one to demonstrate the mechanisms of the AVL-tree, the second step gives the student the opportunity to get acquainted with the concepts of the AVL-tree. The simulation can be suspended at any time for reading the explanations for each step of the algorithm which are displayed in a separate text field. [Fig. 1] shows the screen during a rotation.

It is planned to implement a third step of the learning process by enhancing the applet with a test mode. In the test mode the student is asked to insert or delete elements and then has to rebalance the tree by hand executing rotation operations. The goal of step three is to give feedback about the success of the learning process.

6.2 Molecular Dynamic Simulation of a Polymer Chain

Interest in the physics of polymers was pushed by the need for new materials in all fields of everyday life. Prominent examples for this are plastic bags made of polyethylene or compact discs which mainly consist out of Bisphenol-A-Polycarbonate (BPA-PC). The properties of these materials were investigated by experiments and for some of these materials a theory has been established. Nevertheless computer simulations can give a more detailed picture in this context. Polymers can be modeled for computational purposes in a variety of ways. Depending on the kind of question and the degree of abstraction, one has the basic choice between a lattice model and a model in continuum. If one wants to stay as close as possible to the chemically realistic chain, it may be of advantage to remain in the continuum (i.e. real space).

The Java application simulates a single polymer chain in real space using the united atom model [Bishop, Kalos, and Frisch, 1979] with molecular dynamics. In this model, linear polymers are represented by chains of mass points. The masses are connected by springs. Moreover, angle forces, torsion forces and van der Waals forces between the masses are used. The program reads configurations in some formats and can change the physical parameters even during the simulation which is very useful to demonstrate special effects. As important physical parameters, e.g. potential and kinetic energy, are calculated and plotted during the simulation, it can be used to demonstrate the effect of different forces and the time development of certain observables. The on-line visualization of the polymer chain enables by a hands-on training an intuitive understanding on the interplay of the different parameters of the model and leads to an understanding of the behavior of a polymer chain.

6.3 Enhancing an applet into a shared application

These educational examples can easily be turned into shared applets. Only three modifications are necessary:

1. Instantiation of the Remote Control Object (RCO)
2. Addition of all components that are to be controlled remotely
3. Transportation of all objects that are to be shared via the RCO

This simple mechanism provides all means for a really shared applet even within the Java 1.1 event handling scheme.

7 Conclusion and Outlook

In this paper, we described the Java Remote Control Tool along with some example applications and their field of activity in Tele-Teaching scenarios. The main advantages of our approach are the low bandwidth need and the ability to handle different access restrictions (floor control). Furthermore, our implementation of the Java Remote Control Tool can easily be adapted to already existing Java applets. With the adaptation towards Java 1.1, we could make use of RMI and therefore work with standardized protocols. We believe that the Java Remote Control Tool is an easily adaptable API to produce shared applications which are not necessarily restricted to educational simulations.

Tests over low bandwidth channels - e.g. ISDN and modem - will be necessary to proof the usability of the system in our Interactive Home-Learning scenario. Furthermore, some more extensive performance measurements and results about the scalability of the server-based model we chose for the Remote Control would be desirable and may lead to a more distributed way of communication.

Future work may comprise an API containing high level methods for simulations and state control in order to allow the fast programming of interactive simulations. The concept of Java-Beans [Mauve, 1997] is interesting in this context. Lastly it would be desirable to adapt the Java Remote Control to the MBone-VCR [Holfelder, 1997]. This would enable us to easily record audio explanations of our simulations.

Introduction

The Internet revolution has made a wealth of information resources available for direct and easy access on the user’s desktop. However, finding, organizing, and sharing appropriate information when needed has become a significant problem for many users, including teachers, students and researchers. Organized information spaces are easier to search, but finding or authoring these organizations is difficult. Our research focuses on three areas which require significant technological advances: (1) finding information relevant to users’ needs; (2) organizing information for facilitating access in various contexts; and (3) collaborative information sharing. Current WWW search engines allow users to locate information of interest, but often return vast amount of irrelevant information. On-line centralized catalogs (like Yahoo) provide more relevant and well organized information, but they are costly to author and not customizable to individual users needs. More recent information discovery and filtering technologies attempt to provide relevant information to users by learning from their previous queries or from other users’ queries and feedback, but results are still preliminary [Balanovic 1997][Moukas 1997]. Yet users need an easy way to access information relevant and adapted to their current task and interest at any time.

Once relevant information is found, pointers to it must be locally organized and stored in a manner that allows rapid and effective access for both individuals and workgroups. Current personal information organizing schemes on the WWW are mostly limited to bookmarks (also called hotlists, or favorites). Bookmarks provide an easy way to organize URLs in a hierarchical manner, and to attach personal comments to them. However, hierarchical bookmarking schemes are monolithic, can be tedious to navigate, and cannot be easily shared with other users. They do not support fast changing rate of information, nor multiple uses of information under various contexts or by various users. Recent approaches to organize information at the level of collections of documents rely on metadata standards (W3C Resource Description Framework (RDF)), which require additional authoring effort from Web pages authors, and only support contexts of use anticipated by the author. There is also a critical need for tools supporting collaboration among distributed users with similar interests, or who are part of the same workgroup. Individual users can author and publish Web pages containing lists of related links. Some of them can be quite sophisticated, organized under single categories, or in tables with multiple categories. However it takes time to author and maintain these lists in a textual format. Sharing a common repository of information is a first step, but doesn’t scale up to large distributed and informal groups. Collaborative tools themselves need to be distributed and dynamic, and support collaborative learning and discovery of information.

DIAMS: A Multiagent System for Organizing and Sharing Information

What if you could share your bookmarks with other users with similar interests as easily as you can share/publish Web pages? We propose to combine the advantages of organized published catalogs, personal bookmarks, and the distributed/collaborative aspect of the Internet. We augment hierarchical bookmarking with multiple indexing, facilitate the authoring of organized information spaces by taking advantage of the Web’s inherent distributed nature, and support users in finding and reusing other users’ information spaces. We have developed a first Java prototype of a distributed and collaborative information multiagent system, called DIAMS, which supports dynamic and flexible organization of personal information repositories,
distributed over the World-Wide Web [Fig. 1]. These repositories in turn enable sharing between users at the knowledge-level, and automated discovery of new relevant information through collaborative information exchange between software agents. Each DIAMS agent learns from a user's preferences for organizing information, and provide dynamic views of information according to current user needs. DIAMS will integrate knowledge-based, neural networks and genetic algorithms technologies to develop an ecology of users and agents that evolve over time, and to promote the emergence of collaborative groups of users.

DIAMS is directly accessible from Netscape browser toolbar menu and provides the following capabilities to users: Indexing of bookmarks under multiple hierarchical categories/folders to organize one's personal memory (URLs repository); Direct access to and browsing of other users' memories and display of their associated categories - other users' memories are displayed in the same information space using a different color scheme for each user; Automatic creation of aliases by dragging other users' URLs or entire folders into one's personal memory, or duplication (copy) into one's memory; Narrowing/Expansion of the current information space by selecting different sets of categories from various users - this supports incremental refinement of search results over time; Indirect access to other users' memories though intelligent agents that perform behind the scene categories searches and translation on other users' memories, and find memories of users with similar interests (matchmaking); Importing of existing Netscape bookmarks already organized into hierarchical folders.

We previously developed an adaptive indexing and retrieval agent (ARNIE), which enable users to categorize and share information of interest under various contexts, and is able to learn users' interests based on how they organize information, rather than what they search for [Mathé & Chen 1996]. ARNIE encodes information relevance and structure in a neural network dynamically configured with a genetic algorithm. This core technology was successfully integrated into several applications: NASA/JSC Adaptive HyperMan Electronic Documentation system in use at JSC Mission Control [Rabinowitz et al. 1995], and WebTagger™ (an adaptive bookmarking service on the Web) [Keller et al. 1997]. WebTagger is a personal bookmarking service that provides both individuals and groups with a customizable means of organizing and accessing Web-based information resources. Individuals may access the service from anywhere on the Internet. However, these systems were relying on centralized group repositories for sharing, and offered multiple indexing, but no hierarchical organization.

DIAMS extends the previous architecture with multi-attribute network objects, added semantic knowledge and symbolic processing capabilities. We are developing new information access methods which provide dynamically organized views of personal information repositories using knowledge-based and neural network representation and indexing. We will implement advanced techniques for sharing and gathering of information using knowledge-based, distributed automated agents. In particular, we will use a knowledge exchange protocol for inter-agents communication [Bradshaw et al. 1997], and take advantage of existing agents technology for matchmaking and referrals to find users with similar interests [Foner 1997][Kautz et al. 1997]. Finally, DIAMS design puts emphasis on a modular architecture with flexible interface protocols. The system can hence take advantage of existing tools with capabilities such as text search and automated categorization, and interact with established on-line dictionaries, thesauri, and knowledge bases.

Overview

In the information society, the ability to search for information in electronic repositories effectively, to evaluate claims accurately, to ask the „right“ questions etc. are important cognitive skills which need to be trained and facilitated. In an ongoing empirical project, we are concerned with the question how the layperson can be supported in evaluating claims made in the mass media about certain environmental risks (mainly oil accidents in the oceans). In particular, we are looking into the following issues:

- What advantages has the active selection of information (within the framework of hypertext systems) compared to being confronted with a sequence of information that is selected? According to constructivist principles of learning and information processing [Duffy & Cunningham 96], active modes of information selection/retrieval should have clear advantages concerning knowledge measures.

- Which cognitive skills are needed to search for information in hypertext systems in order to scrutinize and/or build arguments and how are these interrelated? We will present a heuristic, process-oriented approach to problem solving in ill-structured domains which encompasses relevant concepts from the area of critical thinking [e.g. Brookfield 87; Ennis 95; Halpern 96] and informal reasoning [Voss, Perkins & Segal 91]. We extend former theories of critical thinking and informal reasoning by taking into account external information sources and the influence of external representations of arguments.

- How can the empirically and normatively derived skills be improved using computer-based cognitive tools [„mindtools“; Jonassen 96]? Though this question can only accurately be addressed by having a sufficiently detailed theoretical framework of the users cognitive strategies at hand, some preliminary considerations and their practical implications will be presented.

Improving informal reasoning by actively searching for information in Hypertexts

In our first study participants had to criticize and extend an argument about a certain environmental risk which was graphically represented as a concept map. Subjects had to add nodes and relations to the initial argument structure. We investigated the effect of different modes of information availability on (1) the increase of actual and perceived knowledge about the subject-matter and (2) the quality of the final argument structure.

Different modes of information access were realized by a yoked-control-design. In the first experimental group called „active group“, subjects had access to a hypertext-system which comprised background information on the subject-matter as well as relevant media reports about environmental catastrophes [Bosnjak, Reimann & Wichmann 97]. In the second experimental group, the „passive group“, participants were confronted with the sequence of information displays a corresponding person in the active group had selected. Thus, each passive subject was "yoked" to an active information searcher. The rationale behind this design is to analyze the influence of information access - active vs. passive - while keeping the information each subject receives in the two conditions identical. In a third group, the control group, subjects had no access to additional information. Influence of prior knowledge was controlled by assessing it in the course of pre-testing. Our main findings over 33 participants (11 in each group) were the following:

(a) Minimized „illusion of knowing“ by actively using the provided hypertext-system.

Though there were no significant differences in the actual gain of new knowledge from the information system between the groups „active“ and „passive“ (as assessed by comparing pre- and post-test scores), the „active group“ had a more accurate certainty of their acquired knowledge. At the beginning and end of the
experiment subjects had to assess their subjective feeling of being informed on different environmental topics. Members of the active-group perceived themselves significantly more informed on the topics which were actually covered by the hypertext-based information-system (pollution of seas, oil-tanker-average), the passive group perceived itself as being better informed even on topics that were not addressed by the hypertext.

(b) Quantitative differences between the developed arguments with superior measures in passive-mode. The passive group added more new nodes to the argument structure than the active group, which in turn added more arguments than the control group. Using a graph-theoretical measure, we found that overlap between the initial and the final argument structure was stronger for the control group than the passive group, with the active group lying in-between. Concerning the depth of the argumentation, computed with the graph-centrality-index (diameter of the argument-structure), no differences between the active and passive-group could be observed.

(c) No significant qualitative differences between the argument structures in active and passive mode. A qualitative assessment of the developed argument structures was performed with respect to topics covered, relevance/soundness, and the balance of the argument structure. The last two dimensions have strong relations to the concept of soundness proposed by [Voss, Blais, Means, Greene & Awesh 89] and [Voss & Means 91], which consists of the criteria „acceptability of reasons“, „relevance or support the reason provides for the claim“ (grounding) and „extend to which reasons supporting the contradiction of the claim (counterarguments) are taken into account“. For these three qualitative dimensions, no significant differences between the active and the passive group could be discovered.

How can these unexpected observations - (a) the passive group worked quantitatively slightly better than the active group, and (b) no significant differences between the two groups with respect to qualitative measures - be explained? We hypothesize that this is mainly caused by differences in cognitive load [Sweller & Chandler 94]: Whereas the passive group could concentrate solely on processing the linear sequence of information, the active group had in addition to plan for navigating through the non-linear hypertext. In addition, both groups had little knowledge about the domain area, which may make linear presentation of information (as in the passive group) more suited for (initial) learning [Zink & Schnotz 95]. However, in the real world and in particular in widely used information repositories such as the World Wide Web, information does not come in a nicely sequenced format. How can layperson be supported in coping with insufficient initial domain knowledge and working memory load in the context of interacting with hypertext-like information systems? Our first step to answer this question is to build a normative model of a "good information searcher", building on psychological and instructional research.

A Process-oriented heuristic model of critical thinking abilities for the active use of Hypertext-systems in Argument-development

With the dissemination of actively usable information systems – especially over the internet or as CD-ROMs – informal reasoning abilities (e.g., to evaluate given statements, verifying their veridicality and soundness, as well as generating new arguments and counterarguments) become core competencies and crucial components of information literacy. Psychology has analyzed comparable cognitive processes in the course of research on reasoning, critical thinking, writing, and argumentation skills. However, from analyzing this research work we find a lack of consideration for the influence of external representations in form of information resources (databases, hypertext, World Wide Web) and in form of external representation of reasoning (e.g., argument structures). Building on theories of critical thinking skills [Brookfield 87 ; Dewey 33 ; Ennis 95 ; Garrison 92 ; Henri 91 ] we want to come up with a process model of informal reasoning and argumentation which takes into account external information resources.

Our heuristic model on „ideal“ informal reasoning processes supported by an externalized information system comprises three main layers: argument-development, internal cognitive processes and operations within the hypertext-system. Internal cognitive processes, which have a mediating function between the externalized information, the argument development and the users domain specific knowledge, are described as successive phases which are initially triggered by the presented argument structure. In the first phase, a user should develop a representation of the given argument and decompose it for evaluation according to its veridicality and soundness. The evaluative phase itself should trigger exploratory behavior (explicitly searching and asking
questions), which is aimed at finding confirming and/or rebutting arguments relevant to the topic. At the last phase – but not exclusively there - subjects should integrate their (newly acquired) perspective into the given argument-structure.

Given this heuristic model, we currently attempt to empirically determine in which phase(s) of argument development and/or usage of the hypertext-system participants have major difficulties. Based on these findings, testable hypotheses about how to facilitate the informal reasoning process most effectively by computerized cognitive tools ("mindtools"; Jonassen 96) will be derived.

Abstract: Factors such as increasing class sizes, expanding curriculum, added time pressure on students and lecturing staff, contention for library resources and study space as well as the cost of educational administration have prompted the application of advanced technology to both enhance the pedagogical aspects of teaching and relieve administration and management resources. However, no single technology is appropriate to support both the pedagogical requirements and administrative imperatives required for course delivery in a virtual educational environment. This paper identifies student and course delivery management requirements and describes the seamless integration of appropriate multimedia and groupware technologies to support course delivery within a virtual student desktop. The paper presents the resulting experiences and lessons learned in delivering educational services using virtual environments based on the execution of three trials involving over 300 students in Trinity College Dublin.

1. Pedagogical and Administrative Requirements for Course Delivery

A University setting where class sizes are large and schedules are tight provides a unique opportunity for developing courses using a range of advanced information technology. Yet such a scenario places many requirements on the administrative, pedagogical and support services in order to successfully execute technology based courses.

There have been many experiments of tele-education in the US and in Europe [Schank 93][Soloway 93] and many institutions have developed IT based educational material e.g. WWW educational sites and multimedia materials [WLH 97]. The growing availability of authoring tools e.g. [WBT 97][Learn 97] should increase the number of such educational resources; however, these facilities are seldom part of an integrated educational system where the education is formally managed and administered.

For the educators or tutors, participation of class members should be manageable e.g. course registration, controlling access to class discussions, automatic collection/distribution of assignments and projects should all be functionally accessible to the tutor. Computer facilities for courses should also provide a means of monitoring each students usage of the educational resources and comprehension of the content. Educators and course administrators need well defined systems for the certification and assessment of a students progress [Hamalainen et al. 96][Carroll et al 95]. Techniques for ensuring that only students who participate in the course for its duration and achieve the desired results have yet to be properly defined and accepted.

New ways of stimulating and motivating course participants are required which make use of these 'tele-technologies' [Tuckey 92] and early experiments have proved that course composition, presentation and assessment have to be redesigned in order to produce effective courses [Turoff 95]. Tests carried out between two groups of students participating in a traditional educational course have shown that the students who had access to supplemental multimedia (e.g. video, audio and animation) and simulation environments [UTOR 95], did significantly better than the students who did not have access to such material [Kaplan 97]. Students require flexibility in the timing of course delivery and desire the opportunity to participate in the course away from the university campus [Prospect 95]. Existing courses try to reduce the users requirements on hardware and software and allow them choose the time and place more freely [ELMA 96]. Thus course delivery must be
configurable to a wide range of computing environments which offer both a uniform interface and the option of personal mobility [Trollip 96]. An on-line support service is beneficial from an educational and technical point of view [Fitzgerald et al. 95][Sherry et al. 96] as this allows any difficulties or problems that arise during delivery of the course to be easily notified and efficiently handled. Technical support staff in educational institutions identify reliability, configurability and administration as vital elements in course delivery [Prospect 95]. Both educational and technical support must be successfully integrated into the university organisation for any large scale implementations of Internet based education.

2. Motivation and Objectives
In the TCD computer science department, there are several taught courses in database technologies given as part of the daytime and evening Computer Science, Maths, & Computer Engineering degree programmes. Several of these courses cover similar material, namely an introduction to SQL (relational database query language). Therefore in order to reduce the time pressure in lectures, reduce redundancy in preparation/delivery of lectures, ‘improve’ interaction with and dissemination of educational material, and provide more in-depth exposure to subject material, a ‘self learning’ student-centered course was developed for delivery in a virtual learning environment. Other motivations were to reduce the contention on library resources, automate the process of tracking, monitoring and testing/evaluating student knowledge and to provide a basis for course development across the different degree programmes.

The course was designed as a ‘Self Learning’ course concerned with the theories & practical skills (application) of relational database management systems. The Self Learning course was run in parallel to lectures (over a 5 week period) and sought to:

- Provide good overview of subject which can be integrated into different degree courses
- Provide persistent access to educational material
- Stimulate student ‘innovation’ and ‘discovery’
- Capture requirements for tools needed to support such courses
- Integrate educational and communication paradigms into a single virtual environment
- Extend classroom learning paradigm
- Stimulate student experimentation
- Provide greater time flexibility
- Provide a ‘Living’ course content
- Capture student usage & student feedback
- Provide online management of students work and course delivery

3. Virtual Educational Environment
One of the key requirements for delivery of the course is the ability for students to easily access and load a virtual student environment without needing to install customised or specialised software or hardware. For this reason the Virtual Student Desktop (VSD) was developed to provide a single environment from which a range of courses could be delivered and within which the various technologies needed to support pedagogic paradigms and administrative systems are seamlessly integrated. The VSD is accessible using standard WWW browsers e.g. Netscape 3.x (or higher), HotJava browser or Internet Explorer. By accessing a particular WWW site, the VSD is automatically launched on the students machine. This enables the course to be delivered and auxiliary administrative/management systems to be initiated at the remote (educational provider’s) site. All pedagogical and administrative systems (on the educational provider site) are executed transparently via the VSD, giving a single ‘look and feel’ to the virtual environment.

All student interaction is facilitated via the VSD. The VSD is rendered (by the student WWW browser on the student’s machine) as a set of WWW windows, frames, tool bar and icons. All native WWW browser buttons are suppressed (hidden) so as not to distract the user from the main goal of education. A tool bar specially designed for educational use is provided by the VSD at the bottom of the screen and provides an interface to the administrative systems. From this tool bar the student is able to contact tutors or fellow students, access external systems, as well as navigate and interact with the educational course material.
Relational DBMS Architecture and the SQL Language

- Conceptual
- Relational
- Query Language

- Transaction
- Views
- Other Tools

The whole database for a community of users. This description is called the Conceptual Schema of a database and is a global description of the database that hides the details of physical storage structure and concentrates on describing entities, data types, relationships, and constraints.

3. The Internal Level contains the internal schema. This internal schema describes the physical storage structure of the database. The internal schema uses a physical data model and describes the complete details of data storage and access paths for the database.

---

3.1 Virtual Course Content & Student administration

The course content comprises of text, graphics, and animation and is divided into sections, with each section consisting of a small number of modules (a module typically being 1 - 5 pages). The virtual course trialled is concerned with the understanding of Relational Databases and the usage of Relational Database Language (SQL). On accessing the course for the first time, a student is asked to authenticate themselves using a unique user id and password (distributed previously). Then the administrative systems are engaged and the student is subscribed to a course and the appropriate student monitoring systems are loaded. Each student must authenticate herself/himself each time she/he logs onto the course. This allows a log of each student's interaction with the educational material to be automatically maintained by the system for later analysis (in conjunction with tutorial results and evaluation forms). This information can be analysed for various pedagogic reasons (student usage, pattern analysis) and administrative motives (accounting for usage of course content and auxiliary systems).

Overall the course comprised five different types of information: Administrative (i.e. how to use the course etc.); A database of (self contained) modules; Indexes or Roadmaps of specific courses through various modules; Project Assignment specifications & Evaluation Forms; Case Study.

The roadmaps were important as the modules can be combined in several ways to satisfy the different requirements for different degree courses (e.g. business students, computer science students etc.). Each roadmap corresponds to a different learning objective of the RDBMS course. Thus the roadmaps provide a means of re-using existing modules with as little redundancy as possible of educational material and administrative overhead.

A significant feature of the system was to provide direct access to a real 'commercial' RDBMS via the same interface as the educational course. As with the administrative services, the relational DBMS is seamlessly integrated into the student educational desktop. Thus the tool bar offered by the student educational desktop contains an icon which allows students to issue SQL queries on a live database. The idea of this is to deliberately blur the distinction between the educational environment and the 'target' systems. This encourages students to 'try out' various parts of the course before attempting a larger project.

Another feature of the virtual educational environment is the ability of the student to store references to distinct locations in the course material (bookmarks). Traditionally these are stored locally on the student's machine. However this has disadvantages as students rarely use the same machine all the time. The VSD allows such bookmarks to be stored within the educational service and are thus (privately) accessible to an individual.
student at any time. Also if the student has logged off the course and logs back on, the VSD allows him/her the ability to resume at his/her most recent position or restart at the beginning.

Various forms of on-line tutorials are embedded into the course. ‘True or False’ and ‘Multiple Choice Questions’ are supported, with automatic correction and notification of marks to the student. Form based (short unstructured text style) answers are also facilitated in some tutorials. In these cases the student answers are automatically delivered to course tutors for subsequent correction. Also integrated into the course are evaluation forms which, when completed, are automatically submitted and stored for later analysis by course tutors.

The VSD provides buttons to contact other class members or to seek tutor assistance. Again, this is offered via WWW forms and integrated transparently with an email delivery system. The course also provides several larger project specifications one of which each student is required to implement. The implementation of the projects could also be done via the educational interface, providing better pedagogical support for the project implementation.

4. Implementing the Student Virtual Desktop

As described earlier, the course is delivered using WWW technologies. The WWW is based on a client server architecture. Requests are made by the client side (student) browser to the initial VSD engine which sets up the functionality of the student desktop. The server delivers this in the form of HTML, CGI and JavaScript. From this point on, all other requests are made by the client and returned by the VSD server. The tutor(s) are always directly accessible from within the VSD.

Scripting in the client side monitors the users progress through the course material and stores user preferences for each user. At the start and end of each session the user information is retrieved and stored respectively at the server side for future use. In this way the educational environment fully supports the mobility of users between locations. The advantage of client side scripting being the reduction in network bandwidth due to the avoidance of continuous client server communications. The individualised usage data provided by the client side monitoring system enables the tutor to check on each students progress in the course. Information that is stored are user bookmarks, last page visited by the user so that they can return directly to this page at the start of the next session, total time spent on each module which is useful in determining any specific problem modules and the number of times each module was accessed by each student.

A simulation environment is also enabled by providing a gateway between the educational student desk and a real life commercial database. This was achieved using the VSD engine combined with CGI scripting as the middleware between the desktop and the database. Students could query an example database straight from the educational environment thus blurring the distinction between theory and practice. Tutorial questions, project assignments and an evaluation form were also handled online via CGI scripting with feedback to the students and correction by the course engine. Off site access to the virtual desktop (and hence course delivery) was facilitated by ISDN or dial-up modem access to the campus network on which the educational site was available.
5. Trial Execution and Evaluation

The RDBMS course is currently in its third year of academic trials involving a total of 300 students. The first trial (performed in 1995) used a basic text/graphic WWW interface. Having captured and evaluated feedback on the first trial, a second trial was performed in 1996. A third trial has been completed in December 1997. [Table 1] provides a summary of the objectives and an assessment of these objectives based on the experience of those sitting the course (harvested via evaluation forms and student interviews).

<table>
<thead>
<tr>
<th>Original Objective</th>
<th>Assessment</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Topic Covered</strong></td>
<td>Students were able to complete, competently, a medium sized project with little further background reading other than a RDBMS systems User Manual (available on line). Also students undertook an oral exam to evaluate the effectiveness of the course. However, there are always a few topics which could be added!</td>
</tr>
<tr>
<td><strong>Comprehensively</strong></td>
<td>It considerably improved the original method which consisted of several tutorials (paper based) and a couple of unsupervised labs. It generated much greater usage, understanding and questioning of the course as the students knew their work was being automatically monitored and assistance was 'virtually' close at hand.</td>
</tr>
<tr>
<td><strong>Extend Classroom</strong></td>
<td>Most students appreciated this, especially as the term during which the course was taken was heavily timetabled with other lecture courses and project deadlines. However a few students indicated a preference to have their day scheduled for them!</td>
</tr>
<tr>
<td><strong>Learning Paradigm</strong></td>
<td>The educational course was available (and was used!) 24 hours a day, and was still available in the run up to end of year exams. Thus the course also served a purpose as revision material</td>
</tr>
<tr>
<td><strong>Provide greater time</strong></td>
<td>This was surprisingly useful as new information became available during the course execution. Also any ‘errors’ in the material could be corrected and advertised immediately (unlike the old situation which relied on printed handouts)</td>
</tr>
<tr>
<td><strong>flexibility</strong></td>
<td>This can be achieved (to a degree) via on line tutorials (with immediate feedback), access to external resources e.g. access to ‘case studies’ of real-life situations (commercial DB with application data and example usages). The blurring of the division between the ‘real world systems and information’ and the educational material is particularly important in this regard.</td>
</tr>
<tr>
<td><strong>Persistence of</strong></td>
<td>On-line subscription to the VSD and account/usage monitoring of the VSD and course material were the main administrative system implemented and reduced greatly the time overhead in concurrently delivering the course to in excess of 100 students. However full integration of these administrative systems with college wide administration systems has not yet been perform although this can be done.</td>
</tr>
<tr>
<td><strong>Educational</strong></td>
<td>By keeping the same ‘look and feel’ to the educational environment, whether sending notices</td>
</tr>
<tr>
<td><strong>Material</strong></td>
<td><strong>Integrate</strong></td>
</tr>
</tbody>
</table>
to tutors or colleagues, communicating with external systems, or interacting with course material, the student is not burdened with multiple program interfaces or interaction paradigms. This was reflected in the student responses and questionnaires which complemented the easy to use/no manual needed approach to using the VSD.

These requirements were captured from students taking the course using evaluation forms and interviews. The results can be tabulated and stored in databases to facilitate subsequent statistical analysis. Also during development of the course several useful tools became apparent e.g. automatic tutorial builder, road map generator etc.

Table 1 Assessment of Objectives

The overall reaction by the students to the ‘Self Learning’ mechanism employed by the RDBMS course was very favorable. It succeeded in many of its objectives and provides a firm basis for future development.

6. Associated Trial of Educational Service

The work already described to implement a campus-based educational service has been extended to play a role in a wider project which is concerned with commercial applications of tele-education in a pan-European context. The Prospect project [Wade 96] has been examining the issues which would be involved in realising an open service market place where various value added service providers may offer a customised educational service implemented on top of network connectivity services (usually offered by public network operators or enterprise network providers). The Prospect consortium implemented a Tele-Educational environment which provides educational services across pan-broadband networks. This Tele-educational environment provides features to support group lectures using video and audio conferencing, a slide presentation mechanism and also group projects which additionally used a shared whiteboard [Riordan et al. 97]. The VSD has been successfully integrated as part of this Tele-Educational Environment without requiring any re-implementation.

On entering the system a student is presented with a floorplan which shows a lecture hall, a self-study room, a group exercise room and a set of tutors offices. On entering a particular room an appropriate set of support applications were launched to allow the desired interaction to take place. For example, on entering a group exercise room, audio and video conferences are started between the people in the room. A shared whiteboard application is also launched showing the exercise to be completed. The students can then communicate in a whole set of modalities while attempting to solve the exercise.

Figure 2 Prospect’s Tele-Educational Environment
7. Conclusions and Future Work

Our experience has shown significant benefits in using WWW technologies in supporting a virtual educational environment. The virtual environment facilitates the seamless integration of many different technologies to support both pedagogical and administrative systems in a university environment. The success of the trials have shown that network centered virtual educational environments can have a major impact on reducing the pressures of increasing class sizes, time pressure on students and lecturing staff, contention for library resources as well as the cost of educational administration. The trial based experience has also shown that an iterative approach to course design, feedback and then redesign/extension is very important. It is simply too expensive, in terms of development time to attempt the development of sophisticated virtual environments in the first year. A more practical and less risky approach is the iterative, cyclic approach which although facilitating only modest pedagogic benefits in the early years gradually provides a platform and expertise for more rapid growth in later years. The development of several other virtual courses in currently underway, and it is expected that the development time for these courses would be much shorter as the VSD is already implemented and templates and expertise exist for the development of subsequent course materials. A third conclusion was the significance of the linkage between the educational system and adequate administrative systems e.g. student monitoring, project/tutorial correction, course subscription. This is especially true for large size classes and for ‘off campus’ students.

Our future research will involve enhancing the existing course including some adaptivity features and the development of appropriate tools to aid the development of such virtual courses. This would include tools for the auto generation of roadmaps for different applications of the course material. The overall aim of this is to remove much of the manual work from the educator, thereby freeing them to concentrate on the more important pedagogical aspects.

A Visual Tool to Define Multimedia Exercises

I. Aedo, P. Díaz and S. Montero
Laboratorio DEI, Universidad Carlos III de Madrid
Butarque 15, 28911-Leganés (Spain). e-mail: dei@uc3m.es

Abstract: A flexible CAL system should provide teachers with mechanisms to adapt the courseware to their own methods as well as to their students' needs, without being aware of the system architecture and implementation issues. Taking as starting point this premise, we present a general model for describing training material and our experience in the development of a visual tool to generate multimedia exercises. The tool is embedded in a hypermedia learning environment called CESAR and it includes modules to easily define exercises that can be solved applying different strategies.

1. Introduction

The usefulness of computers as educational support tools seems to be unquestionable. Computer Aided Learning (CAL) environments can profit from the use of multimedia contents, insofar as making several senses pick up different stimuli of the same concept can strengthen, within our brain, the connections that make up our knowledge about that concept.

The need for involving teachers in CAL systems has been continuously stated, arguing that a successful introduction of new technologies in traditional classrooms requires the commitment of teachers [Brown 1994]. Teachers can get involved in the development phase of a CAL system in such tasks as creating didactic material, providing valuable information about the needs of students, proposing learning strategies and giving their opinion about the system utility and usability. Nevertheless, most CAL systems are addressed to broad communities and, therefore, it is not realistic to expect all teachers taking part in the development phase either agreeing with the product. In this case, a flexible CAL system that can be adapted to different educational methods would be regarded as a helpful tool. Moreover, it will promote a positive teachers' attitude as far as it provides them with means to adapt the courseware without being aware of implementation details.

In this paper we describe a model that offers a formal framework for the specification of training material. We also present our experience in the development of a visual tool, based on this model, that is aimed at providing teachers with mechanisms to easily create multimedia exercises that can be solved applying different learning strategies. This tool is embedded in a hypermedia learning environment called CESAR [Aedo et al. 1997] oriented towards helping hearing-impaired children to learn the sign and written languages.

2. A General Model for Specifying Trainings

In this section, we present a model that can be used as the starting point of the development of trainings, since it offers a general framework to describe didactic material. In order to provide a formal description of the model, their elements are described using the EBNF (Extended Backus-Naur Form) notation (see [Tab. 1]). Some elements are not completely specified since their definitions depend on the characteristics of the educational application to be developed. In particular, elements that appear in the formal definitions in italic have to be instanced. Their formalisation within the CESAR environment is shown in [Instancing the model for CESAR].
Learning environments should encourage an active student involvement [Quentin-Baxter and Dewhurst 1992] since the passive reception of information does not generate knowledge [Schanck and Kass 1996]. Trainings can improve the learning process by proposing students the challenge of using their knowledge and skills to solve practical problems. Thus, the first element of the model is the Training, defined as a set of exercises oriented towards reaching a particular educational objective. Depending on the particular application to be developed, the training definition can be increased with different attributes (e.g. objective, methodology). Thus, the formal description of a Training includes two elements one of whom will be instanced for the CESAR environment in [Instancing the model for CESAR]:

```ebnf
<Training>::=<Training_Infb> (Exercise> f<Exercise>1)
```

An Exercise is a learning activity that elicits an active involvement of students. As in [Celentano 1995], the exercise is divided into two parts: information items (e.g. text, image and video) that are called Information Objects; and the logic of resolution that is called Strategy. The same as the Training, the Exercise can include also some additional information as it is shown in the following formal description:

```ebnf
<Exercise>::=<Exercise_Info> (Strategy> f<Strategy>1)
```

The separation between information objects and strategies brings three main advantages:
- the same knowledge can be approached from rather distinct ways by combining the same information objects with different strategies;
- the most appropriate strategy can be assigned to each student and, therefore, different learning styles can be taken into account, as stated in [Allinson and Hammond 1990] [Barker 1993]; and
- students can exploit the same procedural knowledge about the strategy to solve different exercises, if the same logic of resolution is applied to different information objects.

Those information items that are used in the exercises are grouped by means of Information Objects. An Information Object embodies all the representations of a particular concept by means of attributes (e.g. a car can be an information object that includes attributes such as a textual description, an image and a video) and it also can have some other information. The formal description on an Information Object is the following:

```ebnf
<Information_Object>::=<Object Infb> (Attribute>(<Attribute>})
```

The Strategy defines the logic of resolution to be applied in an exercise [Díaz et al. 1998]. Strategies are specified through a Generic Model of Strategy (GMS) which defines: how to deliver information items to the student (Presentation Process); how to react to the students' interactions (Interaction Process); and the actions to be carried out when the student gives an answer to the exercise (Checking Process). The GMS allows the presentation, interaction and checking processes to be adapted to each student, providing a flexible way to gather different learning styles.

```ebnf
<Strategy>::=<Strategy_Info> <GMS>
```

The Presentation process generates the exercise statement that consists of combining a number of multimedia items, that are references to attributes of existing Information Objects, and other additional elements (including explanatory sentences). The Interaction process is responsible for managing the reactions to the students' interactions, in such a way that a distinct behaviour can be defined for each item included in the exercise statement. Finally, the Checking process contains the actions to be carried out when the student gives an answer to the exercise. The specification of these three processes depends on the type of actions supported by the system and, therefore, they can not be generalised in this model but instanced in the next section according to the CESAR environment characteristics.
This model, that complements the one presented in [Aedo et al. 1997], has been used to create a tool integrated into a hypermedia learning environment aimed at helping hearing-impaired children to acquire the necessary skills in sign and written languages (CESAR).

3. A Tool to Create Multimedia Exercises

In this section we present the Visual Tool developed for creating multimedia exercises within the CESAR environment. Firstly, the general model presented in the previous section is instanced taking into account the services offered by the tool. Then, the tool architecture and functional modules are described.
3.1 Instancing the model for CESAR

CESAR [Aedo et al. 1995] [Aedo et al. 1996] [Aedo et al. 1997] is a learning environment that makes use of hypermedia stories to initiate the deaf child to the story structure and provide him or her with the necessary experience. Children are presented a library where each book is structured in two parts: the story and the training. The story is based on the book metaphor and the training part, which is the main focus of this paper, includes a Training addressed towards learning the sign and written languages. The general model can be instanced as follows:

```
<Training_Info>::=<training_id>
<<training_id>::="linguistic competence"
```

This training includes a number of Exercises each one belonging to a different category. Each category reinforces a particular type of knowledge. For instance, exercises included in the "Vocabulary" group are used to extend the child vocabulary with the terms used in the story. The definition of Exercise is completed as follows:

```
<Exercise_Info>::=<exercise_id>
<<category_id>> {<<category_id>>}
<<category_id>>::="vocabulary" | "understanding_questions" | "regulators" | "values_motives_consequences" | "narrative_structure" | "expressive_elements" | "grammatical_elements"
```

A combination of different media (text, image, and video) is used to represent the book concepts. In particular, each Information Object is assigned five attributes: a graphical representation, a signed form, an animation, a written form and a textual definition of the concept. Thus, the formal description of Information Object is instanced as follows:

```
<Object_Info> ::= <<object_id>>
<Attribute> ::= [<<image>>] [<<written_form>>] [<<signed_form>>] [<<description>>] [<<animation>>]
```

More than fifty different Strategies have been designed according to the particular contents to be presented to the child and to his/her specific needs. Each strategy has a simulation that acts as a stimulus and indicates how the exercise must be solved. The result of instancing the general model is the following:

```
<Strategy_Info> ::= «strategy_id» «simulation_id»
```

In the Presentation process, several elements can be delivered to the child by specifying their identifier, position and role in the exercise statement (comment, question or answer). The Presentation composition is then the following:

```
<Presentation> ::= <Presentation_Element> {<Presentation_Element>}
<Presentation_Element> ::= <<object_id>> <<position>> [<<size>>] [<<text_style>>]
<Type> ::= <<comment>> <<question>> <<answer>>
```

In the Interaction process, a reaction or a set of actions is defined for each element included in the exercise statement. The instanced Interaction is the following:

```
<Interaction>::=<Interaction_Element> {<Interaction_Element>}
<Interaction_Element>::=<Object_Id> <<Reaction>>
<Reaction>::=list of actions
```

Finally, the Checking process is defined as a list of actions carried out when the student gives an answer. The definition of this process is:

```
<Checking>::=<Reaction>>
```

3.2 Description of the Visual Tool

The tool is composed of five modules that make possible to create exercises that can be used in the CESAR environment. This tool is embedded into the Training System of CESAR as it is shown in [Fig. 1].
Students will interact with the Training System by means of the CESAR Interface, where they are offered the possibility of going to the training part from any page of the book. When a student chooses the training part in a CESAR book, the Meta-Compiler module retrieves the exercise identifier from the Personal Homework where the exercises assigned to the student are held. If there is no assignment for that student, the Homework is accessed to retrieve the exercises tied to that page of the book. Then, the strategy and the information objects involved in the exercise are retrieved. The processes that control the exercise execution are created by translating the visual language used by the teacher to specify the strategy into HyperTalk, which is the programming language of CESAR. The Meta-Compiler sets a frontier between the Training and CESAR, which makes the former independent from the learning environment. In this way, a simple specification language can be offered in order to encourage teachers to get involved in the learning environment.

Teachers will use the Visual Tool to generate the information bases used by the Meta-Compiler to create an exercise, that is: Information Objects, Strategies, Exercises, Homework and Personal Homework. These modules are described below.

3.2.1 Information Objects Management Module

Teachers can manage the information objects used in the exercises by means of this module, that includes tools to add new objects, delete objects, modify their attributes or access them (see [Fig. 2]). Apart from the object identifier, all attributes are optional and can be modified. Images and animations can be visualised by clicking the radio button on the left of the corresponding attribute. PICT and QuickTime formats are supported for both types of contents.

3.2.2 Strategies Management Module

Strategies can be created, accessed, modified and removed. To create a new strategy the three processes of the GMS have to be specified. Teachers can manipulate and drag objects in an area that represents the student’s screen and they can assign properties (type, occurrence order, delivering properties, reactions, etc.) to these visual objects. Allowed objects in the Presentation process are shown in [Fig. 3].
For instance, [Fig. 4] shows the Presentation process of an exercise that presents a description, by means of an image and an animation, three words and their signed forms. The first definition is used to ask children to select the word/sign that corresponds to the description.

To define the list of actions included in the Interaction and Checking processes, teachers can use a set of predefined functions that represent the most common operations in an interactive environment like CESAR. Nevertheless, they can program their own HyperTalk handlers.

### 3.2.3 Exercises Management Module

Teachers can establish the relationship between information objects and strategies in an exercise. With this purpose, they are presented a screen with a series of holes that represent the visual objects defined in the Presentation process. Teachers are asked to assign an existing information object to each hole. The object attribute matching the type of content previously defined is used to fill the hole and make up the exercise statement (see [Fig. 5]).
3.2.4 Homework Management Module

Once the exercise is defined, it has to be assigned to the pages of the book, so it can be directly accessed by the child. One of the main requirements of CESAR is that the training area is specific to each story and its exercises are related to the story contents. With this purpose, teachers can use the Homework Management module that allows to define the exercises that will be tied to each page. This module provides teachers with the list of exercises defined for each category so they can specify the Homework for each page of the book by means of a series of pop-up menus that make possible to select the book, the page, the category, the exercises and the strategy to be assigned.

3.2.5 Personal Homework Management Module

The assignment of exercises to book pages can be particularised for each child by means of the Personal Homework Management module, that also offers a number of pop-up menus that allow to select the student, the book, the page, the category, the exercises and the strategy to be applied.

4. Conclusions

This Visual Tool provides teachers with a series of mechanisms to define the set of solving strategies and exercises that will be used to reinforce the learning process of their students. Teachers do not need to be aware of details concerning the environment architecture and implementation to create new training material. In addition, they can generate a richer exercises base by making profit of the separation between the information objects and the solving strategy, since different combinations of strategies and contents define distinct exercises. In addition, the most appropriate strategy can be assigned to each child. The use of different strategies to solve the exercises was positively considered during the CESAR evaluation [Aedo et al. 1996], although the Visual Tool should be empirically evaluated to assess its usability.

Although the Training System is currently embedded in an environment oriented towards learning the written and sign languages, its architecture and the GMS are generic and they can be used in other kinds of subjects and in different learning environments.

Pusat Pendidikan Persediaan/ITM
Malaysia

Dr. John F. Zurovchak
MUCIA Global Education Group, Inc
USA
zurovchak@muciaglobal.edu

Abstract

This paper reviews the application of a unique combination of distance education methodologies by MUCIA Global Education Group, Inc and the American Degree Program at PPP/ITM in order to alleviate critical deficiencies in human resources and curricular content found at the latter. The introduction describes the growing crisis in higher education in Malaysia, in particular, the dilemma of addressing increasing enrollments with limited resources. The paper then reviews the decade of cooperation between MUCIA and ADP PPP/ITM that eventually led to the application of distance education methods and practices. Finally, the paper reviews the MUCIA Global/ADP program by examining each of its components and assessing its strengths and weaknesses as well as those of the program as a whole.

1.0 Introduction

The demand for higher education and advanced technical training around the globe is growing at an exponential rate. The United Nations Education, Social and Cultural Organization (UNESCO) reports the number of students enrolled and projected to be enrolled in higher education worldwide as follows:

<table>
<thead>
<tr>
<th>Year</th>
<th>Enrollments</th>
</tr>
</thead>
<tbody>
<tr>
<td>1970</td>
<td>28 million persons</td>
</tr>
<tr>
<td>1991</td>
<td>65 million persons</td>
</tr>
<tr>
<td>2000</td>
<td>79 million persons</td>
</tr>
<tr>
<td>2015</td>
<td>91 million persons</td>
</tr>
</tbody>
</table>

UNESCO also reports that the greatest growth in this student population has been and will continue to be in less developed countries, where enrollments stood at only 7 million persons in 1970 compared to 30 million persons in 1991.

An even more urgent picture emerges when increases in enrollment rates are compared to increases in school-age population in the developing world to form a ratio of access to higher education. According to UNESCO's data, this ratio has actually declined from 15.1 percent in 1980 to 14.1 percent in 1991. Therefore, although the student enrollment continues to increase in real terms, access to education is actually declining since enrollment rates cannot keep pace with school-age population growth rates.

This rapidly increasing demand for educational services has been met thus far in three ways. First, local governments have made serious efforts to build and expand their national educational systems. Second, some countries have sent substantial numbers of students abroad for higher education training. Third, educational institutions in the developed world, mainly the United States and Europe, have exported educational services in the form of technical assistance and other offshore programs. In the future, these
options will lose much of their viability from a cost perspective given the rapidly increasing costs of higher education and the projected exponential increases in demand. For example in terms of increased enrollments,

- In the last 30 years, Malaysia higher education has evolved from a single university, University of Malaya, enrolling less than one thousand students in 1960, to more than ten state universities enrolling nearly 100,000 students in the 1990s, with an additional estimated 70,000 students studying overseas.

- ITM alone expects to increase student enrollments from approximately 50,000 students today to 100,000 students by the year 2000.

- The current average annual cost of maintaining a foreign graduate student at a US university has reached US$25,000.00. (The figure is somewhat lower for undergraduate students.)

- Since the 1960s, Malaysia has sent an estimated 30 to 60 thousand students abroad at a drain of more than US$5 billion. Given current estimates, Malaysia will spend approximately the same amount in the 1990s alone.

Regarding faculty and staff development costs,

- The current average annual cost of maintaining a US professor abroad (with dependents) to teach in a foreign institution is approximately US$225,000.00.

- If staff requirements double in line with student enrollment increases, training 15,000 faculty members through the Masters Degree level (approximately 2 years each) at U.S. universities would require approximately US$ .4 billion.

- If those individuals were replaced while on 2-year study leave by U.S. faculty members costs would exceed $3.37 billion, if all of these U.S. professors were accompanied by dependents.

These data clearly indicate the magnitude of the problem facing the future of higher education in Malaysia. In short, they depict a growing demand for education and training that is quickly outstripping the capacities of traditional educational delivery systems, not only within Malaysia, but also in countries, such as the United States, who provide the technical assistance. However, it is essential that the training take place if Malaysia is to sustain its long-term economic development plans in the future.

In response to this situation, the Malaysian government has attempted to curb the outflow of undergraduate students studying overseas and yet maintain and even increase the quality of such instruction. Thus, educational institutions have to formulate new strategies and foster new techniques. PPP/ITM is no exception. Foremost among the new approaches is the ITM/MUCIA Global educational partnership that evolved out of a decade long partnership.

2.0 **PPP/ITM and MUCIA partnership**

2.1 **History of American Degree Program and MUCIA**

The Midwest Universities Consortium for International Activities, Inc (MUCIA) is the oldest and most experienced of several university consortia involved in international development and education in United States. MUCIA represents the Big Ten University Conference and includes ten of the largest and most prestigious public research institutions of higher education in the United States. Its members are: University of Illinois, Indiana University, University of Iowa, University of Michigan, Michigan State University, University of Minnesota, The Ohio State University, The Pennsylvania State University, Purdue University and University of Wisconsin-Madison. MUCIA’s partnership with PPP/ITM began with the first admission of students in 1985.
During the initial phases of this program, students at PPP/ITM were prepared for two years in Malaysia and were provided with an Indiana University transcript with which they could enter American universities or colleges as transfer students. Over the duration of the program, more than 3,500 students were successfully placed at US universities and have earned bachelors degrees in a range of majors. In 1987, a process of "Malaysianization" began in which responsibility of the program was gradually taken over by PPP/ITM. The process was completed in June 1993 when the American Degree Program (ADP) received its first intake of students.

Currently, ADP prepares students for undergraduate studies at American Universities. Students enter the program in Shah Alam and after two and a half years of preparatory courses which include freshman and sophomore courses, they are transferred to selected universities in the United States to complete their Junior and Senior years. The disciplines, courses and curricula offered by ADP are adapted from the MUCIA program.

New courses are added in line with developments with American academic programs. Courses are implemented and facilitated by qualified Malaysian lecturers many of whom were MUCIA/PPP/ITM faculty. A few American faculty remain as lecturers on its academic staff.

2.2 Creating a Global Education Network

MUCIA's response to the emerging crisis in higher education in Malaysia is to apply existing and emerging educational and communications technologies in the creation of a new program that seeks to provide:

(a) an immediate input to meet the content deficit being experienced by many students at ADP PPP/ITM and,

(b) a long-range program aimed at building ADP's capacities to serve its own educational goals as well as those of the global academic community into the 21st century.

Implemented and managed by the MUCIA Global Education Group, Inc., this program is structured around the development of a MUCIA Global Education Network. Using satellite and other emerging telecommunications technologies for distance education, students receive much needed course content while university administrators and faculty members participate in a broad-based institution development program, all in-country and at costs well below those of other models. The MUCIA Global Education Network delivers all the required training to students at their home campus in Shah Alam, and ADP issues the course credits and degree. As ADP takes over more of the direct educational offerings, the Network courses will become more advanced, in many cases transitioning to the graduate level. At the same time and using the same technologies, ADP participates in institutional development seminars and conferences designed:

(a) to increase its capacities to maintain and support itself and its programs, and

(b) to assist in further integrating it into the international academic community.

The advantages of the MUCIA Global Education Network approach are threefold. First, costs to students are lower because they receive expanded course content without leaving ADP or Malaysia and without having to support an expensive staff of expatriate instructors. Second, the ADP, and by extension PPP/ITM, is strengthened, initially because it grants the course credits, and in the longer term through the Network's institutional development program will eventually award the full degree. Third, the institutional certification process provides ADP with the means to enter the global academic community as an equal participant and partner.

MUCIA Global and the American Degree Program, PPP/ITM, launched the Global Education Network on 24th January 1997 as an extension of their decade long partnership in education. As such, ADP students have become leading pioneers in international distance education.
The ADP Program entered the new era of distance learning in Spring Semester 1997. The first course of study to adopt these new techniques was the business major with 22 students. These students enrolled in four courses: Principles of Management, Principles of Marketing, Principles of Finance and Intermediate Microeconomics. These four courses were taken in Spring 1997. The students continued in the Fall 1997 with three more courses: Money and Banking, Production and Operations and Marketing Communications. Eight distinguished MUCIA Global American professors participate in this distance learning education.

3.0 The MUCIA Global/ITM Model

The MUCIA Global/ITM model of distance education incorporates high quality and interactive education components.

Each teleclass comes complete with:

- a video component (30-40 videocassettes with approximately 40 minutes of content)
- support materials for facilitators
- a course manual
- lecture transcripts
- sample exams
- quizzes
- homework
- student support materials (including Internet and Web-based coursesites and courseware)
- interactive components including:
  ✓ direct email to instructors for specific communications and responses to questions drawn from video lectures
  ✓ Internet Relay Chat (IRC) for holding of virtual office hours.
  ✓ Classroom Discussion Groups with weekly discussion questions posted by the instructor to facilitate multi-site group discussion and to foster the building of cross-national peer learning communities
- technical support for course administration.

These video-classes incorporate the latest multi-media technologies available in order to meet the wide range of student learning preferences. By utilizing the latest emerging technologies, MUCIA Global can provide a learning environment that equals, and in most cases exceeds that of the traditional classroom! The end result is an affordable and high quality educational resource that often leads to increased student recruitment and retention.

3.1 Videotape Lectures

The course syllabi are identical to business courses in a typical American university. Each course consists of approximately 35 videotapes at 35-45 minutes each. The teleclass are produced by skilled and qualified MUCIA Global production teams and incorporate a variety of multimedia including graphics, text, animation, whiteboard, video clips, and simulation. ADP students view the tapes under the supervision of the local instructors who assist them from time to time.

3.2 Supplemental materials

Taped lectures are supported by various electronic and print materials including: a course manual that incorporates transcripts of the video lectures as well as course handouts and problem sets. A course website provides course lecture notes and transcripts as well as self-tests, related external links, homework assignments, class announcements, and an area for asynchronous electronic class discussions.

3.3 Electronic mail
In addition, the students have the opportunity to communicate directly with the professors through electronic mail in order to seek direct information or course assistance.

3.4 Internet Relay Chat (IRC)

Internet Relay Chat, or IRC, provides the opportunity for students to interact in real-time with their MUCIA Global professor. IRC may best be understood as "Virtual Office Hours." During IRC, students have the opportunity to ask questions pertaining to homework, exams, lectures, class projects, and a host of other topics that are usually addressed before and after class, in the hallway, or at the routine office hours of professors. Through IRC, MUCIA Global provides Network students with the opportunity to attend "virtual office hours."

IRC provides a flexible and useful method for:
- professors and students to establish rapport,
- students to ask about upcoming exams and exam reviews,
- professors to work through a homework problem step by step in order to assist students in understanding complex concepts, and
- professors to question students about their class projects.

Interaction is an indispensable aspect of MUCIA Global's courses. IRC is just one of the many options available to our students for quality real-time and off-line interaction. Such interactive techniques, in combination with MUCIA Global's Course Manual, and Course Websites place MUCIA Global and ADP at the cutting edge of 21st century education.

3.5 Roles of Local Instructors

Local instructors facilitate the implementation of the teleclasses on-site. Their roles include playing the video lectures, facilitating classroom discussion, administering exams and the final, providing homework assignments and many other classrooms activities. The facilitators work closely with the MUCIA Global faculty to successfully implement the teleclass. Facilitators are also responsible for grading exams and assignments.

4.0 Future Expansion to the program

The MUCIA Global/ITM Model has been in operation for two semesters with some difficulties. Being pioneers, the students and the professors have to get used to the new technologies and methods of instruction. Despite the minor problems, several advantages have accrued from the partnership.

In addition, possible expansion to the existing program would be:
- To expand the existing courses up to Sophomore year
- To have better interactive communication in the form of sound and video, not only text
- To have the courses eventually made available on satellite so that occasional live sessions may occur. In this manner, interactivity between the students and the professors can be enhanced considerably
- To include more majors such as Engineering, Sciences and other courses
- To have local staff serve as instructors for some of the modules

The MUCIA/ITM's partnership will be strengthened well into the next decade with these possibilities brought by distance education technology.
5.0 Conclusion

The MUCIA Global/ADP distance education program has now been in operation for two academic semesters with the participation of 22 students located in the American Degree Program at PPP/ITM. At this time, although some difficulties have occurred, the program may be viewed as an unqualified success.
Experimenting Web Technologies to Access an Opera Theatre

Abstract: A historical opera theatre is a complex reality to communicate in all its facets. We developed an application based on web technology to allow virtual visit and interactive involvement among remote users, for the Teatro alla Scala in Milan. Two modules, based on QuickTimeOVR and VRML technology, realise a visual reconstruction of the theatre: present and past days appearance of the building inside and outside with different degrees of interaction. Text, images, audio, video and voice is also used to emphasise appropriately the messages. Animation of scenes, simulation of audio and lights effects in the space are made possible by VRML and virtual dancers on stage can be controlled interactively by users.

1. Introduction

Internet launches the challenge of an open theatre, distributed over the territory and the entire social body [Mitchell 96]. This is particularly relevant in the case of classical theatre, traditionally conceived as a closed space, both physically and socially: the theatre was hosted in a building in a given urban setting and was identified with a well defined social class. Indeed, the new media are also suitable for the transmission of a message intrinsically multimodal. Opera, ballet and music are expressive languages related to different sensorial spheres and that adopt different means of expression: literary text, sound, human voice, mimicry, gestures, costumes and scenography.

Our attention has been driven by the Teatro alla Scala, which is an important historical theatre for the Italian melodrama, based in Milano and very popular among citizen: designed by G. Piermarini (1731-1808) at the end of the XVIII century, after a fire that destroyed the older Regio Teatro Ducale, whose seasons started in 1589. In the application here described, we provide a variety of remote services: some related to performances on calendar and other current activities (exhibitions, lectures, announces, press releases etc.) and some to the theatre history and cultural heritage.

We face two objectives: to promote an active behaviour in the public and to increase its involvement. Therefore, we want to provide languages through which users can act upon objects to transform them. To this end, we selected among available technologies those resulting more seductive: in this prototype we used text, audio, video, voice, images besides QuickTime®VR (QTVR from now on) and VRML 2.0 (Virtual Reality Modelling Language).

In this paper we describe the application, LaScalaWeb, the web site of the theatre, and we analyse it, considering it as a composite object that can be read following different keys: functional, symbolic or historical etc.. We propose a structural analysis of narrative in terms of its syntactic-semantic relationship [Prince 93]. The understanding of a communicative artifact emerges following the inverse procedure adopted by its designer during construction: a composition of basic elements following given rules in order to produce the integral object providing meaningful effects. Users have to de-compose backward the object discovering its deep structure and
finding out values underlying the object surface. We will apply this methodology to a specific section of the application: the virtual visit.

2. LaScalaWeb

The web site of Teatro alla Scala [LaScalaWeb 95] provides historical information on the theatre, a multimedia presentation of the season, access to the theatre database, news from the press office, biographies of artists, mailboxes, ticket office information, news about audits and a virtual shop.

The events are presented to the general public on a day-to-day base, as the calendar evolves. The performances are documented by giving the program, the subject, the performing cast of the day, pictures taken from the stage documenting artists and the scenography, audio or video clips, pictures of costumes and their sketches. For operas the web site often offers the complete list of discography and bibliographic references.

The theatre manages a database that is used for internal administrative purposes. The web interfaces the information that are interesting to the public about performances held in the theatre since 1953. One can query about an author, an opera or a specific artist; one can also read about the orchestra composition and compare it with present days choices. To this respect the Teatro alla Scala is the first theatre to allow consultation of its archive via the network and the service has been welcomed by users, researchers and scholars but also opera fans. The virtual shop opened quite recently and it sells books edited by the theatre, together with programs of performances, photos and videos.

During these past three years, since it started to be operative, the web site has proved to be an important channel of communication between the theatre and its public. Mails, that in the beginning were mainly general compliments or to point out mistakes, are now used to ask more precise questions and show a high and focused level of interest. Often mails are sent by scholars searching for information about historical performances or news about artists.

3. The Virtual Visit

The virtual visit to the theatre is made possible by a combination of two different applications, integrated with text and different media, returning a virtual reconstruction, which is finalised to increase the quality of virtual engagement in users and to document the historical evolution of the theatre. Our goal is to convey an image of the theatre that goes beyond the building, as it appears nowadays, into its symbolic meaning, as it grew through centuries of art performances, exhibitions and collective imagery. To this end we provide a virtual reconstruction of the exterior and the interior of the building by a 3D model, texts with different level of information accessed opportunely at convenient time during interaction, voice in the background to call attention from users visually involved by applications, audio clips to evoke important events in the theatre and so on.

The sense of history and evolution in time is given through a selection of original drawings and texts reporting some citizen impressions of the building at its first construction. Some alternative projects of the building are also documented, together with a reconstruction of the neighbourhood, which does not exist anymore after a square has been open in its place.

To show the theatre machina and to offer users clues of the complexity of the theatre life, we provide a series of still images of the theatre at work behind the scenery. Moreover, we draw the 3D model of the scenes of the opera Armide by C. Gluck (1714-1787), the opening opera of the past season, in order to allow their movements as during the performances. This animation can also be explored interactively by users, providing a new experience for the virtual spectators, different and more complete than the actual one. In fact spectators may not fully appreciate the complexity of the process of staging a performance and have little idea of the backstage. Virtual dancers can also be positioned on the stage and instructed to perform a baroque dance.

For virtual reconstruction present technology opens at least two possibilities: QuickTime®VR technology [Shenchang 95], that allows to return a powerful impression of the outlook of objects to be rendered, and VRML
2.0 [Ames et al. 97], that allows to implement interactive 3D environment returning spatial cues. The experience in using both technologies has shown advantages and limits, depending on the message that the designer chooses to communicate.

QTVR is perfectly suited to give a synthetic view of a complex environment. The public can navigate the space by selecting viewpoints, panning and zooming. Activating the context links another interior of the theatre is displayed. A different reconstruction of the space is achieved by VRML: placing different textures on the 3D model of the theatre we can return different levels of perception and information. In the VRML application we programmed animation, audio and light effects to convey better cues of the space.

Moreover, QTVR is less expensive than VRML, in that it takes less time to develop, and its transmission over the net is cheaper, because files are in average smaller. VRML requires more time also because it is based on a 3D model; the optimisation of the 3D model for effective Internet browsing is still critical. Both technologies can be make available for low cost computer platforms, but efficient VRML modelling is better done on high end graphics workstations.

3.1 The QuickTime®VR module

We recall briefly that QTVR is a technology that allows to render a 3D space or an object by photographic techniques, using an image rendering method, by texture mapping a series of pictures on a cylindrical space and by removing artefacts due to the mapping process. A detailed description of the methodology can be found in [Shenchang 95]. An accurate colour balance has been necessary to optimise the colour perception and to render the real space.

A sequence of snap shots have been taken to reconstruct a possible visit of the theatre starting from the square, in which the theatre is located, namely Piazza della Scala. The 360° panorama are taken from strategic points in the theatre, from the stalls and the balconies, from the foyer and from the stage, describing an architectural promenade. A specific node from the stage gives the unusual perspective of the scenery seen from the back looking at the stalls. Hotspots are implemented in the node to reference external documents, giving more details in text or photo formats about the theatre.
3.2 The Virtual Reality Modelling Language module

A 3D model of the theatre has been constructed from technical drawings adopting AutoCAD 13. The model has been converted into VRML 2.0 by saving the AutoCAD model in 3DS format at first, then saving it into VRML 2.0 format. The subsequent activities on the module have been done adopting CosmoWorlds and by explicit programming. CosmoWorlds has been used mainly to apply texture maps on the model surfaces, and to program some simple animation. Explicit programming has been necessary to create menus and commands to offer users the possibility of selecting options. To this aim script nodes have been implemented also by means of Java scripts. Acoustic cues have been implemented by using VRML 2.0 features for sound spatialization.

The immersive experience offered to users has been augmented by simulation: the sounds of instruments being tuned, the dimming of the lights, the curtains being raised give the emotion of the onset of the performance. The performance is documented by showing the scene movements and video sequences of the actual performance are displayed on the virtual stage.

The VRML application can be visited by the public in two ways: by direct interactive navigation or by executing pre-programmed visits and animation.
4. Analysis along the Subject-object Relationship

Let us now describe the application focusing on the subject-object relationship, where subjects are of course users and the object is the application, considering two points of view: interactivity and hyperlinking features, engagement and iconicity.

As for the first point of view, interactivity is a category describing users behaviour while hyperlinking features describe the nature of object. We state that active vs. passive behaviour in users is a function of the presence vs. absence of specific characteristics in the object. Active behaviour is promoted by the presence of hypertextual links, implemented in different ways according to interface and technical requirements as buttons, textual links, hot-spots and so on. In some cases, such as in QTVR or VRML applications, a high interactivity is granted even without explicit links: in QTVR samples users can interact, with 2 degrees of freedom, turning left/right and zooming, while in VRML users can navigate freely in the 3D space.

---

**Fig. 3:** The interior VRML model

**Fig. 4:** analysing texts according to subject-object relationships
As for the second point of view, iconicity is a type of speech which is finalised to produce varying degrees of reality mimicry in order to gain users' consensus and emotional adhesion [Marsciani & Zinna 91]. The communicative object is designed and created with different reality-effects to enhance growing involvement in users. Any media (text, images, sound, voice, 3D models ...) can be tuned along the iconicity axis, whose extreme points are abstraction and figurativeness.

In our application, we mostly adopted highly figurative texts¹, allowing us to convey our interpretation of the essence of the theatre or its scaligerità. In Fig. 4 we plot on the subject consensus - object iconicity axes some partial texts, showing their degrees of figurativeness. We want to emphasise that, given a partial text, its degree of figurativeness can vary according to its occurrence. For instance, as it is shown in the figure, we used the original drawings by Piermarini in different contexts: as mere gif or jpeg images and as textures in VRML models. In the first occurrence, even though drawings are rather figurative, because they convey the idea of history and tradition through the pencil stroke and colour for instance, they are more abstract than in the second one, where they convey also spatial cues.

Moreover, for a given meaning there are several nuances, that we tried to convey by selecting appropriate technology. For instance, to express the scaligerità we distinguish between history and present time and according to the point of view we adopted different techniques. We used VRML to give the idea of the evolution of the building through the centuries, or even of the building that has been projected but never built, in synergy with highly figurative literal texts, rich of names, place and time references. Whereas, we preferred to use QTVR to describe the theatre present status. The intrinsic QTVR nature, based on image rendering technique, offers a satisfying perception of the environment, being based on photographs shots, but also limit the perception of the structural complexity of the real space. On the other hand VRML, even in the case when photos are textured on the surfaces, gives a somewhat cartoon effect.

Therefore, we can not conclude that QTVR is a more figurative language than VRML, in any occurrence, because it depends on the local context and the meaning that the designer wants to associate to the text. In this application, we made an effort to accurately evaluate case by case how to combine different parts of the virtual visit without inconsistencies.

4.1 Interactivity and web site architecture

We started this past season and it will become effective in the next one, to design a database to collect, in a structured way, all information that we want to publish, including multimedia documents. This fact will have deep influence in users interaction, that will become qualitatively different. If the web site is structured in a database, users may continue to consult it in the traditional way, through the links foreseen by the designer, but also will be able to query the database in order to create a their own final document, which may be the first and only time that will be generated. Same queries in time can generate different documents and also various users can formulate diverse queries. This of course is the case for all databases, but usually is not for web sites. In LaScalaWeb we at present provide an interface to the historical database of the theatre, therefore this form of interactivity is in some way already present; but will be fully exploited only when all information will be structured in a database.

Adopting a rough metaphor, the database can be seen as a collection of different boxes holding homogeneous data and a set of rules to combine them. The document has a temporary life: once it has been inspected, it implodes again into the database. To this respect we deal with digital way of life, that takes form at the time of its use. Following Hjelmslev [Hjelmslev 73], the database can be conceived as the system of all potential documents and each of them is the tangible result of one of the possible generation process. The designer control is weak on the document generation process, while it is strong on the retrieval system and on the interface design.

¹ In this context text indicates any object that can convey meaning, no matter which is the language used to produce it. Therefore a kind of text can be literal text, but also an image, a video clip or an applicative sample based on VRML or QTVR.
Acknowledgements

The web site is a service offered by the Press Office of the Teatro alla Scala di Milano, with funding provided by the Camera di Commercio, Industria, Artigianato e Agricoltura di Milano. We acknowledge the work of Emanuele Genuizzi, Paolo Maninetti, Daniele Pannuto, Diego Paroni for implementing the QuickTime®VR and VRML applications. QuickTime®VR application has been developed with the support of Apple Computer Italia, and the photos were taken by Paolo Bonacina and Claudia Provenzano.

Abstract: This paper presents the Interactive Neural Network Environment INNE, a graphical environment to design, simulate and analyse the behaviour of neural networks. The aim of the application is to provide a rich and flexible tool for learning neural network models. Therefore the environment provides several different neural models and tools for visualizing the learning phase and the results of the computation. This last feature makes INNE rather different from other simulators and makes it suitable for students at their first approach to neural networks or to a specific model. Nevertheless the environment is general and robust and allows the design of neural networks to solve problems and to verify their performances. At present the models implemented are: Boltzmann machines and Hopfield networks, Back-error propagation networks, Hebbian networks, Simple competitive networks, Kohonen networks. The application has been developed in the CoLoS project.

1 Introduction

The application INNE (Interactive Neural Network Environment) is a graphical environment to design, simulate and analyse the behaviour of neural networks. It has been developed in the European project CoLoS (Conceptual Learning of Science) [CoLoS] [Hartel 94], which has involved several European universities and research centers since 1988 when it started under the auspices of Hewlett-Packard. Its objective is to support concept learning and deeper understanding in the field of science and technology making optimal use of the didactical potential of modern communication technologies.

The aim of the application is to provide a rich and flexible tool for learning neural network modelling. This goal has influenced several design choices and in particular the emphasis that has been given on showing the dynamical processes that occur in the net during the learning phase and the computation. The neural models implemented are: Boltzmann machines and Hopfield networks [Ackley et al. 85], Back-error propagation networks [Rumelhart and McCelland 86], Hebbian networks [Oja 92], Simple competitive networks [Hertz et al. 91], Kohonen networks [Kohonen 88].

Given its didactical purposes, the application provides a number of pre-defined examples in order to teach the main concepts concerning a chosen algorithm while easing the process of gaining experience on the net architecture (i.e. acquiring the ability of defining the network structure and parameters). In fact, the ability of designing neural architectures to solve problems is acquired only by experience, since the demonstration of convergence is based on stochastic approximation techniques. On the other hand the cardinality of the training set is usually very limited and the choice of the parameters that regulate the network behaviour must be found heuristically in several trials. Furthermore it does not exist yet a general theory associating the number of learning steps to the approximation reached and this makes it difficult for beginners to start solving problems by adopting the neural paradigm.

In order to realise a range of examples easy to understand it has been necessary to enrich INNE with some auxiliary tools, for instance a generator of gaussian distributions and a generator of uniform distribution inside polygons. These tools are used to generate strong visual flavoured examples so that one can “see” what is going on during the computation.

Moreover to make examples more concrete and allow students to fully appreciate the implemented models, the environment provides a range of problems solved with neural networks with which students can experiment. For instance we illustrate the principal components analysis with the problem of image compression, the clustering analysis with the problem of image segmentation, the problem of topological mapping with an example of approximation of bi-dimensional figures.
1.1 INNE architecture

The structure of the application is displayed in Fig. 1 and consists of the Kernel module, the Net Editor, the 3D Visualization tool and the GUI module.

The GUI module includes the Net Visualization tool, a graphical window that interacts with the net editor and allows the definition of the network architecture and of its layout. The Net Editor provides tools for managing a subset of nodes and/or arcs as an object to ease the job and allowing the definition of large nets. Moreover, users attach a behaviour to the network they are editing through the GUI module acting on a Simulation Control Panel and choosing among one of the predefined models. The 3D Visualization module helps to understand the processes that occur during the learning phase and, in other cases, to visualize the results of the computation.

The Kernel module is subdivided into two parts: the former to manage the network with its nodes and arcs, the latter to compute the behaviour according to a model. While the interface is written using the X11-R5 libraries and Motif 1.2 the kernel is written in plain C language for portability reasons. The 3D Visualization module, also written adopting Motif libraries, is a tool implemented in the CoLoS project.

2 Simulation of Boltzmann machines

The first neural model available in INNE is the Boltzmann machine, a combinatoric optimization model implementing the probabilistic optimization algorithm called simulated annealing [Hertz et al. 91] and able to avoid local optimal solutions (i.e. networks that do not change dynamically their structure). In the module, a learning algorithm for classification problems is implemented as well, even though the back-error propagation learning algorithm is more efficient to this purpose. The Boltzmann machine can be used to solve combinatorial problems by approximation [Ackley et al. 85]; this can be shown by loading the network of Fig. 2-a that solve the independent set problem. The objective is to find the greatest number of independent nodes not connected directly with each other on undirected graphs.

Users can choose between deterministic or stochastic behaviour and select the sequential, random or full parallel mode of updating the network and experiment the speed of reaching a stable state. The machine can be trapped into local optimal configurations. The experiment will show that the random parallelism mode can be very effective in the stochastic behaviour even though no convergence theorem...
Figure 3: Visualizing the learning phase and the final configuration. (a) Finding the principal components with the Sanger rule in 3D space; (b) Finding the principal components with the Sanger rule in 2D space; (c) Finding the principal subspace with the Oja rule in 3D space.

has been proved so far. In the deterministic case the Boltzmann machine is a Hopfield model which offers the best computational time in the sequential mode as it reaches immediately a stable state chosen at random among local optimal configurations.

3 Simulation of Back-error propagation Algorithms

Back-error propagation is by far the most popular supervised learning method for multilayer neural networks [Rumelhart and McCelland 86]. Back propagation and its variants have been applied to a variety of problems, including pattern recognition, signal processing, image compression, speech recognition, nonlinear system modelling and control. The most appealing feature of back propagation is its adaptive nature, which allows complex processes to be modeled through learning from measurements or examples, updating the arc weight connecting neurons.

In our simulation, this process is visualised and the arcs show different colours and thickness according to their weights. The method does not require specific mathematical models or expert knowledge to solve the problem. Our examples are simple problems often used for testing and benchmarking a network: typically, the training set contains all possible input patterns, so there is no question of generalization. For instance, the network in [Fig 2-b] recognizes the digits between 0 and 9. During the learning phase we can observe the error dropping and after training, we can test the network giving in input a handwritten digit by setting on or off the input neurons displayed in a grid. The network in one step will try to recognize the digit even if some noise is present: setting the value of the output neurons between 0 and 1 according to the recognition probability of the digit [see Fig 2-c].

4 Simulation of Hebbian Algorithms

One of the neural models implemented in INNE is the Hebbian model to which we can apply the fundamental Hebbian, Oja and Sanger rules [Oja 92], [Sanger 89]. These three updating rules allow a different component analysis of the input data and we have added to the environment a number of tools to visualize the 2D and the 3D cases.

In order to produce meaningful examples of these networks, a graphical tool for generating and visualizing 2D and 3D gaussian distributions has been added to the environment. Every input neuron is connected to all output neurons, therefore their arcs define the vectors which can be represented in the input space. The coordinates of the points, randomly generated according to a distribution in the 2D or 3D space introduced by users, are given in input to the network. During the learning phase we can observe how the network analyses the gaussian distribution given in input. Adopting the Sanger rule [see Fig. 3-a] and [Fig. 3-b], the weight vectors of the output nodes individuate the direction of the principal components of the distribution in a 3D and 2D space. On the contrary adopting the Oja rule [see Fig. 3-c], the network only finds the principal subspace.

In [Fig. 3] we can see the input space and the vectors defined by the output arc weights after a simulation of 10000 steps with $\eta_0 = 0.7$ and linear decay. During the learning phase we can observe how the vectors change their position in the space while the network tries to find the principal components of the distribution. At first ($\eta$ is high) the swings are wide, while in the end there are only small swings.
4.1 The example of image compression

As an example of Hebbian algorithms, an application for image compression has been added to INNE. The proliferation of multi-media tools in computer communication networks has increased the demand for techniques to improve the efficiency of transmission and storage of image; therefore a large variety of algorithms for image compression has been realized. The basic idea behind a class of image compression algorithms is to exploit the fact that nearby pixels in images are often highly correlated. A given image is therefore divided into several blocks of pixels and each block, treated as a vector, is linearly transformed into a vector whose components are mutually uncorrelated. These components are then independently quantized for transmission or storage. The reconstruction of the original image is obtained by using the inverse linear transform operation on the quantized coefficient vector. The optimal transform in which the average mean-squared reconstruction error is minimized is called Principal Component Analysis (or Karhunen-Loéve transform).

For this example, INNE allows users to load images in the ppm (portable pixmap) format and after execution returns the compressed image: users can choose either the Oja rule or the Sanger rule for the compression. We can both compress and reconstruct the whole image by using the same neural network. The first choice to be taken concerns the neural network dimension that affects the size of the blocks into which the images are subdivided. In fact different sizes have been tested, but large networks, corresponding to large blocks, showed some difficulties in the training phase and the quality of the compressed image seemed to degrade according to the generalization property. Thus 8 x 8 blocks have been chosen and this is a standard size used in many different coding algorithms. Of course, the compressed image needs to be quantized before being transmitted or archived. [Fig. 4] presents an image compressed using a neural network that has 64 input neurons organized in a 8 x 8 matrix and 8 output neurons. The learning phase lasted 30000 learning steps, with $\eta = 0.3$, a decay function of $\eta$ exponential with $\alpha = 0.3$ and the Sanger rule. After the training phase, the network output is quantized with 8 bits for the first and the second neuron, 6 bits for the 3rd and the 4th and 2 for the others. The decompressed image is shown in [Fig. 4-b], while [Fig. 4-c] and [Fig. 4-d] show a detail of the previous image, before and after compression. Here we can appreciate the faults caused by the block division.

5 Simulation of competitive networks

In unsupervised competitive neural models, single neurons compete for being the one to fire [Hertz et al. 91]. We implemented 2D and 3D displays of a multivariate gaussian distribution so as to allow to generate examples for this model easily. While defining a distribution in the input space, the input points, randomly generated according to the distributions, are fed into the network, which tries to find their centers.

The dimension of the input space is defined by the number of input neurons. The number of output neurons defines the number of clusters in which we desire to partitionate the input points. During the computation we can interactively modify the simulation parameters and affect the network behaviour in order to analyse it and improve its performance. For instance, we can choose to refine the learning algorithm, in case some output units (dead units) appeared to be stuck and never win.

In [Fig. 5-a] and [Fig. 5-b] we can visualize the behaviour of a net in the input space. The net has 3 input neurons, according to the 3D input space, fully connected to 7 output neurons. In the initial state, the 7 visible dots are randomly localized, their position being given by the weight of arcs connecting them to the 3 input nodes. After some training, the arc weights are modified so that the dots will locate...
the clusters. In fact they are positioned at the center of the seven gaussian distributions in the final configurations. In [Fig. 5-c] we can see the same problem for the 2D case, run with the option called *increasing pattern method* which avoids the *dead units* and visualizes the route of the weight vectors from their initial position (0, 0) to the distribution centers. In these simulations we have used 50000 steps and a linear decay term of \( \eta \) from 0.5 to 0.

5.1 The example of colour clustering

Adopting this model of competitive learning, an application suitable to solve the problem of colour clustering has been added to the environment. Much work in computer vision still focuses on gray scale images even though these techniques cannot usually be applied to colour images. For example, the segmentation of a colour image is a more complicated problem than that of a gray scale image. Arbib [Arbib and Uchiyama 94] shows theoretically and experimentally that competitive learning converges to approximate the optimum solution. The net architecture will be affected by the characteristics of the image space and the number of input neurons has to be the same as the dimension of the colour space. In particular, we adopt the Red/Green/Blue space to visualize the colour distribution in the images. The number of output neurons depends on the number of the colour clusters into which we would like to subdivide the image colours. During the learning phase, the Red/Green/Blue values of random pixels of the input image are assigned as state to the input nodes and their positions in the colour space are visualized in a 3D visualization window together with the positions of the output neurons. This animation shows the learning process actually taking place in the network. When the training phase is over the original image is processed [see for instance Fig. 6-a]; the Red/Green/Blue coordinates of its pixels are fed into the network and their values are substituted by the colour of the corresponding cluster [see Fig. 6-b]. This new output image will present as many colours as the number of output neurons in the network. Moreover the application can use the output image to produce the segmented image by applying an algorithm to detect the borders in the colour regions, as shown in [Fig. 6-c]. Image 6-b is obtained by a network of 3 input neurons totally connected to only 4 output neurons.

6 Simulation of Kohonen’s maps

Kohonen algorithms are unsupervised competitive algorithms [Kohonen 88]. These networks, also called Kohonen’s maps, use the spatial organization of output neurons to determine the information in the input data. The network structure consists of a unique level where every input neuron is connected to
all output neurons, which are generally organized into a matrix of $N \times M$ dimension. INNE allows to approximate the input data generated by a uniform distribution inside 2D polygons. Through a graphical representation of the map, it is possible to observe the evolution of the simulations and how the map fits the input form. In this model we are not interested in the direction of $w_i$ (as in Hebbian algorithms) but in their values, which define a position in the input space. Neurons that are next to each other in the network are shown as dots connected by lines and their positions in the input space are given by the arc weight $w_i$ of the corresponding neuron.

For example, let us consider a neural network having 2 input neurons and a 10 x 10 matrix of output neurons. If we give in input a uniform distribution, in a polygon we can analyse the evolution of Kohonen maps tending to fit the input space. At the beginning of the simulation we initialize the net with small value random arc weights so that the neurons are shown all clustered in a small space of irregular shape as in [Fig. 7-a]. During the simulation we can observe how the reticule evolves towards more and more regular shapes [Fig. 7-b]. After the learning phase, if the number of learning steps was adequate, the map will give a good approximation of the input polygon. It is possible to observe that points on the borderline of the network are positioned at a certain distance from the border; in fact, every point represents a portion of the input space. This is divided into regions where neurons represent the centre of gravity. In the ordering phase of the weight vectors, we can have problems so that the network doesn’t approximate the input space correctly. This event is illustrated in [Fig. 7-c]. When these problems occur, the time required for learning increases.

Acknowledgments
We would like to thank our colleagues Paola Campadelli and Alberto Bertoni, who gave us much helpful advice and many suggestions. Moreover we would like to acknowledge the work of Paolo Marelli and students F. Cantarini, A. Muesan, G. Siliotti and A. Trapella who implemented some INNE modules as part of their thesis in Scienze dell’Informazione at the Università degli Studi di Milano.

Abstract: Interactive multimedia (IMM) and problem-based learning (PBL) are both promoted in response to the current need to offer authentic and effective professional education. An emphasis on collaborative work in PBL contexts may have discouraged the application of IMM, more commonly designed for individual use. This paper describes a preliminary instructional design model for IMM using PBL principles and includes approaches to resolving the apparent tensions between the two methodologies. Application of this model to development of a CD-ROM for teacher education is described.

1. Introduction and Background

Traditional approaches to university education promote subject-based learning which encourages teachers to focus on covering material and students to adopt surface learning which fails to integrate knowledge [Margetson 1994]. New approaches encouraging both the integration of existing knowledge and the habits and skills fundamental to lifelong learning are needed. In addition, a need for periodic professional development and the desire of some to explore new careers, have contributed to demand for more flexible access to higher education. Coincidentally, new technologies promise to facilitate access to learning at times and places chosen by the learner.

Problem-based learning (PBL) developed in response to concerns that a subject based approach might not be the most effective preparation for future professionals [Boud 1985]. Since originating in North American medical schools, PBL has spread to many countries and a variety of fields including nursing, engineering, law and business [Boud and Feletti 1991]. Its characteristic focus on authentic problems as the starting point for learning has been credited with increasing the motivation of students and encouraging them to integrate knowledge from foundation disciplines. If it is true that PBL offers advantages for professional education and there is demonstrable demand for flexible access to such educational programs, then it seems logical to consider the use of interactive multi-media (IMM), as a means of making the benefits of PBL more widely available.

1.1 Instructional Design for PBL

The first step towards incorporating PBL principles into the instructional design and development of interactive multimedia resources is to identify the essential characteristics of PBL. Two commonly cited descriptions of PBL come from Boud (1985) and Bridges (1992). In outlining their views of PBL, these authors agree that the focus in a PBL process is on an authentic problem in a group setting where learning stems from collaborative analysis of the problem and is largely learner-directed. An alternative approach in
which teacher education students engaged with a problem individually and prepared a written analysis of the problem in preparation for group interaction, has also been described [Gibson and Gibson, 1995]. Further, the collaboration of students in small groups has been an explicit assumption underlying the development of computer environments supporting PBL [Ronteltap and Eurelings 1997] [Koschmann et al. 1996]. Regardless of author however, each description of PBL incorporates reference to an authentic problem as the initial focus and assigns active, group-based roles to learners, at some stage of the process, for the purpose of determining solutions and synthesising knowledge.

Moreover, Heath [Heath 1997] recognises a trend in instructional design towards replacing traditional behaviourist approaches with constructivist orientations emphasising the use of emerging technologies. By incorporating interaction with an environment, cognitive conflict and negotiation of shared understanding, PBL provides an ideal vehicle for modelling such constructivist approaches [Savery and Duffy 1995].

1.2 Computer Support of PBL

A variety of examples of computer use in PBL programs can be found in the literature. A “Problem Solving Assistant”, incorporating a problem-solving heuristic and research resources has been used to support teacher education students [Ritchie et al. 1995]. [Hart 1996] described a PBL architectural course using computer graphics systems. Computers have been linked to create a Collaborative Learning Laboratory [Koschmann et al. 1996] to support PBL meetings in medical education through access to resources and data exchange. Network technologies, including web pages, have supported collaborative PBL in a biotechnology program [Mackenzie et al. 1997], and a dual electronic environment which supports access to resources and preparation for subsequent group presentation in a collaborative environment has also been described [Ronteltap and Eurelings 1997].

Despite the emergence of computer use in professional courses incorporating PBL, [Hoffman and Ritchie 1997] found no published articles about integration of interactive multimedia in PBL. They suggested that multimedia might support PBL by producing key benefits in fidelity, representational richness, time and timeliness, individualisation, assessment, efficiency and increased power of agency.

2. Issues in the Design of IMM-PBL

2.1 Collaboration versus Individual Learning

Implementations of PBL typically include collaborative group work. Whether such collaboration is an essential component of PBL logically depends upon the role it plays in the overall experience of PBL. On the other hand, interactive multimedia is typically designed for individual use.

Exploring the value of PBL experiences for individual rather than collaborative use may be justified on two grounds. Firstly, professional practice is situated in a variety of contexts including collaborative teams, sole practice and competition. Successful professional practice frequently depends upon individual capacity to solve problems. Logically, educational experiences which develop that capacity should be valued. Secondly, individual PBL experiences may help to address the increasing interest in distance and flexible access to professional education and the increasingly successful integration of technology into higher education.

Studies of the cognitive and metacognitive processes of students during the initial problem analysis phase of PBL support the view that the role of group interactions in PBL is to facilitate activation and elaboration of students' existing knowledge and so encourage conceptual change through cognitive dissonance [De Grave et al. 1996]. If this is the function of group interaction in PBL, then, provided that an alternative mechanism with equivalent effect is introduced, it should be possible to design effective PBL for individual use.
2.2 Free Exploration versus Storylines and Simulated Reality

One of the characteristics of multimedia as an information source is ease of access. Users of multimedia expect to be able to explore the environment encountering a variety of stimuli. A key characteristic of PBL is its use of authentic problems. In real life, resources may sometimes be inaccessible, activities may be time dependent and decisions may be effectively irreversible. These conditions occur in the simulated reality of computer games.

Multimedia materials supporting individual PBL will include problem scenarios sharing some characteristics of computer games alongside collections of resources to be explored in the search for a solution. It seems likely that there will be tension between the genre of the computer game and that of the multimedia encyclopedia with the possibility of confusion for users. The efficacy of story for motivating progress through multimedia training and increasing transfer of content has been demonstrated [Bielenberg and Carpenter-Smith 1996]. Building a storyline around a problem may assist in drawing the user out of exploration mode, into and through the problem.

2.3 Tutors versus Scaffolding

Tutors in PBL groups do not act as informants but as facilitators who model higher order thinking and challenge the thinking of learners [Boud 1985]. The use of scaffolding approaches, such as breaking the larger problem into sub-problems [Savery and Duffy 1995] or including heuristic aids [Ritchie et al. 1995], may be appropriate alternatives for individual PBL using multimedia materials.

3. A Design Model for IMM-PBL

3.1 Scenario Development

[Fig. 1] outlines the process of developing a problem scenario for IMM-PBL. Although the model was refined in the process of developing an IMM-PBL package for teacher education, it is presented here in general form.

![Figure 1: IMM-PBL scenario development](image)

Development begins with identification of key concepts from the content domain [Savery and Duffy 1995] and a typical context in which the concepts might be used. A description of the context including aspects of the environment and the problem is developed. The problem is divided into a series of sub-problems to facilitate scaffolding by considering the types of artefacts, typically documents of various kinds, which might be produced in association with a stepwise solution to the problem situation. Finally, the scenario is completed by devising a storyline which describes the progress of the problem solver from initial encounter with the problem to final resolution and provides the motivation for the user. At each stage, effort is devoted to applying reality checks to ensure that the overall scenario, and each element of it, is plausible, and flows naturally according to user choice. The process tends to be iterative rather than linear and, as indicated in the lower portion of the figure, there is a feedback loop through which evaluations at each stage can influence subsequent revisions.
3.2 Scenario Structure

[Fig. 2] illustrates the structure of a typical problem scenario for IMM-PBL. Again the model has been generalised to highlight the principles of the instructional design.

In order to assist the learner through metacognitive scaffolding, the problem scenario is presented as a series of tasks embedded in a storyline related to a professional context. Each task results in preparation of some artefact relevant to the problem. The Activation Task is intended to situate the learner in the problem context and to begin the process of activating relevant prior knowledge. Elaboration Tasks provide opportunity for recall and reconfiguration of prior knowledge relevant to the specific problem and exploration of additional, context specific knowledge and ‘experience’ gained during problem solution. Consolidation Tasks emphasise relevant knowledge transfer, analysis, integration, synthesis and evaluation of selected, context specific knowledge and problem based ‘experience’. Finally, the reflection task is designed to encourage learners to further integrate knowledge, ‘experience’ and artefacts gathered through the problem solving process into their cognitive structures as though products of real experience.

</tbody>
</table>

“Expert” comparisons

Figure 2: IMM-PBL scenario structure

After each task, users are able to compare their artefact with examples from a panel of experts. These interactions with experienced professionals replace the interactions with peers [De Grave et al. 1996] or with a facilitator [Savery and Duffy 1995]. Except when the storyline requires otherwise, users have access to a collection of resources relevant to the concepts encapsulated in the problems. Because PBL is intended to increase the capacity of learners to solve real problems [Boud 1985] and because identifying critical elements may be counter-productive [Savery and Duffy 1995], the selection of resources for inclusion in the package is gauged to require judgement in selection from what is provided and initiative in employing material from alternative sources.

4. Applying the IMM-PBL Instructional Design Model

The IMM-PBL instructional design model emerged during the development of a CD-ROM package to assist teachers with technology integration [Gibson and Albion, 1998]. The CD-ROM includes a collection of resources relevant to the use of technology in classroom teaching and a series of four problem scenarios based around the common theme of integrating technology into a variety of teaching contexts. Development of one problem scenario will be described as an example of how the design model may be applied.

4.1 Scenario Development

As it was desirable across the intended set of scenarios to represent different teaching circumstances in terms of school setting, pupil characteristics and resource availability, the overall context for the problems was developed around the situation of a teacher applying for a series of short term appointments. For this problem the specific context selected was a small rural school with multi-aged classrooms. The particular class to which the user would be assigned was about to be equipped with a new computer.
Concepts identified for inclusion within this scenario centred around planning and management issues associated with the integration of a single computer into a classroom, including the physical location of resources; planning for individual, small group and whole class work with computers; and behaviour management.

Artefacts identified as appropriate to this context included a brief statement about technology integration, a floorplan showing placement of furnishings and a powersource, notes about planning for technology use for discussion with other staff members and a summary of presentations from staff members in a staff meeting. Using these artefacts as a foundation, a simple storyline was sketched, and embellished with a non-reversible decision point (a chance to visit another classroom via video clips), a tour of the school with the Principal [voice over] and opportunities to interview other teachers (via video).

Checks on content validity, logic flow, professional plausibility and product feasibility were conducted at appropriate stages during the design and development process using a panel of experienced teachers, a cohort of pre-service teacher education students and professional colleagues from several international universities.

4.2 Scenario Structure

Since the overall context of the problem scenarios was devised around the search for temporary employment, the activation task in this problem comprised a brief response to a selection criterion relevant to the technology concepts embedded in the scenario. Planning the arrangement of classroom furnishings using a manipulative graphic floor plan afforded additional opportunity for elaboration of relevant knowledge through a concrete task and represented the elaboration task for this problem.

Work on consolidation tasks, presented as preparation for a staff discussion and supported by outlines provided in the software, required students to access other resources and to structure their own thoughts on the topic. Finally the reflection task offered an opportunity to reconsider the problem and to synthesise personal responses with the samples provided in the materials. Expert comparisons were provided in the form of sample solutions prepared by a panel of experienced teachers. These were made available to learners following completion of each task.

Resources provided on the CD-ROM included documents specific to the problem (school policies and plans), as well as a collection of more general material including video segments illustrating classroom computer use, relevant policy documents from education authorities and additional materials describing computer integration.

4.3 Navigation and Visual Format

Interactive packages of this type require a consistent format for visual display. Further, a means of navigation through the problem which provided intuitive control to the user was a necessity if the impact of the message was not to be subjugated to lower order issues of screen or movement control. In this package, an integral component of the teaching environment, the teacher’s desk, provided a natural navigational tool for users. It was from this desk that all action and decision points, governing progress through the problem, originated.

4.4 Production and evaluation

The complexity of multimedia production typically requires that it be accomplished by a team with a variety of skills rather than through the efforts of one or two individuals. The production process for the package described in this paper has been outlined elsewhere [Gibson and Albion, 1997]. Integral to complicated processes of this type is the need for an evaluation strategy capable of supporting development. The formative
evaluation of an early prototype of this package was carried out with a group of final year teacher education students. Reactions to the presentation and content of the first scenario have improved the useability of the final product. More extensive evaluations will be conducted with the final product. An area of particular interest in future evaluations will be the capacity of this CD-ROM based, interactive multimedia problem-based learning package to induce effects similar to those obtained with traditional approaches to PBL.

5. Conclusion

In combining the recognised strengths of problem based learning and interactive multimedia, issues related to the instructional design of such products became central to the development process. In describing some of these challenges to instructional design, the authors have recognised the difficulties inherent in attempting to translate a traditional, group based approach to learning, into a technology mediated, individual experience. Early indications from sample target group evaluations and analyses from professional colleagues in a variety of international contexts indicate that the effort has a credible foundation.

Abstract: This paper presents the results of an experiment carried out on a random sample of 34 students from The College Of Commercial Studies, one of the colleges and training centres under the supervision of The Public Authority For Applied Education And Training (PAAET), Kuwait Higher Education. The experiment aimed at evaluating the impact of a Multimedia Tutorial Programme on students' learning experience. Two methods of information delivery were investigated: traditional lecturing method and multimedia method. The results show that students were motivated and satisfied with the multimedia approach compared to the traditional way. However, it is difficult to precisely evaluate students' retention of knowledge in this experiment.

The researchers suggests the need for further studies which might present different and various results depending on the type of learning materials, students' background, usability of the multimedia programme, and period of time undertaken in the experiment.

1.0 Introduction

Multimedia technology has now become a powerful tool for our educational experience [Ambron 1990]. It enables knowledge to be conveyed through a rich mixture of video, sound, music, graphics, still images and animation in a single electronic medium, providing the ability to link subjects in a non-linear format. Such technologies are not a threat, but rather, they present a good opportunity for education [Falk & Carlson 1992]. It is expected that this technology will not only improve educational productivity but also the way of learning itself. Implementing this technology will give the educators the chance to motivate the students, stimulate their interest, and encourage different and various ways of learning [Staley 1995].

Educators, all over the world, are challenged to re-energize the educational system to make education more exciting. Towards this goal, multimedia provides the right technology at the right time. Today, many people compare the multimedia revolution to the personal computer revolution of the 1980s. In fact, interactive multimedia is the sum of all these revolutions wrapped up into one revolution of communication that combines the audio-visual power of television, the publishing power of the press and the interactive power of the computer [Wills & Swart 1994].
The advancement of technology energized educators to integrate technology into the curriculum development process. Educators in the Ministry Of Higher Education in Kuwait in general, and in The Public Authority for Applied Education and Training (PAAET) in particular are looking into all issues related to the development of education. As multimedia is considered to be an essential element in educational technology, the researchers aim at, in this paper, evaluating the effectiveness of the use of multimedia learning materials on students’ retention of knowledge, motivation, and satisfaction.

2.0 The Experiment

2.1 Subjects

Thirty four Kuwaiti students (first and second year female students) enrolled at the College of Commercial Studies PAAET, took part in the experiment. They were specialised in banking, insurance, accounting, secretarial and computer information systems. The primary objective of the study is to examine students’ learning experience and retention of knowledge by using two types of learning environments: traditional presentation method and multimedia method. The students were divided into two groups as will be explained later in the procedure section 2.5.

2.2 Learning Materials

The learning materials used for this experiment introduce basic information about PAAET, a key figure in Higher Education in Kuwait. The content covers the basic organizational structure, functions, and activities of PAAET. Choosing such content, the researchers aimed at introducing general information to familiarise students with services, sectors, and facilities of their academic institutions.

The information was pulled out from the PAAET annual bulletin report [PAAET 1994/95]. It was prepared and organised to be introduced to students by two methods: traditional lecture method and multimedia method.

The organization of the traditional presentation was properly set, the content was prepared and transparencies were developed. On the other hand, the multimedia tutorial programme was designed and developed. Arabic language was the communication media in the two methods of delivery used in this experiment.

The multimedia tutorial programme was divided into two parts: part 1, covers the activities, functions, objectives and the training sector of PAAET. Part 2, covers both the applied education sector and the administration of PAAET. The same learning materials, as in the multimedia tutorial, were also prepared to be delivered in a traditional lecturing environment.

2.3 Multimedia Tutorial Design

The multimedia tutorial programme was developed using Action 3.0, one of the multimedia authoring packages from Macromedia. Traditional multimedia authoring steps were followed [Vaughan 1994]. Media elements such as graphics, images and sounds were captured and edited before putting all together. The multimedia authoring process took place, and aimed to create the presentation in order to communicate information as effectively as possible and to make the presentation memorable, to give the students a clear understanding of the learning materials.

Having scripted the presentation, it was helpful to draw a storyboard which basically amounts to the complete presentation. Drawing the storyboard gave an idea as to where to place animation, images and text. It also gave an idea about fonts, text style and size. In addition, It helped to adjust the general sequence of events in the presentation. The navigational structure of the multimedia tutorial is hierarchical. This structure allows the students to go through the presentation in a linear and a non-linear way. A guided chart was designed as shown in [Fig. 1] to give students an orientation and to let them know where they are in the programme. Students had some degree of control over the multimedia interactive tutorial.
Some of the design techniques were considered in the authoring stage of the multimedia tutoring programme:

* Some welcoming text and animated pictures were integrated at the beginning and the end of the presentation to accommodate students' attention and motivation.
* Animation, pictures and graphics were used in various topics in order to illustrate and address topics.
* Human voice, music, and sound effects were adjusted with each screen to augment and emphasise some points and to enhance learning.

2.4 Method of Evaluation

Questionnaire approach was used to mainly evaluate students' learning experience, as well as the usability of the multimedia tutorial. The questionnaire was designed after preparing the learning materials and developing the multimedia tutorial programme. The questionnaire is divided into four sections. The first section is concerned with collecting students' personal data. The second section consists of two parts, each part consists of 15 multiple choice questions, these questions aimed at examining students' retention of knowledge on the topics introduced in the presentation (both the traditional and the multimedia).

The third section consists of 14 questions and aims at evaluating students' feedback and students' opinions on the two different methods of learning environments. The questionnaire uses a set of bipolar semantically anchored items (preferring multimedia versus preferring traditional presentation) with a scale of 0 to 5.

The fourth section consists of 8 questions, and aims at evaluating the interface, media, and usability of the multimedia tutorial programme.

2.5 Procedures

All of the 34 students were gathered in the lecturing room. They were told what they were going to do during the experiment. The students were equally divided into 2 groups, group A and group B. Each group had to go through the whole presentation which was divided into two parts, lecturing part and the multimedia one.

Group A attended the first part of the presentation in the lecturing room. This session covered activities, functions, objectives and the training sector of PAAET. It was delivered as traditional presentation. Group B, at the same time, attended the first part of the presentation in the multimedia lab using the multimedia tutorial programme. Students in the lab were able to navigate the programme and control the flow of the learning materials, the first part took about 30 minutes. Both groups were given the questionnaire and were told to fill
in the first section and part 1 of the second section. Then, the questionnaires were collected from the students. After a short break, group A attended the second part of the presentation in the multimedia lab, they were able to navigate the programme and control the flow of the learning materials which covered the applied education sector and the administration of PAAET. Group B, at the same time, attended the second part of the presentation in the lecturing room which also covered the applied education sector and the administration. The second part took about 30 minutes.

At the end, students in both groups were given the questionnaires in order to fill in: part 2 of the second section; section three which is concerned with collecting information related to the students’ learning experience; and section four which is concerned with collecting information related to the usability of the multimedia tutorial programme. Then, the Questionnaires were collected from the students.

3.0 Results

Based on the analysis of the collected data, the results are as follows:
1- The first section of the questionnaire, which is concerned with students’ personal data, revealed that students were first and second year, business college, female students averaging a 2.5 grade point average (scale out of 4).

2- The second section examines students’ retention of knowledge. Students answering the multiple choice questions related to the multimedia part of the presentation scored a total of 391 correct answers from 480 (81.5%), which is 2 points higher than the correct answers related to the traditional presentation in which students scored a total of 389 from 480 (81%) as shown in [Tab. 1].

Table 3. Usability of The Multimedia Tutorial Programme

4.0 Discussions

There are a number of interesting results in tables [1, 2, and 3]. In [Tab. 1] it is obvious that there is a slight difference among students who answered correct questions related to the multimedia presentation which is 391 compared with those correct answers related to the traditional presentation part which is 389. This may give an indication that there is no significant difference between the two methods of learning in terms of retention of knowledge. For a very short experiment, however, it is difficult to measure students’ retention of knowledge which could be affected by other factors such as type of information being presented, usability of the multimedia tutorial programme as well as the presentation skills of the lecturer.

Students were interested, motivated, and excited by learning through multimedia. The results presented in [Tab. 2] support these propositions. The physical act of clicking a mouse to control the flow of the presentation seems to have a strong attractiveness to students. Their ability to explore and to find information by their own pace seems to give them the chance to put them in the driver’s seat. It seemed that multimedia session had transformed students from passive recipients of information to active participants in their own learning. It was notable that the advantages of multimedia are its ability to re-energize students and stimulate new excitement which led to a general agreement among students that multimedia will be beneficial if integrated into their college curriculum.

Students were asked some major questions related to the interface of the multimedia tutorial programme such as, the degree of interactivity, ease of use, integration of media, integration of content and colours. The results are shown in [Tab. 3], indicate that the tutorial was easy to use and control. Moreover, the integration of media and content was effective. In addition, text and colours were convenient. Although 9% of the students were not totally happy with the multimedia sound, 72.7% agree that sound had aroused their attention to the learning materials.

It is very important to consider designing a good interface for any multimedia educational programme in order to get the best out of it. Mckerlie and Preece have supported that and indicated that good integration of media in an effective and creative way, taking users’ constraints, excitement and support into account will give the
best result. They advised designers to exploit creative talent and experiment with new ideas and ways of thinking [Mckerlie & Preece 1993].

5.0 Recommendations

The researchers make the following recommendations to decision-makers in Kuwait Higher Education in general and PAAET in particular with respect to this study:

1- Integrate technology into its curriculum development process and establish a curriculum development centre.
2- Encourage teaching staff to gain basic understanding of the use of computers and multimedia applications.
3- Establish a Multimedia Unit in each college, institute and training centre.
4- Integrate the Multimedia Unit with the Curriculum Development Centre.
5- Provide an Internet access to students as international networks are being opened up and contain information and media that can be selected and navigated from large numbers of computer systems.
6- Encourage researchers and staff members to contribute to the development of this technology to maximise the use of this type of teaching tool.

6.0 Future Directions

Ropa suggests that within the multimedia learning programme, metaphors, graphics, colours, symbols, and icons should reflect a feeling of the country where the programme is going to be used [Ropa 1991]. In this study, although the interface of the multimedia tutorial programme is developed in Arabic, the researchers did not consider other cultural issues when designing the programme for the Kuwaiti students. As culture has an impact on the multimedia user interface design, it is essential to understand the nature of the target culture.

Future design, development, and evaluation of multimedia learning programmes need to incorporate considerations of cultural issues, not only in language and terms, but also in every aspect of the interface such as: metaphors, mental model, navigation, graphics, look, feel, and taste of the programme.

Abstract: In this paper we report on the design and development of a ‘Distributed Classroom’ involving two secondary schools in Palermo. In particular, we describe the features of the developed learning environment, and focus on the structure of the communication process which has been implemented in order to make the learning process extremely efficient.

The primary goal of this study is to experiment with and evaluate a cooperative learning environment based on telematic tools and to define new methodologies that allow for an effective integration of technologies into curricular activities.

1. Introduction

Rapid developments in interactive communication technologies are quickly leading towards very deep social transformations behind the Information Society.

In this context, the educational system is challenged to play an essential role in promoting and controlling these transformations: only educational systems can effectively lead the way- through specific curricula and by adopting technology for teaching/learning processes - towards a full transition to the Information Society. The educational system must promote and sustain the innovative vision of the Information Society, by introducing - as early as possible in the child's scholastic life - pedagogical activities based on the new interactive communication tools.

The general aim of the reported experience is to make students and teachers, involved in the project, aware of the real potentialities offered by new technology in education, by leading them through a real experience of distributed classroom.

2. The New Classroom

The primary goal of this study is to experiment with and evaluate a cooperative learning environment based on telematic tools, by introducing a specific kind of communication technology in curricular activities of classes of the Italian secondary schools; in addition we have evaluated the changes due to this introduction. To reach this aim we have designed a ‘Distributed Classroom’ that allows groups of students to communicate with one or more other remote groups, according to these main characteristics:

- class sessions involve both synchronous and asynchronous communication by using one or a combination of several technologies such as computer conferencing, electronic mail, etc.
- all students can research, study, review and exchange the learning material in a cooperative way.
- during class sessions students can discuss, clarify concepts and be engaged in problem-solving and group activities and other learning exercises.

To create the on-line learning environment we have adopted the Bulletin Board System (BBS) technology, with graphic interface. Communication and file exchange occur through the tools available on the BBS system: e-mail, newsgroups, shared file areas, chatting rooms.

The students (aged between 12 and 13) of four classes from two secondary schools, subdivided into groups according to sociometric criteria, are encouraged to experiment with telematic communication and then with the different communication paradigms, thus creating a concrete experience of a Virtual Class.

The groups have concentrated on the study of two historical houses in different geographical areas where they come from which are part of the National Heritage.

Moreover, the groups are led through different interaction schemes, which have been designed to stimulate different cooperation strategies and to favour communication within and between groups.
3. Description of Communication Process

The design of the communication model has been central to our work and, at the same time, very useful. A communication model is an essential tool for understanding the organization and relationships between the different stages of a planned communication process.

Firstly, it was important to get models which would be both precise and flexible.

Secondly, the models had to exhibit a very high degree of communicability and comprehensibility, since they had to be understood by people with different pre-skills, competencies and experiences: students, teachers and trainers.

Finally, these models should be able to guide all the people involved in the communication process (teachers and trainers) in the discussion of the organizational problems, didactic programming and evaluation.

In particular, both the teachers and the trainers examined the following problems: hypothesis about the on-line learning process; hypothesis about the modifications which occur, in the students and in the teachers, involved in the on-line communication experience; how to improve the exchange of didactic material and ideas related to a specific subject; the needs for tools, strategies and evaluation methods, suggestions about the scheduling of the activities, and so forth.

In conclusion, the model defining phase has produced many very interesting ideas for each actor in the communication process.

The first step of this process is based on presentation of students, using a telematic identity card or "home page", created according to their fantasy. This allows each student to get to know on-line companions and enables them to understand and use telematic tools.

Once the groups had acquired the necessary skills they were helped to learn and cooperate telematically using a second communication model as follows.

The group communication process was organized according to the plan shown in [Fig. 1]. Remote groups are paired so that two corresponding groups gather information about the same subject; the first group of the pair deals with the general aspects of the subject, while the corresponding remote group analyses a specific case regarding the subject.
In the first stage, the bi-directional communication, between pairs of remote groups, takes place regarding common subject in a horizontal way, from general aspects to specific aspects and vice versa. In this way, the material is collected gradually by the remote groups and is then integrated and elaborated cooperatively in order to carry out a thorough study of the scientific and architectonic aspects of the chosen houses.

When the group had completed its part of the research, using BBS, it communicated to the remote group. In this case, cooperative learning is achieved by means of certain expedients such as: the exchange of results with other groups, by means of telematic forum in order to stimulate comparison; communication, by e-mail, of the partial results of the research to the teachers. In the same way, using e-mail, teachers answer giving them adequate feedback.

Beside the horizontal interaction between remote groups, as described above, during the second stage, diagonal interaction was used. This helped to produce more effective cooperation between the groups which had studied the subject from a general point of view and those which had considered specific aspects of the subject. The meta-cognitive aim of this kind of interaction is to find analogies and differences in order to integrate all the information.

These interactions are indicated by the diagonal lines in [Fig.1].

As hypothesized, the cooperative learning is stimulated by the comparison between the information obtained and, then, by the identification of common features of the material (e.g. an architect who designed several buildings in the different areas of the city).

Finally, using a third model, we have stimulated 'free discussions', by means of telematic forums, of topics examined by pairs of remote groups. The purpose of this is to give all the groups an overall view of the work and so allow each student to cooperate "with and between" groups.

Moreover in this experience it is necessary to underline the role of teachers and trainers. This consisted in the supervision and continuous assessment of the level of learning and participation between the individual groups, where necessary modifying the assignment of tasks or the communication flow between groups.

The communication in the described models, was synchronous or asynchronous as the work required.

4. Lesson Learned

This experience has led us to make the following considerations about how much technology affects the teaching/learning process:

- the use of the computer in the interaction between the actors in the communication process allows students to improve logic-cognitive skills which come from writing and reading textual documents;
- because of the modification of the setting, the members join together, exchange information, establish the rules, plan the activities, organize themselves, in other words, the group cooperates in order to reach a common result;
- in specific situations, the telematic tools simplify the management of the group processes, such as the activities of observation and feedback which are necessary to evaluate the group as a whole and the contributions of each member; in addition, telematic tools encourage a self-evaluation process;
- from a socio-affective point of view, the use of telematics aids the network of relationships among peers; this is due to the fact that telematics provide new and diversified study situations. These situations are based on play aspects and on the cooperative value which are intrinsic in the use of Telematics;
- stimuli and motivation to learn are increased by the appeal which is typical of a new tool and of an innovative communication mode.

Besides the didactic potentialities of Telematics, some drawbacks which might arise during the Distributed Classroom experience must be taken carefully into account. We report those which have arisen: the impact with something new and the resistance to going outside the boundaries of one's own class; the difficulty in organizing the activities of the groups in a synergetic way; the unfamiliarity of interacting in an indirect way; the difficulty of learning about the new technologies and their didactic potentialities.

As mentioned before these possible drawbacks have been carefully taken into account at the project design stage as well as during the whole experience, by performing a constant evaluation process.
5. Conclusions

In this paper we have reported on an experience of a distributed classroom, and we have focused on the design of the structure of the communication process and interaction.

Among the several activities, we have guided students and teachers towards new creative learning and teaching strategies.

The developed environment has proved very efficient in enabling students and teachers to realize the real potentialities of the computer mediated communication, thus going beyond the simple use of new attractive tools.

This experience is the starting point of a wider project that seeks to enhance the potentiality of telematics as a tool to improve the sharing of experiences among different situations and participants, the interdisciplinarity, the development of socio-cognitive skills and, last but not least, the recovery of school motivation in pupils with particular educational needs.

Education of Engineering Students within a Multimedia / Hypermedia Environment — a Review

R. Anderl, U. R. Vogel
Department of Computer Integrated Design (DiK), Darmstadt University of Technology, Petersenstr. 30, D-64287 Darmstadt, Germany, Email: {anderl | urvogel} @dik.tu-darmstadt.de
http://www.dik.maschinenbau.tu-darmstadt.de

Abstract: Universities are facing a challenge like enterprises did during the last few years. With less and less costs, the product (in this case education) should become better and better if the University will hold its rank in the information society of tomorrow. This goal implies that teaching must become very dynamic and link directly to research results in technology-related subjects.

About three years ago Darmstadt University of Technology started to realise these ideas for the education of all mechanical engineers. This article summarizes activities of the Department of Computer Integrated Design in distributed lectures, lectures on demand, hypermedia information environments and multimedia tutoring systems. The main focus was thereby the efficient use of new technologies to improve education within the restrictions of limited resources, rather than the proof of technical realisation. Therefore feedback and evaluation had been an important part of the projects.

1. Distributed Lectures

Lectures are traditionally the kernel of university education. This traditional form implies that everybody who wants to attend has to be in the lecture room at lecture time. If the target group for the lecture is distributed over a larger area, attending the lecture can often be time-consuming or even impossible because of other dates. Attending a lecture course at other Universities (e.g. in special topics) is not possible at all. The situation gets even more difficult if the idea of lifelong learning is taken into account. Therefore the possibility to distribute normal lectures online through a LAN/WAN was evaluated.

The equipment used is shown in [Fig. 1]. Two cameras and several microphones are used to capture the lecturer, the used media like slides or writing on the black- or whiteboard and the audience. The media-
manager chooses the video-signal and mixes the audio-channel that is actually transferred through the net. Both cameras are equipped with remote-control heads. Videos shown in the lecture are directly sent to the remote computers. Requests from remote participants are handled by the media manager and can be posed online by means of audio-amplification with the video signal shown on the canvas of the data display. The workstations used in [Fig. 1] are SUN workstations, as the conferencing tool ShowMe was used.

Practice has shown that the quality of primary sound and secondary video are crucial for the acceptance of distributed lectures by the remote participants who have been spoiled by expensive TV and cinema productions. Therefore a guaranteed high bandwidth e.g., through ATM (Asynchronous Transfer Mode) and the professional skills of at least two media managers (in order to handle requests) in a specially equipped multimedia lecture room is necessary. (In a normal lecture room, the light conditions are normally very poor for taking video especially if overhead projectors are used.) The technical equipment needed to achieve a high quality transmission is considerably extensive and far from plug and play techniques. Consequently distributed lectures can only be considered as an efficient teaching method if the professional equipment and the professional skills of the operators are used full time or at least every day.

Universities should be encouraged to start cooperative efforts with the idea to reduce the quantity of lectures in each location to be able to improve the remaining lectures to a very high quality. These lectures would then be distributed to other locations and related to the quality of the lecture a demand from the remote locations would arise.

2. Lecture on Demand

In the previous chapter, it is shown how lectures can be attended from different locations with the possibility of interaction. In this chapter the possibility to repeat a lecture or to attend a lecture later is discussed. In addition to the distribution in terms of location from the previous chapter, a distribution in terms of time is now enabled naturally encompassing the loss of the possibility of direct interaction with the lecturer. This is called 'lecture on demand' because it shall enable the students to get any of the available lectures throughout the whole year (most lectures are only once a year) from almost every location 24 hours a day.

Therefore the digitized lectures should be accessible from almost every computer in the internet with normal multimedia ability. The materials must be provided completely in standardized formats to ensure platform independence for at least a few years. Digitizing and processing of lecture material must be done using moderate manpower within a day or two, for each 90 minute lecture such that the material offered is always up to date. By attending a lecture on demand the user must get all the information that was provided within the original lecture.

The first goal can be reached by means of the WWW (World Wide Web) in combination with Java applets and source files in independent formats (such as ASCII, GIF, JPEG, SunAudio, etc.) with moderate file sizes. By analyzing lectures based on slides and blackboard writings it becomes evident that nearly all the information is contained in the combination of slides and the sound of the lecturer. Therefore these two media must be supplied in a very high quality. The video picture itself merely helps to get to know the lecturer and to give the impression of participation (which can be quite important) and not to miss important details.

Figure 2: Overview of a lecture structured into sequences
For recording lectures, the arrangement in [Fig. 1] is simplified. One camera records the lecturer himself. The other camera is used to record the slides and the blackboard. This camera also records the sound of the lecturer via the wireless microphone such that synchronic information is available for the digitizing later on. Both cameras are remote controlled, questions from the audience are recorded with separate microphones.

The first step in processing the material is to divide up the lecture into thematical sequences (e.g. each slide shown and explained can be described as a unit). Later on these sequences can be accessed directly or found by a search engine. Therefore the sequences are described within a few words. The relation to the slides and the lengths of the units are also documented [Fig. 2].

Lecture slides made with a graphic program can easily be provided as a GIF or JPEG picture without any loss of information. Handwriting on slides or on the blackboard can by the use of the video-recording easily be redesigned in a graphic program and also presented as GIF or JPEG.

The quality of sound is very important. The biggest loss normally happens right at the beginning of the process chain due to unappropriate microphones or bad recording conditions. That can easily lead to a very low signal to noise ratio. For this reason wireless microphones and high quality receivers without any sound dropouts are essential. An audio mixer is needed to adjust signal strength for the recorder. The signal must be digitized at a high quality (e.g. 16 bit, 22 kHz). Such high quality sound files can then be converted to compressed files with lower border frequency such as .law. This reduces the file size by a factor of almost 4 which is important for the loading time of the lecture later on. Experience shows that the loss of quality in this step is moderate if it has been high enough initially.

The video signal itself contains the greatest amount of data but the least amount of information in this case. For reasonable response times, this amount of data must be compressed drastically. Tests of the acceptance of different presentation forms led to a method where the video-stream (25 frames per second with PAL) is split into a set of individual, high quality, compressed pictures (JPEG) taken at a constant interval (e.g. 1 sec) instead of reducing the picture quality while keeping a high frame rate. An interval of about 1 sec. leads to a high acceptance because the response times for watching the sequence are moderate, the quality of the pictures is so high that details can be seen and the user does not get the impression of a flickering film that is running too slow.

![Figure 3: Sequence of a lecture played in the WWW-Browser by a Java applet](image)

With the method described above 12 lectures (each 90 minutes long) of the course PDT 1 (Product Data Technology) have been recorded and digitized [Anderl and Vogel et al.1996]. With the method described above the entire course has a size of less than 700 MB. For access to the lectures on demand by the WWW a navigation and orientation structure similar to the one described in chapter 3 was designed. The lecture on demand can be used on any machine in the internet where a browser with full Java ability (including the performance of sound) is available. The Java applet loads one sequence at a time (slides, soundfile and video pictures) and plays it with the synchronic information given in the applet-call.
3. Hypermedial Information Environment

At the University of Darmstadt mechanical engineers get an integrated engineering education in design during their basic studies in the first and second year. This is divided into three parts. A detailed description of this education based on Product Data Technology is given in [Anderl and Vogel 1997]. All material for the CAD-course (the first of the three parts) is provided by means of the WWW. This material includes manuals for the CAD- and the PDM-Systems (Computer Aided Design- and Product Data Management-System), exercises, lecture sheets, additional information and examinations.

For an efficient use of this material an information environment had to be designed, which allows a simple navigation in conjunction with an unambiguous orientation. The actual content is separated from the means of orientation and navigation. A structure was developed to describe any of the different branches within Information-System. This allows the realisation of an automatic creation of navigation and orientation for each branch by special tools. This method leads to an Information-System that is easy to maintain. The Information-System is enriched by local search engines and manually created index pages.

The practical use in different courses showed that even though all material was directly available at each work place there is still a great demand for printouts. Normal printouts of the manuals, exercises, etc. from the WWW do not support efficient work. They are just loose pages without header or footer, without a table of contents or page numbers. These printouts cannot be used in a sensible way for personal annotations or for studying somewhere else other than in front of a computer.

Therefore it was necessary to develop and implement a method that allows the conversion of a structured HTML document into a well laid out paper document that achieves the quality of a document created originally with a text processing application.

The result shown in [Fig. 4] was achieved by parsing the HTML manual to TEX using its defined structures and deriving postscript files afterwards. In practice this method has proved to be very efficient for the documents used within the CAD-course which are primarily designed for the use in HTML and secondarily for use in the form of printouts. Changes in these manuals and exercises are done easily and are available for everybody instantly.

It is obvious that only such semantic constructs can be parsed successfully from HTML to TEX which have an equivalent there. E.g. a table containing pictures, often used to arrange pictures on the screen of the browser, cannot be expressed in TEX. Workarounds in the parsing algorithm will never be generally satisfactory. Therefore the best way in such cases is to declare that such semantic constructs must not be used in the HTML sources which may undergo conversion into a postscript file. This results in the declaration of a HTML subset as a kind of styleguide.

On the other hand there are semantic constructs in TEX like the caption of a picture (which is linked to the rule that picture and caption always have to be on the same page) that don't have an equivalent in HTML. For some constructs semantic rules where established within the HTML styleguide that would allow the parser to recognise an artificial HTML caption if it was there or leave it out (after a picture) if not.
For documents which contain a considerable number of mathematical equations and which are primarily designed for use as a printout and only secondarily for the in HTML the opposite approach should be preferred. The quality of the source format will always be better than that off the derived one. Hence in this case it is suggested to start with TEX, define which subset may be used and derive the HTML as a secondary form of presentation.

Important for both ways of working is that the source files contain the structure of the document separate from any layout description. The layout itself is generated by algorithms within the browser or the LaTeX code. Documents that are designed within modern textprocessing systems (e.g. Microsoft Word) are not based on this idea and the file formats of these systems are far away from a fixed standard (even taking RTF (Rich Text Format) into account). Therefore there was no significant effort made to derive these formats from HTML or vice versa.

4. Multimedia Tutoring System

The experience in lectures and courses concerning CAD- and PDM-Systems has clearly shown that demonstrations how to use the various functionalities of these systems are essential for participants who want to comprehend the usage. The techniques of lecture on demand and hypermedial manuals as they are discussed above both are not able to store and reproduce the full information given in such a demonstration. The 'lecture on demand' cannot provide the required picture resolution (e.g. 1024 x 768 pixels) which is clearly above normal video resolution. In the hypermedia manuals such demonstrations could only be transferred to long passages with a few sentences of text in between batches of sequential pictures. Such documents are normally quite tiring to work with, the reader has to switch continuously between description and the pictures themselves to understand all the steps of the process being explained. In the original demonstration the viewer had the possibility to watch the screen and to listen to the explanation at the same time. Within the multimedia tutoring system this possibility is given on demand for a set of demonstrations (tutorials) [Anderl and Vogel et al. 1997].

Each tutorial is divided into sequences of moderate length (e.g. 2 - 5 min.). The digitized sequence consists of a number of high resolution pictures, soundfiles, the text that is spoken in written form and information about the synchronisation. This material is accessed through the WWW by a platform independent Java applet running on the client of the user [Fig. 5]. This Java client offers a wide variety of control possibilities. The sequence can be stopped, rewound, viewed in single steps - even scrolling through the sequence (e.g. to find one special action) is possible. In cases where no sound is wanted, the spoken text appears in a separate window in written form instead.
This technique was frequently used with a high acceptance during the CAD course in 1997 although the performance of Java was still rather poor under the operation systems used at this time. The multimedia tutoring system enabled the students to repeat what they had seen in the lecture right at that time when they where putting it into practise - especially when they got stuck with one or other functionality of the CAD-system. Questions that were posed during the course by email could often been answerd quickly with a link to related sequences.

5. Conclusions

In this article it was shown, how modern multimedia and hypermedia techniques could already be used to improve university teaching. Benefits could be achieved in the amount and the quality of the available teaching material, in the efficiency of the distribution of this material and in some cases in the efficency of teaching large numbers of students. Generally speaking multimedia and hypermedia techniques enable the creation of higher quality course material which should lead to courses of higher quality themselves. But improving the quality of any course will always be time consuming wether multimedia and hypermedia techniques are used or not. Luckily these techniques allow now an instant distribution of all material to a large number of students somewhere in the WWW. If this advantage is exploited through teaching cooperations the resources gained by reducing the actual redundancies in creating course material can be used to improve the material and the courses themselves.

To reach this goal the university must avoid the main mistake many enterprises did in the past: Not the reduction of costs but the improvment of quality and of innovation should be the primary motive power of all structural changes. If the universities make use of the chances that are inherent in multimedia and hypermedia they will be perfectly prepared for the challenges of tomorrow in the educational sector.

Abstract: Teaching in an Internet-based learning environment provides unique challenges. Of particular interest is the question of maintaining link integrity. Although several modern hypermedia systems can guarantee that links within their systems boundaries are maintained, it is more difficult to ensure that links to external Web servers remain intact. The system we have developed maintains consistency to external Web sites for all essential documents (as specified by the courseware authors). It also notifies the link authors when remote documents have been altered or deleted.

1. Introduction

Internet-based learning environments are an important development worldwide. Unfortunately broken links pose a considerable problem for system administrators, teachers, and students alike. For example, it is most frustrating to discover in the middle of a lecture that a link, which was valid when a lecture was prepared, has disappeared—maybe just one hour later (as we have experienced more than once). Students also experience additional stress when they discover, just before an exam, the disappearance of material they have briefly skimmed at the beginning of a semester.

1.1 Our Virtual Learning Centre

We have aimed to create an interactive distributed learning environment, using a combination of new course material and lecture material available from previous years [Lennon & Maurer, 1994]. Since there is a wide range of hardware that has to be supported, we have relied on common Web browsers that support Java applets. Successful features of our project include:

- The inclusion of all lecture material, tutorial notes, assignment descriptions, student projects and assignment marks (in some cases answers for the whole class), as well as past test and exam papers, with their model answers.
- Additional lecture material consisting of PowerPoint slides are stored in Hyperwave, sequentially linked, and tables of contents generated as the course proceeds.
- The ability for students and lecturers to annotate material and restrict access to the annotations through Hyperwave's group access rights.

1.2 A Proliferation of Files

Experience has shown that students expect annotated lecture notes, tutorial notes, assignment information and a whole raft of extra information. They also expect that anything on the screen should have a reasonably high pictorial content, which creates a further proliferation of files since every graphic, however small, has to reside in a separate file. The number of files for one course can easily exceed 200. Since the number of courses given in one semester at the University of Auckland is currently just under 3000 we can estimate that if all courses were given electronically we should be planning for over 600,000 files.
1.3 A Proliferation of Broken Links

The next question to be considered is how many links may be involved in a database of 600,000 files. This is more difficult to answer since authors vary widely in the number of links that they include in any document. Taking our own site as an example, we estimate over one million. This means that someone may have to try to maintain the integrity of over a million links in the database.

Also to be considered is the problem of how an administrator of one server knows when a document on another Web site has been moved or removed. In the current climate, the answer is that they will rarely know.

Hyperwave [Andrews et al., 1995] [Maurer, 1996], which was developed to address these problems, has been used for the management of all electronic material in our Internet-based learning environment.

1.4 Further Motivation For Our Work

It is becoming increasingly popular for publishing agencies to produce related Web sites for their publications. Many books now refer not only to their publisher’s sites, but to other related Web sites. Unfortunately, a book which has perhaps spent over six months in production and contains links within it to various Web sites, may well be out of date the day it is finally distributed. An ideal example of this problem would be The Internet Yellow Pages [Harley Halm & Rick Stout, 1994] published in 1994. This book is entirely dedicated to listings of newsgroups, FTP sites and Web pages, many of which are now well out of date. Following an arbitrary URL from this book will likely result in the infamous "404: file not found" error from the host site, because the original document referred to has been either renamed or deleted.

![Diagram of dangling link problem across server boundaries.](image)

Figure 1: The dangling link problem across server boundaries.

Online guides and lists of links also suffer from this problem to a lesser extent. It is, of course, much easier to alter a Web page to reflect a change in a URL than to reprint an entire book. Changes to a Web site still require manual alteration of the document in question, but more importantly, someone must be available first to notice that a particular link is now out of date.

What is needed is a method of specifying links in relatively stable Web documents and printed material in a manner which allows automatic notification of broken links and provides a simple method of correcting or redirecting these links.

Before moving on to the problem of links to documents stored in external Web servers, we first highlight a few key built-in features of Hyperwave.

2. A Brief Summary of Key Features of the Hyperwave System

Hyperwave (originally called Hyper-G) is an advanced hypermedia document management system developed at the Institute for Computer Science and Computer Supported New Media (IICM) in Graz, Austria. The principal architects are Prof. Hermann Maurer and Frank Kappe [Kappe et al., 1993].

Hyperwave was developed to store high-volume hypermedia resources, which can be spread over multiple servers [Kappe, 1995]. The long-term maintenance and development of databases becomes crucial when
databases grow beyond a certain size. To expedite management, particularly of links, a more structured approach needs to be pursued right from the beginning [Flohr, 1995] [Maurer et al., 1994].

Hyperwave follows a more sophisticated concept than most available Web server systems. The project's aims are [Andrews et al., 1994]:

- System access using hyperlinks, hierarchical browsing, and searching.
- Reducing fragmentation of document collections over multiple systems and servers.
- Support for multi-lingual documents.
- User identification and access control.
- Integration of existing Internet information systems.
- Automatic enforcement of document consistency.

Hyperwave offers a self-contained working and navigation environment, and relies on the Internet as its base communication medium. TCP/IP port 418 has been reserved by the Internet community for communication to Hyperwave servers.

The core of a Hyperwave server is formed by a set of object-oriented databases. It supports customary database features such as the assigning of attributes to objects, indexing, and searching. The server also maintains a hierarchy of user and group information. The following attributes can be assigned to any document:

- Read and write permissions for both groups and individuals.
- Extra search keywords.
- Titles in different languages.
- Display properties.
- Custom attributes.
- Direct debit, from the user's account, of the cost of viewing a document.
- Setting of a time period during which the document is visible to the public.

Since attributes are not stored within the objects (as in most Web servers), but in a separate database, they can be efficiently extracted and manipulated. In addition, objects can be locked to ensure they are not updated concurrently.

2.1 Local and Remote Link Maintenance

There exist utilities which can augment Web server functionality and ensure that all links at a site are pointing to the correct documents, or discard links which no longer point to existing documents. These utilities generally only ensure that all 'on site' links are kept up-to-date.

Hyperwave also addresses this problem on a 'site' basis. The details of a link within a document stored in a Hyperwave server are kept separate from the actual document itself. The server is always aware of exactly which document a particular link refers to and, more importantly, which documents make use of the link.

When a document is moved on a Hyperwave server, all links referring to that document are automatically updated. Similarly, when a document is deleted, all links referring to it are 'deactivated'. As soon as the document referred to is restored or a new one created, the link becomes active once more. This automatic maintenance of local links also works across multiple Hyperwave servers.

A full description of Hyperwave, including all technical details, can be found in [Maurer, 1996].

However, Hyperwave does not check that links pointing out of documents in Hyperwave to documents on remote Web servers remain intact. This issue is the topic of the rest of this paper.

3. Remote Link De-referencing
It is not practical to expect everyone in the world to start using a Hyperwave server to ensure the integrity of links world-wide. We propose the use of special link and document caches, implemented using Hyperwave, which could be used to de-reference links on a local server and protect static documents from changes on the Web at large.

Hyperwave allows links to remote sites to be loaded as entities in their own right. When a user accesses a link in a local document, instead of connecting directly to the remote document it simply connects to the local remote link object. The remote link object automatically refers to the remote document and this redirection is virtually transparent to the user.

![Diagram: De-referencing a link using a remote link object.](image)

**Figure 2:** De-referencing a link using a remote link object.

By using and maintaining the remote link objects, several features can be implemented:

- An automatic, regularly executed program can be used to check the integrity of all the remote link objects.
- The author of the link can be automatically notified via email if the remote document has been changed or deleted.
- The author of a link can update the destination of a link object without needing to directly alter any of the documents using the link.
- If the site containing the remote document is unavailable or temporarily off-line, the author can be notified.
- The text of remote documents can be cached and used when the originals become unavailable for any reason.
- A number of different documents can make use of the same remote link object.

In practice, a user will click on a link in a document, which will refer to a remote link object. This object will either re-direct the user to the remote document, or provide the cached document and explain that the actual remote document is unavailable for whatever reason.

### 3.1 External Link Maintenance

Setting up remote link objects and referencing them is a relatively simple exercise using Hyperwave. The main problem to be overcome is detecting when a remote document no longer exists (or is no longer valid) and what to do when this happens. It is fairly straightforward to detect when a document has been deleted from a Web site, simply by periodically attempting to download the document. Some parameters are required to determine how 'periodically' the links should be checked and to indicate how long a document must be missing or unobtainable before it is deemed to have been deleted (or simply too unreliable to use).

Another complicating factor is that the content of a document may change to the point where it is no longer relevant in its original context. The current relevance of a document must ultimately lie in the hands of the author who decided to use the link in the first place. It would therefore be sensible for the link cache to report to the author that a remote document has been altered.

The HTTP protocol used by Web servers allows document information to be retrieved without actually downloading the entire document [http://www.hmu.com/web_links/http2]. The remote document's modification time/date is ideal for noting changes in a remote document. This modification time can then be added to the remote link object as an attribute for future reference.
3.2 Remote Document Caching

When a remote document has been removed or renamed, and the link author informed, it would be advantageous to be able to supply a strictly temporary version of the document until the author alters the link's destination, or the original remote document becomes available once again.

After creating the original remote link object, and checking the existence of the remote document, the text part of the document will be cached (ignoring images and other embedded items). The remote link object can then use the cached document in the event that the remote document becomes unavailable. When supplied with the temporary cached document, the viewer is warned that the document they are seeing is not the original, and a URL to the original remote document is supplied should they wish to check it themselves.

Figure 3: Supplying the original remote document or the locally cached version.

4. Implementation

We have implemented a prototype link cache, working as described above, using Hyperwave running on a UNIX system. Two separate programs run periodically, cache_setup and cache_maintain. Cache_setup creates new remote link objects from existing links, and cache_maintain maintains the remote link and remote document caches.

When a user on the Hyperwave system decides that they want the external links in a document to be maintained, they add a custom attribute "CacheURLs" to the document. This flags the document to have all external links dereferenced by the cache_setup program, which runs as a CRON job once a day. The user also has the ability to run cache_setup immediately if they wish, via an HTML form/CGI.

Once it executes, cache_setup processes each document on the server with a new CacheURL attribute. It removes all URLs linking off the local site (with the exception of those accessing CGIs) and creates remote link objects in the Remote Link Cache (RLC). Each user on the system has their own unique RLC and remote links, so that changes made by one user to their remote objects in the RLC do not affect the links used by others. The HTML of the source document is altered to use the links in the RLC (refer figure 2). As each remote link is created, a text-only version of the remote document is downloaded and stored in the Remote Document Cache (RDC). There is only one system-wide RDC.

The CacheURL attribute is altered to indicate a successful load and an attribute is added to the remote link object, indicating the last modification time (and date) of the remote document. Finally, the user is emailed the results of the load, stating which links were successfully loaded and reporting any problems.

The cache_maintain program also runs as a CRON job but on a more frequent basis. Under normal circumstances (i.e. when there are currently no broken links) it will attempt to verify all links in the RLC every
six hours. If there are links which have been previously found broken and are using temporary text-only
documents from the RDC, then cache_maintain will check these links once an hour until they are either
corrected or deemed deleted.

Upon execution, cache_maintain checks each remote link in the various RLCs. First it attempts to get the last
modification time of the remote document referenced and compares this to the modification time attribute of the
remote link object. If these time stamps are identical then no further action is required for this link, otherwise the
remote document must have been changed and the owner of the remote link is informed via email.

In the case of a deleted remote document, or a non-responding site, the remote link object will be re-directed to
the temporary cached version of the document. The link owner is then informed of this action. Links that are still
not resolved after a week are deemed to be lost and the link owners are emailed once again, with the advice that
they should remove the link permanently.

5. Future Work

The system we have implemented as described above is certainly not complete, nor as user friendly as it could
be, but it performs its core functions admirably. Users are usually informed of changes in the status of their links
within a day of a link breaking. Unfortunately, at this stage some knowledge of the underlying Hyperwave
system is required to change the destination of the remote link objects.

The actual work involved in creating the raw functionality was quite simple compared to the complications
encountered in making the system as convenient and transparent to the user as possible. Other than improving
the user interface, most of the future work required will be determining the optimum periods for checking links
(both working and broken).

6. Conclusion

The system we have developed on top of Hyperwave lets teachers designate that particular documents should
have all links to external Web sites de-referenced to point to the local server’s link and document caches. This
enables teachers to simply set one attribute on each of the documents they deem to be important and the system
will de-reference all links to external Web sites contained within that document. We believe that this facility will
significantly improve the reliability of electronic courseware and thus reduce levels of stress for teachers and
students alike.

Abstract: The prevalence of the Internet and the Web in higher education has been transforming higher educational institutions in various degrees. There are a wide variety of terms indicating such phenomenon ranging from web-based instruction and online courses to cyber degrees and virtual universities. Those terms are often used without clear definition. In this paper, six different categories of higher educational institutions in cyberspace: online course catalog/clearing house, university brokerage, virtual university consortium, virtual university, online campus, and unaccredited online campus, are discussed to provide a big picture of current trends in distance education. Then, three elements of online courses are discussed in order to give some framework in designing online courses. Lastly, the future trend of higher educational institutions is also discussed.

1. Introduction

As the Internet and Web technologies are becoming the popular vehicle of instructional delivery, we have begun to see the plethora of words referring to such mode of instructional delivery (e.g., web-based instruction/course/distance education, Internet courses/university, online instruction/course/campus/university, cyber class/course/school/university, virtual classroom/campus/university, etc.). Though these terms share some common concepts; some instructional components delivered through computer networks and some degree of time and distance independence, a precise nuance of each term differs, reflecting the diversity of such offerings.

First of all, the spectrum of these terms ranges from a traditional classroom-based course, which uses the Internet/Web to supplement classroom activities. Such a course may use the Internet/Web to deliver class materials such as syllabi, homework assignments, lecture notes, exams, and Q&A sessions. At the other end of the spectrum is a degree-granting program offered completely through online activities without requiring students to physically attend any classes. All of the terms listed above fall in somewhere between the two ends of the spectrum.

Traditionally educational systems in most countries had required in-class instruction by teachers and in-class attendance by students. When distance learning programs started to appear in the early 20th century under the more commonly known name at that time, correspondence courses, their major purpose was to serve the population who could not afford to have higher education otherwise, such as geographically remote students. The primary communication mode between an instructor and students was regular mail.

In the early 1970s, as television became the common household media, some distance learning programs which started to utilize this telecommunications media. However, television is an expensive medium for production and distribution and in order to recoup such cost, those distance learning programs, which utilized television for instructional delivery, followed the model of mass education utilizing satellite
broadcasting or cable television. In such a model, instructional delivery tended to be one-way (i.e., from an instructor to students) and interactivity between the instructor and students or among the students was limited.

In 1980s, the prevalence of VTR made it possible to utilize asynchronous mode of instructional delivery via television, which provided students with flexibility in time in addition to place. But, the model of instruction still tended to be unidirectional, leaving few opportunities for a student to interact with the instructor or other students.

Today's sophisticated interactive communications technologies allow distance educators and learners to go beyond this transmission model of instructional delivery, allowing a high degree of interactivity between a teacher and students and among students at a reasonable cost. The interactivity is defined in the educational context as "...a process whereby students are systematically encouraged to be active participants in their own learning. It is achieved by teaching approaches that engage students in the construction of knowledge."[Center for Interactive Learning, 94]. In the context of the use of information technology in education, there are two kinds of interactivity: interactivity between a student and the material as seen in computer-based training (CBT) and interactivity among people including instructors and students as seen in computer conferencing. The latter form of interactivity is the culmination of the new mode of teaching and learning. The benefits of having more interactions in effective learning have been discussed and attested in various educational communities. As culminated by the Kenneth Bruffee's writing on peer interaction in the classroom, constructivist theorists argue that people construct their knowledge through social interaction with others.

Based on this theory of social construction of knowledge, effective distance learning programs should facilitate social interaction among students and between instructor and students. With today's technologies such as the Internet and various computer network applications, it has become easier to implement interactivity into a distance learning program. Electronic mail facilitates personal interaction between an instructor and a student and computer conferencing facilitates class-wide interaction among students without being constrained by time and distance.

With the prevalence of today's Web technology, there is a danger that the old transmission model of one-way instructional delivery will be repeated, ignoring the importance of students' interaction and leaving students autonomous and isolated. An instructor can utilize the Web to place his/her course materials for students' retrieval, but still the Web may be a primitive media for creating an interactive learning environment. In that sense, the term, web-based instruction/courses/distance education, may not be the right term yet for this emerging model of distance education delivery.

Apart from the Web, there are a number of collaborative technologies or so-called groupware, which support various degrees of interactivity. Some of them are proprietary, but the current overall trend of such technological development is the more integration with the Web. Taking advantage of the wealth of information available on the Web, such a collaborative technology is becoming a great vehicle for effective instructional delivery. However, the mere use of a collaborative technology in distance education programs may not guarantee that it will facilitate learning. Its effective incorporation into a distance learning course requires careful design and the instructor's time and efforts. The role of an instructor in this model will be more of a facilitator of learning than a presenter of a fixed body of information.

In this study authors conducted an extensive survey of current distance education programs in a variety of universities with emphasis on those with some online/Internet/Web components built in, to develop a taxonomy of current distance learning systems and to identify important dimensions that need to be considered in designing a distance learning system. The long history of distance learning programs reflects a variety of modes of distance learning programs. Still a number of programs rely on the communications mediums of one-way presentation. On the other hand, the number of distance learning programs which take advantage of more interactive communication mediums, namely computer networks and the Web is increasing dramatically. This study examined such recent phenomena and categorizes those newly emerged distance learning programs in order to provide a clear picture of higher education in cyberspace. (The listing of institutions under the following categories and matrix of technologies used by each institution can be found at http://ritdl.rit.edu/Research/higher-education.htm.)
2. Taxonomy of Higher Education Institutions in Cyberspace

Buzzwords such as virtual university, virtual college, virtual campus, online campus, electronic university, and electronic campus are being used without putting much thought, and a variety of online degrees are being offered by unaccredited institutions (see "Is the Internet Becoming a Bonanza for Diploma Mills?" Chronicle of Higher Education, December 19, 1997). Though the idea of providing anytime/anywhere learning environment is notable and many reputable institutions offer such alternative learning programs with quality, for a prospective student such diversity of distance learning programs is rather confusing.

After closely examining more than 80 online distance learning programs, the author came up with six different categories: online course catalogs/clearing houses, university brokerages, virtual university consortia, virtual universities, online campuses, unaccredited online campuses.

2.1. Online Course Catalogs/Clearing Houses

Online course catalogs or clearing houses catalog online and distance education courses offered by universities and colleges and create searchable database to make such information readily available to public. They are solely information sources and they don't offer any courses or degrees themselves though some of them call themselves as "university", "academy", or "campus".

2.2. University Brokerages

University brokerages are those institutions which do not have any faculty members of their own and do not offer any courses but do award degrees to those students who have taken required number of credits from specified universities and colleges. This seems to be the emerging trend of distance learning programs as two such organizations, Regent College and Western Governors University, are newly formed and have been attracting a great deal of media attention. They are mainly comprised of universities and colleges in a specific region and aim to provide students with flexibility and mobility to take courses from different institutions in the region. This form of degree offering may become popular in future once policies and academic support systems have been worked out in a wider scale.

2.3. Virtual University Consortia

Virtual university consortia are similar to university brokerages in the sense that those are the associations of multiple universities/colleges. The difference between university brokerages and virtual university consortia is that the former offer degrees of their own while the latter do not. For example, SUNY Learning Network is a good example of virtual university consortia as it is an association of eight colleges, and students can take courses from any of the eight colleges. However, the degrees are awarded only by either one of two existing colleges: SUNY Empire State College or SUNY New Paltz.

2.4. Virtual Universities

Virtual universities are identical to universities and colleges in the traditional sense as they have their own faculty members, they offer courses to their students, they provide students services, and they award degrees. The only difference between traditional universities/colleges and virtual universities is that in virtual universities students don't have to commute to the campus and physically attend classes to earn a degree. There are universities of this type catering to masses as the distance learning format allows them to expand their markets regardless of their geographical location and reach as many students as possible. An example of this type of universities is University of Phoenix. The university is a for-profit organization and claims itself to be one of the nation's largest private accredited institutions for business and management.
There is the other type of virtual universities, which can be called "niche universities". The ability to reach millions of people beyond geographical limitations allows educational institutions of a special kind to exist. Examples are: The American College of Prehospital Medicine, California College for Health Sciences, and ISIM University. This kind of virtual universities are more likely to increase in the future as the competition among different universities/colleges become fiercer and universities/colleges struggle to find a way to survive.

In addition to such distinction in terms of audiences they serve, there are two types of virtual universities in terms of their course format. Many virtual universities that rooted in traditional correspondence schools do not have classes; in other words, they provide no support mechanisms for students to communicate or collaborate with fellow students to ask questions or to discuss issues. The students have to study on their own in somewhat isolated environments with a little guidance from an instructor or a tutor. Though those institutions can be also called "virtual universities", as they do not have physical campuses but have faculty members, offer courses, and award degrees, those institutions should be distinguished from the other kind of virtual universities; virtual institutions that emulate traditional universities in providing class-based learning environment. The former type has an advantage; it offers true asynchronous learning experience as it usually allows open entry (meaning a student can register and start a course any time he/she wants) and it allows self-paced learning. However, without the opportunities to interact with other students, the learning experience it can provide may be somewhat limited.

2.5. Online Campuses

Online campuses are online version of traditional universities/colleges campuses. It means that those institutions in this category are universities/colleges which exist in physical campuses and have been offering courses and degrees to on-campus students. As the recent popularity of the Internet, many of such universities and colleges have started to move some portion of the courses or some part of their degree programs online. There is a wide variety of such offering, ranging from universities and colleges which utilize the Web as supplement to on-campus course offering to those offer complete certificate, associate, bachelor's master's and doctor's degree programs online. In offering those degree programs online, inevitably the institutions have to create not only the courses online but also a learning environment for students to register for classes, pay tuition, order books, seek academic advising, and search for resources.

2.6. Unaccredited Online Campuses

As mentioned previously, there are unaccredited institutions that offer courses and degrees online. As long as those institutions are clear in their goals that they don't intend to offer degrees in a traditional sense but to offer training and workshops for career development, this type of online campuses become a good supplement to higher education. However, some institutions (most notoriously Columbia State University) are not clear about their accreditation and offer degrees that may not be recognized by other institutions and organizations. Due to the ease of setting up a virtual campus in comparison to a traditional physical campus, these kind of unaccredited online campuses may proliferate. Prospective students must be wary of such "diploma mills" and should thoroughly examine the mission of the institution before enrolling and paying their tuition.

3. Elements of Online Courses

Virtual universities and online campuses usually have a nice Web interface to some or all of the following components of a university or a college: course catalog, registration, academic calendar, library, financial aid, student advising, career counseling, bookstore, and user support.

At a micro level, the components of a virtual university and an online campus are individual courses. The use of the Web and computer networks in the courses has potential to be advantageous in four ways. First, the nature of its platform independence and easy sharing of data enable collaboration among distant peers. With the computer conferencing tools, students in disparate places and in disparate times can
attend virtual classrooms where thoughtful ideas and comments may be exchanged and heated discussions may be held. Second, the hypertext links allow integrating disparate sources of educational materials and disparate formats of information into one place. Connecting ideas and presenting information in different formats are easier and students have easier access to the wealth of information. Third, the updating the information is easier on the Web and not like print-based or computer-based training materials, the information on the Web can be constantly updated and adjusted as the class progresses. Lastly, the Web, especially the next generation of HTML called XML (eXtensible Markup Language) will provide the potential to dynamically customize the content of the course materials according to the skill and knowledge level of the student. The courseware tailored to an individual learning style will make the learning experience more efficient and effective.

Each course consists of three parts: course material presentation/distribution, communication between an instructor and students or among students, and assessment of students' coursework. In distance learning, different technologies can be used for each course component.

3.1. Course Material Presentation/Distribution

The most common approach to online course is putting syllabus that will serve as the navigational tool for the content of the course. The course syllabus page usually contains the links to the lecture materials presented in the HTML format or PowerPoint format, and links to other resources. Many sites require a student to log in with his/her user ID and password so that the course materials are not available to those who have not registered for the course. Some colleges and universities provide a template for the course web page so that all the online courses in the institution have a consistent look, which may be less confusing to students.

The most technologically advanced course material presentation and distribution would be the Stanford Online project, which digitized and compressed the videos developed for Stanford Instructional Television Network (SITN) courses using VXtreme streaming video technology and then stored them on a video server, making those classes available to company-sponsored students as well as campus students in an on-demand, video-streaming environment. Though it would be nice to utilize desktop videos for course material presentation and distribution, currently this is limited to a corporate environment or on-campus environment where students have access to high-speed lines directly. Another advanced course material presentation example can be found at USC ITV Distance Learning Online. It uses the RealVideo streaming video technology with the synchronized slide presentation in another frame of the web browser window.

3.2. Communication

Communication should occur between an instructor and students and among students. It can be one-to-one and can be one-to-many, and can be synchronous (i.e., real-time) or asynchronous. The authors strongly believe that one of the major advantages of online courses is the facilitation of interaction between an instructor and students and the high level of student involvement in their learning. As this component of online course is rather intangible compared with the presentation aspect of online courses, it is often overlooked or underestimated in implementation of online courses. The key to a successful online course is the creation of virtual microculture [Aoki, 95]. Virtual microculture is a unique group dynamics, which arises as a result of frequent interaction and collaboration toward a common goal.

There are a number of tools which are designed to facilitate interaction and collaboration in an online course [Aoki, 98]. But tools are just tools; tools themselves do not create a successful online learning experience for students, but instructors who utilize those tools to moderate, direct, and facilitate online discussions. Those tools enable more thoughtful discourse, as interaction is not bounded by time.

3.3 Assessment

There is always a suspicion among educators who are just starting to put their courses online, that in online courses an instructor cannot tell the person who is taking the exam or quiz is actually the person

154
who claims to be. In traditional distance learning programs proctored exams have been widely used as the method of assessment as in proctored exams the authentication is rather easily done by checking the student's picture I.D. Online quizzing seems to be gaining its popularity recently because of the availability of tools, which make the creation and administration of such quizzes relatively easy. However, only few courses actually utilize such online quizzing systems as a primary means of assessing a student. Instead, most online quizzing systems are used for students to self-test their learning.

The concept of competency-based assessment of learning has been implemented in some virtual universities, including Western Governor's University. The concept tried to assess an individual's skills and knowledge instead of clock hours spent in courses. The concept is noble as most learning may actually occur outside of formal educational settings. However, it is still uncertain to what extent such competency can be standardized and measured across a variety of disciplines in such a rapidly changing world. As the major focus of the Western Governor's University's mission is to develop such assessment tools, we will see how they develop the assessment tools.

4. Conclusion

As the Gutenberg's printing press made education more accessible to masses centuries ago, computers and the Internet has the potential of transforming public education into the learning opportunities for everyone at anytime in anyplace. We have started to see some of such a trend in higher education in a fairly subtle way, but still the transformation has not been realized to its full potential yet. As Jack Crawford mentioned in his article [Crawford, 95], "for the most part all we have really done is used the new technology to 'speed up' the old way of doing things rather than to reform it." This is an easy trap that many institutions may fall in as it is much easier to use technology to extend what they have been doing than fundamentally transforming the nature of institutions. The beauty of the global Internet is that it enables people to participate in professional dialogue regardless of their location, gender, social status, and national origin. Abundant resources, which were not accessible to public before, are now available on the Internet. In a way, microcomputers and the Internet can put more education into the hand of students; in other words, it can make education more student-centered. A student can now be more in charge of what, when, and where he/she learns. Along the line, higher education institutions will no longer be the center of power and control of dispensing information and knowledge, but service organizations that cater to students' needs for guidance and leadership. The higher education institutions that will thrive in the next century may not necessarily be the ones who have adopted the most advanced technologies, but the ones who have made the shift in the role of educational institutions to enable truly student-centered learning.

Abstract: This paper is an overview of our work in establishing ways in which to critique and creatively utilise the full potentials of the new electronic deliveries for education. It examines how sets of criteria can be established to ensure that each element of any interactive multimedia (IMM) presentation works both within its own terms and within the new electronic medium. In doing so it argues that while we can draw upon extant criteria for effective print, video, and sound materials, new insights are needed into how they might be applied in order to understand more fully their combination in an interactive environment. This paper considers how extant criteria can be taken be taken beyond their original application to develop new criteria appropriate to the understanding and utilisation of IMM and its modes of discourse. These new criteria recognise that effective IMM is greater than the sum of its parts and that success in its own terms is measured by the degree to which its parts combine to work together in a richer interactive environment. Without such criteria we have no benchmarks for discussion, understanding, critiquing and application of the new electronic deliveries.

1. Introduction

In our work in presenting Masterclasses in Writing, and in developing curriculum and teaching undergraduate classes for Media, electronic textuality has confronted us with challenges and possibilities. These include the development and application of the new media in practice and also an understanding of its place within a theoretical and critical framework.

We teach from a tripartite system of print (course outlines), and electronic texts (CD ROM, Oz21: Australia's Cultural Dreaming, [Arnold, Green and Vigo: 1998] and World Wide Web sites.) Our understanding of the intersection between theory and practice has led us to develop criteria for writing and critiquing cybertexts. This paper addresses some of the ideas behind our work and opens up the establishment of criteria for interactivity, three dimensionality and virtuality.
Clearly a new medium develops its own criteria, but there are clues embedded in our understandings of print, typography, television, film, literature, genre (and so on) upon which we can build or which we can challenge. We have placed this within a theoretical understandings provided by postmodernism.

Print has given power to authorship, authority and hence to authoritative structures like schools and universities. In simple terms, the knowledge industry began to construct itself as keepers who allowed incomers to succeed only after several hurdles had been overcome. Knowledge was something rarified, something out of the ordinary, something denied the common person and the popular culture. It was stored away and given certification in a way that storytelling, entertainment and general information were not. It underpins 'high' culture. The Academy which allows academics to join only after they have completed doctorates is an example of this.

Film and television have been largely locked out of this dominant knowledge paradigm. They are part of 'low', or 'popular', culture which is only being acknowledged as worthy of study in this late 20th century period. They have taken the privacy of print and made it more open, more common, if you like. Perhaps they have returned the power of the personal that was once evidenced in the oral historian, the poet, the jongleur. Defenders of the knowledge-keeping paradigm have seen the input of film and, in particular, television, as a part of the 'dumbing-down' of society.

Like Neil Postman, the American critic of the low standards of 'popular culture', particularly television, they see the "openness" of the text as having an inevitable correlation of 'amusing ourselves to death':

"In [Amusing Ourselves to Death] I argued that American public discourse has been changed by the electronic media from serious exposition into a form of entertainment, and I concurred in the view of Aldous Huxley that in the future people might well be controlled by inflicting pleasure on them rather than pain." [Postman:1992:51]

This fear arises from the introduction of mass media like television into people's homes. It reinforces the idea that, broadly speaking, information as knowledge is seen to reside in the authoritative textuality of print. In this context, electronic textuality is most challenging. Available as it is to a single person locked in virtual contact with unknown intimates, it invites interactivity and offers multimedia including virtuality and three dimensionality within a global discourse. The electronic text provides us with singular challenges to produce a common understanding of how to discuss or critique it.

This paper discusses how, at the same time as they are being applied and built upon, many of the criteria that we have established for print are being altered by electronic deliveries. Take, for example, the language used on email or in chatrooms: it is very much that of speech, a discourse which has been pre-empted by print since the renaissance. Yet it is speech in writing, at least for the moment, for already we have 'see-you-see me' style programs. So the discourse has no real grammatical or stylistic structure, spelling is irrelevant, upper case is rude shouting. Yet it isn't speech moderated by the directness of body language, gesture, and eye contact. It is a new form of oracy: it is virtual speech.

The formalities that have long been established in print in even personal letter writing but certainly in business discourse, are not embedded in email or chatrooms. Graffiti, despised by print textuality as destructive, has a place on graffiti boards on the internet or as invited comments on web sites. Interestingly, the greatest formality of print: ownership or authorship, is not central to electronic discourse, much of which may even be undertaken by people whose 'true' identity is not revealed, indeed, is concealed behind entirely self-constructed personalities. These 'personas' may participate in the sense of being 'lost' in a story that is common to the involvement of readers of fiction. Yet their involvement is obviously more writerly than that. In this way, they provide an excellent example of Jacques Derrida's 'readerly-writer'. This is the bringing to life of a text through the actions of the reader, not the author as owner and authority. That is, there is no authorised version.

The private persona and the public global textuality of internet discourse is more than a coming together of print, speech, and visuals. Interactivity, virtuality, three dimensionality and immediacy add a component that doesn't exist in the complex production worlds of print, film and television. Yet the criteria that we have developed for each of those singly and all of them together is a very useful starting point for a consideration of the elements of critiquing electronic discourse.

Neil Postman would challenge this idea that nothing comes from nowhere and thus that past cultural textual constructions underpin new electronic textualities:
"...when a powerful new medium like television enters a culture, the result is not the old culture plus the new medium, but a new culture altogether." [Postman, 1992:66]

2. Print as a taxonomic text

Clearly, the web relies upon an understanding of textuality which is prepared to give up the dominance of one authoritative reading. The idea of a web is of interconnected sites which have gaps and interstices. A web both contains and allows movement of discourse. The gaps can be seen as having importance in themselves.

The greatest difference between print and electronic discourse is the empowerment of the reader through interactivity. That is, the reader and the writer are as one. The binary oppositions which underpin questions of authority are no longer necessary. The main player is the person using/making electronic texts. Unlike the print book, a cybertext thus far eludes capture by established genre criteria.

Flowing from its title and author, the content of a book places it firmly within an established genre system. This system has the binary opposition of fact and fiction which has been challenged by postmodernist thinkers such as Gregory Ulmer:

"To approach knowledge from the side of not knowing what it is, from the side of one who is learning, not that of the one who already knows is a mystery. What is the experience of knowing, of coming to or arriving at an understanding, characterized as following a path or criss-crossing a field, if not a narrative experience, the experience of following a narrative?" [Ulmer, 1989:106]

and Gayatari Spivak:

"...human textuality can be seen not only as world and self, as the representation of a world in terms of a self at play with other selves and generating this representation, but also in the world and self, all implicated in ‘intertextuality’...such a concept of textuality does not mean a reduction of the world to linguistic texts, books, or a tradition composed of books, criticism in the narrow sense, and teaching." [Spivak, 1988:78 her emphases]

Nevertheless, it remains a dominant mode of authorising print texts. It is heavily embedded in as well as acting to underpin taxonomic systems themselves. Electronic deliveries, such as the web, as we shall see, resist such genre and taxonomic systematisation and show themselves to be most able to be understood when these are open to deconstructive readings by individual players making individual constructions of meaning and discourse.

Genre acts to provide the reader with an authoritative placement and guide to what is being read. So we know that literature claiming to be fiction is not about the factual world per se although it acts to reveal the interactions between people in virtual re-enactments of the real word itself. We understand that poetry presents itself on the page in a certain way and is most important in the relationship between the intellect and the emotions with the musicality of language itself. Drama in its many forms in television, the theatre and film is shown to be a way in which we can come to understand ourselves through the externalisation of acting-out story-telling. Scientific and academic writing present themselves in a specific genre based on methodologies which are established and agreed upon as important or part of the established ‘rules’. This is the epistemological certainty of the academy and of science.

This sortive principle of genre has led to the major binary opposites of ‘fact’ and ‘fiction’. Such a binary opposition inevitably leads to the valuing of one form of discourse over another, and so fact has become a more considered and important text than fiction. In this context it is instructive to consider where the law and the church reside in such a value/genre system.

3. Possibilities in electronic discourse
If we argue that this binary opposition leads to constriction rather than knowledge, as we do, then we open up the possibilities of new ways of connecting human stories. Gregory Ulmer has coined the term ‘mystory’ for this:

“... the mystory does not repeat, is not reproduced, in that no two are alike. Their recognisability as a kind derives from the relationship among three levels of invention juxtaposed in the process of conducting research. Mystory itself is more a relay than a model, produced not for its own sake but as the trace of convergence of living and artificial memories.” [Ulmer, 1989:171]

Once all textuality is seen as a construction, then we are no longer constricted by genre itself. The tidy criteria that this brings to our reading/writing is disrupted. As such criteria find themselves under challenge as new textualities of electronic delivery evolve, new ways of thinking about textuality are imminent and necessary. Our response to what Caputo calls the ‘the post-paradigmatic diaspora’ is one of understanding new dimensions of textuality and new possibilities of discourse. [Caputo, 1987]

These new ways do not fit in to the taxonomic and point-of-focus way of thinking that dominated western culture throughout the Enlightenment and which still provide benchmarks for critical thinking and cultural analysis. In discussing Lyotard, Norris says that he sees the current period as:

“...an epoch that must witness the final irrevocable demise of all ‘enlightenment’ ideas and values. Historical developments have made it impossible to believe any longer in those great ‘meta-narratives’ of progress, freedom. And a universal truth at the end of all inquiry which once sustained the thinking of philosophers from Kant to Hegel, Marx and their successors. In the absence of such totaling narratives we must now fall back on a humbler, more pragmatic, or context-specific kind of storytelling, one that lays no claim to ultimate truth but enables us to make at least provisional sense of ourselves and our historical predicament.” [Norris, 1988:77]

Clearly, in the proposition that nothing comes from nowhere, working against previous cultural constructions is as important as building upon them.

The new millennium will see not only a communications era but also a breakdown of categories and boundaries in how we think about information and knowledge. This dispersal of certainties presents challenges for those of us who critique and problematise those occurrences which are commonly perceived and accepted as most ‘natural’ or ‘normal’ in our society.

The most pressing of these challenges is the creation of a set of criteria by which we can evaluate new electronic textualities and which can provide the basis for critical interchanges about them. There is, of course, a point of paradox here. In trying to establish guidelines and critical vocabulary, we appear to be participating in the very taxonomic methodologies and epistemological certainties which we are claiming can be displaced by the new textualities with their open-ended potential for multiple navigational ‘readings’.

We are proposing an alternative reading: rather than solving the paradox, we propose to determine the fruitful possibilities that might occur from working within its apparent contradictions. The recognition of evaluative criteria that we have brought to texts of differing genres in the past will enable us to build upon their strengths for flexible critical frameworks by which we address electronic deliveries. They will enable us to think and talk about cybertexts as well as to construct and participate in them.

4. Fact and fiction: binary opposites

One example of this process of criteria development is the bringing together of the ways we evaluate ‘fact’ and ‘fiction’. Interactive multimedia relies upon an altered understanding of both of these oppositions so that they can be seen as one. There has been a great deal of thinking done in this area. Both Lyotard and Ulmer have something useful to say, and feminist theory in its many different attributes also confronts this unnecessary dichotomy. According to Lyotard:
"The complicity between political phallocracy and philosophical meta-language is made here: the activity men reserve for themselves arbitrarily as fact is posited legally as the right to decide meaning...If 'reality' lies, it follows that men in all their claims to construct meaning, to speak the Truth, are themselves only a minority in a patchwork where it becomes impossible to establish and validly determine any major order...we Westerners must re-work our space-time and all our logic on the basis of non-centralism, non-finality, non-truth." [Lyotard, 1989:120. His emphases]

Feminist Rosemary Tong suggests:

"Whether women can, by breaking silence, by speaking and writing history overcome binary opposition, phallocentrism and logocentrism I do not know. All I do know is that we humans could do with a new conceptual start. In our desire to achieve unity, we have excluded, ostracized and alienated so-called abnormal, deviant and marginal people...as I see it, attention to difference is precisely what will help women achieve unity." [Tong, 1989, 223 - 237]

<table>
<thead>
<tr>
<th>FACT:</th>
<th>FICTION:</th>
</tr>
</thead>
</table>

- Based on research which documents the procedures followed
- Sets a highly specific and clearly defined field of contention
- Has a clear methodology which specifies and follows accepted guidelines and epistemologies
- Is usually written in the passive tense to indicate authorial disengagement
- Is not usually written in the first person so that the personality of the writer is disguised
- Sets numerical and statistical statements as objective and personal storytelling as subjective
- Is often supported by diagrammatic representations, graphs and spreadsheets
- Claims to have stated reality with any reference to data well documented
- Situates itself within a framework of academic or critical thought which is unambiguous in its "voice" or context
- Is often published by scholarly publishers or arms of publishing houses
- Is categorised as fact in bookshops and libraries
- Replicable

- Claims to be an imaginative construction and is recognised as such by the reader
- May have instructional intention but this is disguised as entertainment
- Creates characters who live only on the page and within the covers of the book
- Is an exercise of the imagination and clearly indicates the writer's engagement
- Provides an escape from the real world into another space
- Is intended for relaxation and pleasure with use of "objective" text relegated to dramatic device
- Is categorised in libraries and bookshelves as non-academic, non-real
- Contains constructed dialogue which is not a record of real speech
- Written in a variety of tenses depending upon the 'voice' that is being 'read': authorial, point-of-view of character/s; commentary by character/s; dialogue
- Has no methodology or epistemology stated or sited unless used as dramatic device
- Is categorised as fiction in bookshops and libraries
- Singular (non-replicable)

Table 1: Fact and fiction: binary opposites

Much postmodernist and feminist thought has acted to enquire into the disinterestedness claimed by 'fact' and to propose that it occurs in an environment which is really a certain kind of storytelling. If we drop the binary labels of fact and fiction and accept the idea that they are all constructions: all a form of storytelling, then we can apply the criteria we have developed to critique both fact and fiction to the new electronic textualities. We can fruitfully follow Spivak's idea that 'the world actually writes itself with the many-leveled, unfixable intricacy and openness of a work of fiction' [Spivak, 1989:95]
In doing so we can move beyond the past implied by the 'postmodernist' label into the electronic future and explore where postmodernist deconstruction might lead us in the IMMateral world.

5. Conclusion
This paper has conveyed something of the critical, practical, creative and theoretical journey we have made in creating, using and understanding interactive multimedia. It indicates the rich field to be mined when we understand and critique the new electronic text of interactive multimedia and develop its particularities in such areas as: Characterisation; The creation and Manipulation of images; Interactivity; Argument; Connectivity; Discourse; Dialogue; Representations of reality; audio-visuals print graphics online; Audio-visuals; Design concepts; and The plot, the story, scenarios.

Internet-R@dio

Rudolf Arnold
Valckenburgschule Ulm, Germany
E-mail rudolf.arnold@extern.uni-ulm.de

Abstract: The „Valckenburgschule Ulm“ is a vocational school with the profiles nutrition, social management, health and nursing care. There are about 1260 pupils and over 110 teachers. Since June 1996 it is possible to connect to the Internet from 55 workstations via proxy server, router and ISDN. Internet-R@dio teams are designing short radio programs based on teaching units, which are also interesting for the public. They are using online services and especially the Internet for their investigations. The Internet is also delivering acoustic information that could be cut into the programs. The young radio journalists are editing their material in a fully digital environment. The short programs are transmitted by „Radio Free FM“, a noncommercial radio station in the area of Ulm. In any case the programs are not lost, they are preserved as texts, pictures and sounds on a web server. The audio files can be heard worldwide over Internet. Other schools, radio stations and interested people can use the programs for lessons or information.

1. The Basic Idea

Valckenburgschule Ulm has repeatedly produced and broadcasted programmes with various topics with the help of the non-commercial station Radio Free FM. As a vocational school the Valckenburgschule has different sections like dietetics, agriculture, health and care. Therefore as an example the subject “dietetics in combination with ecology” was introduced in a programme together with a discussion between the pupils from the dietetics section of the school and farmers of the region.

A fundamental disadvantage of the medium radio is, that on one frequency you can only obtain one bit of information at a certain place and time. The question is therefore, how these programmes can be made available in an acoustic form to other schools, groups, radio stations and stations run by citizens.

The solution is Internet Radio! The internet has the possibility to offer or retrieve acoustic information (speech, music, and sounds) besides the worldwide exchange of texts, images, and programmes. As a consequence two disadvantages of radio transmission do not apply, which are the binding to a certain time and the local limitation as audibility is concerned. The key word is “Audio on demand“.

Moreover one can use the permanently rising number of existing audiofiles (e.g. internet-talk-radio) both to enrich classroom teaching and to produce specific programmes. This simultaneously means that the listeners of stations like Radio Free FM can obtain information from the internet, although they themselves do not have access to these on-line services. Of course these on-line services should be used as an aid as programming is concerned. E-mail and news can additionally be included to ask experts or persons involved in something or to let them state their opinion.

The project “Internet R@dio“ therefore decisively enriches teaching and it enlarges the opportunities of non-commercial broadcasting by using the internet and vice versa.
2. The Aims of the Project

Integrating of: Teaching - internet - radio broadcasting.

Inter-disciplinary debate about topics that are both relevant for teaching and public interest.

Creating both transparency and public interest for subjects within the local community.

Usage of the medium “on-line services” in classroom so that pupils can work out certain topics.

Research via on-line services to prepare radio programmes.

Retrieving audio information from the internet and integrating it into one’s own programmes.

Digital production of programmes together with Radio Free FM about topics derived from school and topics of general interest.

Putting these programmes and interviews in a compressed acoustic form in the internet, so that other schools, educational institutions, and radio stations can retrieve them.

Working out newsflashes in texts and images about existing programmes, so that schools and educational institutions can retrieve them.

3. The Technical Requirements

Pentium PC running with windows, additionally a large and quick hard disk;
ISDN-connection, ISDN-card or network card and router;
Internet Access and clients for www, Archie, FTP, e-mail, news, IRC;
Right to write on a www-server;
Portable and stationary DAT-recorder with optical I/O and microphone;
CD-player with optical I/O;
Digital audio interface with optical I/O;
Active speakers;
Editing software;
Software to compress audio data;
Different audio player;
Web-publishing-tools.

4. The Form of Organization

As the Valckenburgschule in Ulm has only one digital editing station and digital audio tape it is not possible to do the complete production of a programme related to the school subjects with a whole class. It is, however, desirable that the research is done in certain subjects or in data processing.

Especially interested pupils, after having had a discussion with the class and the teacher, then form a project group, to deal with the results of the research in order to get a high-quality programme.
5. Necessary Skills to take part in such a Project

It cannot be expected that all pupils have the same amount of skills and knowledge at the beginning of such a project. The work for such a programme is based on the division of labour, as it is done in broadcasting as well. It is very important, though, that the pupils can follow each single step concerning the production, even if they do not master these steps.

These steps are:

Secure handling of on-line services;
Professional handling of recorder and microphone;
Writing texts for broadcasting;
Good intonation and being able to give the gist of a text;
Handling of the editing place;
Realizing the crucial and irrelevant contents of statements and interviews;
Feeling for rhythm of speech concerning editing;
Being able to produce HTML-pages with a suitable programme;
Handling of a scanner and image editor;

6. Execution of a Project

6.1 Planning

At the beginning the topic of the project, suggested by pupils or teachers, has to be checked out concerning the following criteria:

Relevance as the curriculum is concerned;
Public interest;
Suitability as a radio programme;
The topic must be intelligible to everybody within 10 minutes;
Suitability to use it in a classroom.

One of the suggested topics was “genetically altered food”.

The first criterion “relevance as the curriculum is concerned” is given, as the topic “novel food” is included in the subject “dietetics in combination with ecology” at “Ernährungswissenschaftlichem Gymnasium“ (Grammar school with profile dietetics). Moreover there are links to other curricula in biology, politics, social studies and other subjects (Topics: genetic engineering, consumer protection, European law, law). And in general there is public interest.

It is somehow more difficult when one looks at “suitability as a radio programme“. First a rough concept has to be worked out with the pupils. That means one has to think about vital aspects of the topic, which aspects can be put in an acoustic form and which aspects cannot. It is also desirable to have an interesting or emotionally attractive starter for the programme. With regard to the existing case the group used a short newspaper article, which said that Switzerland would withdraw 500 tons of chocolate from the market, because the chocolate contained genetically altered soya. This chocolate was falsely declared. With the help of this article one could easily limit the project to “genetically altered soya beans“.
In most cases a limitation on one special aspect of a topic is no problem and very often desirable. Especially when you think about using it in class: First of all it is very difficult for pupils to listen for a longer period and secondly the programme should help to discuss the topic more intensively in class (e.g. questions asked by the teacher: "Which aspects were covered?", "Which other aspects are additionally important?", "What correlations exist?" etc. ...)

Whether the final two criteria can be fulfilled can only be said after the production of the programme. They must be regarded as a guideline while the project is in progress.

6.2 Research

Once the topic is fixed and limited the necessary research has to be done, first of all with the help of the www-service in the internet. In the existing case the following search strategy was suitable (in Alta Vista Advanced Search): "Genmanipulation" (gene manipulation) and "Sojabohne" (soya bean) and "Deutschland" (Germany).

It is advisable to write a short summary about the data that were found, especially in view of a later presentation.

The planning of the programme can now be specified with the help of the data. A list of the facts and statements collected beforehand shows the focus the programme covers: Pros and cons of genetically altered food, consumer rights, pros and cons of food-labelling.

6.3 Interviews and Statements

It is vital for a good broadcast that the persons affected, experts and perhaps also politicians get a chance to speak. A survey carried out in the streets can support acoustically statistic data that were found. At first glance this seems to be fairly easy, there are, however, traps as the interviewing technique is concerned: So yes-no questions should be avoided as in extreme cases you get very short responses to a reporter’s flood of words. Questions beginning with who, what, why, where etc. are more suitable. Even here you have to be careful, if you want to avoid unnecessary difficulties while editing. The answers to the question "Why do you do your own yoghurt?" all began with "Because I can ..." and this blocks the possibility to replace the question by a presentation. Moreover it is important to ask the interviewee to answer in complete sentences. As an example one could mention: "I am against the manipulation of genes in food, because ...". Once you have informed the interviewee you get the answers in the expected form. In general it is better to ask for the willingness to take part in an interview, when the recorder is turned off. This avoids unpleasant situations.

To get an expert’s view requires a lot of preliminary work. The first barrier one has to clear is to establish the necessary contacts. E-mail is certainly one way, as it is embedded anyway in working with on-line services. In our case telephoning was finally easier and more reliable, although the costs were considerably higher. The greatest difficulty was, of course, to find an expert who was in favour of gene manipulation concerning food. Instead of interviewing the experts they were asked to present their point of view within 90 seconds, so that it was generally intelligible. Of course they were informed about the structure of the programme.

6.4 Retrieval of Audio Documents from the Internet

It was a surprise for the pupils that the opinion of a politician (here: Minister Rüttgers) about gene manipulated food labelling was in the internet as an audiofile. Although the sound quality was not very good - due to the Sun-audio-format being out of date - it was still used because the minister mentioned his opinion very briefly and detailed. Unfortunately audiofiles that are useful are rare in the internet. There are only various audiofiles to topics that are related to space ("The spacedoor").
6.5 Editing of the Interviews and Statements

One listens to all the interviews and statements, once they have been recorded, and then they are transferred from the DAT - recorder via the digital audio-interface-card to the hard disk. The single takes are edited with a suitable programme. The handling of the editing software is very easy, when you only use simple operations like, editing, adjusting the volume, arranging the takes, and simple fadings (e.g. with CUTmaster PRO). One does not need more for the production of a programme consisting only of words. It is to emphasize that each cut and editing can be reversed any time, as the actual audiofile is not dealt with. All the information about cuts etc. is stored in separate files. As the work was done with unexperienced pupils this proofed to be a decisive advantage in comparison with the common analogue technique where the editing was done mechanically on a tape recorder.

![Screenshot of the audio editing program](image_url)

Picture 1: Screenshot of the audio editing program

6.6 Writing and Working on the Presentation

The writing of the own presentation for the programme is the next step once the interviews and statements have been edited. Writing in this context does not only mean to summarize facts and to write connections to the next paragraph, writing for broadcasting has ist own rules: The sentences must be short, they should not contain foreign words, and facts and figures should be as clear as possible. Example: Instead of "... 52 % of the interviewees were of the opinion that ..." one can easily say "... more than half thought ...". To speak the texts on the radio requires some practice and various repetitions. Even texts the pupils have written themselves turned out to be more difficult than expected.

6.7 Completion of the Programme and Broadcasting

Once the texts are edited the single paragraphs are put together in a reasonable way. The editing software makes it possible to arrange the takes with the help of the mouse. Adjusting the volume and if necessary the fadings complete the production. Sometimes there have to be further cuts and rearrangements in order to
achieve a good programme. Finally the programme is transferred from the hard disk to the DAT and is ready to go on air.

6.8 Compressing of Audiofiles to place them in the Internet

Next to the broadcasting in the local station the main aim of the project is to supply audiofiles for the internet. Besides the production of HTML-pages, in which the audiofiles are embedded, this requires the compression of the programme with suitable software, because one minute of a monophone sound requires about 5 Mbyte storage space, when it is in CD-quality.

The most common procedure in the internet is "real audio". The audiofile can be compressed in such a form that real time broadcasting is possible. The higher the transmission rate the better the sound quality. The necessary software which is the encoder and the player can be taken from the internet.

With both slow lines and PCs there is also the possibility to load the audiofile completely and then to decode and listen to it. As teaching is concerned this procedure is not advisable as it consumes too much time. This should only be done if you want to reuse it (e.g. in own programmes or to transfer it on a cassette for using it in rooms without PCs).

6.9 Forming of HTML Pages for Teaching

The audiofiles will be embedded in HTML-pages. Pictures of interview partners also excite interest. Especially in view of using it in classroom it is important to offer the texts presented. So it is possible not to listen to the whole programme, but to read the text and only follow the statements and interviews.

Eventually one can arrange the links going along with the topic as far as they are considered relevant for teaching.

The end of the single project is the transfer of the complete pages and audiofiles with the help of FTP to the web server.

7. Usage in teaching

Schools which want to use the finished programme in class need at least a PC and a sound card. Additionally they need a player for both "real audio" and "MPEG Layer 3". The necessary links can be found on the internet pages of "project Internet-R@dio".

If one has only a PC with sound card available the programme can be transferred via the outlet of the sound card to a cassette recorder. You should use high quality (MPEG at best) so that the programme can be heard in class. The text can be printed, if necessary, and supported by information from the link pages.

Of course it is better when all PCs in the classroom have access to the internet, a sound card, and headphones. A local proxy server is useful, if you want to listen to the audiofiles in high quality, otherwise there will be bottlenecks and therefore interferences as the transmission is concerned. If the teacher does not have this possibility he should do an intermediate storage and copy the audiofiles in a folder to which all the pupils have access.

If one can do without a supreme sound quality there should not be any problems using both an ISDN connection to the internet and "Real Audio 14.4", even if there is a simultaneous retrieval from different work stations.
8. Digital Audio Broadcasting - DAB

*Radio Free FM* takes part in a DAB pilot scheme with a 24-hour licence. DAB offers besides the mobile reception in CD quality, which is free from interferences, also the possibility to transfer data services. Among other things pages can be retrieved virtually interactive. The page description language is HTML (with some limitations). So it is possible for programmes connected with educational radio to transfer additional information, key sentences, hints for literature, simple graphs or pictures. It is intended to integrate new possibilities of DAB into the project "Internet-Radio".
Images of Proteins on Multimedia: Creation of a Language for Expressing Biological Concepts

Liliane ASSAIRI Institut de Génétique et Microbiologie, CNRS, URA 2225, Université de Paris-Sud, Centre d'Orsay, 91405 Orsay Cédex, FRANCE

Abstract The electronic media is becoming the main media involved in the transfer of scientific knowledge. Several databanks collecting sequences of genomes and tridimensional structures of proteins have already been created and organised. Researchers from laboratories around the world are providing these databanks as well as, are demanding for more scientific information related to their research projects. It is tempting to offer all the scientific information which is already stocked in databanks, to the students, since now, many universities have access to these databanks. However, we must analyse if, the scientific results collected in these databanks are directly understandable by students or any users who have not the basic knowledge necessary to correctly handle all the information provided by research laboratories. Also, it is important to reorganise scientific data for the unspecialists. In this perspective, I propose the elaboration of a scenario for presenting data concerning the protein study and the beginning of a specific language for expressing some biological concepts.

Introduction

The human genome project is one of the biggest research project [Chadwick 1994] that mobilises a lot of research laboratories around the world. Several genomes of various organisms have been sequenced [Fleichmann et al. 1995, Bult et al. 1996, Hudson et al. 1995 Wilson et al. 1994, Dujon et al. 1994, Tomb et al. 1997] and a comparative analysis of the genes sequence, allows us to deduce the evolution of some enzymatic function. In the future, we expect to be able to predict the tridimensional structure of any protein, directly from their primary amino acid sequence deduced from the gene sequence.

From the genome project, the drug design project is now evolving, including researchers from biology, biochemistry, chemistry and bioinformatics fields, who will design and synthesise new drugs that are inhibitors for enzymes or in contrast better substrates for deficient enzymes. Thus, from the genome project towards the drug design project, the future seems very exciting and the field of biosensors [note] is now emerging.

In this perspective, we need to prepare students to be able to handle all the information already collected, in the huge databanks accessible on the internet. Also, in order to prepare these students who will be the future users of the scientific information, we are collecting now, several research laboratories have joined a team for realising a CD-ROM, concerning the protein study, protein structure and the drug design, to be used at university and in industry [Assairi 1995]. The development of this project stimulates the idea to create a specific language for expressing biological concepts when presenting images obtained from scientific instruments.

Description of the Project

The CD-ROM concerning the study of the enzymes involved in DNA metabolism [Assairi 1995] is composed of two kinds of documentary spaces: the main documentary spaces and the satellite rubrics "[Fig. 1]". The main documentary spaces concern proteins, nucleic acids, methods, instruments, biological role of the enzymes analysed, relationship between science and society, glossary, bibliography. These documentary spaces are connected altogether and several chapters located within one documentary space, are connected to a unique platform forming an arborescence "[Fig. 2]". On the other hand, the satellite rubrics provide the basic knowledge which is required to correctly understand the scientific information delivered on the main documentary spaces.

**Synthesis of Peptidomimetics**

Figure 2: Common arborescence.
The main space concerning the enzymes is connected to several satellite rubrics such as protein motifs, drug design, drug synthesis and organic chemistry.

The interactivity will be organised by presenting questions with their specific answers to the users, in order to control the understanding of the given information "[Fig. 3]". The level of interactivity will be tested with the students themselves, all along the realisation of the CD-ROM.
Several research laboratories as well as teachers from universities, are involved in this project. Several European languages as well as Chinese will be used and an English glossary will be established since the English is the main language used by the science community. Thus, from research laboratories, scientific results will be treated for delivery towards universities and industry. Also all researchers will be involved in this diffusion of scientific results in such a way that the results will be understandable by other users than researchers themselves.

Images Are the Main Source of Information Used on Multimedia

The CD-ROM which is presented in this article, deals with the structure of protein and the drug design. Also, images of proteins will be the main mode of expression for transferring scientific information. Crystallographic pictures will be presented to the users and software for molecule modelling will be installed on the CD-ROM, for giving the opportunity, to the users, to exercise themselves [Sybyl]. However, the main objective is to teach the user, to be able to deduce judicious structures for the drug design and furthermore for the drug synthesis. Also, it is important that the user correctly understands the images of proteins which are presented on the computer screen. Indeed, the user has to discover by himself what is the most important on the structure for the function of the enzyme. However, he does not know enough basic knowledge, to correctly deduce the right conclusions by himself. In this case, a very high level of scientific information will lead to a complete misunderstanding.

Although it is important to prepare student by using a high level material (scientific results obtained directly from research laboratories), it is important to think about the way, these high level of scientific results, are delivered to the users. When the images are stocked in the databases and delivered on the internet, any user can access to unmodified images provided by research laboratories and delivered by scientific instruments. But on the CD-ROM, where images can be reorganised, it is possible to elaborate a judicious scenario with modified images.

Scenario for Presenting Images of Proteins

The main objective is to teach the user's eye giving thus, the ability to deduce upon the structure of the active site of a peculiar enzyme, the best potent inhibitors of activity or on the contrary, a better substrate for some deficient enzyme.

In this perspective, a scenario has been elaborated [Assairi 1996]. It is composed of several sequences of images connected altogether "[Fig. 4]". Thus, a sequence of several views of a specific protein will be
organised in a unique way. Of course, the organisation of the views, to be shown must be decided by the experts on the proteins analysed because they know what details which are figuring on the image, should lead to a misinterpretation. A second sequence of images showing several views of an homologous protein to the first protein, presented will be connected to the first sequence. Again, this sequence of images will be visited in a unique way. Then several other sequences organised as above and showing other related proteins or non related proteins but sharing some biochemical properties will be connected to the previous sequences of images.

Figure 4: Scenario for presenting the crystallographic images.
Several views of the same protein A are connected forming a unique sequence, several unique sequences concerning the proteins A, B, C and D are connected altogether.

Collection of Signs Used for Expressing Biological Concepts

Several concepts like duration of a biological mechanism, efficiency of an enzyme, reversibility of a chemical reaction and so on, are usually expressed when using the text information, but they are not mentioned when using the image information. These biological concepts are necessary for understanding the image of protein which is presented on the computer screen and for correctly deducing important features in order to set up the bases of new hypotheses. What is important, is to replace the picture of the protein shown on the computer screen within its biological context.

<table>

<td></td>
</tr>
<tr>
<td>intermediate of the biochemical reaction</td>
<td></td>
</tr>
<tr>
<td>reversibility</td>
<td></td>
</tr>
</tbody>
</table>

Figure 5: First signs proposed.

Also, it is necessary to mention, at the attention of the user, whether the image presented corresponds to either the active or the inactive form of the enzyme, by using specific signs able to express some biological concepts "[Fig. 5]" and I propose that these signs will surround the images forming thus, a specific language "[Fig. 6]". This collection of signs will be increased following the advances of science and the need for expressing new biological concepts. The signs will be furthermore uniformised by the experts working in the protein field, for clarification and elaboration of a more structured language.
Figure 6: Crystallographic pictures surrounded by specific signs. The unphosphorylated protein uP is inefficient although the phosphorylated protein P is efficient, the protein shown here catalyses a reversible reaction.

Conclusion

The use of new technologies is increasing for education and the transfer of knowledge. But the contents delivered by these new technologies need to be presented in such a way that the information will be correctly understood by any users. A specific language is being created in order to present a very high quality of specific results to users like students and to allow them to be ready to handle the huge amount of scientific information collected in databanks from research laboratories. This language includes the creation of specific signs to be used for surrounding the pictures of proteins indicating their physiological state (active or inactive form).

Generalized Replay of Multi-Streamed Authored Documents*

Chr. Bacher, R. Müller
Institut für Informatik, Universität Freiburg
EMail: {bacher|muller}@informatik.uni-freiburg.de

Abstract: We report about a new open multimedia document type which can be replayed by a generalized kind of multi-stream presentation. The considered documents combine an arbitrary number of time-based media streams altogether fulfilling the prescribed requirements. We introduce the Random-Access Property as well as the Master-Slave Synchronization of media streams. The aim is a general model for an application which is able to replay any instance of the defined document type. We present a prototype and discuss our experiences with the integration of these documents in multimedia learning and teaching environments.

1 Multi-Streamed Documents - Generation and Replay

The simultaneous presentation of several time-based data streams causes many problems. This ranges from the physical transmission of distributed streams via well-known communication channels, through exhausted system resources while decoding and replaying continuous media like audio and video, to the synchronization of the streams and their access at arbitrary given points.

The data streams discussed in this paper and if belonging to the same document presented on the same machine. The documents we consider are built of several (at least one) heterogeneous streams. Furthermore it makes no sense to present these streams simultaneously if there is no content-related correlation between them. In most cases these documents have been generated during some kind of live presentation, demonstration or session, where different types of media have been used in parallel, i.e. media which can be recorded online in an analog or digital way including all time-related information necessary to replay them in the same way as presented.

To give an idea of these documents, we can consider sessions on a computer, for example some kind of advanced training, where the instructor of the course explains the features and the handling of some new applications (e.g. a word processing tool) to the participants. In this case the voice of the instructor - this produces the first stream - and his actions performed on the desktop - this produces the second stream - are recorded. Lotus ScreenCam [10] is a suitable tool for such a task. During the replay the two streams are presented synchronously in a convincing way. As far as Unix is concerned, there are some interesting experiments in recording and replaying X-Sessions [6, 7]. Drawbacks are: This kind of replay as well as the generation itself is restricted to certain window systems and platforms (e.g. ScreenCam: PC/Windows). The recording at the low level of a window system leads to huge data amounts necessary to store the documents exceeding those produced by the audio.

Another example are MBone Sessions [5], teleconferences where usually the voice of the different participants, their video and their whiteboard actions - each producing one data stream - are multicast over the Internet. These streams generated at various locations can be recorded from the network with a tool called MBone VCR [8]. The playback is done by re-multicasting the recorded streams. But similar to ScreenCam it is not easy to navigate inside these documents, to find and to jump to the interesting sections of such recordings. Re-multicasting does not solve the problem of recording telelectures or teledemonstrations at the presentation site to generate products for local synchronized replay and offline use.

This leads directly to the last example called Authoring On the Fly [3, 4]. In this scenario the online lectures are multicasted and recorded at the same time on the presentation machine. The lecturer uses the well-known whiteboard \textit{wb} from the MBone Toolset [5] or the enhanced \textit{AOFwb} [2] especially developed for this task. Audio, that

*This research is supported by the German Research Society (DFG) project \textit{Erzeugen multimediaer Dokumente on the Fly}, No. Ot 64/13-1.
means the voice of the lecturer, animations running on the presentation machine and (in some special occasions) video are the additional media employed in this environment. The resulting documents meet exactly our requirements discussed in detail later on. They are always a concrete example for all those general documents and media streams considered in the following sections.

In the next section we introduce data streams and some of their characteristics as far as they are interesting to fulfill our idea of a generalized simultaneous presentation of several streams. We define what we call the Random-Access capability and a Master-Slave Synchronization of media data streams. It results in the composition of these streams to a type of multimedia document. In section three we present a general model for an application which is able to replay arbitrary instances of this document type. Finally we report about our realized prototype and the experiments we made with it during the last months.

2 Data Streams - Synchronization and Random-Access

The connection-oriented transmission of a sequence of data packets from a source component to a destination component is globally called a Data Flow or a Data Stream [11]. It is guaranteed that the packets are received in correct order. Examples are the writing to a file, the reading from an audio device, FTP or Pipes on a Unix system. All data streams considered here must be locally available and completely stored on the filesystem of the presentation machine. Thus they have to be transmitted from same kind of storage media (hard disk, CDROM, DVD, etc.) to the memory handled by the presenting application like the replay of a Quicktime movie by a common tool.

2.1 Time Dependency

Data streams containing some kind of time-related information can be called Time-based Data Streams. This could be any arbitrary kind of relation between a time line and the data in the stream without any rules how this should be interpreted during a presentation. It could be a function in its mathematical understanding from the considered space of time to the index set of the packets in the stream. A good example for this time dependency are Media Streams generated by same media input like audio or video devices. But also applications like whiteboards or the direct mouse and keyboard actions (desktop session recording) could be considered as input devices. All of them generate a data stream including time-related information which makes it possible to replay the streams correctly with regard to time.

To be more precise we consider a strongly monotonous increasing sequence of time stamps \( (t_i) \) as part of the stream which divide the stream into data blocks \( (b_i) \) called Presentation Elements (PE). The information in the presentation element \( b_i \) describes what should be presented during the time interval \( [t_i, t_{i+1}] \) (Fig. 1). These streams are called Synchronizable Streams.

![Figure 1: Time stamps and presentation elements in a data stream](image)

Examples for PEs are single video or audio frames as well as the drawing commands for graphical elements (line, circle, text, etc.) of a whiteboard action stream. In uncompressed continuous media streams (audio/video) the sequence of time stamps is implicitly given by the frame rate and the frame size (and sometimes the number of channels). With regard to these two values it is easy to determine the sequence of time stamps and the corresponding mapping to the byte positions in the stream. But also captured desktop events (e.g. mouse clicks, keyboard input) timestamped automatically at the generation time or later on by the receiving event handler are examples for PEs in a synchronizable stream.

There is no restriction in the number of elements presented in parallel during the same time interval. This is not a problem for strongly regular media streams where each PE has the same size and parallel PEs start at the same point of time (e.g. stereo audio stream). With regard to all other cases it is necessary to allow the PEs the overlapping of
several consecutive time stamps (Fig. 2). To avoid flickering (i.e. tiny gaps in the visual or audiovisual presentation of elements) the presenting application has to ensure that PEs which overlap a timestamp do not disappear at that point of time (e.g. usage of double buffering and clipping mechanisms during graphical output).

![Diagram of PEs overlapping several time stamps](image)

**Figure 2: PEs overlapping several time stamps**

A suitable solution to realize discrete synchronizable media streams is the combination of **Object Lists** and **Event Queues**. An Object List is a numbered list including all PEs used in the considered media stream. An Event Queue is a strongly monotonous increasing list of time stamps where each entry points to a list of object identifiers. These ids correspond to the objects (PEs) presented in parallel during this period of time (Fig. 3).

Indeed there is no restriction to the kind of objects used in these lists. This can be drawing commands as well as application control commands (e.g. execute the specified animation, browse the specified HTML-page). The recording tools within Authoring on the fly [3, 4] generate streams of this kind to describe the whiteboard actions performed by the lecturer.

### 2.2 Random Accessibility

In order to facilitate the navigation and content-based orientation within a media stream we suggest a kind of **visible scrolling**, i.e. the simultaneous display of all included visual data while scrolling forward or backward along the time line. It depends on the scrolling speed and the resolution of the scroll bar how many of the PEs become visible to the user. This makes it very easy to get a quick overview of the presented contents and to locate the parts in the stream which the user wants to focus upon.

In order to enable the visible scrolling we need to provide access at any arbitrary point of time, i.e. the random accessibility of media streams. We call a media stream **random-accessible** if it is nearly free of history. This means that it should be possible to determine all corresponding PEs for any given point of time \( t_0 \) without rescanning larger earlier parts of the stream. To fulfill the given time constraints during the replay it must be possible to the to find the highest time stamp below \( t_0 \) with the following PEs in a period of time which must be under a given threshold \( \tau \). This value \( \tau \) is influenced by factors as human perception (e.g. the human eye is usually not able to distinguish between more than 25 video frames/sec).

Examples for random-accessible streams are continuous media streams like uncompressed audio and video where it is easy to compute the requested frame and file position out of the frame rate and frame size. But even compressed continuous media like MPEG can be considered as random-accessible, if the distance between independent frames (e.g. I-frames in MPEG) is small enough to fit within the threshold \( \tau \). In order to decode the requested frame (e.g. P-frame or B-frame in MPEG) we mostly need only the frames between the surrounding independent frames. With some preprocessing effort (to find the byte position of the frames) and some additional amount of memory (to store the positions) it can be possible to access the requested frames directly. Streams realized through object lists and event queues as mentioned above are random-accessible by their definition. These streams do not have any history. Each entry contains the complete list of object identifiers which could be presented independently from any other event occurring before the specified point of time.

The property of random-access combined with the control of a presentation from outside the application enable the external indexing of a media stream. Hyperlinks for example (out of HTML-Pages or PDF-documents) can reference to points inside the stream. It is possible to generate an interactive index, a contents overview or combine it with corresponding articles or other related work. This way random-access facilitates the integration of media streams into multimedia learning and teaching environments or other CBT-products.
### 2.3 Master-Slave Synchronization

We are now in the position to define what kind of documents we consider for our approach of replay. **Documents** are a combination of several synchronizable random-accessible media streams. At least one stream must be a so-called **Master Stream** and all other ones are **Slave Streams**. Master Streams are uncompressed and continuous, usually audio or video as well as combined audio/video. As introduced in the previous section all streams in a document are usually related with regard to their contents and are presented simultaneously. In order to synchronize them we use a **Master-Slave Synchronization** where the Master Stream is used instead of a global clock to synchronize the Slave Streams. The idea is to divide the Master Stream into small equal-sized blocks and to use their time stamps as points for synchronization. These start points are also time stamps of the Master Stream. Everytime when one of the blocks in the Master Stream is completely replayed we look up the corresponding time stamps in all Slave Streams to find out which sets of PEs have to be presented in parallel at the current point of time. This is possible because all Slave Streams are synchronizable and random-accessible. The real-time replay of the whole document is now given if the Master Stream is replayed synchronously to the global clock. This is usually the case with audio and sometimes it may be possible with video.

An interesting aspect in Master-Slave Synchronization is the block size in the Master Stream. If we assume, that all Slave Streams present only visual information and no audiovisual information the block size is small enough if the frequence is roughly equal to 25 time stamps/sec. But even an audio stream with the a frame rate as low as 8000 samples/sec and probably the most continuous media streams have a granularity which is fine enough for every human visual perception.

### 3 A General Application Model

In the following we want to describe a general model of an application that is able to replay arbitrary instances of the document type defined in section 2.3. As a realization of this application model we want to present our prototype and its integration into multimedia environments.

#### 3.1 The Model

The application is divided into several independent **presentation modules**, one for each media stream in the considered document. All these modules are individual applications running on the presentation machine. Each module is able to read and to present its assigned stream individually. Usually the modules are developed for a certain type of media stream and cannot present other stream types. There are two connection-oriented simplex communication channels between the **Synchronizer** - the module presenting the Master Stream - and every other module (**Helper**) (Fig. 2).

![Figure 2: Simplified application workflow](image)

The main channel in direction to the Helper is used to control the Helper and to realize the Master-Slave Synchronization. The Synchronizer is presenting the blocks of the Master Stream one after another. Everytime when one block has been presented completely (e.g. an audio block has been replayed) the corresponding time stamp is sent to each of the Helpers through the main channel. The Helper is queueing the time stamps while always processing the most recent one. Earlier time stamps are ignored. Processing a time stamp means presenting the concerned set of PEs as fast as possible. Control sequences sent through both kinds of channels are either **events**
These control sequences are also queued on both sides and processed immediately. There are several reasons to choose a distributed application model in contrast to a monolithic structure: Monolithic programs are difficult to develop and especially difficult to maintain. Strong dependencies between different modules increase the probability for unexpected errors. The main advantage is apparently the ease of extension: It is straightforward to add new Helpers to the application. The specification of the simple communication protocol is everything the helpers must provide, no other details of the modules especially of the Synchronizer has to be known. At the initialization stage the Synchronizer reads the document description, calls the helpers corresponding to the streams specified in the description and opens the communication channels. The call of the Helpers is identical for all of them.

3.2 The Prototype

The existing prototype is actually implemented on different unix-based platforms. The communication channels are realized through FIFOs (named pipes). The Master Stream in this prototype is always an audio stream. We have implemented three different helpers so far. One Helper is replaying the whiteboard action stream generated by the AOF recording environment [3, 4]. Helper two is presenting a stream including start- and stop commands for external applications. In most cases these applications are animations integrated into a lecture. The third helper is a movie player replaying an arbitrary Motion JPEG video. We tested the application with several documents generated by the AOF recording environment where always the first helper is used, in most cases the second helper and sometimes the third helper (for the lecturer video) is used, depending on the considered document.

Additional features are:

- Visible scrolling is enabled.
- Control from outside: It is easy to force the application to jump to specified time stamps (e.g. via HTML-Browsers through certain hyperlinks). Thus every kind of indexing of the document is possible.
- Control via Helpers: The user can jump to start points of animations or to slide changes on the whiteboard replay.
It is possible to add new media streams by specifying the corresponding files and the replaying helper in the document description.

The application can be used as simple audio player (documents without slave streams).

This application is used in a new kind of multimedia book [9] just published in fall 1997 as well as in our local learning and teaching environment where every member and every student of the department can access and replay the documents on every workstation. We provide demo packages including one document and the replaying applications for different platforms on our web-server [1].

4 Conclusion

We presented a model and its realization of an application replaying locally arbitrary instances of a general stream document type while the synchronization of streams is always guaranteed. The considered documents are a combination of several time-based synchronizable random-accessible media streams. Indeed there is no restriction neither to number of streams in the document nor to the kind of included media streams, if the specified requirements are fulfilled. For synchronization purpose we divide the streams within one document into Master Streams and Slave Streams and use one of the Master Streams to synchronize the other ones.

The defined document type covers a wide range of multimedia documents which can be replayed in this way as a high-quality presentation. It is straightforward to integrate the documents into multimedia educational environments. A central argument is the Random-Accessibility which enables the indexing of the document and the linkage with arbitrary document collections. Interactive content overviews with active links to the corresponding positions in the documents are possible as well as the combination with other content-related material (e.g. articles, books, references, simulations). The availability of the replaying application for the platform PC/Windows which we are just developing together with the already available Unix versions ensures a wide area of application.

Collaborative Meaning-Making in Computer Conferences: A Sociocultural Perspective

Maria Bakardjieva
School of Communication, Simon Fraser University
Canada
mbakardj@sfu.ca

Abstract: The goal of this paper is to propose a perspective on how the sociocultural approach, and in particular Cole and Engeström's model of activity, can inform the design and introduction of computer conferencing in the context of university education. It is argued that computer-conferencing systems should be seen by educators as new mediational means that become formative components of new activity systems. Conceptualizing and modeling these activity systems as complex sets of learning objects and objectives, rules, roles and tools, rather than a narrow focus on the technical aspects, is therefore the actual challenge facing the educational community.

1. Theoretical Framework

The sociocultural approach to human psychology, most notably to thinking and learning, is taking shape in the dialogue among conceptual models and research agendas related to the theoretical heritage of Vygotsky, Leont'ev and Bakhtin, to cultural psychology [Cole 1990], situated cognition [Lave & Wenger 1991] and distributed cognition. In a recent volume, Wertsch and his co-authors summarized the central tenet of this approach as follows: "The goal of a sociocultural approach is to explicate the relationships between human mental functioning, on the one hand, and the cultural, institutional, and historical situations in which this functioning occurs, on the other" [Wertsch et al. 1995]. The main unit of analysis of sociocultural research is recognized to be human action. Although different exponents constitute this unit in different ways [Engeström & Cole 1997], they all seem to agree that, as an analytic category, action holds the potential of transcending the false antinomies between mind and environment, individual and society [Wertsch 1991].

Another central building block of sociocultural research is the notion of "mediating artifact" [Cole & Engeström 1993], "mediational means" [Wertsch 1991], or "cultural tools" [Wertsch 1995]. Mediational means provide the link between the concrete actions carried out by individuals or groups and the surrounding social and cultural environment. The importance of mediational means is derived from the work of Vygotsky and his followers who laid an emphasis on the formative role of tools (both material and symbolic, or "psychological" in Vygotsky's terms) on human action and thought.

Following Vygotsky's tradition, and building on Leont'ev's "activity theory" in particular, Engeström [Engeström 1987] and later Cole and Engeström [Cole & Engeström 1993] have proposed a model of human activity as a systemic formation taking into account its tool-mediated nature, its object-orientedness and its rootedness in community practice. This latter aspect makes the model applicable not only to analyzing individual behaviour, but also to activities performed by collective actors such as groups and communities.

According to Cole and Engeström's model, the central components of an activity system [Fig. 1] include the individual actor (subject), the community in which this actor is constituted and the object of activity representing its motive. The relations between subject and community are mediated by the artifacts (tools, mediational means) applied to the activity on one hand, and by this community's rules of action and interaction, on the other. The relationship between community and object of activity is specified through an elaborated division of labour - "the continuously negotiated distribution of tasks, powers and responsibilities among the participants of the activity system" [Cole & Engeström 1993]
The goal of this paper is to propose a perspective on how the sociocultural approach, and in particular Cole and Engeström's model of activity, can inform the design and introduction of computer conferencing in the context of university education. It is argued that computer-conferencing systems should be seen by educators as new mediational means that become formative components of new activity systems. Conceptualizing and modeling these activity systems as complex sets of learning objects and objectives, rules, roles and tools, rather than a narrow focus on the technical aspects, is therefore the actual challenge facing the educational community.

2. Background

This paper draws on in-depth discourse analysis of computer conferences carried out within the framework of post-secondary level courses in the fields of the social and human sciences using Virtual-U. Virtual-U (VU) is a web-based asynchronous learning environment including a computer-conferencing feature called Virtual Groups (VGroups). It was developed at Simon Fraser University, BC as one of the beacon technologies of the Canadian TeleLearning Network of Centres of Excellence.

The conference transcripts were analyzed with a view to their thematic structure, and the functional characteristics of the “speech acts” performed by participants. Proceeding in a bottom-up fashion, that is working from the empirical material towards generalizing concepts, two sets of categories corresponding respectively to the observed two main types of discursive action: "acts of meaning-making" and "interactive moves" were devised. Acts of meaning-making are speech acts aiming at interpretation of the subject matter thus making it personally meaningful to the speaker and the group. Interactive moves are speech acts in which the goal is to establish relationships between and among participants in their capacity as thinkers, group members and persons. Each utterance found in the conference transcript was classified according to the kind of meaning-constructive and/or interactive function it performed. For a detailed discussion of the coding scheme see [Bakardjieva & Harasim 1997].

The analysis described above focused on the level of actions. Actions, according to Leont’ev’s model of the general structure of activity [Leont’ev 1981], are the basic components of various human activities that translate them into reality. Taken by themselves, without a reference to the activity they constitute, actions are hard to make sense of. Why the process that unfolds in front of our eyes takes the shape it does? What would be the optimal set of actions that educators would like to see performed by students in online conferences with a view to their instructional goals? Such questions posed by practitioners incorporating online conferencing in their university teaching cannot be answered by analyses restricted at the level of action. That is where we need the concept of activity and activity system in order to provide a systemic framework for the guidance of pedagogic intervention.

3. Computer Conferencing as Activity System
Computer conferences as a specific type of software and an associated chain of operations can become a part of different activity systems in the context of university education. Therefore, to make any general claims about the pedagogical uses or effects of computer conferencing would be misleading. Leont'ev maintained that the main feature that distinguishes one activity from another is its object: "After all, it is precisely an activity's object that gives it a specific direction. ... an activity's object is its real motive" [Leont'ev 1981]. Computer conferencing, when viewed as an activity is thus defined by its object. This object could be community-building and socialization, mutual help with technical or other problems, exchanging information on topics of shared interest, etc. Most typically however, the object of computer conferences representing components of university courses (taught fully online or mixed-mode) is the subject matter of the course and more specifically students' need to achieve deep understanding of the subject area. The following discussion will deal with this particular activity although, admittedly, it is not the only one that can be identified in relation to computer conferencing in the context of post-secondary education.

Figure 2: Educational computer conferencing as an activity system.

Figure 2 represents educational computer conferencing oriented towards deep understanding of a subject area employing the general model of activity system proposed by Cole and Engeström [Cole & Engeström 1993]. In this concrete activity system, the main components are the individual learner (student), the online learning group and the object/objective of the activity as a whole. The activity is mediated by two central mediational artifacts (or more generally, means) - language and a computer conferencing system comprised of the respective technical hardware and software. The relation between the student and the learning community is mediated by a set of rules specifying what is appropriate and recommended to do in this particular setting. The relation of the community (learning group including the instructor) to the object/objective is mediated by a set of roles constituting the structure of power and responsibility of individual members vis-à-vis the activity's object. This activity system as a whole is situated in the larger context of the particular university course and in the institutional setting of the university. These two higher level activity systems can be characterized respectively by their objects - knowledge acquisition/construction and post-secondary education.
The character of the mediational means and the object of computer conferencing as an activity system determine the general nature of actions that will translate this activity into reality, to paraphrase Leont'ev's formulation. These will be discursive actions and interactions, communicative manipulation of symbols and meanings, implemented through operations related to the conferencing interface and the computer input and output devices. The specific content of these actions and interactions however, cannot be foreseen or deducted solely from the character of the mediational means and object alone. It is also largely dependent on the content of the rules and social roles making up the whole of the activity system.

At this point, attention should be drawn to the fact that unlike other educational activities such as classroom discussions, seminars, laboratory experiments, etc., computer conferencing is a newly emergent activity system with which participants have little or no prior knowledge and experience. This means that no clear and widely accepted cultural conventions specify the action and interaction rules and roles of participants. Both instructors and students engaged in computer conferencing perform a sort of cultural experimentation with this activity bringing to bear elements belonging to other settings and eclectically combining them in a new practice. Given the institutional context and the object of the activity, what could be the cultural resources that will be drawn upon in this process of experimentation? The following are some of the factors that can be expected to influence the character of the rules and roles defining computer conferencing as far as its development represents a naturally unfolding cultural process:

### Rules of action and interaction:
- University culture
- Youth culture
- Discipline culture
- Competence
- Internet culture
- Medium related de-individuation

### Roles played by students and instructors:
- Division of labour in the university
- University standards
- Participants' levels of competence
- Principles of evaluation

### 4. Creating the Activity System: A Tentative Guide

If, on the other hand, a particular instance of educational computer conferencing is to be designed reflectively as an activity system, pedagogic decisions have to be made regarding the concrete content of its various components. General institutional arrangements such as semester duration, course enrollment, instructors' work hours, nature of course material, evaluation standards and expectations, as well as pedagogical objectives have to be translated to the level of computer conferencing.

1. **Conference object:** Conferences typically focus on either a particular discussion topic or a particular activity (socialization, research, help, etc.) Arrangements have to be made to ensure that all participants have access to the object of the conference, for example sources of information dealing with the topic of discussion.

2. **Conference objective (or direction of transformation of conference object):** The character of the conference objective, affects the self-organization of the group, the interactions among members and the degree of closure the discussion reaches. Depending on whether any particular end product is expected, and whether it is a collective or individual responsibility, different patterns of group dynamics and meaning-making activity are observed.

3. **Time frame:** Corresponds to object and objective. Ensures completion of object transformation, for example meaning construction and understanding.

4. **Number and character of participants (community size and structure):** Ensures reasonable "air-time" and thus reasonable degree of involvement of participants. Determines the pre-existing cognitive and cultural resources of the community.

5. **Participation format (rules of action and interaction):** Specifies quantity and timing of participation as well as what kinds of actions and interactions are desirable and appropriate. Reduces performance anxiety. Provides students with support in terms of goal-formation.

6. **Roles students play:** Assigning defined roles to students ensures coordination of actions vis-à-vis activity’s objective. Relations of power and responsibility become clearly recognizable. Undesirable effects could be subversion or withdrawal.
5. Implications for Design: Responsive Mediational Means

5.1. Language

A number of linguists have argued that different “areas of human activity” [Bakhtin 1986] or “situation types” [Halliday 1978] evoke specific variations of linguistic forms. Bakhtin has introduced the notion of “speech genres”. Speech genres are typical forms of utterance which “correspond to typical situations of speech communication, typical themes and, consequently, also to particular contacts between the meaning of words and actual concrete reality under certain typical circumstances [Ibid.]” Halliday [Halliday 1978], for his part, has spoken about different linguistic “registers”.

A close correspondence between the determinants of a speech situation as characterized by Bakhtin and Halliday and the defining parameters of “activity systems” as described by Leont’ev and Cole and Engeström can be observed. Therefore, it follows that with the evolution of activity systems involving language as a mediational means, typical speech genres corresponding to the structure of the activity system take shape. Subsequently, participants in this activity system are guided in their discursive performance (as to what is necessary and appropriate to “do with words”) by the speech genre, thus reproducing the activity in the socially prescribed way.

Indeed, the discourse analysis of computer conferences described earlier in this paper shows indications of the spontaneous emergence of a characteristic mode of discursive performance related to the activity of collaborative meaning-making in electronic educational environments. I would like to call this form of speaking the online-learning genre. This hypothetical speech genre seems to take an intermediate place between the "learned" discourse of the academic field (which students typically try to imitate when writing papers) and a laid-back peer discussion of issues of common interest (which would normally take place after classes or in the cafeteria).

The online-learning genre represents a mixture of scholarly propositions and argumentation on one hand and peer-interactional forms involving gestures of sharing, self-disclosure, solidarity-seeking and building, on the other. In conference entries stating their positions on problems identified in the subject matter under consideration, students also support their classmates or talk about the group interaction, or give out personal information or personal feelings. In this way the social risk of stating a position regarding matters in which students perceive themselves as novices is managed by establishing a human relationship with the peer audience.

Thus, the online learning genre can be conceptualized as a discursive “tool” specifically suited to the activity of gaining deep understanding of a subject area while working in a collaborative online group. One important question to be considered by educators employing computer conferencing, then, is what steps can be taken to further develop the online-learning genre in pedagogically desired directions on one hand, and through what means students can be taught to recognize and practice it, on the other. This last skill may prove to be as necessary to the successful participation in educational computer conferences as the mastery of the technical aspects of the conferencing system.

5.2. Conferencing System

Technological mediational means are usually developed with one set of practical purposes in mind, and later, carried over into different spheres of activity with or without sufficiently careful adaptation. Computer conferencing emerged in response to the need of groups of scientists and decision-makers to
exchange information and comments at a distance. It was modeled after the format of electronic mail which presupposed an initiation-reply sequence of communicative exchange. Branching into different threads was the innovative conference feature which allowed structuring of group conversations according to topic. These two features characterize most contemporary conferencing systems including VGroups - the one our study was based on.

The conference interface as it appears in VGroups includes two central action prompts: The choice between “New Message” or “In Reply To” options offered to participants allows them to either initiate a new topic or follow up on others’ contributions. The “Subject” field calls for a succinct specification of the point of the exchange. Contributions, then, can be represented on the conference overview screen as a branching tree-like structure.

With a view to the actual character of the mediated activity, two main problems can be found with this interface. First, the tree-like structure is in no way homologous to the network of interrelated meanings woven in the process of the group pursuit of understanding of the area. Secondly, the type of entry classification feature (limited to initiation or reply) reveals almost no information about the rules of action and interaction and the various participants’ roles in the activity system. As a result, in the actual use of the conferencing system by students, as shown by the discourse analysis, both prompts are perceived as formal, get twisted and subverted and do not serve well the coordination of the process.

There is no easy solution to the problem of how a conference interface could be designed to inform, enable and coordinate the complex activity under consideration and represent its outcome in an adequate way. One possible approach could be the iterative introduction of various new features into the conferencing interface and their testing in the practice of online learning groups. The danger related to this approach is that given the potential of cultural tools to shape action [see Wertsch et al. 1995] educators may end up with an activity system centered on its mediating artifact rather than on its object and objective, that is a practice of educational computer conferencing structured to accommodate its mediating technology. Another way to go is to design conferencing systems on the basis of detailed models of the educational activities they are supposed to mediate. Such models would include all three hierarchical levels of the structure of activity. That means they will rest both on theoretical construction of the activity system with a view to its object/objective and main actors' relations, and on empirical studies of the actions and operations fleshing this system out.

E-mail: mario.barajas@doe.d5.ub.es

Abstract: The integration of new telematics-based teaching methods in traditional universities will be an important challenge for academic institutions in the future. Telematics is the tool that can definitely change many of the methods normally used to deliver lectures. It makes the organisation of curricula and the delivery of courses more flexible. This paper deals with the evaluation of the implementation of two experiences, a web-based module that combines regular face-to-face interactions, and an international debate. The experiences are part of the project REM (Réseau d'Enseignement Multimedia), funded by the European Union (Telematics Applications Program). In this project, eleven Higher Education institutions collaborate producing course materials and teaching resources with the aim of offering international courses in virtual classroom environments. We conclude with some recommendations for future developments, especially for those situations in which participants share the same virtual classrooms.

1. Introduction

This paper describes two experiences in which traditional face-to-face and Web-based teaching methods were combined at the University of Barcelona as part of a regular course in Environmental Education for student teachers. Both experiences belong to a two-year project funded by the European Union and included in the Telematics Applications Program. This supports projects in different areas, aiming to research, develop and demonstrate innovative applications of telematics environments; one of these areas is Education and Training.

The first experience took place at the University of Barcelona with no external participants. During the first semester of the academic year 1996-97, we delivered a Web-based module in Environmental Education to a group of pre-service teachers attending the regular course at the same time. The design of the module interface included both tutor-student and pier-pier communication areas, allowing a full telematics-based delivery system.

The second experience was carried out in collaboration with the University of Bangor-Wales, the University of Illes Balears and Nottingham Trent University. Thirty-five lecturers and pre-service students took part. It involved an on-line debate about the role of teachers in environmental education. In both cases the students were assessed.

The results of the evaluation of both experiences are intended to pave the way for overcoming many problems we identified during the activities and at the end of them. This will serve to design models of collaboration and course delivery in international settings during the third year of the project.

2. Background

Over the last years, a lot of attention has been paid to studying the possibilities of using Internet as a vehicle for distance education. The communication between the actors of the teaching and learning process is an added value to the varied learning environments created around telematics support tools. Moreover, the emergent web-based learning systems allow us to envisage a very changeable panorama in course delivery.

New virtual learning environments make it possible for a course to be delivered fully through the network, thus opening the possibility of a virtual classroom. New institutions are blossoming around this powerful idea, including new distance universities generally based on Web interfaces.

How are traditional Higher Education institutions facing this new panorama? What cultural and
organisational changes will these institutions face in the future? How do teachers and students take advantage of the possibility of participating in international courses using Internet? Before having a clear answer to these questions, we need to validate experiences in which all the mentioned factors are put into practice.

Since 1996, eleven universities in seven countries are involved in a project funded by the European Union. This is called REM (Réseau d'Enseignement Multimedia).[1] The main objective of this project is to create a telematics-based environment for co-operation between lecturers and students in international settings. The project, currently in its third year, aims to produce a distributed database of multimedia resources for teachers training accessible through the Web. It is also aimed at creating collaborative teaching experiences between universities across Europe, including the delivery of common courses.

So far the University of Barcelona, one of the participant universities, has created several modules in the areas of Environmental Education, Open and Distance Learning and European Learning.

The REM chapter of the University of Barcelona has already organised several collaborative experiences in this project, such as web-based course delivery, and international debates on different issues. In this paper, we analyse some of the issues arisen from the experience.

3. Evaluation Approach

As Cullen points out [Cullen et alt., 1995], focusing on innovation as the subject of evaluation implies evaluating the project in all its complexity, considering both space and time dimensions and in relation to its integration in the project, in the programme and also in organisational and social environments. It is also important to understand the nature of the innovation, not as a finished product or service, but as a process. The evaluation should be multi-faceted, contextualised and evolving and there should be a holistic approach to needs.

Following this approach, we focused the evaluation process in the study of a number of factors when planning to study the key issues related to the use of this new learning environments. These were: institutional/organisational issues, communication processes, teaching and learning processes, expectations and attitudes of participants, and technological factors.

The students and the lecturer who participated in the experiences were chosen from a "Environmental Education" regular course. The lecturer had already participated in the design of the module as subject matter expert. Students were selected on the basis of computer skills (basic use of computer programs) and their command of English. The trial itself lasted for one month and a half.

For the gathering of data, we used several methods and tools. We decided to collect relevant data, so we used both traditional and innovative tools to obtain different types of information. We used observations of pupils while they followed the module, face-to-face meetings and personal interviews. But we also followed some work sessions in which we digitally recorded the students' interactions with the Web-based material by using a program that created a file with the path students followed up throughout the module. We used a program called "Lotus ScreenCam". Since this program also allowed us to record sound, we asked the students to "think aloud" during some sessions, so as to reconstruct interactions in a reliable way.

The main and most useful source of information were the personal diaries the students sent to the tutor weekly, in which they reviewed critical aspects of their work, motivation and learning.

A thorough evaluation of the process and results was undertaken during and after the experience in order to identify, describe, analyse and critically assess the results of using a so-called "REM module" in combination with face-to-face interactions. A similar process was undertaken for evaluating the second experience, an asynchronous international debate, that we describe later.

Now that the evaluation analysis has been completed, we will move on to present some of the most relevant results.

4. First experience: Web-Based Module Delivery Combined with Face-to-Face Regular Classroom.

At the beginning of 1997, REM-Barcelona organised a "pilot course" using a Web-based interface for delivering a module which belonged to a course on Environmental Education. The course is attended by student teachers in their second year.

Learning arrangements were carried out around three main figures: the tutor, the lecturer, and the technical staff. The role of the tutor was very important. First, the tutor was in charge of the day-to-day

[1] You can find more information about this project in http://eric.doe.d5.ub.cs/rem
communication, which meant answering the students' queries about the module content and organising the virtual environment. The regular lecturer received and marked the assignments, and then contacted the students to reply them. The technician was in charge of keeping the system running and solving any query from the participants related to the functioning of the system.

In order to give support to the lecturer and students on the uses of the communication tools, we also included a Web-based module called "Telematics Tools", which belonged to another REM course area. This training took place in both face-to-face and self-learning sessions. For two weeks, participants learnt how to use different telematics tools such as e-mail and distribution lists, querying databases and net search, and became familiar with the Web environment.

4.1. Institutional aspects

The University of Barcelona provided computer rooms with enough equipment for the students. Nevertheless, we found numerous management problems, something we consider to be characteristic of traditional institutions such as the UB. For instance, those responsible for the labs were reluctant to give access to the students. In addition, many technical problems arose during the experience: old communication protocols that needed to be updated, different software versions, etc. The fact that the University has a centralised maintenance service was a disadvantage for setting up the whole experience.

The Environmental Education lecturer participating in the experience showed much interest in it from the very beginning. The lecturer wanted to offer the students a different concept of learning in a new environment. The lecturer was also enthusiastic about being in contact with innovative technologies. However some problems arise, in our opinion, when putting innovations into practice, since some attitudes are difficult to change. For instance, the distance tutoring methods were not totally assumed by the lecturer, as demonstrated by the fact of sometimes giving feedback in the regular classroom instead of using e-mail. It was not a technical problem, but a "cultural" one [Fullan 1993], [Sancho 1993]. Lecturers need to become familiar not only with the new tools, but also with the flexible learning interaction processes. Such changes take time.

4.2. Communication processes

The students followed the module and other activities during a time-sharing schedule independent from the regular face-to-face one. The communication framework set up during the experience was based on e-mail and distribution lists. In addition, we included Internet Relay Chat. We then designed two main areas of communication in the virtual classroom:

- **Private area.** It was a space very close to the participants. There was one-to-one interaction (teacher - student and/or student - student). The communication needs of that area were covered basically by regular e-mailing.
- **Public area.** It was a common space that allowed participants to express their opinions in public, share their homework, etc. The communication needs of this area were covered partly with an e-mail list and partly by using World Wide Web as a vehicle to deliver course material. Internet Relay Chat (IRC) was used as a secondary tool to contact piers.

With respect to the message flow, students sent as many as 113 messages. The distribution list (public area) received 43% of them, while the Environmental Education tutor received 33%, the regular lecturer 18% and the technical staff 11%. Regarding these figures, we must make it clear that we are not including personal messages between students, since we decided to respect their privacy.

From this data, we clearly see that the level of communication was high, considering that the students had never used these tools before. Most of the messages were related to the module content. The low number of messages related to technical or institutional problems demonstrates that, although there were some problems in this respect, the communication was successful and achieved its aims. Participant students were surprised by the fact that Computer Mediated Communication tools were so effective and able to communicate not only knowledge, but also personal emotions.

We identified some gaps in the communication processes which had to be filled. First of all, students needed more practice at using tools, for the 4-hour training sessions we delivered were not enough. At the end of the experience, all these problems could be overcome. Management of the computer rooms also hindered the communication processes to some extent, for the labs were open for all university students at the same time. This meant those involved in the experience found it hard to access a computer.

More important than that was the lack of feedback by the regular lecturer. The students indicated that the face-to-face lecturer was not sending responses as often as they expected. This means the lecturer needs to play a much more active role in this setting. We also detected some problems of information overflow. The students were not used to accessing the fragment-based information in the WWW and felt
stressed ("I felt sunk in an ocean of data").

4.3. Design of the materials and activities

All students pointed out that both the materials and the learning activities had been very innovative. The students showed a positive opinion about the content of the Environmental Education module, as well as about the introductory module (Tools for Communication) they completed. They were positively impressed by the possibilities of the hypermedia content organisation, including access to materials in the Web different from the ones specifically included in the pages. The selected activities achieved the learning goals and allowed reflecting on the contents in a different way than in the face-face class. The Chat, integrated as an important learning activity in the designed module, was also considered as a positive experience for students. However, the fact that no other REM universities participated (as originally planned) hindered its efficiency. Chats integrated in the activities of the module are an opportunity for communication and reflection, but they are useful with peers not belonging to the Campus.

We have detected some minor problems concerning the materials. For instance the use of video-clips caused some problems because of the poor quality of the images and the still slow delivery over the net. On the other hand, the sequences selected were not very significant for learning, given its short duration.

Students had the opportunity of printing the materials, so they did not need to read for long in the computer screen. Another problem was posed by the fact that some materials were in English, and although foreign language skills were relevant in the selection process, students had problems in reading these texts on time. This shows the need to find new ways of organising texts, such as using translated documents in all participants’ languages combined with abstracts of the same documents.

There are opposed opinions regarding the organisation of materials and the scheduling of activities. While some students said that the freedom of browsing the module contents caused a waste of time, others appreciated this possibility very much. We consider this to be related to the different learning styles, but we do not have enough information at present. Therefore, this issue should be taken into account for further research.

Some participants find it hard to organise their time in flexible learning environments, since they have to combine a fixed class schedule and the flexible interactions of telematics. As a result of this, some tensions arise.

4.4. Participants' expectations and attitudes.

Participants' expectations varied depending on their roles and responsibilities. We basically analysed the expectations of students and lectures.

Fourteen students were willing to participate in the experience. Six of them were selected according to a main criterion: their command of English. Other considerations, for instance computer skills, previous experience in international projects and further activities in the Environment area were also considered. As a result of the selection procedure, we had a group of students with different skill levels and experiences. The expectations of the students were different according to their background.

The expectations were formally related to the contract the students agreed to sign up. They committed themselves to browse the course module, contact students from other Universities, learn new Internet tools, and have an e-mail account for a semester. The students could have the module recognised as part of the subject “Environmental Education”, since they were formally assessed. They then stated their commitment to develop the module activities, answer two questionnaires, participate in an entry-training course, and produce a personal diary as well as a final report. At the end, the students also received a certificate of participation.

During the trial process, we took into consideration the attitudes of the students when confronted with new learning situations. We concluded that there were no negative attitudes towards the teaching methods and tools used during the experience. On the contrary, they adapted very well to the new learning environment. It is important to mention that students reacted well to the new demands of the activities proposed. They soon realised that they had a much more active role in their learning process. They increased their level of reflection [Knapp & Petersen 1993] during the course, evolving from providing mere descriptions to relating the environmental issues to social and political contexts. This was shown in the written assignments, which were qualitatively different from the oral discourse of the face-to-face classrooms. Furthermore, a new attitude appears to arise in the relationship between students and tutors/lectures: a more friendly environment emerged around the electronic mail, as demonstrated by the use of more informal language between all participants than in the regular classroom and the greater number of enquiries. Students were definitely confronted with the possibility of breaking the narrow wall
The expectations of the lecturer were ambiguous to some extent, and in fact close to reproducing the models of the face-to-face teaching. The lecturer did not have a clear idea of the new teaching role. This fact suggests that it is probably more difficult for lecturers to change attitudes than it is for students. Maybe the accumulated experience of a professional career hinders the understanding of new teaching methods in some way.

5. Second Experience: International debate

The second experience was an international debate with 30 participants, between students and teachers, from 4 REM universities. These were Bangor, Nottingham, Illes Balears and Barcelona. The debate, called "Environmental Education in a Distance Learning Environment: The Role of the Teacher", was also part of the module on Environmental Education.

Participants were regular lecturers of this subject in the universities mentioned, students, tutors and two secondary school teachers doing practice in Environmental Education. The local tutor of the University of Barcelona acted as moderator.

The main goal of the debate was to test an adapted version of the Lehrer model [Lehrer et al., 1994] in a telematics-based situation. The Lehrer model is an important component of REM pedagogical foundations. It organises contents in four basic steps: planning, transforming, evaluating and revising. This provides a very solid base for students, who can research a knowledge area and then discuss their findings in an organised way, by following the mentioned steps.

All participants could also access a base document for brainstorming (a sub-phase of planning stage) the discussion. This document, "Computers and the Environmental Education", was available in English and Spanish. In this case, English was the language used in the discussion.

From the technical point of view, the debate was hosted in the server of the University of Bangor and developed in a First-Class server. The role of the moderator was unobtrusive. He had to make sure that the messages were related to the topic of discussion and decided when to shift to the next step according to the model mentioned before. A Web page (http://www.doe.d5.ub.es/etic/Debate/index.html) was created for all those interested in analysing the debate process.

According to the participants, the results were highly satisfactory, although we detected a far too great influence of the Anglo-Saxon lecturers in the discussion, given that the debate was carried out in English. Too long messages hindered the discussion, since the participants did not take into account the limitations of the textual-based exchange. Local students in Barcelona and in Balearic Islands, although they were relatively fluent in this language, sent less messages than the students from the UK Universities.

The role of the moderator, who kept the discussion very open, was also an obstacle for coming to conclusions in the different stages of it. We assume now that the moderator should lead the discussion, and set clear rules of debating from the very beginning.

6. Some recommendations for the future

Despite the difficulties mentioned, we have demonstrated that the REM telematics-based collaborative teaching and learning environment is feasible, not only in our traditional universities, but in nearly all learning situations. The REM pedagogic model proved to work in a satisfactory way, for it allowed flexible course delivery and international collaboration.

With this experience, we have paved the way for REM to successfully undertake course-lecturing collaborations in Telematics environments in the future. This experience has clearly demonstrated that Computer-Mediated Communication learning tools can be used in traditional institutions, such as most of the REM universities, although improvements are necessary in many respects.

First of all, if REM deals with collaboration, we have to determine how, who, and when the collaboration takes place. During the validation, there was a feeling of disappointment, especially among the students. This was due to the fact that the promise of international participation in the course delivery was finally honoured in the breach.

It is also important to ensure the in-site institutional collaboration before launching a programme of activities, and to make sure that we will have support for solving technical and organisational problems. If we want this kind of learning system to become commonplace in traditional institutions, we need much stronger support from them, as well as a policy of innovation able to integrate experiences like that in the day-to-day teaching. We do not mean that research teams should make a greater effort to solve all the technical and management issues. The solution would be a shift in the way large institutions (based on face-to-face education) incorporate flexible teaching methods. There is a need for a new mentality. Education institutions are to consider the introduction of innovative methods and technologies as part of
their policy, which means planning resources and facilitating the involvement of the regular staff. In that respect, staff training is a key issue, not only in relation to the use of telematics tools, but first and foremost, in the implementation of flexible teaching methods. Easy access to telematics tools should be ensured in the institution, and ideally in the participants’ home.

There is a clear tension between a flexible approach to the delivery of the courses and the need to have a fixed timetable. This will be much more important in future REM collaborations, especially if we also consider another added problem: the different course calendars of Universities in Europe.

Finally, language problems are also a key issue in international learning settings. At the European level, in which language diversity is seen as a cultural plus, there are not clear responses to that.

Abstract: Mental models are cognitive structures that have an important impact on everything we do - particularly, teaching and learning. This paper discusses the basic nature of mental models and summarises some work we have been undertaking relating to a study of how multimedia and hypermedia techniques can be used to develop rich mental models. A case study is described relating to the teaching of the subject of Human-Computer Interaction. The work that has been undertaken is intended to illustrate how multimedia environments can be used to develop and enhance learning activities within different domains.

1. Introduction

As a result of their interaction with the world human beings develop internal representations of it. Such representations in the head are called mental models. One purpose of these representations is that they allow us to solve problems and use artefacts such as computer systems. The literature of mental models in psychology dates back to Craik [Craik, 1943]. Different conceptualisations of mental models have been developed and reviewed by van der Veer [van der Veer, 1990].

Given that there are many different conceptualisations, it is not surprising that unanimity about the organisation of mental models is lacking. According to Staggers and Norcio, many authors think mental models are organised structures consisting of objects and their relationships [Staggers and Norcio, 1993]. On the other hand, Redish suggests that they consist of propositions, images, rules of procedure and statements as to when and how they are used [Redish, 1994].

Wilson and Rutherford discuss the relation between mental models and other proposed types of knowledge representation in humans [Wilson and Rutherford, 1989]. From their discussion, it is possible to conclude that knowledge structures such as schemata and frames are hypothesised to represent 'background knowledge'; mental models would be the instantiation of such structures when they are used to plan actions, explain and predict external events.

In our view the study of mental models investigates the real world and its cognitive representation (both internal and external) - this is discussed in more detail in the following section. Unfortunately, neither a uniform framework nor a uniform terminology currently exist to facilitate this. Therefore, in this paper we present our own perspective for discussing mental models - building on the previous work that has been described in the literature.

It is our conjecture that all environments and experiences generate sequences of stimuli that can be used either to activate a person's existing mental models or initiate the development of new ones. The relationship between environments, experiences, stimuli and mental models is illustrated schematically in [Fig.1].

Within this diagram the importance of learning activities are twofold. First, if a model (for any given situation) does not exist then learning processes provide the mechanisms by which new models can be generated. Second, if a model exists, but it leads to incorrect behaviour then, through reflection, remediation and reconstruction processes the model(s) can be adapted and amended to take into account feedback that is derived from unsuccessful experiences. Modification of mental models therefore takes place in such a way that the next time they are used in a similar situation they will lead to correct behaviour being exhibited.
Environments generate Experiences initiate Learning Activities involve produce Stimuli activate control BEHAVIOUR

Figure 1: Overview of the learning process

As can be seen from [Fig. 1], mental models are developed as a consequence of learning activities; these may be both conscious and sub-conscious. Thus, as is illustrated in [Fig. 2], when a student reads a book, attends a lecture, performs an experiment or uses an item of CAL software, mental models are created (if they do not already exist) or are enhanced (if they do exist). Similarly, in a 1:1 (or small group) conversational situation (such as a tutor/student or a student/student dialogue), knowledge transfer similar to that indicated in [Fig. 2] occurs. The knowledge transfer that takes place is driven by the mental models owned by each of the communicating partners. Of course, the ‘quality’ and nature of the dialogue that occurs on any given topic will critically depend upon the richness of the mental models that each dialogue partner has. Naturally, during the course of a conversation mental models may be adapted as a result of the acquisition of new knowledge acquired through the dialogue process. In our view, the process of becoming an ‘expert’ in any particular discipline involves (in part) the development of rich and powerful mental models relating to that subject domain.

Mental models are an important consideration for designing resources to support teaching and learning activities. Because of their importance in the context of developing multimedia and hypermedia
teaching/learning resources, the remainder of this paper discusses some of the currently available methods for their study. It outlines a case study that illustrates some of the approaches that we have employed for studying mental models within the context of teaching human-computer interaction using both a conventional approach (lectures and practicals) and by means of electronic course delivery.

2. Studying Mental Models

In the work described in the following section of this paper we have employed a range of methods to study both the declarative and the procedural knowledge embedded in mental models and to relate these models to task performance. Because of their underlying importance to research in this area, this section of the paper reviews some of the more important techniques that are currently used for studying mental models. It then outlines the framework which we have employed in order to undertake the work described in the case study that is presented in the following section.

2.1 Representation of Declarative Knowledge

There are two broad types of declarative knowledge. These are: (a) knowledge about concepts (their attributes and the inter-relationships between these); and (b) knowledge about the relations that exist between concepts. Within any given domain, (a) can be measured by asking people to identify important concepts and the meaning of these. The literature on mental models has focused on (b) and the following techniques have been used to perform measurements in this area: ratings, sorting, diagrams and laddering.

**Ratings** can be used to measure the network relatedness of paired concepts [Cooke and Rowe, 1998]. Participants individually rate each pair of concepts (for one or more dimensions of relatedness) on a scale ranging from slightly related to highly related. If the number of concepts exceeds 25 to 30, [Cooke, 1994] advocates the use of a sorting technique. Here participants sort concepts into ‘piles’ or concepts per pile and then label the piles after sorting.

**Diagrams** can be used to measure in a graphical way the network relatedness of concepts [Cooke and Rowe, 1998]. In this approach, participants draw diagrams of the domain being investigated (or part of it); the diagrams consist of concepts and links - reflecting the different types and strengths of relationship involved.

**Laddering** is a structured interview technique which can be used to measure the hierarchical relationship of concepts [Cooke and Rowe, 1998]. Participants are asked to identify certain key concepts followed by additional ones which are either subordinate to or superordinate to those initially identified. This is preferably done in the context of a problem statement in the domain being investigated.

2.2 Representation of Procedural Knowledge

In order to measure procedural knowledge the following techniques have been used: action sequences, concurrent protocols (think aloud and constructive interaction) and teach back.

**Action sequences** can be used to investigate the network representation of actions [Cooke and Rowe, 1998]. Here, the actions carried out by participants during task performance are recorded chronologically. These are then analysed for patterns.

Verbal **concurrent protocols** can be used to measure network representations of procedural knowledge. In this approach participants verbalise all of their thoughts during task performance. There are two important techniques. First, **think aloud**, which is a technique in which participants produce their verbalisations while carrying out a task individually [Cooke and Rowe, 1998]. Second, **constructive interaction**, a technique in which two participants solve a problem together [Rutherford and Wilson, 1992].

**Teach back** is another important technique for studying procedural knowledge [Van der Veer, 1990]. Here, after exposure to some target system, participants are asked to describe (on paper) to another person how to perform a given task using that system. In doing this, subjects use their own preferred mode or representation. These descriptions can then be scored to measure the following aspects of mental models: completeness, correctness, interaction levels and style of representation.
2.3 The Current Research

Our approach to studying mental models is depicted schematically in [Fig. 3]. In this diagram there are two important perspectives: reality (the world as it is); and representational space (the world as it is represented - for example, in books, films and computers). In our view, the study of mental models links these two perspectives together. Mental models exist in the domain of reality; their study attempts to place exteriorisations of them into representational space. The process of exteriorisation involves using the techniques described in the previous sections of this paper in order to build representations of mental models verbally, on paper or within a computer system. Exteriorisation processes are normally triggered by stimuli that are derived from various sources - for example, researchers studying mental models and conversations with others - see [Fig. 2].

![Figure 3: The representation of mental models](image)

As well as experience with a target system (through its projected system image), users can acquire mental models through the study of existing conceptual models [Norman, 1988; Staggers and Norcio, 1993] - for example, the use of computer manuals to understand the way in which various computational processes work.

In order to capture mental models within the representational space depicted in [Fig. 3], some form of linguistic framework is needed. This may be a mathematical notation (for example, a metanotation), a language of some form or a diagram. Van der Veer, for example, uses several different ‘modes of representation’ in his work on teach back: visual description, visual-spatial images, use of icons, production rules and programs [Van der Veer, 1990]. The various techniques that we have used in our research are summarised in the case study that is presented in following section.

3. Case Study

The case study described in this section of the paper relates to the teaching of the subject of Human-Computer Interaction (HCI) as part of a final year modular degree course. It deals with experiments that students undertake in order to study text editing and word-processing systems.

Text editing and word-processing are probably two of the most common processes undertaken using a computer system. The study of the HCI involved in these activities is therefore of significant importance from the point of view of (1) designing end-user interfaces to editing and word-processing software, and (2) studying the mental models that users construct as a result of exposure to this type of software. Therefore, in this type of study students are usually exposed to a variety of different text editing and word-processing-systems; they are then asked to ‘exteriorise’ the mental models that they have acquired as a consequence of using the different
systems. The software items used in our HCI course are readily available packages running within the Microsoft DOS, Windows 3.1 or UNIX environments. Typical examples of the systems employed are edlin and edit (DOS), notepad.exe and Microsoft's Word for Windows (Windows) and vi, sed and awk (UNIX system).

In order to enable us to study students' mental models (and their performance at text editing) we conducted an experiment using Word for Windows. Students were required to carry out two types of task. Tasks in the first category involved the use of the Word system while those in the second category did not. For the first category, action sequences were recorded; these enabled us to study both mental models and task performance. For the second category, a variety of other methods were used to investigate the students' mental models - ratings, sorting, laddering, diagramming and teach back. The first three of these methods were used to assess the students' knowledge of the relations between concepts. In the rating task, students had to rate the pair-wise similarity of concepts. In the sorting task, students sorted domain concepts into piles and labelled these. The laddering task involved several steps. First, students were presented with either a text editing or word-processing task description. They then had to identify a sub-set of concepts (from a given list of domain concepts) that applied to the task. Subsequently, they had to identify the superordinate and subordinate concepts applying to the task. Finally, they had to identify subordinate concepts from a list that did not apply to the task. In the diagramming task students had to construct a diagram of domain concepts and their relationships; they also had to indicate the strength of each relationship. In order to study the procedural knowledge associated with the use of Word for Windows, two methods were used: action sequences (described above) and teach back. In the teach back, students had to explain on paper (to a fellow student) how to carry out a given text editing/word-processing task.

4. Discussion and Future Work

The preliminary results from the study revealed that students formed two broad types of mental model - generic and specific. Generic models were those which applied 'across the board' to all the text-editing and word-processing systems that were used. Primarily, the generic models involved an understanding of two major concepts. First, the general principles underlying the use of text editing and word-processing systems; these involve ideas relating to the creation, storage, retrieval and maintenance of various types of electronic document. Second, an appreciation of the basic types of operation that are necessary to achieve these goals - for example, the concepts of insertion, deletion, copying, moving, searching, replacing, and so on. The specific models also involved two types of understanding. First, a detailed understanding of how a particular text-editing or word-processing system (such as Word for Windows) actually operates. For example, when using Word for Windows, the model of the editor involves a knowledge of the concepts of screen-based editing and mouse interaction. Second, an understanding of the types of operation available within a given editing system and a knowledge of the action sequences needed to achieve particular text-editing goals. Naturally, as we would predict from the GOMS model of text-editing [Card, Moran and Newell, 1983], the different action sequences used to achieve particular goals in any given system depends upon the level of expertise and experience that a particular student has gained with that system. More experienced users were found to have a wide repertoire of problem solutions for a given task (and could easily choose the most effective one in any given situation). In contrast, novice users of a given system did not show this repertoire and selectivity.

We believe that the outcomes of this research have several implications for the design and use of multimedia and hypermedia teaching resources. For example, the graphical representations of the models of text-editing and word-processing systems that we have derived could be used as a basis for the development of interactive teaching and learning facilities to support these activities. These graphical representations could be further augmented through the use of animation techniques in order to illustrate to students how particular types of operation are performed. Naturally, multimedia augmentations of this sort could be developed for all the different types of text editor described in this paper. Using this approach, we believe that it is possible to design and create highly motivating interactive learning resources which will lead to the effective and efficient creation of rich mental models - with a corresponding increase in task performance.

In our future work within this area, we intend to use the techniques described in this paper in order to investigate a variety of issues that are of major importance in the teaching and learning of the subject of human-computer interaction. For example, we are currently formulating some experiments that are intended to enable us to study the types of mental model students develop as a consequence of: (1) using web browsers; (2)
reading information from computer screens; and (3) trying to explain the relationship between various screen design parameters and end-users' behaviour. We believe that the outcomes of this research will provide us with a valuable basis for the development of multimedia and hypermedia material to support the teaching of these aspects of HCI.

5. Conclusion

Mental models are important because they are assumed to form the basis of all human behaviour. Indeed, the current study lends considerable support to the hypothesis that mental models form the basis for effective task performance: the richer a student's mental model then the better will be his/her performance. Within this paper we have outlined how mental models can be measured using a variety of techniques. Our study has reflected the importance of designing learning activities so that they create both generic and specific models of text editing and word-processing. Although the current work deals with this particular domain, we believe that this finding is applicable to many other areas.

Abstract: Information and communication technologies offer new tools that can contribute to facilitate, enrich or help us to rethink the way teaching, learning and management activities are carried out in schools. This paper describes the work in progress of a research team at LICEF Research Center (Télé-université, Quebec, Canada) in developing an object-oriented model of a computer-enriched high school. This work is being carried out within an action-research project called L’école informatisée Clés en main ("The turnkey computer-enriched school").

1. Introduction

The implementation of information and communication technologies (ICT) in Quebec schools has been ongoing since the 1980's. However, although several innovative instructional uses of technology have emerged, recent reports point out that Quebec schools still do not sufficiently take ICT into account [Berthelot 1994; Comité consultatif sur l’autoroute de l’information 1995; Conseil supérieur de l’éducation 1994; Conseil de la science et de la technologie 1994; Fournier & McKinnon 1994].

A variety of factors contribute to this situation, notably the lack of four elements essential to the successful integration of ICT in education: a systemic perspective; a long-term vision; consultation; and a clear school model facilitating the optimal use of ICT [Guidotti 1994]. In 1994, a research team from the LICEF Research Center (Télé-université) developed a systemic model of a computer-enriched high school as part of a project called L’école informatisée Clés en main ("The turnkey computer-enriched school"). The high school level was targeted because the educational use of ICT is not as widespread as at the elementary level [Bédard Hô 1994; Danvoye 1993]. The objectives of this project are to build a model of a computer-enriched high school and to develop an information technology implementation procedure that could serve as a framework for all Quebec high schools. This paper presents the work in progress regarding the model.

2. What Is a Computer-Enriched High School?

A computer-enriched high school implies more than simply the installation of cables, hardware and software. Rather, it implies a complete rethinking of the school in all its functions in light of the potential of ICT. It is not a matter of just introducing technology into the organization but rather of redefining the organization through the use of technology. This redefinition must focus on organizational processes, since a process crosses functional borders and is independent from the organizational structure [Bernier, Pinsonneault, Rivard & Blouin 1995]. Process reengineering allows us to take a new look at school processes. Process reengineering is a concept borrowed from industrial engineering and is an organizational design approach based on information technology [Aubert, Bouchard & Gingras 1995].

A school may be seen as an organization where different actors (students, teachers, non-teaching professionals, managers, parents, etc.) receive, consult, process, handle, produce and communicate information in order to accomplish various activities such as teaching, learning or managing [Rocheleau & Basque 1996].
These processes are governed by a set of principles and can be carried out with tools such as job aids, hardware and software. ICT offer new tools that can contribute to facilitate, enrich or help us to rethink the way these processes are carried out.

3. How Is the Computer-Enriched High School Model Designed?

The model is designed according to the object-oriented modeling technique developed by the LICEF Research Center [Paquette 1996]. It uses a formalism according to which various object types are represented by specific graphic shapes, linked by arrows and a qualifier that give a meaning to each type of relation. Our model has three types of objects [see Fig. 1]:

- **Processes** (ovals). A process is a set of sub-processes and tasks that uses inputs and transforms them into products.
- **Actors** (hexagons) that are responsible for processes.
- **Inputs/products** (rectangles) include printed documents as well as hardware, software and data. Those tools are identified in a generic manner; examples of existing tools are provided so that each school may choose tools according to its specific needs and to keep pace with technological developments. Hence, it is a variable-geometry type of model.

Five types of relations may exist between objects:

- *is composed of* (C)
- *is input to/product of* (I/P)
- *precedes* (P)
- *is responsible for* (R)
- *is a sort of* (S).

![Diagram of process model](image)
The model includes four levels:
- The first level [see Fig. 2] shows the four main processes that contribute to achieving the school mission: insuring student learning. These processes are: Teaching; Learning; Managing the school; and Insuring use of multimedia resources.

The model includes four levels:

- The second level [see Fig. 3] shows sub-processes that are linked to each of the four main processes. For example, the actor "Teacher" is responsible for the "Teaching" process. This process can be broken down into five sub-processes: Planning the learning environment; Organizing the learning environment; Implementing learning activities; Supervising the learning environment; and Assessing student learning.

Figure 2: Processes that contribute to achieving the school mission (level 1)

Figure 3: The "Teaching" process and its sub-processes (level 2)
The third level [see Fig. 4] shows tasks related to each sub-process. For example, “Planning the learning environment” is broken down into four tasks: Planning learning activities; Planning instructional materials; Planning learning support infrastructures; and Planning assessment of learning.

Figure 4: Tasks of the sub-process “Planning the learning environment” (level 3)

The fourth level does not have any sub-processes. It shows only the actors and inputs/products related to each task [see figure 5 for an example].

Figure 5: Actors and inputs/products related to a task (level 4)
While developing the model, computerized notecards were produced for each process. These notecards contain a definition of the process, one or several categories of actors who carry out this process, and a list of all inputs and products (including computer tools). They also provide more detailed information about principles that govern the use of computer tools within each school process. In addition, each category of tools has its own descriptive entry.

The model is based on a theoretical framework for each school process; the goal was to bring about a new vision of education through the use of technology. The main principles enunciated in the theoretical frameworks [Basque, Rocheleau & Winer 1998; Michaud & Rocheleau 1998; Rocheleau 1998] are:

- Cognitivist and constructivist learning approaches for the Teaching and Learning processes;
- Systemic management and learning organization principles for the Managing the school process;
- A resource-based pedagogical approach for Insuring use of multimedia resources.

The model and notecards are based on readings about ICT educational integration as well as from action research in two Quebec high schools. The action research project enables us to both support and observe changes as they occur in schools integrating ICT into all aspects of their activities [Basque, Rocheleau & Chomienne 1996]. This information was used to build the model.

4. Conclusion

This model does not remove the school’s responsibility in making technological choices; however, it facilitates decision-making by offering a global and integrated view of various uses of technological tools, in a flexible electronic format.

The decision-makers in a school can use the model to plan short or long term ICT implementation and to pinpoint processes, sub-processes or tasks that should be given priority within the plan. They can also obtain a portrait of a particular tool’s possible uses across the four processes in order to make a strategic choice among existing tools.

Abstract: Reflection on the forms and possibilities of Internet use in education does not keep pace with the speed with which access for schools is provided worldwide. For an in-depth educational discussion, we need to differentiate types of Internet applications. We will present a model that was developed for the categorization and evaluation of (stand-alone) interactive media ([Baumgartner 1995] [Baumgartner and Payr 1994 and 1996]) and that we use now to contribute to a more detailed and specific educational discussion of Internet use. After a short review of the foundations on which the model is built we will illustrate its application to the Internet, using existing sites as examples.

1. Internet as medium, Internet as tool

In order to submit the multitude of Internet services and applications (like e-mail, Telnet, FTP, Gopher, WWW, mailing-lists, newsgroups, chats, computer supported collaborative work etc.) to theoretical inspection, we have to distinguish between three basic aspects of software use, namely as

i) Software entered the classroom as a subject: programming languages, application software and the like. The issue was to learn the use of software and to train skills and qualifications that were deemed necessary for the labor market.

ii) Software is considered a tool (cf. [Taylor 1980]) if it is not the skilled use of an application etc. that is in itself the issue, but the use of application software to realise student projects and carry out tasks in various subjects (e.g. publication of a student newsletter or design of a database for collected data). This kind of
software use is characteristically "pedagogically neutral", that is, the design of the educational setting remains completely open. Of course, using software to do a certain job presupposes a certain mastery of it, so that acquisition of the necessary skills (as in i)) is often integrated in the tool aspect.

iii) Software is a medium in those cases where the software itself transports contents (educational software in its broadest sense). Applications range from simple vocabulary drills to complex simulations. In this aspect, the software is not pedagogically neutral, but always transports (often implicit or hidden) theories about the user's learning process.

The medium aspect is the central domain with which the discipline of educational technology usually deals. The first part of our discussion of Internet applications will also fall into this domain, for which especially the multiple uses of the WWW are typical.

2. Dimensions of the Learning Model

The heuristic model of learning that we have proposed before ([Baumgartner and Payr 1996]) is based on work by Dreyfus and Dreyfus [Dreyfus and Dreyfus 1987] who distinguish five steps in the learning process – from novice via (advanced) beginner, competence, fluency to expertise. Starting from these steps, we have opened up the model to three dimensions: action (of the learner), teaching/learning, and organisation of the learning process [figure 1].

![Figure 1: A 3D heuristic model of learning](image-url)
The dimensions of the heuristic model needs some further explanation:

*Learning/teaching dimension:* With its help, rough definitions of subjects and learning goals (e.g. "solving equations") can be refined. For example: Should the students be able to solve equations following a certain method, should they also be able to choose the method, or should they even learn to construct systems of equations out of everyday situations (text description)? In the first case, the contents are context-free rules (level 1). In the second case, the rules to learn are context dependent (level 2). Level 3, in this example, would mean solving whole systems of equations, using and selecting all the rules and methods available. On the highest levels, the problem has first to be constructed from a real world situation so that it can be solved with the known methods.

*Dimension of action:* This dimension lists the forms and possibilities of interaction between the learner and the "world" (society) and recognizes that novices are not able to "take in" a complex situation as a whole. This can be easily misunderstood as an old-fashioned hierarchical conception of learning, whereby novices have first to rote-learn facts or be drilled in rules until they can finally pass on to more complex tasks. But this is not what we mean: this dimension should rather reflect the experience that learners develop themselves strategies for interacting with the world, obviously in order to avoid stress and information overload.

*Dimension of social organisation:* This dimension describes the role of the teacher, but also that of the media: are they "teacher" (= explain, demonstrate), "tutor" (= observe, help) or "coach" (= accompany, cooperate)? [figure 2].

3. Internet Applications and the 3D Model
We will now try to distinguish types of Internet applications from the perspective of the learning model:

1. **Learning facts and rules/remember, receive**: every application whose main purpose is to present and transfer contents (verbal, multimedia) falls into this group. Most of the Web, being a networked information resource in the first place, thus falls into this category. The main activity of the user (interaction) is to navigate among pieces of information.

   *Example*: The examples for this type of application are therefore very numerous, almost as numerous as the number of web sites of institutions, electronic journals, project presentations, companies etc. There are, among them, also lots of sites with educational contents and goals, as for example the exhibition „Auschwitz – Terminal to Holocaust“ (Auschwitz – Endstation Vernichtung, [http://www.wsg-hist.uni-linz.ac.at/Auschwitz/HTML/Seitel.html], last access 04-04-98), created and realised in the Web at the University of Linz/Austria. This site has a simple and predominantly hierarchical structure. From the index, the user can visit the different chapters, composed of authentic photos and easy-to-read texts. Difficult terms e.g. expressions that were coined by the prisoners, can be looked up in a glossary by clicking on them.

2. **Rules, procedures/apply, imitate**: Internet applications falling into this group are characterised by exercises and tests. They do not only present contents but also offer the users interactive possibilities to control whether they are able to apply what they have learned. The learner acquires and tests procedural knowledge.

   *Example*: We chose the „Waste Management Game“ as an example for such an application (Mülltrennungsspiel, [http://www.kraftwerk.co.at/mltmanagerspiel.html], verification unsuccessful on 04-04-98!). In the training section the user selects different types of waste (e.g. spraycans, oil, fax paper ...) and the correct type of wastecan is demonstrated graphically. In the quiz part, the user must himself „throw away“ correctly randomly presented objects and substances.

3. **Problem solving/decide, select**: This group of applications deals with more complex problems that have to be solved in the Internet. While on the lower level, individual steps and operations were presented, trained and tested, the learner now has to select herself the steps and procedures.

   *Example*: Tutorials containing tasks and interactive practice, e.g. the hypertext textbook accompanying the VSNS BioComputing Course at the University of Bielefeld ([http://www.techfak.uni-bielefeld.de/bcd/Transfer97/welcome.html], last access 04-04-98). This textbook is the cornerstone of a complex media-supported distance course. It contains assignments that the students have to submit on Web forms. However, the assignments are not analysed automatically but by the teachers and tutors who use electronic communication to give feedback and support. This integration of human tutors is a good solution to the long-standing and mostly unsolved problem of analysing and supporting automatically the complex learner actions and decisions on such an advanced level of learning.

4. **Gestalt perception, pattern recognition/explore, understand**: open learning environments and simulations are applications supporting learning processes on
this level. The goal is to perceive and understand holistically processes with their causes and effects, and to discover common characteristics and pattern in diverse "cases".

Example: An interesting example for such an environment is the Open University's "Art Explorer". An article with interactive demonstrations is openly accessible in the Internet ([http://www-jime.open.ac.uk/jime/01/jime-01.html], last access 04-04-98). The Art Explorer is an interactive introduction to the history of art. The main purpose is awareness of old and acquisition of new "habits" of seeing. The tasks include grouping of pictures, developing 3D patterns from geometrical forms, or transforming individual objects and figures in paintings. There is no pre-defined solution and no feedback for the individual tasks. The goal is to support students in the acquisition of "seeing skills" without feeling controlled by external interpretations.

The site "Wild Wings Heading North" ([http://north.audubon.org/], last verified 04-04-98) is quite a different application also falling into this group. The project was designed specifically for schools: In spring 1997, ten wild geese were caught and marked with transmitters. Their signals were detected as they pursued their northward migration towards Canada and Alaska. The route and current position of each goose could be requested via the Internet, where they appeared on a map of the U.S. so that children were able to accompany "their" favorite goose. Background information on habits and migrations of wild geese, a discussion forum and a little game where children could make their bet on the way a certain goose would take next accompanied the maps. By its very nature, the "result" of this project was completely open, even for the researchers involved. Nobody knew at the start how many of the geese (or of their transmitters!) would survive the yearly migration and where they would travel. The site made it possible to discover and understand a phenomenon of natural life beyond the limits of space and time.

5. Complex (real) situation/invent, master, cooperate: Internet applications on this level typically are the very tools that experts use in their work. They can also be adapted "student" versions that introduce students to the use of the full-fledged tools. Some sections of the above mentioned BioComputing Course fall into this group, namely the integration of international online databases of DNS sequences. These databases are commonly used by researchers to check whether a certain sequence is already known and registered.

Another typical application is the "CyberLab" of the University of Osnabrück ([http://marvin.physik.uni-osnabrueck.de/CyberLab/], last verified 04-04-98), running an experiment that studies magnetic surfaces and layers. The computer controlling the experiment and processing its data can be directly accessed via the Internet (observation is open for all, but — of course — only authorised users can actively control and modify the experimental setting). The experiment can be run from a distance by all the associated researchers. The data are not only presented graphically (in as real time as the Internet permits), but are also logged in files that the remote researchers can analyse afterwards. Such remote experiments or even complete virtual labs will be of increasing importance in the Internet: they can help to use more economically the increasingly complicated and costly lab equipment, making it available to a large number of researchers and students simultaneously.

On this level of learning, we would also have to mention all the Internet services for communication and cooperation (like newsgroups, mailing-lists, online chats or Internet tools for CSCL, e.g. the Basic Support for Collaborative Work developed by the German
Finally, the Web itself, seen as a whole, is a real and indeed complex situation. Its contents are „real“ (that is, not specifically selected, processed and/or simplified for educational use). With the Internet, the „world“ enters the classroom more massively than ever before, creating new problems and challenges. Mastering this situation demands new skills. We do not mean technical or programming skills here, but the skill to arrange, analyse and evaluate huge amounts of information and to use them for one’s own learning and knowledge.

4. Internet: Chances and Challenges

The examples discussed before can also be used to illustrate the features that distinguish Internet applications from stand-alone educational software:

- **Integrated media and (communication) tools**: A complex learning environment like the BioComputing Course contains not only information resources and interactive software, but also tools specifically tailored to communication and teamwork among participants. This seamless integration of interactions with software and interactions with teachers/co-students is only possible in the network and offers new possibilities for the design of technology supported social settings for learning.

- **Up-to-date information**: Accompanying the wild geese continuously on their migration would hardly be possible without the Internet. In the Internet, the signals and data need only be processed in one place while being accessible from everywhere at any time and on demand.

- **Accessibility**: Other examples like the waste management game could be equally used locally and distributed traditionally. But this is only true if we look at one application at a time. The added value of the Internet is to be sought on another level: namely by making applications like this one accessible to everyone, easy to use and cross-platform portable.

The learning model that we have used here to distinguish Internet applications can be seen as a first orientation for the design of media supported learning situations. Starting with the types of Internet applications and their features, teachers are able to ask concrete questions concerning their target group and to develop, from there on, models for the educational uses of the Internet. The complexity of the information resources, the multitude of interaction types and the integration of media and tools are the new challenges for the teacher. At the same time, the Internet, with its possibilities for networking and cooperation, also offers possibilities to answer to these challenges.

A Proposal for Wide Area Multimedia Instruction in a Northern Environment

Stan Beeler, English Department, University of Northern British Columbia, Canada, sbeeler@quarles.unbc.ca
Ross Niebergall, Mathematics Department, University of Northern British Columbia, rossn@unbc.ca

Abstract: This paper consists of a brief outline of a proposed research and development project in which the authors intend to explore the possibility of delivering complex course materials to students in remote locations of northern Canada. Although the project will focus on presentation using the World Wide Web, it will also explore various means of compensating for the limitations of slow Internet connections.

Background

The University of Northern British Columbia is located in the city of Prince George which is in the north central area of the Canadian province of British Columbia, and is roughly 700 kilometers away from the nearest larger population centre. It is a one hour flight or an eight hour trip by automobile to reach Vancouver, Edmonton or Calgary. The University was opened for full operations in 1994 with the mandate to meet the post secondary degree needs of citizens in communities that are up to 500 kilometers from the main campus in Prince George.

The size and sparse population of our mandated area mean that faculty must adjust teaching methodology to deal with the problems of distance delivery. It must be emphasized that UNBC does have a central campus in Prince George, which is a city of around 70,000 inhabitants and most teaching is done in traditional face-to-face fashion. However, it is imperative that the institution also deal with our regional students. For this reason, courses have been given by telephone, live video link, video tape, printed mail, and local lecturers at satellite campuses. None of these methods has been completely satisfactory, and as a result, we have a relatively large number of students who are willing to take the time and spend the money to move to our city to complete their education.

Past Efforts in Regional Delivery

A recent development in the struggle to provide better services to our regional students is the offering of instruction via the World Wide Web. In 1995-96 one of the authors of this paper, Beeler, received a provincial government grant to develop software for four English courses on the Web [Beeler 1997]. This software package was designed to deal with the special problems of web teaching in our vast northern environment. Although things are improving rapidly, as of two years ago the backbone network in northern British Columbia was not yet able to manage the high speed transmission of intensive graphics and sound. Moreover, the computers available to students in our northern region were often nearing the end of their useful life cycle and barely, if at all, capable of multimedia presentation. Therefore, the package developed for our English Web courses used a database structure to create virtual web pages of manageable size and transmit these on demand to the student. This greatly reduced the load on web connections by increasing the load on the server. The package included monitoring software to allow instructors to have some idea of the time that students spent in various sections of the material as well as a Web Conferencing system (called Natter) which was designed to replace classroom discussion.

Limitations

The success of the English courses has prompted interest in providing a broader spectrum of courses to our regional students through the Web. A significant number of students at UNBC are taking courses of study directed towards Environmental Science, Forestry, Natural Resource Management and Business. Additionally, many of the students pursuing degrees in the first three categories are located in more remote parts of the region that UNBC serves. While it is not possible for these students to complete their studies in these remote locations, it is desirable that they be able to take their first year
or two regionally before traveling to the Prince George campus to complete their studies. It is often necessary for these students to delay taking some courses, especially those in science (with labs) and mathematics, until they get to the main campus. This obviously causes difficulties, and in many cases, makes it impossible for students to even begin their studies in the home communities. An example of a course that causes difficulties is Math 152 - "Calculus for non-majors". This is a course needed by students in all of the disciplines listed above, and it is required very early in their studies as it is a prerequisite for many courses. Until now this course has never been offered by UNBC away from the Prince George campus. Preliminary research indicates that these same imperatives apply to non-university training in our region. Courses are often delayed until expensive teaching programs can be set up locally, or students are sent south to learn new skills.

The WEB based courses currently offered by the English program have been very successful, but there is clearly a need to branch out and offer additional courses and perhaps allow students to make significant progress towards science degrees away from the central campus. Although the model used by English could be easily altered for many other humanities courses, there are certainly drawbacks in using this method for a course like Math 152. The courses in English were primarily text based. The students were able to participate in discussions (using the Natter discussion group software designed for this purpose) and turn in assignments online. This would be very difficult, or perhaps even impossible for students in a mathematics course without having the students learn some sophisticated mathematical typesetting system such as TeX. Additionally, students in mathematics courses often find it extremely difficult to read a mathematics text without a supplementary form of explanation. This supplementary explanation is usually verbal. Previous models for Web course delivery do not allow for this kind of supplemental instruction. Without feedback, discussions, verbal explanations and the ability to monitor student progress a Web course in mathematics may be no better than a traditional correspondence course. In recent years there has also been a growth in CD-ROM based texts for mathematics. Certainly the multimedia enhancements of a CD-ROM text have the potential of making a course much more accessible to the student, it still lacks monitoring and discussion forums. In all of these cases, Web based courses and correspondence courses, there have been few attempts that could be described as successful. Student attrition and failure rates have usually been very high.

The challenge that we are faced with is developing a course that incorporates the aspects that made the English courses successful and introducing enhancements that make it usable for a first course in Calculus as well as non -University training.

Proposed new delivery system

Clearly the pagination protocol developed for the English project is useful in a mathematics course. It is also generally recognized that it is a good idea to parcel out the information to the students in such a way that they must proceed through the material in a linear fashion, since students of mathematics are usually unable to understand more advanced material before gaining a good understanding of the basics.

The key idea of our proposal is to not only present the course textually and with pagination, but to also have a synchronized audio voice over corresponding to each page. Thus, the course would have a virtual lecturer. This would be enhanced by having some markings in the text to draw attention to the passage that the lecturer is currently discussing. This may be achieved by having parts of the text "flash" or change colour to indicate the textual/auditory correspondence. The idea of this system is that it simulates to a traditional classroom lecture experience that is used successfully worldwide - a classroom lecture being delivered by overhead transparencies with the lecturer indicating particularly relevant parts of the text by pointing to them on the overhead or using a light pointer. We believe that this system is technically possible, but the research will involve investigating the various audio protocols available for Web transmission and systems of presentation of mathematical typesetting. The work will involve developing a method to synchronize the audio with the visual presentation. We believe that this will result in system of curriculum delivery that not only mimics a successful traditional classroom style, but also allows students to view some pages repeatedly if necessary. The material would be parcelled out one lecture at a time, but students would always be able to review previous lectures. Students would be encouraged to treat the parcels as individual lectures and not try and cover several in a single day. Of course, the technical limitations of the network mentioned above would have to be taken into consideration. It is likely that a hybrid system would be needed that would retrieve high volume materials from a CDROM. Additionally, the possibility of high-speed connections based upon ISDN technology or cable-modem links will have to be explored as an alternative that may become more economically feasible in the near future.

The lecture presentation would also be enhanced by the inclusion of appropriate video clips in addition to the audio. These video clips could contain demonstrations designed to enhance understanding of the material, or simply images of the lecturer providing an explanation. This adds a more personal touch to what students may view as a rather impersonal course
delivery scheme. An example of the anticipated use of video is to have the instructor appear at the beginning of each lecture to give some motivation for the particular lecture and review some of the important aspects from previous lectures that will be used. This would allow students to identify the course with a particular person and give it a more human touch. There are various video protocols available for Web use and it will be necessary to experiment with them to determine the most appropriate system for our diverse needs. It will be necessary to develop some software tools to integrate the video and audio components into the paginated lecture structure.

The second difficulty that we address is a method of monitoring student participation and understanding. Ideally this would be done in an unintrusive way without the ethical dilemmas associated with having the instructor monitor the time that students spend online working on the course. This monitoring would be performed by having a question or two at the beginning of each lecture referring to material from the previous lecture. Should students not be able to answer these questions, they would be encouraged to go back and review the previous lecture. It may even be useful to occasionally prevent students from continuing until they have demonstrated some understanding of material already covered. The questions would have to be created in such a way that the response requires no special knowledge of mathematical typesetting, questions would elicit single word or numerical responses. We will be experimenting with various technologies (Java, Perl based CGI Scripts or ActiveX) for embedding these quizzes.

As most students of calculus are aware, an integral part of the learning experience is asking questions and having an opportunity to discuss course material. Students often have difficulty enough verbalizing these questions, and it would be impossible to have students only access this discourse via email or other strictly text based medium (without requiring students to learn TeX). While we would encourage comments and questions by email or a Web based discussion forum, we would also allow students to fax in or scan and transmit questions to the instructor. These questions could be hand written and would be scanned and posted to a discussion portion of the course site (possibly anonymously). Instructors could then answer the questions and make the answers known to the whole class. Although this system is not immediate, it may even have advantages over the normal classroom discussion, since it forces students to clearly think out their question and write it down. It would also take advantage of the asynchronous nature of Web based teaching in general. One of the advantages of this format of instruction is that it does not demand that all students and instructors be present at the same time. Students who work at full time jobs could still participate in the course at their convenience.

We will also be examining the feasibility of synchronous teaching technology such as the use of a shared whiteboard with the instructor and an Internet telephone link. With proper lab co-ordination and reasonable class size, it would be possible to have the transmission shared by several students using an open microphone and speakers.

Finally the course would also involve students submitting homework assignments that would be graded and returned to give them constructive feedback. This delivery system could be either by fax or by scanned images attached to email messages. The course would also include midterm tests and final exams which the students would write in their own region. These could be administered with the assistance of local colleges or high schools.

It is likely that when such a course is offered many of the students will be distributed in pockets rather than completely isolated. If this is the case it would also be beneficial to have teaching assistants that offer tutorials in the particular region on a regular basis, perhaps one tutorial every two weeks. This would benefit the students by allowing them to clear up any major difficulties that they might encounter.

It should be noted that there would be a heavy responsibility on the students in such a learning environment which would extend beyond the usual learning of the material. The proposed research project would include experiments to find the optimum balance of lab equipment and technical training for students and lab monitors. It is hoped that this project will provide a cost effective method of providing instruction beyond simple textual transmission that will be applicable to both academic and technical material.

Conclusions

It is clear that there several possible avenues of research in this rapidly expanding area of education and training. It is obvious that the need for Web based distance instruction can only increase in a university framework. Moreover, the need for a more technologically competent workforce in our region will make the proposed project relevant in a non-university environment. Northern Canada has traditionally had a resource based economy with most employment.
opportunities available in non-skilled positions. It is a responsibility of institutions like UNBC to expand the economic base of the North, and as the economy shifts its focus, educational institutions as well as business interests will have to adapt to the necessities of providing more highly trained individuals. We believe that our project will provide the means to apply technological solutions to the problems presented by the sheer size of our region.

Integrating Face-To-Face and Online Education:  
a Case Study

Vincenza Benigno  
Guglielmo Trentin  
Institute for Educational Technology, National Research Council, Genoa, Italy  
benigno@itd.ge.cnr.it  
trentin@itd.ge.cnr.it

Abstract: This paper describes the study of a mixed onsite/online approach adopted for a training course called EDIT (Educating with Internet and Telematics); the topic of the course itself was the use of network resources to support schooling. The distinguishing feature of the approach used is the alternation between complementary face-to-face training and online activities.

Introduction

The term mixed training is used to indicate a form of training that draws on specific aspects of both face-to-face teaching (classroom lessons, basic introduction to technology, etc.) and online education (discussion, assisted distance exercises, etc.).

Figure 1: The cycle of mixed onsite/online training.

As Figure 1 shows, mixed training features a three-stage cyclical process: traditional face-to-face teaching; a self-study phase usually based on the reading of articles and books; and an online phase centred on discussion, exercises, collaborative work, etc.

Hereafter, we shall examine a mixed-approach teacher training course whose subject was the application of network technology to education.

Case Study: the Edit Course

Sponsored by the Pistoia City Council, EDIT was initially planned as a traditional-style course but following an agreement with the council’s Resource Centre for Educational Innovation, it was subsequently redesigned with the aim of testing a specific mixed approach for teacher training. The designers of EDIT bore in mind the shortcomings of both face-to-face training (usually limited to a series of meetings lasting just a couple of hours) and of online training (where it is assumed that the participants are willing and/or able to interact principally in written form). These limits are even more evident when the course objectives involve highly innovative themes and call for a degree of technological know-how.
The Course Objectives

The main objective of EDIT was to provide teachers with methodological skills for using network services to support their work in class. This embraced a number of secondary goals: acquisition of knowledge and skills in the use of the major network services; acquisition of know-how in employing telematic resources to support teaching activities; acquisition of basic knowledge for designing online courses; devising ideas and plans for the possible uses of telematics in co-operative learning.

Contents

The course topics were both technological and educational/methodological in nature, and included: Internet services such as E-mail, mailing lists, computer conferencing and the WWW; ways of using the network to access and share information and knowledge; aspects of planning online courses; the main strategies for using telematics in co-operative learning.

Participants

Out of the twenty teachers (of various subjects) who participated in the course, seventeen taught at upper secondary level and three at lower secondary. They all had some basic know-how in computers and network services. It should be noted that when the teachers signed up for the course they had no idea about the methodology that would be adopted, and hence did not know what type of effort would be expected of them.

The Learning Methodology

As stated earlier, the methodology adopted for the course was mixed: four face-to-face events were held at intervals ranging from a week to a fortnight, during which exercises, group discussions and self-study were conducted online.

In accordance with the overall approach, the onsite events held at the Resource Centre centred around the subsequent online activities. Hence, there were lessons on theoretical/methodological aspects, as well as practice with the tools and network services to be employed in the distance activities.

EDIT was a “project-based” course, meaning that the participants were engaged in the production of educational projects to be implemented after the course had ended.

All the teachers were provided with a course guide and an information pack containing the reading material related to the learning activities within the course.

Course Structure

EDIT was held over a five-week period and comprised four face-to-face events and three periods of online activity managed by the course participants themselves (Table 1).

![Table 1: The EDIT course schedule.](image)

Over the whole span of the course, individual work (reading, exercises, etc.) alternated with periods of interaction with the other participants (colleagues, tutors) either in face-to-face or distance mode.
Networking was done using the FirstClass (FC) computer conferencing system, which has a simple graphic interface and offers users a series of functions for interpersonal communication (synchronous and asynchronous) and file sharing.

**Phase 1 (onsite)** The topic of the first meeting was an overview of the main network services that can be used for teaching. After the introduction, the teachers were divided into work groups and explored the functions of the computer conferencing system that would later be used to handle network communication.

**Phase 2 (online)** This covered a period of two weeks. The teachers were set two tasks: to get familiar with the computer conferencing system, and to explore several network services. The latter activity was managed by opening up two secondary work areas on the FC system to handle the WWW and E-mail activity organised into mailing lists.

**Phase 3 (onsite)** The second face-to-face meeting dealt largely with theory. The focus was on two areas: the use of telematics as an auxiliary technological support in teaching; and the special characteristics of online courses, in particular design considerations and collaborative learning strategies.

**Phase 4 (online)** Given that there was only a week before the next face-to-face meeting, the participants were asked to carry out further investigation of what they had seen so far. This included suggested reading on the methodological approaches to the work and to online collaborative learning. In addition, the teachers carried on with the practical telematics exercises they had begun in previous phases.

**Phase 5 (onsite)** The aim of this face-to-face meeting was to consider what kinds of network activity the teachers could adopt in the classroom after their training was completed. Consequently, the meeting began with explanation and discussion regarding the key aspects of collaborative learning, with special attention to the management of the online learning process. To these ends, the teachers were divided into three work groups, one for lower secondary level and two for upper secondary.

**Phase 6 (online)** The aim of the last network-based phase was to discuss and clarify the draft projects developed at the previous face-to-face meeting. Consequently, a separate FC work area was devoted to discussion and delivery of the participants’ draft projects. By the end of this two-week period, before the final face-to-face meeting, three draft projects had been delivered: the two mentioned above and a third one which was drawn up after the deadline.

**Phase 7 (onsite)** During the last meeting, group discussion and clarification of the draft projects finally took place. The focus subsequently shifted to the planning of measures for putting the projects into action.

**Evaluation of the training course**

Evaluating a distance training course poses a series of problems at different levels, but two in particular stand out: evaluation of learning and evaluation of the participants’ level of involvement, seen in terms of time and of activity effectively carried out at a distance.

This problem is less critical for mixed training courses as there are opportunities for face-to-face interaction in which the participants’ performance can be monitored. What’s more, basing distance communication on the computer conferencing system means that one can access the automatic recordings (log files) that the network server makes of each participant’s activity (messages written, messages read, level of interaction with other participants, the time and duration of online connection, etc).

Evaluation of the EDIT course was therefore based on these two evaluation techniques, as well as analysing the results of an end-of-course questionnaire that sought the participants’ evaluation and general feelings about the experience as a whole. Without a doubt, the most interesting of these techniques from a research standpoint was the monitoring of the online activities the participants engaged in between one face-to-face meeting and another.

[1] In these files the computer conferencing system automatically records every single action that the participants perform during network interaction: reading/writing of messages, chatting, duration of connection, etc.
The participants’ level of online activity

With the exception of more exercise-oriented activities, general online participation was noticeably lower than expected. In short, discernible interactivity did not take place. By and large, the participants confined themselves to the tasks set by the remote tutors, rarely engaging in meaningful online exchanges about their different opinions and/or proposals. The likely cause is the fact that only sixteen percent of the teachers had access to the network in their school: the others had to go to the Resource Centre to take part in the online activities. It must also be recognised that this innovative learning method calls for a far greater effort than traditional onsite courses, especially given the more active, initiative-taking role that the participants are required to assume in the process of their own training.

Computer conferencing communication

When making quantitative evaluation of computer conferencing communication, we must take account of two factors: the types of activity that the participants have engaged in (exercises, discussion, group work, collaborative production, etc.); and the management strategy consequently adopted by the tutors. This is especially true where online training is concerned. Both the two factors may strongly affect the messages produced both by the tutors and by the participants.

The ratio of tutors’ messages to participants’ messages in the EDIT course was roughly one to three. It is safe to say that this is a fairly well-balanced ratio, considering that the course included both exercise/tutorial activities (requiring greater tutor “presence”) and discussion/exchange activities (where the tutor acts as moderator and is less directly involved).

Conclusions

The case study we have reported is an experimental course called EDIT on the educational use of telematics. In this course, telematics was used simultaneously as a study topic and as a tool for conducting the online part of the training process. This allowed the teachers who participated in the course to get first-hand knowledge of the potential and limitations of telematics applied to education.

While the overall results of the project were satisfactory, the pacing and content of some areas of the course need to be adjusted. For instance, the training course would benefit from a longer time span, and greater effort should be made to ensure that at the outset of the course the participants all have a similar level of technological competence.

From the standpoint of the adopted approach, the project has undoubtedly yielded positive results. This is borne out by the positive feedback from the participants and by the surmounting of problems often faced in onsite training (the lack of communication and support offered to teachers between one meeting and another) as well as in online training (the difficulties posed when communicating solely in written form).

Abstract: This article discusses a cooperative approach for developing educational hypermedia in an university environment. We report about experiences from the development of ORWelt, a hypermedia learning environment for Operations Research. The project team consists of researchers and varying groups of students. We argue that if adequate support is provided this model is a way to address lack of resources, while at the same time providing a valuable educational experience for students. We describe the development process with special focus on quality assurance and offer some suggestions for transferring this approach to other problem domains.

Background

The objective of the ORWelt project is the development of a complex hypermedia environment for business students learning Operations Research (OR). OR is a complex subject area dealing with the use of mathematical methods to solve business problems. OR methods are used by faculty and practitioners in several fields, e.g. production planning, transportation, personnel planning and finance. The fundamentals of OR teaching are comparatively stable over time and there is an established standard content for introductory classes including linear programming, mixed-integer programming, modeling techniques, network algorithms and often basic discrete simulation. Though our students differ in their faculty background (we have business students, students of business computing as well as engineering students) they all have one in common: They need OR as a basic technique and they need to transfer this basic knowledge to very different real problem situations. Realizing that traditional forms of education do not support the adequate transfer of knowledge, the need for a new way of teaching was acknowledged [Cunningham, Duffy, Knuth 93].

The ORWelt project started in February 1996 with the intention of providing a hypermedia learning system covering all standard introductory material, supplemented by tests. Additional case studies are meant to provide different contexts for the methodological content. In some subject areas that are of special interest to OR teaching at the University of Paderborn advanced topics should also be included.

The long-term objective of the ORWelt project is to change the way of teaching towards application-oriented learning [Blumstengel, Kassanke, Suhl 97]. Lecture time should be used more efficiently to discuss realistic problems while teams of students learn part of the material (especially basic algorithms) with support from the learning environment. It can also be used as a reference and for exam preparation.

In 1996, the researchers were faced with a situation of very limited resources. At this time, no external funding was immediately available while on the other hand there was a lot of content to be covered.
In addition, we expected the participation of students in the development process to be a valuable educational experience for them. It is recommended that students not only learn how to navigate in a hypermedia information space, but how to create one [Honebein, Duffy, Fishman 91]. Writing hypertext is not intuitive and requires certain skills in structuring information. "Unfortunately, even though you can easily get some ideas about hypertext authoring from your experience as a hypertext reader, we face the general problem that people have not learned how to structure information in hypertext networks the same way they have learnt to write linear reports through writing endless numbers of essays at school." [Nielsen 95]. Furthermore it is quite demanding for students to develop educational material.

Development Process

Preparation of the Project

Before starting the actual development, a questionnaire was mailed to OR instructors in Germany. It included questions about the content of relevant classes, the use of software (especially educational software), the additional need for such software as well as instructors’ expectations and concerns. Students are questioned on a regular basis about their computer literacy, frequency of computer use, available hardware equipment and attitudes towards computer-based learning, including expected advantages and disadvantages. The project started with an experimental phase followed by iterative refinements of the development process leading to the process steps presented here. From the beginning students were participating in the development of ORWelt. We used teams of typically 2-3 students attending a project seminar with a total of 2-6 groups per semester. The students are majoring in different fields, namely business studies, business computing, industrial engineering, computer science or business education. The seminar is held by a group of two problem domain specialists and one or two programming specialists. The authoring environment we use is Asymetrix Toolbook, currently version 5.0 (Instructor II).

After an initial agreement about the content scope students are required to give a midterm presentation of their storyboard. This gives a detailed account of their concept for presenting and visualizing the material. Students use a two-level storyboard approach [Fisher 94]. On the first level they present the overall structure of their hypermedia network. The second level consists of detailed visual outlines for all pages. The storyboard can either be presented in electronic or in non-electronic form while students show clear preference for the electronic form.

At the end of the term the student teams give final presentations of their modules. The seminar sessions are mainly used to discuss different ways to visualize a certain concept, programming techniques and guidelines or particular problems the participants face. Since initially instructors and students were inexperienced alike in hypermedia design, the first semester was used as an experimental phase. Students had to cover certain topic areas, but no styleguide was available. The intention was to collect ideas and promote creativity concerning navigational tools, styles, designs, user interface elements and the use of hypermedia elements in a phase of explorative prototyping.

The resulting programs were indeed very different, but all quite colorful. Students experimented with different media and interface design styles. Most prototypes were mainly linear and while navigational support was provided, it was not sufficient for more complex systems.

ORWelt Approach

We chose a modular approach for structuring ORWelt, so students can work quite independently in their problem domains. Requirements for navigation and features of the system were derived from the explorative prototypes. For getting a consistent user interface, basic guidelines and module templates with common navigational features were developed for the next semester. A few methodological core areas were implemented as first modules of ORWelt:

- Linear Programming,
- Simplex-Algorithm,
Duality,
Sensitivity Analysis and
Branch and Bound.
At the same time guidelines for navigation, animations, use of colors, hyperlinks and the common glossary were
developed and refined.
As a next step, components for other topic areas like:
• Simulation,
• Warehouse Location Problems,
• Basic Stock Control,
• Modeling Techniques,
• Applications in Production Planning and
• Case Studies
were developed with additional test modules for most of them.
During the whole development process navigational tools were refined and system functions centralized by
researchers of DS&ORLab. By now the features of the system include a graphical browser, customizable guided
tours, bookmarking, annotations, history function, full-text search and anonymized log files.

Introducing Students to hypermedia design
For introduction into Toolbook and its programming language OpenScript we decided to start each semester with
a whole-day Toolbook workshop.
A very detailed programming styleguide is available by now as well as documentation guidelines and refined
module templates for topic and test components.
The feedback process for the modules written by students was refined several times. Besides the permanent
detailed feedback during the development process we conduct an evaluation session after the final presentation.

Evaluation Cycle
The modules are evaluated by the problem domain specialists together with at least one programming/system
design-specialist. Evaluation sessions typically last for 3 to 4 hours per module. The criteria we use are (ranked):
1. content: correctness (the scope was agreed upon already at the beginning of the semester)
2. adequacy: usefulness of hypermedia elements
3. formal correctness: adherence to programming-, style- and documentation-guidelines
Based on the detailed evaluation protocol, a separate meeting with each group is held. It is used for discussion of
the protocol and to reach agreement upon further changes that are still necessary. The student teams get about
two weeks time for revision of their work followed by a second evaluation session. In some cases, a second
revision is necessary. The documentation is due about two weeks after completion of the software. The formal
grading uses the following criteria (ranked):
1. level of creativity, adequate visualization, realization of agreed upon changes
2. quality of midterm and final presentations in class
3. formal criteria (documentation etc.)

Outlook
During the last two years we have developed more than 500 pages of content with lots of animations and
interactive elements as well as additional 170 glossary entries. All main topic areas are covered on an
introductory level, some even deeper. So far, a total of 30 students has participated in the development process.
Further development will concentrate on case studies and advanced topics (like genetic algorithms). A further
integration of linear optimization software (like it is already used in the component about modeling techniques)
is also planned and a translation into English is intended.
The prototype is currently tested by 60 students in an introductory OR class. It is used as an additional resource
for learning by individual students or student teams. To further confirm positive feedback from students we
conduct a thorough evaluation using log files and questionnaires. The results will be available by April 1998.
Experiences, Suggestions and Conclusions

One potential problem of the described approach is that the quality of content and content representation developed by students might be low or at least not sufficient for learning purposes. Since there is a large group of students involved, there might be very different styles of writing and visualization which affect the common "look and feel" of the system. Also, the need for standardization in such a large system limits the creativity of the students involved to a certain degree.

So, quality assurance is a major concern during the whole development process. Our experience suggests:

- If the instructors' initial skills on hypermedia design are quite low, an experimental phase is very helpful to determine system requirements and potential problems.
- Standards and guidelines are crucial, but can hardly be stated in detail right from the beginning. Instead, they have to be developed and refined over time.
- Good hypermedia design is not intuitive! Today's students usually start with a presentation of the content very close to a paper-based form: The first designs are mostly linear, text-focused, use illustrations with few interactive elements and often make inadequate use of animation. So, it is very important to give continuous feedback starting in the early stages and discuss in detail different representation forms and their specific use for educational purposes. Since good design is much more demanding for students, it has to be supported by instructors.
- For good quality, programming/design and content specialists' support is equally important.
- An advantage of the presented approach is that students generally understand very well how to teach fellow students. They know of the specific learning problems and needs concerning the material from their own recent experience. Often it is easier for them than for instructors to assess what is difficult and what not.
- Diverse development teams are definitely a plus because they allow to take advantage of different skills and talents of team members. If there are inexperienced programmers in the teams (which is almost always the case in our project) it is crucial to keep the level of programming skills required as low as possible. This gives students time to concentrate on content and content representation. Also, it avoids unnecessary bugs and frustration. Therefore, we use a specialized authoring environment which offers a powerful script language, graphical tools and direct manipulation. In this case, ease of use for the developer is more important than performance. A large part of the system's common functionality is encapsulated in system components. Also, through templates, a library of functions and strict guidelines we provide a clear and easy framework for the technical realization of planned representations.

Through the cooperative development involving student teams a system covering a large scope of content could be realized in short time. Good quality can also be achieved, but permanent support is essential. However, the selected approach does not only provide one possible solution for capacity problems, it is also useful for the students involved. They acquire a deep understanding of the particular subject area and different contexts of its use. Students are encouraged to present the material in a way that supports learning. They have to develop good representations, examples and test items and to relate their modules to the existing parts of the system through hyperlinks. In addition, they learn useful skills in hypermedia design and programming fundamentals.

From our experience with the ORWelt project we recommend to transfer the cooperative approach to other problem domains.

Abstract: The paper refers to a project aimed at designing, implementing and evaluating a hypermedia system, IPER-3, facing the three 'classical' problems in the history of mathematics (trisection of the angle, quadrature of the circle, duplication of the cube). The aim of the project is to study the opportunities offered by this kind of technology to the presentation of mathematical topics both in teacher training courses and in classroom work.

Introduction

In this paper we refer to a project aimed at designing, implementing and evaluating a hypermedia system, the IPER-3 system, facing the three 'classical' problems in the history of mathematics (trisection of the angle, quadrature of the circle, duplication of the cube) and some issues which have developed around them. The aim of our work is to study the opportunities provided by hypermedia systems in dealing with topics of interest for the training of teachers and/or for class work, exploiting the possibility of a non-linear presentation, representation of heterogeneous pieces of information, modularization, increment and flexibility of use, as discussed in the literature [Conklin, 1987; Tomek et al., 1991].

In the paper, first of all we motivate the choice of the history of mathematics and, inside this, the choice of the three classical problems. Then we present the structure of the hypermedia system IPER-3 and some design and implementation choices which are interesting from a teaching viewpoint. In the last section we analyze an experience of actual use of the system and delineate some possible developments of this type of activity.

Background

The field of knowledge of the history of mathematics appears particularly suited to a representation of a hypermedia type. At the level of both research and, with the due change of scale, work in class, tracing the history of mathematics is a complex activity in which there coexist two different investigation needs, the purely 'informative' one (characters, events, dates, places, etc.) and the 'conceptual' one of the analysis of ideas. Discovering history also means consulting sources including illustrations, manuscripts and various documents, and, since the same topic can be viewed in various milieus and in various epochs, it also means referring to history in general, art, geographical and ethnic situations, etc. In common texts of the history of mathematics, because of the very structure of the book, it is very difficult to handle the non-linearity of the historical development of ideas and hence, for the non-professional historian (for example, a student or a teacher) it may prove difficult to grasp the various connections or the influence of the context and, consequently, also the thread linking the developments of these ideas.

In making our choice to work with a hypermedia system in the history of mathematics we have taken into account, on one hand, these aspects of history and, on the other, the specific characteristic that hypermedia systems have of lending themselves to presentations of a different type than the book, being more dynamic and flexible in both spatial and temporal representation.

The association between the history of mathematics and computer technologies is not a new one. Apart from the massive use made of databases for the organization of historical material, which here does not concern us, it must be remembered that much information of a historical type is available on the Internet. Some students who have participated in the experience have used this resource for getting first information on certain historical facts, which they have then compared with other (more canonical) sources.

Apart from the reasons linked to the specific characteristics of the medium used, the choice of the history of mathematics is also connected to our opinion on the role that this discipline has in the teaching of mathematics [Furinghetti, 1997]. We believe that this role is central in the training of the mathematics teacher, in an outlook which has to do not only with knowing facts, which is certainly important, but above all with epistemological reflection as an integral part of the teacher's craft. In this sense history may be one of the contexts which can be
activated both for constructing concepts and for attaining awareness of the epistemological obstacles lying behind the difficulties met. These considerations concern not only the training of teachers, but also classroom practice.

Within history the choice fell on the three classical problems for a 'structural' reason: they are a multifaceted subject, a catalyst of many theories and many cultural contexts but one which for this very reason is mortified by the traditional presentation. Moreover, we were interested in the teaching implications of the three classical problems. These implications are linked to their cultural importance which is due to the fact that mathematicians attempted to solve them using the rule and the compass. Only in modern times it was proved that this way of solving them is not possible. The importance of this subject, from the teaching viewpoint, is founded on the belief that it is necessary to account for the reason why algebraic structures were introduced.

In the way of presenting the historical content we bore in mind the exploratory character of this work and we did not choose to consider a single type of user. For this reason, on one hand advanced developments are suggested, while on the other the language and form of presentation are conceived in such a way as also to be accessible to secondary school students, and some space has been devoted to topics of an elementary type (e.g. the detailed explanation of certain geometrical constructions).

The Iper-3 System

As already stated, the IPER-3 system deals with the quadrature of the circle, the trisection of the angle and the duplication of the cube. The present prototype only gives full development of the quadrature of the circle. Work is still in progress in relation to the other two problems.

Information islands and viewpoints

IPER-3 consists of a structured set of information islands. Here the term 'information island' is used to mean an organized set of pieces of information which can be accessed by means of hot-words, buttons and sensitive areas. The information islands are six: 'introduction', 'classical problems' (one for each problem), 'rule and compass', 'glossary'. It is to be observed that the pieces of information thus organized are interconnected.

The 'introduction' allows one to obtain general information on the system and on the three problems dealt with in it. From this information island one can get to the specific ones for each of the three classical problems. The latter are structured in accordance with four "viewpoints". Viewpoints give the possibility to deal with each classical problem according with a different perspective: "general information", "historical development", "solutions", "tools".

The "general information" viewpoint identifies information of a general character (presentation of the problem, different formulations of the problem, cultural references, anecdotes, etc.). The "historical development" viewpoint identifies a section presenting some of the main contributions to the study of the specific problem in various periods. The "solutions" viewpoint is structured in accordance with the type of approach followed for the solution (geometrical, analytical). The "tools" viewpoint is closely linked to the previous one: it concerns the instruments used to arrive at the solutions proposed (mechanical, geometrical, etc.).

Each perspective has an internal pathway (see Fig. 2 for an example of an historical pathway concerning the problem of the quadrature of the circle) and also allows access to information, referred to the same topic at hand, from different viewpoints, as shown in Figure 3. For example, the quadratrix was one of the tools used to face the problem of the quadrature of the circle (see Frame 1 of Fig.3); by means of this tool a geometrical solution to the problem was obtained (see Frame 2 of Fig.3) by Dinostratus (see Frame 3 of Fig.3). It is also possible to see the dynamic construction of the quadratrix from both the tools and the solutions viewpoints (Frame 4 of Fig.3).
Fig. 2: Four IPER-3 frames referring to the historical development of the problem of the quadrature of the circle

Fig. 3: Four IPER-3 frames relating to the quadrature of the circle
It was felt to be useful to devote a specific information island to the rule and the compass in order to accentuate
the link between the subject we are dealing with and Euclidean geometry.
The information island relating to the glossary is made up of information sheets briefly explaining some
important terms. The user accesses the glossary by selecting the words or phrases which in the text are boxed
(e.g.: geometrical constructions, absolute field of rationality, etc.).
For the mathematical and/or historical contents to put into the system use was made not only of the specific
literature but also of notes on teaching experiences in classes at upper secondary schools, and of the Internet. The
latter constitutes a work instrument supplying an enormous information patrimony which is continually
expanding, though with some limits from the historical viewpoint (frequent lack of bibliography, approximate
notices, etc.).

The interface

The system's interface has been designed in such a way as to be as user-friendly as possible, even for people
who are not expert computer users, and for this reason reference was made to some of the principles and
guidelines of human-computer interaction relating to user-centered design discussed in [Norman, 1986]. The
interface is based on an icon paradigm: from the implementation viewpoint, this corresponds to the creation of
buttons which are often semantically evocative. The icons are distinguished into two categories: those for
handling the system, and those related to the topics faced. In creating the buttons, to guide people in using the
system and reducing the risks of confusion often linked to the use of a hypermedia system, use was made of
colors, voice and pictures. Color takes on three fundamental functions: it characterizes the perspective,
characterizes the different sectors within the perspective (for example, the historical development is subdivided
into three periods, each marked by a different shade of green), and distinguishes buttons according to their
function (e.g. light blue ones allow management of the system). The voice is used to give an instruction or to
suggest a cognitive pathway to follow. The pictures provide a visual support for information (maps, or photos or
drawings of mechanical devices, etc.). In the system it is also possible to activate dynamic constructions and
step-by-step constructions. The former are used to visualize the generation of curves obtained by means of
movements of geometrical entities (e.g. two points on two different lines, the quadratix of Dinostratus, etc.), the
latter to visualize in successive steps the solving procedure for geometrical problems (e.g. the construction of a
segment whose length is the square root of x).

Experimentation With The System

Organization of the experimentation

The first experimentation of the system was carried out with university students in the mathematics degree
course who were studying for a specialization in teaching. The experimentation, carried out during the last
month of the course, was divided into the following phases:
- Introduction to hypermedia. This phase provided an introduction to hypermedia systems as a means of
  representing and accessing information. The theoretical basis of such systems was presented; concepts,
definitions and explanatory examples referring to their main characteristics were given.
- Presentation of IPER-3.
- Use of IPER-3 by students. They were initially assisted in using the system and then left free to explore.
- Writing of a report by the students (individually) on their impressions regarding the use of IPER-3 and the
  way they had explored the knowledge incorporated in the system, as well as what they had learnt about
  hypermedia systems.
- Creation of a project (only on paper, not implemented) by the students, divided into two groups, to complete
  IPER-3 as regards the problems of the duplication of the cube and the trisection of the angle.

We consider the population chosen as suited to this type of experience. Thanks to the course they were attending,
the students were wholly used to dealing with mathematical topics and hence it was possible for them to focus
their attention on the means of transmission and the type of mediation. Furthermore, many of them had attended
the course on the history of mathematics.
The considerations made in the pages which follow are based on the students' reports and on their projects for
the completion of IPER-3.

The students' observations
The students' reports were analyzed by means of a reading grid in which observations were collected in accordance with the following main parameters: observations of a technical nature on the computer and the software, observations on the mathematical contents and how it is organised in the system, observations on hypermedia as learning instruments, observations on their own work and reactions.

Table 1 shows the most significant observations which emerged from the students' reports. In general, we notice curiosity and appreciation in relation to the technological instrument, but also some diffidence regarding its teaching potential.

The students' observations show up a rather generalized need for guidance in the exploration of a new subject; hence the suggestion to include features in the interface (some suggest a sound-based guide) to which one can have recourse in case of uncertainty about which way to go.

The request made by many that in the opening pages there should be a statement regarding the impossibility of solving the three classical problems in an elementary fashion, may indicate some resistance towards the 'open' and exploratory approach which the system would allow. This impression may be linked to the fact that the majority of the students consider the technological instrument as useful for revision, but not for a first introduction to the subject. By contrast, some students emphasize that the possibility of following personal pathways is the aspect they perceived as most positive in the use of IPER-3.

The content chosen is judged very positively in that it makes it possible to deal with mathematical contents in a way which is not static but follows a historical evolution lending itself to different readings (solutions, instruments, epochs) and permits connections between topics often dealt with separately from one another.

Students' projects for completing IPER-3

In the projects made by the students for the completion of IPER-3 we noticed both common tendencies and diversified ones. Both groups exploited certain elements (color, icons) and accepted the IPER-3 idea of distinguishing various approaches to the problem. Hereunder we report some observations on they way of working.

The "Trisection of the angle" group with respect to the prototype added the viewpoint "curiosity", but created no explicit links between this viewpoint and the others. It is interesting to observe that, thanks to curiosity, the students used the Internet source in addition to books. This source was also exploited to obtain figures, portraits, etc. The group realized the importance of dynamic constructions. The necessity of a user's manual was suggested. In the last part of the project they highlighted the links (and hence they stressed their importance) with some graphic schemata for describing their work, which in the other groups did not happen.

The "Duplication of the cube" group introduced the new viewpoint "demonstrations" which makes navigation more flexible, considering whether one is interested in a given theorem in itself or only in its enunciation in order to go on dealing with a given topic. However, subsequently the group did not make good use of this route with appropriate links, maintaining, by and large, a marked sequentiality in the treatment.

Summing up the behaviour of both groups, it can be stated that in one of them (Duplication...) the worry about the mathematical contents prevails over interest in the medium. In the other group greater interest was observed in hypermedia opportunities. Having worked on the basis of an existing prototype accelerated and facilitated both acquisition of knowledge of the specific problems studied and hypermedia design, but it did not prevent students' elaborations which were to some extent new and personal.

Prospects

The system presented is a prototype of a way of constructing a hypermedia system in the history of mathematics. Our way of working with it (in both the construction and utilization phases) can also be considered a prototype and we feel we can make some considerations on it which are transferable to other situations. The points on which we wish to focus our attention are the following:

- working with a hypermedia system can promote meta-cognition;
- a hypermedia system can be seen as an environment which lends itself to the study of the dynamics of teaching and learning processes.

The concept of meta-cognition is present in many theories of education, though with varying interpretations due to the different frameworks (psychology, mathematical education, etc.) and authors. We refer to a recent article [Robert & Robinet, 1996] for an overview of the studies which rotate, in a more or less broad sense, around this concept. We are particularly interested in the approach to meta-cognition, closely linked to practical teaching situations, found in [Schoenfeld, 1987]. In this paper the concept of meta-cognition is introduced explicitly and the author explains that it is necessary to interest the student in knowledge of knowledge ("thinking about thinking"). The author makes a classification of those elements which he considers most important in meta-cognition: knowledge of one's own thought; control of one's own thought in work situations; mental
representations. Schoenfeld describes four modes of developing meta-cognitive skills in the students: using videotapes on badly organized ways of working in mathematics on the students’ part, highlighting the teachers’ way of working in mathematics in front of the students (with constant questioning and changes of strategy), organizing discussions with the class in which the teacher has the controlling role, getting the students to work in small groups in which the teacher periodically intervenes on the solving strategies.

We can deduce from the analysis of our experience that working with hypermedia serves precisely to promote a new mode of developing meta-cognition skills. From students’ observations we can see two different levels of metacognition that the work have stressed: the reflection on how one faces an articulated content (see Points 3 and 5 of Table 1) and the reflection on how teaching a complex topic on the basis of one own experience as student (see Points 2 and 4 of Table 1). The idea of reflection on strategies is inherent in the very idea of ‘non-random navigation’ in the hypermedia. Becoming aware of one’s own way of approaching a topic is detected in the phase of discussion on the use of IPER-3, and even more in the project completion phase, in which contents are organized in accordance with conceptual schemata differing from one group to the other (see the different viewpoints introduced by the two groups).

Hypermedia technologies, in an appropriate use context, can be a means for having information on the students’ conceptual networks, since when they work on rendering their strategies explicit they provide the teacher with a key to their mental schemata. In this sense the work with an hypermedia system can offer a different perspective to the study of the dynamics of teaching and learning processes. This observation is an hypotesis we have done after analysing students’ work. The study of this hypotesis was not an objective of our experience but it appears an interesting perspective for our future work.

We believe that, over and above the interesting practical aspect linked to easy access to information, seeing the hypermedia as a promoter of meta-cognition and as an environment for studying teaching and learning processes is a significant approach to the analysis of the role that this instrument can play in the teaching/learning of mathematics.

References

1. **Observations of a technical nature on the computer and software**
   There is appreciation for the use of different media, e.g. sound.
   There is appreciation for the interface and the use made of 'evocative' icons; it is seen as useful to always keep the buttons in the same position on the screen and to limit their number.
   It is considered useful to be able to keep more than one page open at a given moment with the same interface layout.

2. **Observations on the mathematical content**
   The history of mathematics is considered an interesting subject; in particular, the importance of being able to see the historical evolution of a mathematical problem is stressed. It is observed that usually mathematics is 'imposed' as something finished and bare.
   Students observed that it would be possible to utilize IPER-3 with secondary school students, marking out some possible itineraries to follow (e.g.: general information, simple line constructions, rule and compass constructions, demonstration of the transcendence of π).

3. **Observations on the way the content is organized in IPER-3**
   The need is pointed out to state, in the first phase of the system, the impossibility of solving the three classical problems in an elementary fashion. This is seen as important because the user by himself may not become aware of this impossibility.
   According to some, the hypermedia should be constructed after the users have been identified.
   The need is stressed for innovative instruments for school updating. Obviously, it is observed that in its present formulation IPER-3 is incomplete for any teacher desiring to use it for updating.

4. **Observations on hypermedia as a learning instrument**
   It is considered a useful instrument for looking deeper into a given topic and for revision.
   By contrast, it is considered a distracting instrument for the first approach to a subject for those who have no knowledge of the contents.
   Freedom of navigation is seen as useful, though it is pointed out that there is a need to guide focusing on the main topics.
   It is observed that a hypermedia instrument can permit the development of greater mental elasticity, favoring a link-up between different topics.
   It is observed that instruments of the type examined can be useful for accustoming students to using other technology-based learning instruments.
   There is positive consideration for the opportunity given by hypermedia to connect kindred topics with one another.

5. **Students’ observations on their own work and reactions**
   A student observes that she feels the need to be able to construct the geometrical figures on her own, instead of finding figures already drawn (from this point of view step-by-step constructions are positive).
   Almost everyone notes the usefulness of the instrument in the revision phase (better than notes); in any case it is an instrument seen as a support to the book.
   Some stress that instruments of this type provide an opportunity to approach technology, and to promote a new work mentality.
   All express their own curiosity and interest.

Abstract: How does one design for interactivity in videoconference-based telepresentations? Observations of instructional interactions in videoconference-based telepresentations that were made during a series of sessions between a university in France and one in Quebec are reported. Two communication channels were used: 1) voice, image and data transmission over ISDN lines, and 2) data transmission over IP. Four highly interactive instructional methods that could take advantage of this technology were tested. Two major processes were analyzed: preparation and delivery. Results indicate the potential and limits of the four instructional methods, as well as requirements of the two processes.

Overview of the Project

As part of a larger project between Quebec and France on Methods and Tools in a Virtual Campus, the following learning situation was studied: two groups of university students on two sites, participating in a series of sessions on one topic, with telepresenters on either one or both sites; two communication channels: voice, image and data transmission over ISDN lines, and data transmission over IP. Observations were made in both Quebec and France; those reported here are from Quebec, with a focus on which instructional methods can take advantage of this technology and under which conditions.

The Design Questions in Videoconference-based Telepresentations

Telelearning situations require detailed instructional design in order to best provide opportunities for effective learning, following general instructional design principles [Gagné et al., 1992] as well as principles specific to distance learning [Bourdeau & Bates, 1997; Laurillard, 1993; Romiszowski, 1997]. The modeling of these situations in a Virtual Campus Environment [Paquette et al., 1995] requires a detailed knowledge of the actors, actions, possible events, as well as the conditions and constraints. The focus of the observations was on understanding the potential interactivity in various instructional methods as well as identifying the conditions for good or reasonable success. Telepresentations are viewed primarily as unidirectional techniques, most suitable/appropriate for lecture-type teaching. While current trends in education and training are to increase interactivity and learner activity in learning situations, university teaching still relies mainly on lecture-based teaching. Innovative telelearning situations appear at the other end of the spectrum with inter-individual and team-based transactions based on asynchronous communications [Bourdeau et al, 1997]. However, group learning remains the basis of most university teaching, and the design question to be tackled is: what interactive instructional methods can be applied in a video-based telepresentation, and what conditions need to be fulfilled in order to ensure effective and significant instructional interactions?
In a course on Techniques and Tools for Instructional Telecommunications, four instructional methods were applied and tested: team-teaching, panel, seminar, and laboratory. Team-teaching involved two professors, one on each site, who prepared (using e-mail and videoconferences) and presented the course together, sharing the floor and also sharing the IP application for presentation and annotation. The panel was a session where several experts on both sites presented on and discussed a common topic. The seminar involved two students on each site who prepared and gave a presentation on their respective work. The laboratory included a manipulation of the telecommunication tools to illustrate various capacities in transmitting voice and image. These four methods were selected for their potential to support interactivity between actors as well as for being appropriate to university teaching, to the content and objectives of the course, and to the teaching style of the professors involved. A lecture-type method was included for comparison. Two specific challenges were considered: having students as telepresenters, and having two telepresenters interacting spontaneously between the sites. Preparation for instruction as well as technical tests were conducted over a period of several months before the experimentation.

A set of specific issues were considered: 1) the geographic distance, which meant that there was a significant time difference (5 hours), 2) the cultural distance, which is reflected in differences in curricula and academic practices, 3) developing a consensus on the most meaningful tele-presence modalities, and 4) a concern for not letting the tools take too much room, both physically and psychologically. Part of the preparation process included the production of instructional material that had to be digitized, edited in a hypermedia format, installed on the server in France and tested before the session, thus reducing the flexibility of making last minute productions or changes. Discussions among the design team members related largely to the optimal balance between planning and spontaneity, a discussion topic which is typical of a hybrid situation between on-campus teaching - that relies on live events, and distance learning - that requires detailed and extensive planning.

Technological Tools and Room Organization

Tele-Amphi, developed by the CNET research center at France Telecom, was tested used in this trial. Tele-Amphi is original in that it unites a traditional synchronous switch-based network with pseudo-synchronicity on an IP channel. A video-communication channel runs on a set of ISDN lines, and carries voice and image, and more rarely data. A second channel runs on IP and consists of an application software that connects multiples sites on a server where instructional material has been installed, and manages synchronous delivery to the sites; a set of functionalities allows annotations on the spot and alternating control from either site. This software has editing capabilities for high quality hypermedia material, and management capabilities for files and libraries by sites and by authors. A data projector with very high resolution is required for displaying the material on a large projection screen.

Adequate space and room organization for a participating group is a critical issue, as group interaction means sharing a common physical or virtual space, and such technology requires space, connections, lighting, etc. [McVey, 1997]. On the Quebec site, the room was equipped with a turnkey videoconferencing system that includes a control panel for the telepresenter, programmable cameras, video screens, one printed document (or 3D object) camera system, one computer with Internet connection, and microphones for each participant. The telepresenter has to select the image source (scene, printed document or 3D object, video tape, computer screen, combination of these) to be displayed on both sites, to check the display sent from the distant site, as well as to address both sites visually and verbally; participants can take the floor by pressing a button on their desk, thus activating their microphone as well as causing a camera to focus on them. The room lighting is calibrated to send a good quality video image of the scene. Introducing a data projector for high quality material disturbed this calibration and caused major problems in lighting and room organization, as well as disturbances from having two visual foci for participants. A different room organization was found on the French side, with a manually operated video camera, while individual microphones were available on each desk. Differences between the two sites reflect a different emphasis.
placed on the quality of the image of the class (for tele-presence and social interaction) or on the display of instructional materials.

Methodology

The experimentation took place over a period of nine weeks, and delivery consisted of a series of six sessions of two hours each. The time difference meant that all sessions were held in the late afternoon (Quebec time). Two groups participated, each of them having approximately twenty students. Data collected include observations, recordings and interviews. Two observers used a grid to collect data on the instructional methods, and the instructional events, with specific emphasis on the use of the technological tools. All of the sessions were videorecorded in two ways: the participants were filmed live, and a recording of images and sounds transmitted over the phone lines was made automatically. A series of individual interviews with participants was conducted by the observers in order to complement the data collected by observation. Qualitative analysis of the data was conducted with a framework of categories to allow understanding and interpretation of instructional events, and triangulation was used to come up with a unified set of data. In addition to the data collected during the delivery process, the documentation on the preparation process was used for interpreting the results.

Results

Results indicate a good potential for highly interactive methods, a high level of motivation among participants, and several conditions for success. A number of negative events can be traced to to various technical and logistical problems; others can be seen as stemming from a lack of preparation, such as communication breakdowns, or simply as an inherent limit of the situation, such as the loss of eye contact. Launching time took too much of the learning time; many participants were to shy to use the various media; visual quality was not up the sound quality. The combination of synchronous and asynchronous tools proved to be promising and should be effective with the upcoming generations of Internet tools, such as increased bandwidth allocation and reservation protocols for synchronicity.

Analysis of the results after triangulation produced three categories: 1) impact of technological tools, 2) social interactions, and 3) efficiency of instructional methods. The technological tools were very much appreciated in that they gave the opportunity to interact in real-time with other professors and students and share with them, an interaction that is otherwise not available; provided access to high quality instructional material that could be annotated from any site was of great value to participants. The high level of motivation also created high expectations that could not be fulfilled. The reduced channel of communication in a tele-presence situation as compared to a physical presence caused a feeling that we call "sensory deprivation" where participants on each site want to share all of the details and nuances of the events at the other site, and feel deprived that they cannot. Also noted is the technological risk associated with increased interactivity: the more interactivity (between actors, sites, resources), the more "time-to-tools" (delay or bugs) required, time that was seen as stolen from "time-to-students". Consequently, as soon as a tool required too much attention to make it work, the reaction was to skip the interaction and move on with less interactive modes.

Social interactions are known to play an important role in group learning, and again, the limitation of the communication channels did not allow real socialization between participants; time dedicated to getting familiar with each other should have been planned; on-campus life allows continuity in social exchange which was not compensated by any means, leaving all participants with a feeling of having missed something. Eye contact, considered a key for success in instructional transactions, was too often lost, not only between sites, but also on the same site, given the attention requested by technological tools.

Efficiency of instructional methods was measured based on effective time, both presentation and interaction time. Interactive methods proved equally effective, while the lecture-type was more effective, which can be easily understood given the fact that more interactivity required more "time-to-tools", seen as non-productive time. Efficiency of all methods could be improved by investing more time and effort into
preparation of instructional events and material, including a back-up plan in case of breakdowns. We have every reason to believe that interactive methods have the potential to be effective in telepresentations, but we need to learn how to handle unusual and unexpected situations.

Toward the Modeling of Interactive Telepresentations

Knowledge gained from this experiment is being used to further the modeling of one case, Interactive Telepresentations, within the framework of the Virtual Campus Environment at Télé-université [Paquette et al., 1995]. A Telepresenter is defined as a role that can be played by various actors such as professor, student, expert; she or he presents content by addressing other actors verbally and visually, by showing documents that can be seen by actors on all sites, and by interacting with other actors in various ways. Several instructional methods can be applied, and several types of instructional events can take place, based on design principles as well as on teaching style. Tools used include video-communication, application software for delivery on all sites, data projector, and room-size shared virtual space. Certain conditions specific to this case apply, such as duration and rhythm for interactions, adequate room organization and lighting, appropriate ratio between preparation and delivery processes, and time for participants dedicated only to social interaction. Coordination aspects are crucial to this type of instructional events, and could benefit from an interdependency analysis such as the one done for collaborative telelearning [Wasson & Bourdeau, 1998]. This modeling includes transitions between various multimedia spaces (individual, team, and group) and communication modes, both synchronous and asynchronous.

Conclusions

Maturity in interactive telepresentations require not only more integrated and more robust solutions, but also more design knowledge, based on both principles and experience. Among conditions for effective interactivity are: increased ratio of preparation vs. delivery time; allow participants to become familiar with each other and be introduced to the use of the media before instruction time; room organization that provides adequate space and lighting. One question that remains partially unanswered is: when does the media act as an obstacle to interactivity instead of a way to interact? Transitions between sessions need further study, to obtain instructional design knowledge on transitioning between various media spaces. Alternative and innovative instructional methods need to be developed in order to take advantage of potential interactivity offered by this technology. Modeling and interdependency analysis can help gain the knowledge needed, as well as variations in experimental settings, such as intercultural settings, or heterogeneous technological platforms.

Abstract: The growing use of the Internet and other digital modes of delivery for higher education challenges universities to identify new criteria for the design, production, and quality assessment of programmes delivered via digital learning media.

This study reports on phase one of a research project undertaken by a team from the University of South Australia and Victoria University of Wellington to design and deliver educational applications of digital learning media, and to identify criteria for assessment of the efficacy and quality of the use of such media from a comparative analysis of three credit-bearing courses delivered in both on-line and conventional modes of delivery.

The paper examines a set of assumptions derived from a constructivist approach to learning design, in the context of a case study of an Internet-based course on electronic publishing, known as "Infotrain", developed at the University of South Australia, by Philip Marriott and Michael Brittain.

CONTEXT OF THE STUDY

Digital learning media is most often encountered either in the form of self-contained courses of instruction on CD-ROM discs or by the presentation of interactive learning programmes on the World Wide Web. In the future, other digital technologies including DVDs (digital video discs), digital satellite transmissions and fibre-optic cable are anticipated to supersede CD-ROMs and the present form of the World Wide Web.

Although courses on a CD-ROM disc and Internet-based programmes engender fundamentally different learning experiences, both of these new modes of educational delivery have provided individual learners worldwide with new patterns of flexibility.
The focus of this paper is primarily upon Internet-based learning activities. Accordingly, all references to
digital learning media herein refer to courses offered on-line which may be supplemented by storage of
intellectual property such as textbooks on an associated CD-ROM disc.

This paper is the product of four years of research and experimentation with emerging educational
technologies in an effort to identify the most appropriate uses of the digital learning media. One application of
this research has been the creation of an Internet-based course on electronic publishing, known as "Infotrain"
at the University of South Australia, by Michael Brittain and Philip Marriott. This course, which has been active
since 1995, serves as a case study against which theoretical approaches to digital design may be considered in
context and evaluated.

FUNDAMENTAL PREMISE

The basic premise underpinning this project is the belief that widespread adoption of digital learning media
requires academic staff to completely rethink the nature and practice of higher learning.

The advent of digital learning media profoundly alters the relationship of the learner to his or her university,
tutor and course material. The control of when, where and how one learns shifts from the provision of the
academic manager to become the primary responsibility of the individual learner.

An extensive literature search was undertaken in order to delineate contemporary views of educationalists of
the best practice for the design and delivery of digitally presented learning media.

The main thrust of the design approach advocated in this paper is to shift the teaching process from "subject-
based" instruction to "problem-based" learning. The tasks and exercises component challenges students to:

a) Discover what they already know about a subject and attempt to apply that knowledge to find methods of
solving similar problems which are likely to arise in their professional and private lives. This orientation
meets the design criteria that generic course material be applied, coherent and problem-based.

b) Attempt increasingly difficult tasks supported by hints, model approaches and methodological suggestions
(but not "correct" answers). Problems posed will be supported by Socratic instruction (whereby student
questions are answered by questions which encourage the student increasingly rely on their own powers of
analysis).

CURRENT BEST PRACTICE CRITERIA FOR DIGITAL LEARNING DESIGN

The following ten design principles have been delineated from an extensive literature review should be
considered in the production of educational applications of digital multimedia:

Principle 1: Foster Critical Thinking as Well as Core Skill Competencies

Constructivism (a cognitive approach to learning in which the core objective of educational design is to
facilitate the development of critical thinking and problem-solving skills) is superior to content-oriented
curricula which promotes rote learning. [Clift & Chambers, 1994]

Principle 2: Create Problem-based Learning Modules

Problem-based learning techniques engage learners by posing relevant problems in a context which challenges
the learner to discover how to use theoretical concepts within a discipline as practical tools of analysis.
Principle 3: Frame Problems in Learner's Life Context

People learn best when presented with problems which they may reframe to be relevant to their life circumstances, goals and interests.

Principle 4: Non-linear Problem Sets

No single solution path can be deemed correct and will enable the learner to utilise virtually any aspect of the materials available on the CD-ROM (or Internet) in an integrative fashion to synthesise a solution. In solving problems, a learner is encouraged to first subjectively formulate the criteria by which an optimal solution to the given problem may be judged.

Principle 5: The Essential Role of the Mentor

Learning, as with all forms of communication, entails an intersubjective social negotiation of meaning through interpersonal discourse. Accordingly, a mentor-learner relationship is crucial to optimal learning experiences. An application of an non-programmed design approach to learning media design rejects structured non-linear instructional modules, as well as the production of mere linear digital textbooks, in favour of media which present problems without any predetermined solution paths. Such non-structured learning experiences will require the participation of a mentor who can provide cues and Socratic support to the learner as he or she constructs meaning relevant to a specific context or vocation.

Principle 6: Making Optimal Use of Digital Storage Potential

Educational uses of digital multimedia are most effective where the vast storage capacities of the media are used to simulate the array of relevant information pertaining to a discipline which the learner must develop skills at searching and evaluating for use in solving the type of problems typical of the discipline being studied.

The digital learning media should be designed such that regardless if it is in a CD-ROM, DVD or World Wide Web format, the learner can readily access from within the programme the unlimited resources of the Internet. Hypertext encourages a decentering process by potentially linking all texts in unmapped and unprogrammable network paths. [Landow & Delany, 1990] It is this attribute which merits close attention in the design of digital multimedia. Hypertext challenges us to comprehend how documents are related. We no longer can experience a book as the authoritative and permanent product of an author. With hypertext, a document is no longer linear or fixed. With hypertext all documents are dynamic and fluid “re-writings” produced by their readers.

Principle 8: Foster Navigation Skills and Access to the Totality of the Resources Available

Learners are empowered to creatively draw upon the totality of the resources available to them in the search for solutions to problems. The learner would then be encouraged to utilise the digital technology only as a starting point to commence the search for the required solution. In this manner, the self-confidence and initiative of the learner would be fostered as would the recognition that all knowledge is dependent upon underlying assumptions.

Principle 9: No Preferred Solution Path

The design of multimedia rejects predetermined non-linear structures for learning materials on CD-ROM or the World Wide Web, as well as linear programming, in favour of media which present problems without any predetermined solution paths. Such an approach to the use of multimedia simulates the unstructured nature
which one often encounters problems in the workplace and every other facet of life. This compels a learner to utilise his or her own judgment in formulating a solution rather than seeking to replicate the solutions proposed by course designers.

It is recommended that where possible, problem sets be presented to voluntary study groups of learners for collaborative problem-solving and mutually supportive learning interactions.

**Principle 10: A Guide Through the Labyrinth**

Implementation of Principle 9 above serves to promote an unstructured approach to making sense of the world by grasping whole systems, rather than minute analysis of their perceived parts, reinforces the central role of the mentor in the learning process. Without an interactive guide, an "unstructured wholeness" approach to the presentation of problem-based learning modules could leave a learner submerged in his or her options in a labyrinth of information.

A theoretical rationale for the indispensability of the interpersonal interaction between a mentor and a learner, in an optimal learning experience, can be found in the work of the social constructionists who contend that all perceptions of reality (including learning) are constructed from discourse and negotiation.

Biocca [Biocca and Levy, eds. 1995] has theorised about the social construction of a learning experience embedded within the design of the course materials. Each educational technology entails the communication of a discourse that influences how learners think about reality. The pre-programmed, self-contained course material frequently encountered on CD-ROM and many Internet-based courses are not able to simulate a dialogue that will meet the learning needs of any individual learner. This requires personal interaction from an intelligent and perceptive mentor. Accordingly, an optimal learning strategy recognises the essential role of human interaction whose support of the learner facilitates a constructive dialogue as the learner constructs meaning from the educational experience.

Educational multimedia may supplement a learning experience by presenting a powerful simulation of a particular facet of the external world. However, what digital multimedia commonly lacks is the ability to interact dynamically and intelligently in a discourse with every learner about what such a simulation means.

The provision of a dialogue is the role of the human mentor that facilitates and manages the learning experience of an individual acquiring the cognitive and domain skills of a discipline. Again what is sought is not the acquisition of specific content knowledge but rather the growing sophistication of a learner in addressing problems typical of a discipline by using theories and concepts as tools of analysis. This process of development in a person’s cognitive reasoning capacities is best facilitated by a dialogue with an accomplished mentor. Until machines are capable of fully simulating the cognitive and social repertoire of humans, the role of a mentor will continue to be an irreducible element of an optimal higher learning experience. The mentor fades from the learner’s endeavours as he or she becomes more confident and self-reliant.

**THE "INFOTRAIN" CASE STUDY**

Infotrain [Marriott and Brittain, 1995a, 1995b] was developed in the period 1995-1996 at a cost of approximately A$50,000. Upon opening the course for enrolment in 1996, Infotrain attracted 50 students. Soon, the course generated hundreds of emails each week as learners gained competence at interacting on the Internet with their tutors and "classmates". In 1997 approximately 97 students are enrolled, across a wide range of disciplines. The project team has analysed the Infotrain experience from the perspective of three stages:

a) Trialling

b) Learner feedback
c) Reflection by course managers based on 3 years' experience of delivery

Feedback from Infotrain students suggests that they tend to fall into one of two groups: those who drop out of conventional classroom lectures and rapidly rely solely on the Web-based course materials to complete their studies, and approximately 30% of the students who require continuing contact to achieve learning objectives. It is recognised that for many students the social aspects of the learning experience are a vital component and for these students non-verbal communication elements within the classroom context are as important as the expressed verbal content. Other factors appear to be a need for some to enjoy the "theatre of the lecture hall", the presence of a mentor to help the learner impose personal discipline to performing one's learning tasks as well as a guide to suggest pathways through the labyrinth of information confronting students on-line.

Underpinning the Infotrain initiative is a desire to create a flexible and efficient learning environment. As Infotrain has matured since 1995, each iteration of the course has made a closer approach to this goal. Students may take the course in a structured teacher-centred, lecture-tutorial way, or a student-centred, internet-based, distance manner. They can also move backwards and forwards between these two options as they wish - attending lectures and tutorials for a few weeks before changing to an online approach. The same materials are used in lectures and online. Students can work in groups or as individuals. Ideally we would like students to have the opportunity to determine their rate of progress through the course - however the present constraints of assessment timelines and staff workloads have not made this workable.

The ability to rapidly apply the results of student feedback has enabled the fast development of the online materials. We are presently looking at a means of easily localising content. The intention is to target the Infotrain materials to specific client groups. In 1998 Infotrain will offered at the University of South Australia and Victoria University of Wellington. A cut-down version of Infotrain to be delivered by CD is under development for the general public.

CONCLUSIONS

The authors have derived the following preliminary conclusions to be considered in Phase II design of new courses incorporating digital media:

a) Digital learning media has the potential to transform the very concept of the traditional university by deploying distributed expertise and altering resource requirements for the provision of quality learning experiences. Infotrain has demonstrated that there is a new role emerging for tutors which necessitate a redefinition of how a University must commit scarce time and teaching resources. This emerging mode of delivery raises the prospect that international networks of tutors may emerge to collaborate on courses offered simultaneously at several institutions throughout the world.

b) These transformations will require academic staff to develop new qualifications, skills and tutoring methods. Of primary importance for academics will be the acquisition of excellent navigational and searching skills and the ability to transmit those capabilities to one's learners.

c) Current best practice is served by cognitive and constructivist approaches to course design. Digital learning media should be to foster critical thinking skills as well as generic competencies. Learners should be encouraged to use content-specific principles as tools of analysis rather that required to replicate course content.

d) A substantial percentage of learners require continuous interpersonal contact to achieve satisfactory learning outcomes. It is urged that the regular synchronous or asynchronous participation of a mentor be regarded as an indispensable element of the learning process.

Abstract: Pedagogy embodies the beliefs one holds about students, about the various attributes of media technologies, and about the essential qualities of the content at hand. Teachers make decisions based on the interactions of these beliefs. Therefore, it is imperative that one begins the process of designing and contemplating instruction with a consideration of the beliefs one holds concerning the components of this instruction. This paper offers some observations about the pedagogical implications for teaching and learning gathered from our experiences with the development of two types of distributed learning systems: the North Carolina Information Highway, a video-based system and CaseNET, a World Wide Web-based system.

The widespread interest in network-based learning – partially spurred by the 1993 introduction of the World-Wide Web – has instigated an examination of the underlying structures and assumptions in K-12 and higher education concerning what constitutes sound instruction, and the role that distributed learning environments play in such educational endeavors. What is emerging from such interests is a recognition that traditional teaching practices are often at odds with those to which the new media lend themselves. The result is often a state of cognitive dissonance in which the teachers and students struggle to bring old knowledge to bear on new situations. In a recently released report entitled Technology and the New Professional Teacher: Preparing for the 21st Century Classroom, the National Council for Accreditation of Teacher Education [NCATE 1997] offered the following:

Teachers may be forgiven if they cling to old models of teaching that have served them well in the past. All of their formal instruction and role models were driven by traditional teaching practices. Breaking away from traditional approaches to instruction means taking risks and venturing into the unknown. But this is precisely what is needed at the present time. (Pg. 5)

The “old models” and “traditional approaches” mentioned in this study are deeply rooted in the beliefs teachers hold about teaching and learning, as well as the images they hold of themselves as teachers and their students as learners. These images provide the foundation for the development of certain metaphors which teachers use to guide their practices in instructional environments. What we offer in this paper are some observations about the pedagogical implications for teaching and learning gathered from our experiences with the development of two types of distributed learning systems: the North Carolina Information Highway, a video-based system and CaseNET, a World Wide Web-based system.
The North Carolina Information Highway

The North Carolina Information Highway (NCIH) is a video-based information delivery system developed by a consortium of state agencies and private industry. Widely regarded as one of the most well-developed information systems in the United States, the NCIH is a fiber-based network that utilizes the latest telecommunications technology — including ATM and SONET — to create a statewide network for information transfer. The following vision is offered from the NCIH website:

The implementation of the network will result in the construction of an information highway ... analogous to the building of the interstate highway system in the 1950s and 60s. Just as the structure of interconnecting multi-laned highways has provided a faster and more efficient way to move products and people, the high-speed network will carry information to all points of the state reliably and economically. This information includes ... interactive video-based education classes for sharing the best teachers to improve the quality of instruction and to offer advanced courses ... to all of the state's students, statewide access to books, periodicals and technical journals contained in our leading research libraries, and vivid, detailed results of complex engineering and biological/medical calculations performed by our supercomputer for universities and advanced research centers.

Indeed, the NCIH is a technically advanced and sophisticated system. North Carolina now boasts a digital infrastructure that is unparalleled, and supports the potential for commerce, education and communication between individuals at all ends of the state.

However, a lack of consideration for pedagogical issues and an ill-conceived vision for its use in learning environments have hindered utilization of the system for educational purposes. For example, the cost for utilization is prohibitive. The implementation model employed by the developers requires sites to secure funding to participate. Although the state Office of the Controller provided grants to qualified applicants for one-time expenses, no clear vision for sustained funding has ever been advanced. One consequence of this is that sites that have secured funding are almost compulsive about using the system, even if it does not address a clearly articulated need. Another consequence is that the statewide system reaches many fewer locations than projected.

In addition, data is not part of the standard NCIH package — though it is an option. This may, initially, be viewed as a possible oversight; in fact, it is not. The NCIH is, by design, a video-based network. This fact makes explicit some implicit beliefs which decision-makers and developers hold about the nature of the delivery of effective “interactive” education, since video sites rarely have the computing capacity requisite for a combined video- and computer-based learning environment. The composite result of such conditions is that many school systems have been effectively left behind because resources went toward building a system they could not afford and that the system that has been built is used more to justify its use than with good pedagogical practice in mind.

What is evident to us, concerning the dilemma presented by the NCIH, is that decision-makers associated with the design and implementation of the system are clearly operating under some assumptions about teaching and learning that are not conducive to the effective utilization of the environment for teaching and learning. The most obvious fallacy lies in the assumption that teaching via the NCIH is really the same as teaching in a classroom. When the traditional approaches fail to elicit the expected responses, many are unable to make the appropriate adjustments required to make it work. While Newton's law — that every action has an equal and opposite reaction — does not quite fit here a version, modified for human terms, which reads that every action has unintended consequences fits very well. What we see is a large number of unintended consequences that are not always recognized as artifacts of applying traditional pedagogical practices to new communications environments. What has been noticeably lacking is any systematic way of looking at the various telecommunications tools and analyzing them in terms of what they can and cannot do within a learning environment.
Alan Kay [Kay 1992] of Apple Computers suggests that people often view new technology in terms of solving old problems before learning that the new technology may make the old problems irrelevant and bring with it new problems or issues. His primary example is the motion picture camera. It existed for 50 years, used primarily as a novelty and as a way to bring a stage play to audiences – using a fixed camera in the position of the audience, focused on the actors on a stage. Such was the prevalent model until D.W. Griffith introduced the motion picture as a distinct art form, through use of close ups, wide-angle shots, different camera positions, and cutting from or into action, and so forth.

The same can be said of the computer and of telecommunications technologies and their use in teaching and learning settings. First efforts historically have been to use the technology in the context of existing pedagogies. Yet, if one studies and understands the inherent characteristics of the various technologies -- what the technology can and cannot do -- one begins to recognize the need to break down the old models and get to the essence of what we want to accomplish. To achieve this recognition requires an analysis of the various modes of communication and interaction enabled by the technology, itself, that are conducive to supporting the kind of learning and engagement desired.

Some [Perkins 1990; Pea 1990; Salomon 1990] have suggested that distributed environments result in a diffuse sense of cognition where what is “known” lies in the interaction between individuals and artifacts, such as computers and other technological devices. However, Kozma [Kozma 1991] suggests that:

> Some students will learn a particular task regardless of the delivery device. Others will be able to take advantage of a particular medium’s characteristics to help construct knowledge. Many teachers, it may be said, are no different with regard to their instructional methodologies. (Pg. 205)

A focusing question for those interested in implementation would be: what enduring cognitive and pedagogical effects are enabled when an individual is engaged in and with such distributed environments? Previous conceptions of teaching and learning are informed or altered by interaction within such environments and, perhaps even more important, such interactions shape and alter the media, as well. In his reaction to Clark [Clark 1983], Kozma [Kozma 1991] offers the following support:

> Medium and method have a more integral relationship; both are part of the design….the medium enables and constrains the method; the method draws on and instantiates the capabilities of the medium. (pg. 205)

**CaseNET**

CaseNET is a set of WWW-based courses jointly organized and offered by institutions of higher education and district professional development teams from the U.S., Canada and Norway. Participants include both inservice and preservice educators. CaseNET is not "distance education" in the typical sense of the term. Students meet physically at a particular site and given time and are guided by an instructor on-site. Course readings, instructional materials, and opportunities to discuss educational issues are available through Web-based discussions and videoconferencing.

Site instructors use case methods—similar to instructional approaches used in business, law and medicine—to bridge educational theory and real-life practice in schools through “slices-of-life” scenarios that capture situations in real classrooms. Participants attend to standards of learning and assessment, issues of teaching across the content areas, and challenges of using technology to solve problems in schools while applying an educational problem-solving model for making sound judgments in the demanding situations educators so frequently encounter.

CaseNET encourages participants to:
1. cooperate within teams and compare analyses across teams in search of solutions to real-life educational problems,
2. link with people from other sites to concentrate on case issues,
3. write cases for use in school-embedded staff development and/or in their classrooms, and
4. prepare for continued professional development through "reflection."

CaseNET is an attempt to match the inherent characteristics of certain types of communication tools with learning activities deemed useful for teacher development. Instructors are using technology with an understanding of what it is that students need to do to develop as professional educators and also with a clearer conception of what role they, as teachers, play in such an environment. In large part, both student and instructor are actively engaged in sharing, questioning, and directly experiencing the consequences of making teaching decisions. The developers of this environment have gone to great lengths to construct a distributed learning environment that allows for support and encourages the requisite behaviors listed above. Successful CaseNET instructors do not try to match the method to the media but, rather, extract the meaningful components of the media to support their pedagogical decisions.

The Role of Pedagogy and Belief

One's pedagogy embodies the beliefs one holds about students, about the various attributes of media technologies, and about the essential qualities of the content at hand. Teachers make decisions based on the interactions of these beliefs. Therefore, it is imperative that one begins the process of designing and contemplating instruction with a consideration of the beliefs one holds concerning the components of this instruction. William James, the founder of American psychology, suggests that belief must begin with the act of believing as it relates to hypotheses and options.

James introduces live and dead hypotheses in his essay The Will to Believe [James 1897]. Live hypotheses are ones that truly may be possible, for example: “Students learn best through direct lecture.” Dead hypotheses are ones that are not believed possible. When competing hypotheses present themselves, belief is engaged, and a decision requiring action and decision between two or more genuine options must be made. Though options may be a combination of (1) living or dead, (2) forced or avoidable, and (3) momentous or trivial, a genuine option is one that is living, forced and momentous.

Options are living when a choice between to live hypotheses is presented, as opposed to a choice between a live and a dead hypothesis. For example, choosing between “Students learn best via lecture” and “Students learn best via student-directed activity” presents a live option, since either may be considered plausible. However, choosing between “Students learn best via lecture” and “All students are incapable of learning anything” is a dead option. An option is forced when the option of “doing nothing” does not exist. Choosing between instructional methods is often a forced choice, especially when presented with an unfamiliar teaching setting. Finally, an option is momentous when the opportunity to choose between competing hypotheses presents a situation that is unique, significant and irreversible. Certainly, choosing to teach via a distributed learning system like the NCIH or CaseNET would qualify as unique, significant and – for the duration of that particular period of instruction, at least – irreversible.

Genuine options exist for teachers in all instructional situations. However, when considering instruction via distributed learning systems, the element of clarity is often missing from the decision-making process, due to a lack of understanding of which options, exactly, are the genuine ones and which are not. The implications of these options are often less clear because of an inadequate amount of attention to beliefs and their roles. However, the pedagogical constructs, which result from the choices between perceived genuine options, are still explicit. These constructs are girded by the beliefs and assumptions teachers hold about how students think and how students learn, stemming from what Bruner [Bruner 1996] refers to as a “folk pedagogy.”

The similarities between traditional instructional methods and those methods most effective within distributed learning environments that some have implied are not as closely aligned as many wish. Projecting such similarities upon the distributed learning environment suggests a certain amount of continuity and congruence with more familiar environments for teaching and learning, and tends to reinforce some reasonably poor
teaching decisions. The instructional method that appears to offer the closest point of confluence appears to lie within the lecture mode so teachers and students often find themselves slipping comfortably into the roles of didactic teacher and learner which have seemed to serve them so well in more traditional environments.

There appears to be an inverse relationship between the amount of bandwidth available and the degree of creativity exhibited by the teacher and learners working within the distributed learning environment [Riedl 1994]. That is, the people with the largest amount of bandwidth, which often presents an environment that appears to be very much like a regular classroom as in the case of the NCIH videoconferencing environment, seem to be the least creative. Those with virtually no bandwidth -- typified by those with simple modem access, only -- tend to create very interesting learning scenarios.

There is a kind of "professional dissonance" that the use of narrow bandwidth causes when good teachers encounter it. Their habits and assumptions about teaching and learning are challenged -- a bit of the Deweyan "problematic" is introduced -- and they have to be more cognizant, more aware, more active in how they address the idiosyncrasies of the learning environment. Those with bandwidth, however, may fall more easily back on older, more comfortable models that fit -- more of a "resonance," between new technology and old teaching. This opportunity is often unavailable to those without the bandwidth.

Successful implementation requires an understanding of the characteristic considerations of early adopters and a recognition of how these early adopters perceive the innovation [Rogers 1983]. How effectively the adoption and diffusion of a particular innovation proceeds is directly related to the:

(a) advantageousness of the innovation;
(b) compatibility with existing values, experiences and needs;
(c) level of complexity during use;
(d) testability; and
(e) observability of direct implications of the innovation [Rogers 1986; Wells & Anderson 1997].

Diffusion relies greatly on the ability to capture those characteristics and somehow relate them to those widely held beliefs common throughout the social/institutional culture system. Teachers who are not looking for different ways to do things do not venture into the narrow bandwidth environment at all.

Those who are looking for ways to open new experiences and exposures to their students do explore the technologies looking for ways to open new opportunities and, thus, we find more creativity. The desire to be creative and to do things differently is the impetus that helps these teachers move into more interesting ways to use the technology and to solve the problems that threaten to get in the way of their efforts. In order to successfully sustain creative and effective usage of distributed learning systems, teachers and decision-makers need to be tuned into the pedagogical assumptions which guide their decisions when planning for integration into educational settings.

Abstract: The Multimedia Teaching Strategies project at Memorial University of Newfoundland, Canada has its home page at http://www.cs.mun.ca/k12media. We focus on providing the classroom teacher with flexible instructional strategies for their classroom, which can be understood and adapted without requiring detailed expertise in the technology. This is achieved by the use of narratives of successful classroom experiences coupled with a breakdown of the resources and information needed to evaluate and establish similar activities (i.e. replication) by the teacher. In this way, we encourage teachers to think about technology integration in their teaching, without requiring any special prerequisite knowledge, training or aptitude with the technology. Thus, we seek to include teachers typically disenfranchised by the technology movement, and at the same time avoid the technology-driven curriculum in favor of pedagogically-driven uses of the technology.

Introduction

"What do you need?" the salesperson asks the teacher. "Well", answers the teacher, "What can a computer do for my students?" Aha! The salesperson has the opening he wants. "I know exactly what you need" says our salesperson. "It's the latest, fastest multimedia system with on-board MPEG III and 100X CD-Rom. It'll put the latest technological advantages at your students' fingertips." he exclaims.

Often, teachers are not making the purchasing decision, but this scenario still illustrates the problem of a focus on the technology. The salesperson has no interest in the pedagogical needs of the students, and the teacher cannot make the connection between the technology and the curriculum without specific technology expertise. We often end up with a school containing the latest equipment, but no strategy for appropriate exploitation of this technology.

In our school system, we see teachers with little choice in their approach. Heavily laden with a full schedule, the teacher is doing counseling, administration, instruction, as well as instructional development. The pressure to integrate technology and multimedia into their teaching creates further demands. The situation has lead to a quest for what we call the "Plug-n-Play" curriculum. It is natural in this circumstance to look for ready-made solutions that can "plug into" your existing classroom milieu and prove immediately effective.
The Plug-n-Play Syndrome

Ready-made solutions are attractive in an administrative sense. They allow you to standardize classroom practice, making it easy to share resources; they distribute development costs among many technology users and come with vendor support; they guarantee a minimum level of delivery to the student.

In our Kindergarten to Grade 12 (K-12) school system, standardization is simply not feasible. Small rural schools with few computers and minimal Internet access are part of the same system as larger schools with industry-financed resource centers, local area networks and technology resource personnel on staff. Standardizing the level of technology support throughout the system is neither administratively feasible nor desirable. Where schools are comparable in technology resources, there are differences in the network configurations, distribution of technology resources, and the expertise and interest among the school staff.

Where plug-n-play curriculum is feasible, it tends to kill innovation at the classroom level. The components (e.g., CD-ROMs with packaged multimedia materials) are designed for a minimal technology platform, to which the classroom must conform. Moving beyond this minimal configuration becomes difficult; succeeding with less advanced equipment becomes impossible. Pick up any professional magazine that advertises commercial curriculum resources, and you find several articles focusing on the problem of standardized delivery, for example: "We've spent billions on innovative models designed to jump-start the school reform movement. But it will only have the desired impact if the dissemination process works" [Salpeter 1997].

The more serious drawbacks to plug-n-play learning are pedagogical; the materials come with packaged instruction to match its packaged curriculum. Individual learning styles, student learning problems, the local context and culture, or innovations in teaching technique become harder for the teacher to address, as control over the instructional elements are taken out of the teacher's hands. Innovation in the classroom is reduced to trying to get the newest piece of hardware, and is co-opted by an administrative activity, i.e. resource acquisition. Taking a portion of the responsibility for instruction out of the hands of the teacher is, we believe, a serious step. We run the risk of fostering the belief that the technology is all-important; that as long as the students have technologically advanced material and equipment, they have also advanced their learning. Promoted by commercial and administrative interests, this attitude may create a false sense that the environment has improved. Instead of being a vehicle for change, the technology has become the change. We believe that critical assessment and adjustment to the instructional environments has to be in the hands of the teacher if the materials are to be effective.

Even when these problems can be mitigated, there is difficulty finding "good" plug-n-play material to use: "Research shows that powerful, new technologies exist that can assist in developing better learning environments for all students... yet these technologies are not used by local public school teachers because they exist as isolated products, without a school-based curriculum tied to well-designed instructional strategies" [Wieburg 1997].

Teacher as technology expert (Beware of the "TechnoGeek")

Our bias is that teachers are the appropriate persons to decide how to use materials in their own classes. However, teachers themselves are generally reluctant to make decisions about the use of technology in the classroom because they are unfamiliar with it; they feel inadequate to assess the potential impact the technology will have on their teaching and classroom structure. Consequently, our local school system, like many others, has had many in-service training programs to provide teachers basic technology skills.

The danger in this approach is undue focus on the technology, rather than the student. It assumes you must know what the computer can do, and how the computer can do it, before you decide how you want it used in your classroom. There is some natural justification for this belief; after all, a fair understanding is required to confidently estimate the time, effort and benefits in a new approach. McKenzie [1996] puts it this way:
Teachers trained in one technology and mind-set sometimes find themselves gridlocked into old patterns and perceptions. Thrust into a world of new technologies, they persist in seeing them in terms of the familiar; the wordprocessor, for example, is viewed as a glorified typewriter with powerful editing features rather than as the idea processor it can be. To understand the computer's power for idea processing and improved composition, one must take a computer home, live with it, and write with it. Only by embracing the technology can one experience the kind of immersion that breaks through the surface understandings to a deeper level of involvement.

This kind of approach leaves the teacher continually in need of training; as new technologies appear, demand for teacher training will follow; in everything from printer technology to virtual reality the teacher will be playing “catch-up” [Ainge 1997]. Otherwise, we ascribe to the teacher technical incompetence to make decisions regarding instructional delivery. Once again, this is done in service to the technology: teachers will be given a standardized, general training which may not prepare them to think about their own classroom context or problems.

In our school system, we were faced with the situation that not every teacher could or would want to become a technology expert. We wanted to reach and involve teachers who were reluctant to adopt technology or had no means of thinking about multimedia technology in the context of their own teaching. For these teachers, there is a need for them to understand what the computer can do; but the teacher doesn’t necessarily need to know how the computer does it before evaluating the merits of an innovation in their own teaching situation. This is the belief behind our Multimedia Teaching Strategies project.

The Project Perspective

Our project is a Web-based presentation of successful strategies for exploiting multimedia technology in the classroom. These strategies are not prescriptive, but rather anecdotal in nature, highlighting the elements of successful experiences drawn from different schools in the local area. An anecdotal approach encourages visitors to the site to investigate the experiences of other teachers who have used multimedia technology, and to think about how to adapt and use these approaches in their own classrooms. In highlighting these experiences, we attempt to capture underlying philosophy, resource requirements, successes and demands of each “experience”. This is an attempt to provide the visitor the information they need to consider each approach in light of their needs and resources, without an in-depth and detailed expertise in the technology required to establish each strategy. When successful, the teacher can decide what they want to do with technology, and then seek the resources, expertise, advice and input they need to make it happen. The required expertise (as outlined with each anecdote/experience) can usually be extracted from within the school staff, the local community, and often found among the students in the classroom.

To us, having to learn the technology before conceptualizing its integration into the classroom, is analogous to learning how to run a typesetting shop before using textbooks in the classroom. Our belief is that teachers don’t have to be able to construct technology solutions before they can think about appropriate application of the technology. Given appropriate teaching models and support, a teacher should be able to look beyond the technology, and instead think about how the classroom can be changed, and what new activities are now available. It should not require a great deal of familiarity with the workings of machinery. Like Ainsworth [1997], we believe the appropriate “expertise” lies in knowing the correct critical questions to ask:

Understanding the hardware is easy. Hardware is the box that holds the ideas (software). If the box can't keep up with the software, get a better, bigger, or faster box. Hardware either works or it doesn't. If it breaks, call a mechanic. This is all you need to know about hardware.
The second thing you must know about in order to be a computer expert is the software, which is the interesting and exciting part. When you can pick out the really good software from the junk, you will have become an expert. To do that, you only need to learn to ask three questions. Ask simply:

1. **Do I need a computer to do this?**
2. **Am I learning anything?**
3. **Will this help me teach?**

Ainsworth's suggestion is restricted to the selection of software, but we want the teacher to go further, and envision specific projects and activities that integrate multimedia technology into their teaching practice. This is the claim that our project is intended to test -- is it possible to have a strategy for multimedia integration without being a technology expert?

Our research centered on extracting what worked for some teachers in our K-12 school system and identifying the elements that would help a teacher critically evaluate and implement any components of those experiences in their own setting.

The information for our Web site was collected via both informal and structured interviews. Sessions were video-taped for transcription or for playback to other teachers utilizing the Web site. (After all, we could not discuss the integration of multimedia without incorporating it into our site as well!) The site is structured as a guidebook, divided into five separate, but related, sections: Pedagogy, Equipment, Projects, Resources, and Skills.

The Pedagogy Section introduces some discussion of multimedia in the classroom through interviews with teachers and administrators working with multimedia, and their impressions of the technology. Included in this section are comments from a number of Educators with "hands-on" experience using multimedia to instruct. Sub-sections are divided by individual so that you can get a feel for each one's experiences and knowledge. Some may hold differing opinions so that you can get a feel for the true state of multimedia in the curriculum. The intent is to help the teacher develop a teaching philosophy that incorporates technology. By examining differing viewpoints and approaches, the teacher should start critically evaluating their own practice, and imagining what can be done to augment their approach to the classroom.

The Equipment Section is designed to introduce teachers to the equipment used for creating multimedia presentations. For most people, computer equipment is one of the most difficult things to learn about because it deals with the technical side of computers, and that may seem intimidating. Principally, this section provides explanation of the jargon and terms used in the narratives, so the site visitor will be able to get simple explanations when the discussions get a little technical. Furthermore, in spite of our concern about technologically driven instructional choices, we realize that good ideas can be sparked by the technology. Knowing about the equipment, you can extend the innovative uses of the technology for many years to come, making the computer work for you not the other way around.

The Projects Section introduces projects that we have created or found to be successful ways for using multimedia in the classroom. Links to a number of projects created by educational professionals that use multimedia to enhance instruction and improve understanding are provided. Projects are also analyzed in terms of their essential components - resources required, learning objectives, preparation, technical competence, and so on. We anticipate this will evolve into the "central" visitor location; the best insights and ideas should come examining other peoples' successes (and failures) and envisioning their procedures and activities as they correspond to your own situation.
The Resources Section is a place for teachers to go to find resources for their multimedia activities. It includes a searchable, on-line collection of programs, curricular materials, and plans. The intent is for users to search our database for particular resources, or to add specific resources that have been found effective or useful. Like many others, we are hopeful that a community of sharing can be encouraged at our site, (or nearby), for our intended audience.

The Skills Section elaborates on skills that are necessary to complete specific tasks that are typically needed in multimedia activities. These skills are looked at in smaller sections to target different components of a multimedia presentation. Although we stress that we do not support training, it is important for the teacher to have access to information about developing and applying each skill. In planning their multimedia activities, the teacher will need to decide from where the required skill will come: will they use a staff person, learn it themselves, use knowledgeable students, train all the students, or even bring in outside help?

Conclusion

Reaction to our project site to date has been slow building; different visitors are praising different areas of the site they have found useful. Unfortunately, these visitors are the technological elite, and we have yet to reach the “technologically challenged” teachers (to whom we hope to provide help) in any substantial numbers.

Our Web site is very much in development. As we anticipated early in the project, we have reached a stage in which we must attract users, including many who would not normally browse the World-Wide Web regularly. We have plans to produce supplementary media (mailouts, promotion through school boards, etc.) to attract teachers that are less immediately involved in technology. Our second objective at this stage is to increase the size of our resources, and produce more narrative examples of multimedia usage. The more ideas teachers are exposed to, the more likely they are to encounter something relevant to their own situation.

Overall, we are pursuing a “grass roots" approach; innovation must originate from the classroom. Our project is attempting to encourage and foster innovative effort and thinking at that level. Simply put, we ask teachers to examine the current strategies being effectively used by other teachers. Our job is to provide examples and/or ready strategies to allow teachers to investigate environments in which successful uses of multimedia have been shown, and extract general strategies that can be used in other environments with other resource bases. Therefore, once a teacher has judged the learners and the subject matter, and they are familiar with a number of multimedia concepts and experiences, they can then consider whether to attempt to build thematic units using technology with the potential of reinforcing what is taught in the classroom, or integrating the technology as a tool for the students themselves to create specific projects. Regardless, the solution lies with devising a suitable approach to technology integration, and we believe that a key component to this is familiarity.

Finally, we will look at our initial scenario again, but this time the teacher has developed a strategy or concept beforehand, and knows what s/he wants to do, but perhaps just not how to go about it.

“What do you need?” the salesperson asks the teacher. “Well”, answers the teacher, “In two weeks my students will be working on a unit covering architectural styles, and will want them to create a computerized survey of some of our local buildings, including pictures of buildings. Our resource people tell me I can have two video cameras, and we can take images from them onto the computer. But I want to divide my class into 5 work groups. I haven’t got the budget for three new video cameras. How can the other three groups collect pictures?” Now our salesperson has something to which to respond. “Well, we sell some inexpensive CCD cameras that hook up to almost anything. Do you have access to portable computers for your groups to use?”

Theorema:
A System for Formal Scientific Training
in Natural Language Presentation
Bruno Buchberger, Tudor Jebelean, Daniela Vasaru
RISC-Linz, Austria
last-name@risc.uni-linz.ac.at

Abstract: Lack of formal training is hindering the application of high-level information technology in
science and engineering. The Theorema project addresses this need by implementing a sophisticated
automatic reasoning system with an easy-to-use interface which can be used in various interactive ways
both locally and over the internet. We report on the use of this software for the training of mathematics
and engineering students in problem solving and theorem proving.

Background and Motivation
Deep understanding and skilled usage of mathematics and logic are essential ingredients of most scientific and
engineering activities, particularly in the fields of Mathematics and Computer Science, but also in many other
areas. In Information Technology applications, these skills are becoming crucial as the systems become more and
more complex and only the use of formal techniques can guarantee their proper behavior.

Unfortunately - as the first author has learned over many years of didactic and research activity in mathematical
logic - practical training in this field is severely under-emphasized in the vast majority of Math and Computer
Science curricula all over the world. In contrast, at RISC-Linz we have offered for over a decade a comprehensive
study and training program in mathematical logic and practical problem solving and proving [Buchb-Licht:81].
Based on this experience we are now in the position to develop concrete tools for the practical usage of the working
mathematicians and for the students, which can assist them in teaching / learning mathematical logic and proving
skills, as well as in mathematical textbook writing, problem solving, and scientific research.

In this paper we present the tools developed in the frame of the Theorema project for the training of students in
Computer Science, Mathematics, and Engineering in the language of predicate logic and in establishing proofs in
this language. These tools form an interactive theorem prover in high-order logic, written in the computer algebra
system Mathematica 3.0 [Wolfram:96], which is presented to the user in the form of an intelligent environment for
developing mathematical texts in natural language (e. g. in the style used by scientists in typical text-books).

The main objectives of the formal training in our system are:
- Language training: learn and train the use of mathematical language for concise and exact expressing of
  models.
- Formal models: learn and train how to build mathematical models for concrete real problems (defining
  concepts, defining properties, defining and exploring problems).
- Conjecture and prove: learn and train the formulation of conjectures about the properties of mathematical
  objects, prove and disprove conjectures.

The last activity - proving - is one of the most difficult formal activities for the human intellect, and
consequently it requires most of the learning and training. Our system offers computing support for all the
objectives mentioned above, however we will emphasize in this paper the proving and the proving-assisting
capabilities of our software, which took most of the effort to develop.

We believe that providing computer support to the working scientist and to the engineering student opens the
way for:
- a new understanding of mathematics and computer science;
- a new level of creativity and productivity in mathematics;
- a new quality of education of teachers and students, both at academic and pre-academic levels.

These aspects are certain to have a "boule-de-neige" effect on the general education in mathematics, computer
science, and engineering, with obvious benefic effects on all sectors of human activity.

It is beyond the scope of this paper to document extensively the state-of-the-art in the field of automatic
theorem proving, rather we will shortly review this (for more details see [Homann:96], [Buchb-et-al:97]).
Currently the most successful and effective computer-assistants for the working scientist are the computer algebra
systems, which contain a large collection of mathematical knowledge implemented as mathematical models and
algorithms (Mathematica, Maple, Macsyma, Scratchpad, etc.). All these systems have quite efficient computing
and solving capabilities (over numerical domains), but none of them offers support for constructing mathematical
models and for proving (which is a lot more than just being able to compute with logic formulae - facilities recently
added to few such systems).

On the other hand, a long-time research in automated reasoning produced a mature theory and many quite
powerful systems for proving, however they are rarely used outside academic laboratories and quite unsuitable for
use by non-experts. Their user-interface is most of the time quite cryptic, also the presentation of proofs and the
way reasoning is performed differ significantly from the way human mathematicians operate on mathematical
models.

The Theorema Project

Our project aims to close the gap between computing and proving by adding proving support to an existing
computer algebra system. A similar approach is pursued by few other research groups: Isabelle [Paulson:96],
Analytica [Clarke-Zhao:93], NQTHM [Boyer:88a], Nuprl [Constable:86], Coq [Huet_all:94], HOL [Gordon:93],
Oyster-Clam [Horn:88], [vanHermelen:89], Redlog [Dolzmann_Sturm:96].

The distinctive features of Theorema are:
- integration of an existing rewrite rule language (Mathematica) into our logic;
- imitation of human proof style;
- natural language formulation of proofs;
- combination of functor style programming with proving;
- integration of proving into math textbooks generation and interactive math teaching;
- multi-style proving triggered by special context.

The Theorema system is being built up in the following layers:
- A mathematical language as a common frame for both non-algorithmic and algorithmic mathematics. The
syntax of this language is implemented by using the syntax extension facilities of Mathematica and it allows
to write logic formulae (theorems) containing executable parts (function definitions using induction and
bounded quantifiers).
- The concept of "functor" as the general mechanism for building up towers of mathematical domains, which
allows the user to construct mathematical models.
- A general predicate logic prover of a "natural style" introduced in earlier papers by Buchberger (see e.g.
[Buchb-Licht:81]).
- Various special theorem provers (and / or interactive proof developers) corresponding, in a natural way, to
the various functors that build up mathematical domains. All these provers produce proofs that imitate the
proof style of human mathematicians. By now, an induction prover for the natural numbers and one over the
domain of lists over a given domain are already implemented, a prover for the domain of multivariate
polynomials over a given domain of monomials is under way.
- A general facility that allows the presentation of proofs in the form of "nested cells", which is crucial for
being able to read complicated proofs without losing the overview. This facility is based on the manipulation
of cells in Mathematica notebooks and can be automatically translated into HTML collections.

For a more detailed description of the components, as well as of the theoretical and algorithmical background
of the project, the reader is refered to [Buchb-et-al:97] and [Buchb-Vasaru:97].

Examples

Due to space limitations we can provide in this section only two examples of proofs produced by the predicate logic
prover and by the prover by induction on natural numbers. Other examples produced by these provers and by the
prover by induction on lists are presented in an extended version of this paper which is available on the internet at
"ftp://www.risc.uni-linz.ac.at/pub/techreports/1997/97-34/edm.html".

Example 1: Predicate Logic. Universally quantified formulae are used here in order to define the relation of
congruence by bidirectional less-or-equal. Then, one proves that the this congruence is transitive by using the
transitivity of the ordering relation. Note the brackets on the right-hand side of the page, which show the hierarchical structure of the cells.

Prove:

\((\sim \implies \sim) \forall (x, y, z) (x \sim y) \land (y \sim z) \implies x \sim z\)

under the assumption(s)

\((\sim \implies \sim) \forall (x, y) x \sim y \iff (x \leq y) \land (y \leq x),\
(\leq \implies \leq) \forall (x, y, z) (x \leq y) \land (y \leq z) \implies x \leq z.\)

We prove \((\sim \implies \sim)\) by natural deduction.

For proving \((\sim \implies \sim)\) we prove, for arbitrary but fixed values,

\((\sim \implies \sim) \forall (x_0, y_0) (y_0 \sim z_0) \implies x_0 \sim z_0.\)

We prove \((\sim \implies \sim)\) by the deduction rule.

We assume

\((\sim \implies \sim) H) (x_0 \sim y_0) \land (y_0 \sim z_0)\)

and show

\((\sim \implies \sim) C) x_0 \sim z_0.\)

From \((\sim \implies \sim) H)\) and \((\sim \implies \sim)\) we obtain by modus ponens

\((\sim \implies \sim) C1) (x_0 \leq y_0) \land (y_0 \leq x_0)\)

From \((\sim \implies \sim) H)\) and \((\sim \implies \sim)\) we obtain by modus ponens

\((\sim \implies \sim) C2) (y_0 \leq z_0) \land (z_0 \leq y_0)\)

For proving \((\sim \implies \sim) C)\), by \((\sim \implies \sim)\), it suffices to prove

\((\sim \implies \sim) A) (x_0 \leq z_0) \land (z_0 \leq x_0)\)

We prove the individual conjunctive parts of \((\sim \implies \sim) A)\):

Proof of \((\sim \implies \sim) A1) x_0 \leq z_0.\)

For proving \((\sim \implies \sim) A1)\), by \((\sim \implies \sim)\), it suffices to prove

\((\sim \implies \sim) A) (x_0 \leq y_0) \land (y_0 \leq z_0)\)

Formula \((\sim \implies \sim) A)\) is true because it is the conjunction

of \((\sim \implies \sim) C1)\) and \((\sim \implies \sim) C2)\).

Proof of \((\sim \implies \sim) A2) z_0 \leq x_0.\)
Example 2: Natural Numbers. Here the symbol "circled-plus" denotes the addition of the natural numbers, "x^+" denotes the successor of the natural number "x" (i.e., "x + 1") and "congruent" denotes the equality predicate.

**PROPOSITION:**

\[(T) \forall (\alpha) 0 \circledplus x = x\]

under the assumptions

\[\alpha(0) \forall (\alpha) m \circledplus 0 = m,\]

\[\alpha(+) \forall (\alpha, \alpha) m \circledplus n^+ = (m \circledplus n)^+\]

**PROOF:**

We try to prove by simplification:

\[(T) \forall (\alpha) 0 \circledplus x = x\]

Now we prove the formula

\[(T) \forall (\alpha) 0 \circledplus x = x\]

by induction on \(x\).

**Induction base for \(x\):**

\[(T, \text{IB}) 0 \circledplus 0 = 0\]

**Induction hypothesis for \(x\):**

\[(T, \text{IH}) 0 \circledplus x_0 = x_0\]

**Induction step for \(x\):**

\[(T, \text{IS}) 0 \circledplus (x_0)^+ = (x_0)^+\]

A proof by simplification works.

**Simplification of the lhs term:**

\[0 \circledplus (x_0)^+ = \text{by (\circledplus)}\]

\[(0 \circledplus x_0)^+ = \text{by (T, IH)}\]

\[(x_0)^+\]

**Simplification of the rhs term:**

\[(x_0)^+\]
Using Theorema for Proof Training

One major use of the Theorema software is for training students how to construct mathematical proofs. The system is already used by us in the classroom in the frame of a lecture on proof training. The provers can be used at various levels of interaction:

**Passive Mode:** The student studies the proofs produced automatically (eventually embedded in a textbook), in one of the following formats: printed on paper (when no computer is available); as HTML files (when no Mathematica software is installed); as Mathematica notebooks (needs only the free version of the software).

The later two versions have the advantage that the proofs can be read at various levels of details, and they are also accessible over the internet.

The passive mode is intended to be used in the early stages of the proof-training process, when the teacher introduces the students to the proof-techniques in classroom presentations, and the students study individually the lecture notes distributed either on paper or electronically.

**Interactive Mode:** The student uses the Mathematica software and the Theorema software in order to produce proofs for a collection of theorems distributed by the teacher. This mode is suitable for the more advanced students, who can now interact with the system by modifying the theorems, adding new assumptions, proving additional lemmas, etc. In this way they get more insight into the proving mechanisms and they begin to train in formal construction.

It is important to note that this increased level of interaction allows the students to learn individually at their own pace. This is crucial in proof training, because typically the students have different background in formal mathematics, and also in various mathematical fields: some proof techniques are more familiar to ones than to the others because they are more used in the field of their particular background.

**Active Mode:** In addition to the Theorema provers, the student uses a special set of functions allowing a more intimate interaction with the provers. Namely, the proof is displayed in a step-by-step fashion, and the user has the possibility to direct the process in various ways:

- navigate backward and forward through the proof;
- remove redundant assumptions in order to simplify the proof;
- introduce additional subgoals in order to speed-up the process or to give "hints" when the problem is too complicated to be solved automatically;
- indicate which proof technique should be used at which point in the proof, etc.

Figure 1 (file “Figure_1.doc”) presents a typical screen when using the predicate-logic prover in active mode, with several Mathematica notebooks:

- "Proof Control" displays various buttons for controlling the proofs and the level of interaction.
- "Textbook" contains the theorems to prove. By selecting a command of type "Proof..." and then pressing "Execute" from the proof control window, the proof is initiated.
- "Proof Window" contains the actual text of the proof. In interactive mode, the partial proof obtained at the current stage is displayed with gray cells for the still unsolved subproofs and with framed cells for the most recent proof step which was executed. By pressing "Next Step" in "Proof Control" a further proof step will be executed.
- "Proof Situation" shows the current goal (formula to be proven) and the current assumptions.
- "Log Window" shows a trace of the proof steps and other operations performed.

The IMEJ of Future Scholarship:  
A Prototype for an Interactive Multimedia Electronic Journal

Abstract: Although hundreds of journals have gone online in the past few years, most are simply a translation of text from paper to electronic form. Very few of them take advantage of the multimedia capabilities of the Web. Web technology is ready to support a new kind of publication, one which augments text with motion, sound, 3-D images, simulations, and tutorial or experimental interactivity. At the same time, interest in computer-assisted instruction is high, and a journal that presents ideas for technology-based education -- especially a journal that can do so dynamically and interactively -- would have a ready audience. Bringing together these converging trends, we propose the creation of The IMEJ of Computer-Enhanced Learning, an "interactive multimedia electronic journal" in the new mold. We describe our conception of the journal, outline our editorial and production approaches, and raise the difficult issues which arise in the publication of an IMEJ-type journal.

1. Introduction

The time is right for a new kind of interactive multimedia electronic journal. We are not just talking about another online journal. And we are not defining "interactivity" as it has generally been defined in online journals thus far, which has been little more than the reader's ability to download articles or email comments to the author. We propose an interactivity that includes experimenting with demonstration software, taking sample tests, going through tutorials, running programs written by the author, initiating net conferencing meetings, playing movies or sound, manipulating graphs and three-dimensional images, and searching text and even video.

Opportunity and need are converging at colleges and universities across the nation in the creation of the kind of journal we describe. A growing number of schools are making it their policy that all students and faculty have their own personal computers [Burg and Thomas 1998], creating a flurry of teaching innovation, experimentation, and, for many, just plain worry over computer-enhanced learning. As laptop computers are being placed into the hands of university professors, they feel obliged to figure out what to do with them, fearing that they may be left behind in empty classrooms with their blackboard, chalk, and lecture notes. They want ideas for how to integrate technology into their teaching and use computers to deepen rather than distract from learning. But where "technology-supported learning" is the subject, flat paper articles in hard-copy publications are unconvincing and not greatly illuminating. Teachers need to see innovations in action; they need to fiddle with application programs, try the tutorials, hear the words, see how things work, and ask questions. An interactive multimedia electronic journal -- or IMEJ (pronounced "image"), as we call it -- is an ideal medium for this kind of pedagogical exchange.

The technology is ready to support IMEJ-type journals and is evolving in directions which will make such journals even more useful and user-friendly. Through programming languages and tools like Java, Perl, CGI scripts, Dynamic HTML, VRML, ActiveX, Macromedia Director, Shockwave, ScreenCam, streamed audio and video files, and net conferencing software for real-time video, Web pages can be loaded with motion and sound, give direct access to executable programs, and respond to user input. Movies and audio files no
longer need be a test of the user's patience. With direct network access, greater bandwidth, single-user segments, and ATM networks on campus [Brown, Burg, and Dominick 1998], and with faster modems and ISDN or cable connections for remote access, users have the high-speed connections they need to make Web-based multimedia feasible.

In short, we have the means to create an IMEJ. The interest and tools are there, particularly in the growing number of schools with ubiquitous computing. The technology has evolved to make interactivity feasible. The need for objective evaluation of efforts in computer-enhanced learning calls out for peer reviewed publication of teaching innovations. And publications of this type can offer the exposure and measurable reward-system that will continue to stimulate and disseminate worthwhile ideas for using computers in education.

In what follows, we describe the creation of an electronic journal to be edited and published at Wake Forest University. Since the fall of 1995, all incoming freshmen at Wake Forest have been issued new laptop computers, and as a result of this initiative, interest in the potential of computer-assisted instruction has been high. Our journal, The IMEJ of Computer-Enhanced Learning, responds to this interest. The journal can be visited at http://www.wfu.edu/IMEJ.

2. Background

What kinds of electronic journals already exist, in what ways do they differ from traditional journals, and what can be learned from them?

When the Internet became graphical and accessible to the general public through the World Wide Web, it didn't take long for librarians and researchers to see its potential as a publication medium. Already in 1989, prominent librarians were proclaiming printed journals obsolete and calling for a university-based system of self-publication [Rogers and Hurt 1990][0kerson 1991]. The public has quickly been spoiled by instant access to information, and, increasingly, year-or-more turnaround times for scholarly publications are considered into unacceptable. The quickened pace in the research environment, coupled with the high cost of hard-copy journals, inevitably has led to the emergence of online academic journals.

Hundreds of electronic magazines and journals, both scholarly and popular, can already be found on the Web. (See http://www.lib.ncsu.edu/stacks/, http://info.lib.uh.edu/sep/sepb.html, http://gort.ucsd.edu/newjour/, and http://www.edoc.com/cejournal/ for lists.) The emphasis thus far has been placed on the initial, daunting task -- that is, transferring to the Web the huge body of already-existing journal literature -- rather than creating new journals of a more graphic, dynamic, and interactive nature. Notable projects and organizations that have tackled the job of moving journals online have included the Online Computer Library Center (OCLC), JSTOR, Project Gutenberg, Project Muse at Johns Hopkins, ACM's Digital Library, and The Scholarly Communications Project at Virginia Tech. (Charles Bailey's bibliography of scholarly electronic publishing offers a more complete list of "trailblazers." See http://info.lib.uh.edu/sep/rtrail.htm.). Along with developing the technology and databases for large electronic collections, the early contributors in electronic publishing also have worked on devising new models for sharing and paying for electronic publications [Bailey 1994], creating search tools, and coming up with new systems for peer review [Harnad 1996] [Wheeler 1997]. The SuperJournal Project (undertaken by the University of Manchester in cooperation with the SuperJournal Consortium and the HUSAT Research Institute at Loughborough University) is one of the few projects that purports to move toward multimedia innovations, but progress in this direction has been slow. Much of the work in the first two years of this three-year project was devoted to making clusters of journals available to the academic community and, more generally, "determining the features and functionality that will make electronic journals useful to readers" (http://www.superjournal.ac.uk/sj/project.htm).

Among the newly-founded online journals, a small but growing number are billing themselves as "multimedia" publications, or cite the advantages of sound, movies, and animations in their self-descriptions. For most of these journals, multimedia extends no further than the use of chat forums for responses to articles, online review procedures, hyperlinked footnotes, static graphs and pictures, and downloadable software or pdf versions of papers. (See The Journal of Interactive Media in Education at http://www-jime.open.ac.uk/, The Chemical Educator at http://journals.springer-ny.com/chedr/, Trincoll Journal at http://www.trincoll.edu/~tj/trincoll/journal.html, and The Electronic Journal of Geotechnical Engineering at http://geotech.civen.okstate.edu/ejge/Announce.htm and for journals moving toward multimedia). Very few of
the journals use any significant amount of video or manipulable objects, and there is almost nothing that you could truly call "interactive." A few music journals are making good use of sound clips (EOL at http://research.umbc.edu/efhm/eol.html and Music & Anthropology at http://GOTAN.CIRFID.UNIBO.IT/M&A/, for example). But overall, the level of multimedia interactivity in existing journals is quite limited.

3. IMEJ -- A New Kind of Electronic Journal

In what way is the journal we propose different from what already exists?
- Our journal will have a significant level of interactivity, and will use pictures, motion, and sound extensively.
- It will demonstrate effective examples of computer-enhanced learning across the disciplines.
- It will use a search tool to index articles by author, title, date, discipline, or pedagogical method.
- It will combine narrative descriptions of technology-based pedagogical approaches with interactive demonstrations of tutorials, exams, exercises, simulations, visualizations, collaborative tools, communication mechanisms, or learning environments.
- Articles in the journal will be refereed by peer reviewers, who not only will accept or reject the articles, but also will offer thoughtful feedback about the pedagogical value of the application being presented.
- The presentation format of articles will be a collaborative effort of the author, the reviewers, and the production team of the journal.

Representative IMEJ articles can be viewed at our Web site, http://www.wfu.edu/IMEJ. The first full issue of the journal is planned for December of 1998.

Our first example article demonstrates the use of online tutorials and practice problems for students learning how to balance redox equations in a beginning chemistry class. The tutorials allow students to read through explanations and then test their understanding with questions that offer immediate feedback. Answers to the questions include motion and visual pointers back to relevant places in the figures. The tutorials are accompanied by a jotpad where students can record notes. Online exercises are also available as self-tests for the students. (See Figure 1.)

![Figure 1. An Exercise in Redox Equations for Beginning Chemistry Students](http://example.com/image.png)
The tutorials and quizzes are written in Macromedia Director and Shockwave. To guide the reader in the use of the tutorials, we also give an .avi screen-capture movie showing a tutorial as it is being run. Since the tutorial programs are Web-based applications, links to the fully implemented versions, runnable by the reader, have been placed in the article as well.

Our second example article shows the use of a Lotus Notes-based environment called the Wake Forest Template in an English writing seminar. The Template, designed and implemented at Wake Forest University, is a Lotus Notes filing system built upon a metaphor of cabinets and drawers. A cabinet can be set up with special drawers for course material, the schedule, and online discussion and collaboration. In the discussion drawer, students can brainstorm as they develop ideas in their pre-writing phase; post rough drafts of their essays; comment on each other's work with different colored "pens"; and collaborate on a final document [Brown 1997]. Template cabinets are accessible through the Lotus Notes client software (part of the Wake Forest "standard load" of software on laptops); or, for participants off-campus who may not have Lotus Notes on their computers, the cabinets can be entered via a standard Web browser served by a Domino server. Figure 2 shows the discussion drawer of a cabinet shared by students at Wake Forest University (in North Carolina, USA) and Acadia University (in Nova Scotia, Canada), whose assignment was to write about their different perspectives and sense of place in the world. This shows how the cabinet looks when accessed through a Web browser.

This IMEJ article allows the reader access to a "simulation" of the actual cabinet used by the Wake Forest and Acadia students. The simulation was made by downloading the html files of Web pages created by the Domino browser and customizing them so that certain features of interest could be pointed out to the reader. The Web pages were then annotated with audio files to focus the reader's attention on important points and to help the reader navigate through the cabinet.
4. Challenges

The representative articles we have published thus far should show that an engaging level of interactivity is already possible in electronic journals. Yet we do not mean to imply that all the problems are solved. To guide others in similar multimedia publishing ventures, we lay out some of the difficult issues below, and our thoughts toward their solution.

4.1 Technical Considerations

While technology has indeed reached a level where multimedia interactivity is feasible, not all users have state-of-the-art networks, nor do they all have the same software on their computers. A major technical difficulty lies in incorporating multimedia features that are robust, quickly downloadable, and accessible to the largest number of readers. Download times are less of a problem on university campuses with direct network connections, but readers reaching multimedia articles through modems will not have the patience to wait for sound or video files of any significant size. This problem will eventually be solved by faster network connections and even fully-networked communities. For now we are trying to minimize the problem by

- making multimedia features available but unobtrusive, with small, clearly-marked hyperlinks set off to the side or embedded in images;
- when possible, streaming in files rather than requiring that they be downloaded first;
- compressing files as much as possible without losing quality; and
- alerting readers where plug-ins are needed and directing them to appropriate download sites.

Making multimedia accessible to the largest number of readers entails adopting industry standards -- or at least current favorites -- in browsers and production software. We are currently using standard html, Macromedia Director, Shockwave, Javascript, and occasionally Perl and CGI scripts. We have chosen the .wav format for sound files. At present, we use the .avi format for screen capture movies instead of QuickTime movies (in spite of the fact that .avi is essentially designed for the PC-platform) because it produces smaller files. We are planning eventually to use streaming technology, such as RealVideo. We would like to use Dynamic HTML (dhtml), which facilitates the definition of "styles" and richly-formatted journal pages. However, since dhtml is a feature of the newest browser implementations, pages formatted with dhtml would be lost on many readers with older browsers. One solution to the lack-of-standardization problem is to dynamically detect a reader's platform and browser and display journal pages in the appropriate format accordingly. This entails making multiple versions of articles -- a labor-intensive solution that we hesitate to adopt.

4.2 Editorial and Production Considerations

Our first problem in getting this project off the ground is one faced by all upstart journals, but exacerbated by the fact that we are an electronic publication -- that is, attracting submissions of articles. The legitimacy of electronic publications has not yet been established in the academic community, and where there is no promise of credit toward tenure and promotion, there is little motivation to publish. This is the Catch 22 of today's electronic publication. No one will submit high quality work (wasting a publication that might see print in some more prestigious journal) until someone submits high quality work. We remain confident, however, that the current keen interest in computer-enhanced learning, the quality of our production, a careful peer-review process, and the recognition that multimedia journals are an idea whose time has come will continue to attract articles to our publication over time.

Another big challenge lies in sorting out the writing, editing, and production tasks related to an article's publication. To what extent is the multimedia production the responsibility of the author? If scholarly publication is to take this new multimedia form, do scholars now have to be technical wizards as well? The problem should be less pronounced in a journal where the subject matter so closely matches the manner of presentation, as is the case with IMEJ. Since some authors will be describing software that they have developed, they may have created a product which is inherently interactive and multimedia and which can be plugged almost directly into a Web page. Others, however, may be using commercial software in the context of a novel lesson plan, or software that is not Web-based and must be presented in the form of figures, audio, video, screen cam movies, or simulations.
Other practical issues to be settled are a reasonable policy for updates, revisions, and responses to articles, as well as a plan for archiving documents. Online publications can be more dynamic than printed journals, since changes can be made so easily to electronic documents. But for research purposes, it seems that each article must exist in some definitive final version, available to readers indefinitely. What commitment is an electronic journal making to both the readers and authors when an article is published? What happens to these articles if the journal folds? Our plan is to allow changes to an article only until the article's issue is made public. Any later changes or corrections would have to be in the form of addenda. Articles will remain online indefinitely after publication. We do not anticipate that disk space will be a problem at current rates.

We plan for our journal staff to work in collaboration with authors to translate their work into the IMEJ format. This is quite a different thing than the usual "Guidelines for Authors" that require authors to produce their articles in a camera-ready format. The need for collaboration between authors and editorial/production staff may very well be the biggest obstacle to a proliferation of multimedia journals. It remains to be seen if this collaborative model is a viable one for journal production, or if industry standards and general computer-competence among scholars will make Technical Guidelines for Authors and the author's own multimedia production possible.

However this may play out, it is clear that multimedia publication is inevitable, and we believe that it will find a useful place in scholarly publication. It will serve some purposes better than others, and is especially suitable where concepts can be visualized, demonstrations can supplement explanations, 3-D images are explicative, voices can humanize a topic, or music underscores the text. Our intention is not to replace text with graphics, sound, and animation, but to augment text in publication; not to turn the computer into a television for passive viewing, but to do something quite the opposite -- drawing the reader into exploring a subject interactively. This is an inevitable next step in publication, a step toward engagement and collaboration in scholarly communication.

Support Services For A Training Network

Abstract: This document presents the services and facilities offered by a developed training network. Due to the network characteristics it can be considered as an Intranet where, over some basic Internet services, there are other value added services which conform an integrated environment from the user point of view. The description of the services will be done through the User Interface via which the users have access to them.

Introduction

One of the objectives of the TRaining Educators through Networks and Distributed Systems (TRENDS) project was the establishment of an European Teachers' Training Network aiming to train 2400 teachers throughout Europe [Tsakarissianos 1997]. This network consists of six main nodes called Training Centres (TC). The TCs are placed in the countries belonging to the TRENDS consortium (one TC in one Country): France, Greece, Italy, Portugal, Spain and United Kingdom and they are connected among them via Internet. Twenty schools are connected directly to each Training Centre, but they also have access to all the TCs via Internet.

The TRENDS network integrates Information and Communication Technologies (ICTs) related services into a common environment available for the TRENDS users (secondary school teachers). The purpose of establishing the TRENDS network is to create a forum where users will become familiar with the facilities and services provided by the ICTs, in order to apply them in the development of their work (teaching and learning process).

System Architecture

Starting from the analysis of the users' needs the network nodes architecture was designed [Cabrera 1997]. The nodes follow the client/server model: the server is placed at the TCs and the clients are located in the schools from where the teachers have access to the whole network. In both, the client side and the server side, it can be distinguished two levels:

- The basic level that consists of a set of existing tools providing basic network services which are widely spread in the Internet community. These tools provide the following services:
  - Electronic mail service.
  - The WWW service.
  - FTP service.
  - News service.
  - Directory service.

- The system level. This level comprises a set of services, denominated System services, to achieve an integrated environment when accessing (client) and providing (server) the services of the Network. First of all, a user has to register him/herself as a TRENDS user in the network (registration service). Then he/she will be able to enter the network (authentication) and will be allowed to have access to the remaining services (authorisation). Through the User Interface the user is able to reach the information of the network and to

[1] Work done within Telematics- ET-1024: “TRaining Educators through Networks and Distributed Systems (TRENDS)”. It has been partially supported by the Comisión Interministerial de Ciencia y Tecnología of the Spanish Government.
perform different actions over it, depending on the kind of information and on the type of user he/she is registered and modification service).

The remaining of this paper presents the services and facilities offered by the TRENDS network. Due to the network characteristics it can be considered as an Intranet where, over some basic Internet services, there are other value added services which conform an integrated environment from the user point of view. The description of the services will be done showing the User Interface through which the users have access to them.

Network Data Organisation

As aforementioned, one of the basic services supported by the TRENDS network is the Directory Service. This service conforms the data structure of the network. The distinct elements that compose the network are registered in the directory structure in order to be used either by any other network services or by the final users. The directories comprised in the network are:

- **Management Directory.** The Management Directory is responsible for storing the access information of every TRENDS user. This directory is the key to enter the network.
- **Information Directories.** These directories contain descriptive information.
  - TRENDS users directory, (yellow pages) containing information about the TRENDS users.
  - TRENDS centres directory, containing information about the schools connected to the network.
  - TRENDS lessons directory, containing information about the lessons stored in the network.
  - TRENDS distribution lists directory, containing the TRENDS distribution mailing lists.
  - TRENDS fora directory. This directory contains the description of the fora that can be held at the network. Depending on the service supporting the fora they can be:
    - Chat fora for the chat service.
    - News fora for the news service
    - Collaborative fora for the collaborative services.

The users' interaction with the information contained in the directories is controlled by the System services.

Registration in the TRENDS Network

The first action that has to be performed is the user registration. Users have to register in the Training Centre to which their school is connected. The registration is made via an HTML form which collects the data needed for this operation. This service automatically detects the country from where it has been invoked and displays the information in the appropriate language. The detection is performed via DNS and, in case that the country was not determined, the data will be displayed in the default language: English.

There are a set of fields that are mandatory, that is, they must be filled to perform the registration, otherwise the operation will fail. These fields are name, surname, centre where the user belongs to andClient Package Installation Path in order to integrate with the client software. The other fields are informative ones: category of the user, URL related to the user, e-mail address, telephone, fax, and address.

Once the user is registered, a login/password is associated to him/her. This information conforms the key to access to the network. The login string is composed with the first letter of the user's name concatenated with the surname. For example if the user has filled:

**Name: juan Surname: perez** his login will be: **jperez**.

The password is the same character string as the login, but if the length of the string is over eight characters it will be truncated to eight characters. The left ones are ignored. This password should be a provisional one and it should be changed for other more suitable.
Accessing the Training Network Services

Each Training Centre supports a set of services (the basic and the system ones) capable of being accessed by any potential user through Internet. However, the TRENDS network has a mechanism to restrict the access to only the TRENDS users (those who are registered in). The control access is performed by the system services (authentication and authorisation services) making use of the access control mechanisms of the basic servers.

Before having access to the network services, the users have to be authenticated as TRENDS users. This operation is performed by the Training Centre where they have been registered in since the user's data are stored there. When the user connects to the Training Centre, the HTML page showed in [Fig 1] appears. As it happened when displaying the registration form, the TC automatically detects the country where this service has been invoked (via DNS) and displays the information in the appropriate language. The fields present in this form are:

- **User**: The user's login assigned by the registration service.
- **Password**: The user's password. The first time the user enters TRENDS network his/her password is that assigned by the registration service.
- **Language**: The language in which the information will be displayed. It can be chosen among English, French, Greek, Italian, Portuguese and Spanish.

Once the user has been authenticated by the correspondent TC, the authorisation process starts. The first step is to allow the access to the local basic network services modifying the server access files. Depending on the service, the authorisation is either IP based or user based. Then the TC broadcasts the user's information to the other TCs to make them allow this user to have access to their servers.

This process leaves a trace of all the logins in a log file, so the access to the network can be monitored. This information joined to the server log files can be used to elaborate statistics of the services' use, to be applied to tasks such as optimising the network working for instance, or doing somekind of network accounting.
System Services Interface

The User Interface designed to access to the system services is based on HTML technology. It consists of an HTML page with two frames:
- The first one is fixed and contains the controls (TC toolbar) to manage the user interaction with part of the system services (see [Fig 2]). The Toolbar is developed in Java and allows to invoke different services pressing on the icons it contains.
- The second frame shows the forms and pages associated to the different services and it changes depending on the service selected. It can also display the information of any of the links contained in those pages, such as the lessons registered in the network.

Language Selection

The labels and messages that compose the user interface can be displayed in any of the languages of the countries that belong to the TRENDS consortium: English, Spanish, Italian, Greek, Portuguese and French. Although the TC automatically detects the user's language, it is possible to change the language in which the information is displayed. The control that allows to select among those languages is shown in [Fig 3]. It contains six icons representing the flags of each country. Clicking on the correspondent flag the language is changed.

![Figure 3: Language Selection Controls](image)

Searching Directory Service

It is possible to look for information contained in the different TRENDS directories. The search facility is able either to retrieve just a listing of all the entries stored in one directory or to retrieve a specific entry/ies using keywords. Depending on the directory the user wants to seek, the user should click one of the following icons.
- To search entries in the Users, Centres, Lessons, Fora and Distribution Lists Directory respectively.
Then the correspondent HTML form will appear (see [Fig 4]).

Register and Update Directory Service

Users can either register new elements (centres, lessons, fora, etc) that have been incorporated to the network, or modify, and even remove the information contained in the directories that it is no longer valid. To control all these operations, it has been created what has been denominatd the person responsible for the element registered in. Whenever a new element is registered in a user is associated to it. Only that responsible user would be able to modify or to remove that element from the directory. The icons that lead to the registration or update of the directories are:
Distribution Lists Management

Another task performed by the System services is the management of the distribution lists. These are the only elements whose creation and deletion is automatically performed when they are registered and removed from the directory. In other cases, the directory entry is just a link to the already existing element (e.g. lessons). Besides, the subscription and unsubscription processes are also managed by the system services. The user can subscribe to any of the existing lists of the network or unsubscribe from it invoking the service represented by the appropriate icon:

- To subscribe/unsubscribe to/from an existing distribution list.

Notification Service

This service cannot be invoked directly using the toolbar. After the registration of a new element in the network, it is possible to notify it to part of the TRENDS users by mean of the distribution lists. This service automatically generates a default message indicating the registration of the new element, and allows to select to which lists the message is going to be sent. The notification service is in charge of generating the mail message and sending it to all the users that belong to the selected distribution lists.

Evaluation Service

In the network, there is a profile associated to each TRENDS user. This profile reflects the "Educational level" that the user has got. This level may vary depending on the results of an evaluation process. With the evaluation service it is possible to modify the TRENDS user profile. The change of the user profile must be performed by a privileged user: the Evaluator user. It is the only authorised user allowed to change the user profile.

The form that allows to perform this operation appears clicking:

- To invoke the evaluation service

The fields of this form contain the Evaluator Password, the login of the user whose profile wants to be changed and the new profile value.
Frequently Asked Questions

There is a set of HTML files that contain the FAQs relative to some topics. The links to these files are comprised in the HTML page displayed when clicking the button:

- To access to the FAQ files
- The links to the files are: Internet, World Wide Web, e-mail, FTP, News, Chat, Collaborative.

Web Navigation

The System services page allows to navigate through the WWW. The toolbar is always present allowing to invoke any of the services at any moment by just clicking the correspondent icon. On the other side, the other frame supports a full document navigation, that is, it can display any HTML document referred by a link. For example, if there is an HTML lesson available it could be possible to navigate in it, keeping direct access to the System services (see [Fig 5]).

Conclusions

The TRENDS network can be considered as a some kind of Intranet. It is intended to contain a set of elements, related to some extent mainly to educational environment, whose access is going to be restricted to just the TRENDS users. To support the access and to deal with the management of the elements the System services have been developed.

From the TRENDS user side, this added services are accessible via the user interface showed in the paper. This user interface is based entirely in WWW technology getting benefit from all the facilities and services it provides.

References

Abstract: As learners use Web-based distance learning system over years, large amounts of learning logs are generated. An instructor needs analysis tools to manage the logs and discover unusual patterns within them to help improve instruction. However, logs of a Web server can not serve as learners' portfolios to satisfy the requirements of analysis tools properly. To resolve this problem, a data cube model is proposed to store learning logs for analysis. We also depict the method of using query language to retrieve information from database to construct the data cube. Furthermore, user friendly operators for manipulating a data cube can retrieve the statistical information from a data cube. Although statistical tools for managing Web logs exist, none specifically address the needs of a distance learning instructor. The paper uses data cubes and database technology as fundamant of analysis tools to satisfy a distance learning instructor's requirements for managing and analyzing learning logs.

I. Introduction

"Educators are managers. They manage students, resources and time to create the most valuable learning experience possible." [Thomson, Cooke, & Greer 1997] Traditionally, an instructor manages students by paper records. Paper records include students' name, sex, age, major, courses, grades, homework, project works, behaviors, etc.. Those paper records are called students' portfolios [Paulson et al. 1991; Crouch, & Fontaine 1994]. Many educators think that learners' portfolios are very important for assessing learning performance [Gillespie, Ford, Gillespie, & Leavell 1996]. At the same time, learners' portfolios are also required for a distance learning instructor to evaluate a learner's learning performance in a distance learning environment. However, to reconstruct learners' portfolios, a distance learning instructor must make great efforts to organize learners' behavior records in a distance learning environment.

To manage a distance learning environment, an instructor need to explore the teaching strategies and their effects on learners with different characteristics. For instance, an instructor may want to know the answers of questions such as 'Are male learners more active than female learners in the debate learning activity?', 'What is the ratio of learners that using the on-line discussion in midnight?', 'Will learners get higher grades if they enjoy answering question in the distance learning environment?', and etc.. However, a distance learning instructor is not easy to verify those hypotheses from the huge amount of learning records. Thus, there should be summary reports to abstract information relating to an instructor's various questions. Thereafter, a distance learning instructor can know the relationship among strategies, student portfolios, and student characteristics.

The basic requirements for evaluating students' behaviors in a distance learning environment are learners' behavior records, statistical description of records, and pedagogical meanings of records. A distance learning instructor needs feedback from learners' behaviors to manage and improve the distance learning environment. For instance, an instructor may want to know what a learner did before he/she asked. However, the logs of a Web server are huge and without structure so that it is very difficult to get the required information. Besides, the logs do not record some information for a distance learning instructor to make decision. To benefit the Web's potential, a distance learning instructor must have tools to reconstruct learners' behaviors from the Web logs and to analysis learners' behaviors records for observing the relationship among strategies, student portfolios, and student characteristics and making decisions for scaffolding student learning. To sum up, the major difficulties to construct evaluation mechanism in current Web-based distance learning systems are as the following:

First, an instructor of a Web-based distance learning system has the difficulty of observing learners' behaviors because Web system do not record enough information for analysis. If an instructor wants to observe
learners’ behaviors in a Web-based distance learning system, the instructor needs to know ‘who has ever read a specific document?’, ‘how many times a learner reads a specific document?’, ‘what a learner did after he/she read a specific document?’, and so on. Existing system can not answer those questions by retrieving information from the large amount of logs because there is not proper repository format to keep logs for evaluation. For instance, the logs of existing Web-server are sorted in time sequence order. A distance learning instructor can not get all information about a specific learner easily. These issues are referred as the recording and repository problem.

Second, an instructor does not have an effective tool to find pedagogical meanings from logs of a Web-based distance learning system. Some works attempted to manage logs of a Web server, for instance AccessWatch, Analog, Gwstat, and WebStat. Those works devised mechanisms for generating various statistic results from the logs to help the server administrator improving the server efficiency. Thus, the server administrator can modify the hypertext structure of the server to reduce the network traffic. However, that kind of statistic results can not satisfy the requirements of a distance learning instructor. An instructor requires the statistical results of various aspects of learners’ behaviors in a distance learning environment, such as average duration, frequency of asking question, interaction pattern, etc. These issues are called statistical and analysis problem.

Third, to diagnose a learner’s behaviors, an instructor must make a great effort to find the similar behavior patterns in the large volume of learners’ records. Diagnosing learners’ behavior patterns is a complex work for a distance learning instructor in a distance learning environment because a pattern may be composed of many dimensions. Although learners’ behavior records were properly recorded and analyzed, an instructor can not easily figure out the pedagogical meanings of the relationships among strategies, student portfolios, and student characteristics. As the saying said ‘a picture is worth a thousand words’, an instructor needs an efficient mean of illustrating complex data relationships. This issue may be called the behavior pattern visualization problem.

In other words, an instructor must make great efforts to trace the historical records of group behaviors before making decisions. This paper proposes a data cube framework to solve the recording and repository, statistical and analysis, and visualizing problems. The point here is that the instructor does not have to remember, or be bothered with intricate, yet meaningless, information; he can remain focused on the validation task at hand. Hence, the instructor will fast and accurately react to learners’ statuses by the supports of data cube technology.

I. A group discussion example

It is assumed that an instructor would like to observe and evaluate learners’ discussion behavior in the group discussion from the portfolios. Portfolios indicate that every discussion article will contain additional messages. For instance, the additional messages of every discussion article include the type of a discussion article, the date of a discussion article, who and when post a discussion article, and so on. The discussion articles of the group discussion must contain the information such as “who is the owner of an article?”, “when was an article posted?”, “what is an article talking about?”, etc. For example, learners’ portfolios might have a table NODE to represent the discussion article. There are four attributes in the NODE table. First, the NODE table uses the Node(N) attribute to indicate what an article was talking. Second, the NODE table uses the Date(D) attribute to imply when an article was posted. Third, the NODE table uses the Learner ID(L) attribute to denote who posted the article. Fourth, the NODE table uses the Group ID(G) attribute to point which group the owner of an article belongs to. The instructor may want to observe the relations among the attributes, that are N, D, L, and G, by asking the following questions.

- Sum of nodes by L
  For every learner, list how many discussion articles posted by the learner.
  \[ (1) \]

- Sum of nodes by G
  For every group, list how many discussion articles posted by the group.
  \[ (2) \]

- Sum of nodes by month of D, G
  For every month, list how many discussion articles posted by every group.
  \[ (3) \]

Thereafter, a distance learning instructor may want to observe the relations between learning performance and group discussion. Suppose there is a table GRADE recording learners’ learning performances of paper tests. The GRADE table uses attributes Learner ID(L), Test ID(T), Date(D), Score(S) to indicate the learner, the name of the test, the date of the test, the learner’s score of the test, respectively. In other words, the GRADE table records the learners’ score of every test and the date of every test. Furthermore, an instructor wants to know
whether learners’ behaviors in a group discussion correspond with learners’ score. For instance, an instructor may want to know whether a learner with high score is more active than a learner with low score. Moreover, an instructor may want to know whether learners are more active before a test than normal. The following expressions show the requiring information.

- Sum of nodes by GRADE S, GRADE T (4)
  For every test, list the total number of discussion articles proposed by learners with the same score.
- Average of nodes by GRADE T, GRADE D - D < 10 (5)
  For every test, find the average number of discussion articles posted during ten days before a test.

Furthermore, the pedagogical statistics can help an instructor to predicate learners’ behaviors. Hence, an instructor can improve the teaching strategies by verifying some hypothesis. For instance, an instructor may want to verify the following hypothesis:

- The citation number of a discussion article is positive to its length. (6)
- Learners are more active in the group discussion near the date of a test. (7)

A distance learning instructor can not already know what is the observed relations between attributes to make decision before recording learners’ behaviors. Hence, an instructor needs a functionality supporting multiple aggregates among attributes to answer those questions. The data cube technology can be used to compute all possible combinations of a list of attributes [Gray, Bosworth, Layman, & Pirahesh 1996]. In the data cube technology, a multidimensional cube is expressed as:

```
SELECT T, D, L, S, G, Sum(N)
FROM group discussion articles
CUBE-BY T, D, L, S, G
```

This query will result in the combination of T, D, L, S, G, TD, TL, TS, TG, DL, DS, DG, LS, LG, SG, TDL, TDS, TDG, TLS, TLG, TSG, etc.. Furthermore, an instructor can use multidimensional analysis tools to find the results of TD, TS, and L, that are the answers of the illustrative example. [Fig. 1] illustrates how an instructor manages the discussion environment by the support of data cube technology.

To solve the recording and repository problem, a database is necessary to store learners’ records and provide a query interface for learners’ records. One of the famous query interface is the Structure Query Language (SQL). The data retrieved by SQL is called raw data because the SQL can not easily retrieve records with complex relations. For instance, the SQL can easily solve the problems of (1), (2), and (3), but the problems of (4) and (5) need complex SQL expressions. Hence, the SQL is not suitable for most instructors. Furthermore, the SQL can not express the problems of (6) and (7) because most commercial relational databases use tabular style to store learners’ records. However, an instructor often needs to analyze the relations among tables. The data cube can create calculated measures by specifying mathematical formulas. Measures are created from tables or other measures. For instance, the measure “active” of (7) is calculated by subtracting a prior period average number of discussion articles from the average number of the period near a test. The measure can create another measure with the percentage style when divided by the average number of the prior period. Consequently, the cube repository can provide an intuitive expression to represent the relations among tables.

Researches make efforts to investigate how a teaching strategies affects learners’ behaviors in a distance learning system [Wissick et al. 1995]. Those researches provide guidelines for a distance learning instructor using feasible teaching strategies to promote learning outcomes of a distance learning system on Internet. However, an instructor requires to know how the teaching strategies affect learners after he/she applied the teaching strategies under some conditions. A distance learning instructor may want to trace into various detail

---

*Figure 1: Manage the group discussion records by data cube technology.*
level of learners’ behavior records to comprehend the causes and effect for the summary information. For instance, assume that a distance instructor wants to on-line observer how strategies encourage students participate the group discussion. Suppose that a distance learning instructor uses four strategies to encourage students participating the group discussion. **Strategy I** indicates the stage for all learners to practice posting and discussing freely. **Strategy II** denotes the stage that the instructor announced learners’ ranks of post amount of each week. **Strategy III** shows the stage to announce the list of learners who have never contributed to the group discussion, neither presenting questions nor sharing answers. **Strategy IV** indicates the state that a distance learning instructor assigned a suitable question to a learner and constrained the learner to solve the question before the deadline. A distance learning instructor can on-line monitor how the strategies effect learners by a cube with **LEARNER**, **NODES**, **TIME**, and **STRATEGY** axis. That cube can be view as two-dimensional spreadsheet with sum of **NODES**, and **STRATEGY** axis with flexible period definitions, see [Tab. 1].

A distance learning instructor may want to observer the relation between students’ grades and the posted discussion articles. A distance learning instructor can on-line analyze the relation by dividing students into three groups according their grades of a test. A distance learning instructor then drills down on the group dimension, displaying the number of articles posted for every group. Consequently, an instructor can figure out how the [Tab. 1] was generated. In contrast to the drill down operation, an instructor can get a summary table, that is [Tab. 1], by rolling up from [Tab. 2]. Finally, the instructor requests results are shown in statistic style, that is the average number of discussion articles posted per day and their standard deviation (SD). [Tab. 3] indicates the concluded results to satisfy an instructor’s requirements. Furthermore, a distance learning instructor may need to visualize the results as [Fig. 2].

The data cube technology provides several operators, including **roll-up**, **drill-down**, **cross-tabulation**, **pivot**, **flexible period definitions**, **sub-total**, etc., to manipulate the cube repository [Mattison 1996]. A distance learning instructor can dynamically explore learners’ portfolios at any level of detail by roll-up, and drill-down. The **cross-tabulation** operator enables an instructor to dynamically create, save, and monitor relations among tables. To get a summary report with proper layout, a distance learning instructor can use the **pivot** operator to dynamically cast and recast dimensions. The **flexible period definitions** support a distance learning instructor to define the period of a teaching strategy, including noncontiguous periods, period ranges, period calculations, and

![Figure 2: The visualization of the results.](image-url)
period variables, such as "recent". A distance learning instructor can easily analyze learners' portfolios by multidimensional operators on a data cube without learning complex SQL expressions. Furthermore, the results of the multidimensional analysis can be shown as a graphic style for an instructor to find learners’ behavior pattern. To sum up, the cube technology can satisfy a distance learning instructor’s requirements because it can overcome the difficulties for observing relations between teaching strategies and learning behavior.

I. System Architecture

To observe learners' behaviors, the system should first completely record how the learners create and access discussion articles. The reason is that most distance learning system can not know the information about how a learner reads the discussion article, such as the duration, times of review, actions while reading the discussion article and etc.. Then, the cube technology must be integrated to manage learners’ behavior records. Finally, a distance learning instructor can use multidimensional analysis to observer how learners’ behaviors change after applying a teaching strategy.

There are three components for using data cube technology to providing that functionality. First, a relational database and a recording sub system are responsible for accumulating learners’ logs. This part is used to store raw data about learners’ behaviors is recording. Second, a cube repository and cube operators are implemented by complex SQL expressions. This part describes the derived data type for query and the processes of constructing cube repository and operators. Third, a method is depict for mapping SQL into multidimensional operators and a distance learning instructor can analysis student portfolios by the multidimensional operators. A distance learning instructor can also verify his/her hypothesis by the multidimensional operators.

[Fig. 3] illustrates the system framework of integrating data cube technology with a distance learning environment. The left part of the leader is the client for learners. The right part of the leader is the server. They are connected via network. The gray parts are our implementations; the other parts use existing software to support the framework, for instance WWW server, and database. The major part of the client is a browser for client agent, user action area, and WWW query interface. The server includes WWW server, WWW document, log agent, database, query process, and CGI interface. The log agent is responsible for receiving, checking, and recording messages from log client. There are three phases in the recording process, that is entry, learners’ actions after enter the system, and exit. The entry phase will ask learner entering user name and password. Then, the client agent uses the identification code to access all the other WWW pages. Hence, the log agent can record learners’ behaviors after entering the system. When learners exit the system, the client agent will notify the log agent. Then, the log agent will transfer learner’s behavior records as a complete transaction.

To construct a cube from database, the query processor should use GROUP BY operators in SQL expressions to retrieve data for every dimension. The GROUP BY operator can get data that have the same value of some attributes. For instance, an instructor may want to know everything about a specific node. If we have the dimension that groups only by NODE, we only need scan the dimension and output the answer. We can also answer the question about relations between learners and a specific node by the dimension that groups by USER and NODE. In the first level, the query processor will group the information by (USER), (NODE), or (LOG). Hence, a distance learning instructor can easily use the multidimensional operators to get the required information about a learner, a discussion article, or a period. In the second level, the query processor will join the information of the first level. For instance, the (NODE, LOG) step will report the access records of a discussion article and when a discussion article was created. The process continues until the highest level. Consequently, a distance learning instructor can analyze portfolios starting from a summary table, indicating a discussion article, its creator, and creating time. Then, a distance learning instructor can get any detail level of learners’ portfolios.

A distance learning instructor can use roll-up, drill-down, cross-tabulation, pivot, flexible period definitions, and sub-total operators to manipulate the cube of learners’ records. Multidimensional operators should be able to directly access standard relational database without the need to extract and place data in a proprietary multidimensional environment. Hence, there are two interfaces to access data cube. First, a distance learning instructor can send multidimensional analyzing operators to query processor directly through any application. Second, a distance learning instructor can send multidimensional analyzing operators to CGI interface, that will transfer it to query processor, through a WWW browser. The query processor will translate multidimensional analyzing operators to SQL expressions because the infrastructure of the recording component is a database. After the query processor gets the summary results of the SQL expression, the CGI program or application can generate a picture to show the summary information. Many papers depict how to implement the multidimensional analyzing operators by SQL expressions. Those works make effort to improve the efficiency of
the cube operators because a cube operation will cause a huge amount of calculation. Some commercial products also add the cube operators for reports, for instance Microsoft™ SQL Server 6.5. Hence, we do not describe how to implement the cube operator in details.

![Diagram](image)

**Figure 3: System framework.**

I. Conclusion

This paper identifies a distance learning instructor's requirements for managing and analyzing learning logs. However, existing tools for managing and analyzing system logs do not consider the pedagogical purpose. Consequently, a data cube model is proposed to reserve the pedagogical meanings of learning logs. Based on the data cube of learning logs, a distance learning instructor can observe learners' behaviors from various perspectives, called multidimensional analysis. This paper also introduces the data cube technology and the method of constructing a cube by a relational database. The guideline and experience for implementation are depicted by a group discussion example. Hence, a distance learning instructor can transfer existing tools and get the advantages of a cube with little efforts. Most important of all, a distance learning instructor can expose the pedagogical meanings in the large amounts of learning logs to support decision making.

'Savoirs collège' an Attempt to Create a Suitable Toolbox for the Secondary Schools

Alain CHAPTAL - Centre National de Documentation Pédagogique (CNDP) - France
email: Alain.Chaptal@ie.cndp.fr

Eric BRIANTAIS - Centre National de Documentation Pédagogique (CNDP) - France
email: Eric.Briantais@ie.cndp.fr

Abstract: To accompany the reform of the first cycle of secondary teaching the french Ministry of Education and the Cndp create 'Savoir collège' a set of resources and services dedicated to the teachers. Taking into account that learning is also available from new digital educational supports the concept brings together for the first time in France Internet, CD-Rom, and television. 'Savoir collège' aims to give to the teachers the professional tools to facilitate their practices, to raise the use of technologies in the classroom, and to stimulate the educational multimedia market which is gestating in France.

The situation may be unique, but the question addressed seems far more general. In France, a single public organisation takes care of the largest part of the overall production of educational resources dedicated to the teachers of the primary and the secondary schools. Cndp -ie. the national center for educational resource publishing- issues its manuals on evergreen materials as such as books and weekly newspapers. Also, it taps new digital medias like CD-rom and Internet, and has been largely involved in the television field production, for years, even managing a near video on demand (N.V.O.D.) channel on cable. A large multimedia publisher, indeed.

The revolution there, wasn’t the proactivity necessary for a 2,000 people organisation like Cndp and its network, spread throughout the country, to assume the right move on the right new ‘technology hype’, and to do so on time. By the way, Cndp launched its web site very much ahead compared to the other french educational agencies. The big news was to integrate the television programmes, the web and CD-rom publishing released by Cndp under one banner 'Savoirs collège'. One can say that Internet permits the convergence of different - but complementary- medias to serve the good cause of facilitating and improving teaching practices. A goal that Cndp has assigned itself since the Ministry of Education added instructional technology design, 'ingénierie éducative' in french, to its set of missions (see Chaptal 1994, Chaptal & Briantais 1996, Chaptal 1997).

This thinking arises from the reform of the first cycle of secondary teaching known in France as 'le collège', and the renewal of its teaching programmes. Coming from the classical approach at CNDP concerning the possible contributions of pictures, and the changes that this implies for TV transmissions broadcast on 'La Cinquième', the educational channel in which CNDP is the principal partner, the thinking rapidly took account of the fact that, in the near future, learning will also be available from new digital educational supports (see Becker 1994, Fulton 1996, Glenman 1996, Riley 1996). It followed that, from now on, a more global approach was essential which rejected the idea of competition between one support and another, but, on the contrary, use should be made of their complementarity.

The concept that arose from this was called the 'Savoirs collège' and was developed in collaboration with the national Ministry of Education, and with the support of France Télécom. It brought together the Internet, CD-Rom and television with the more traditional supports, so as to offer to educational teams a body of educational resources, products and services from CNDP which were organised in a coherent manner.

We tried to take into account the lessons of the past experiments (see Saettler 1990, Fulton 1993, Becker 1994, Cuban 1986) because we believe that those who forget the past condemn themselves to commit the same mistakes. We keep in mind that technology is still of limited use in our schools and that one of the major reasons responsible for this situation is probably that teachers are already under pressure to fulfil all their 'ordinary' educational objectives (e.g. complying with the curriculum, establishing a true pedagogical relationship with their students, managing classrooms within the rigid framework of the 55 minutes sequences, responding to parent and administration demands, etc.) and that technology appears too often as an additional burden of...

We consider that teachers are the gatekeepers for technology use at school. To put technology at students' reach and then to modify progressively the educational process, teachers have to be persuaded by the advantages it offers. Therefore, it is of decisive importance to give them the professional tools, the teachers' bureautics, that can help them efficiently (see Cuban 1993, OTA 1995, Fisher & al 1996, Glennan 1996, Sandholtz & al 1997). Media are a resource, not a goal. We must help teachers to prepare their lessons and to support their own educational practices.

The driving idea behind this pilot project is to simplify teachers' life. Everyone among them is on his own to implement the new curriculum in his/her class. What resources can help them to better do their job? How to save teachers' time and efforts when looking for information about what to do, which resources are available and how to get them? Can technology really simplify that obstacle course? This is the challenge of 'Savoirs Collège' which is basically a concept for documentary and pedagogic assistance.

One of the most important motive was how to best put educational resources at teacher disposal with using the emerging Internet network. In the classroom, the ideal situation would be to have over a broadly available digital network, at teacher reach, a variety of suitable tools by simply opening a unique toolbox located with the URL 'Savoirs college'. Internet technologies are likely to offer this simplistic approach to everyone.

**A Knowlegeable Mix of Television & Internet**

Taking into account that one can learn from watching a video or from surfing the Internet, the concept brings together for the first time, in september 1997, in France the Internet, CD-Rom and television with some more traditional supports. Cndp created an on-line documentary and a pedagogic assistance based on the following guidelines -available off-line on a CD-Rom for those with no access to the net, still the majority of schools:

- the educational policy applied in the college claims the teachers to appropriate the new tools in their classes for teaching specific branches of instruction and general education (citizenship education, orientation education and health education),

- the development of media competence amongst the college students assumes that the teachers themselves find a simple and concrete assistance in these knowledge supports, and notably the digital networks,

- in many of the points made by the programmes, and in most of the disciplines, images have become an element which constitute the make up of knowledge, and help with its acquisition.

Two core medias, television and Internet, are mixed in a set of television programmes 'Galilée' broadcasted on La Cinquième -the french educational television channel- and in a fully integrated web service.

**Galilée : A New Set of Television Programmes**

The new television transmission 'Galilée', which is a co-production between La Cinquième and Cndp is concerned with an approach seeking to put images at the heart of teaching. In these new programmes, several of the training contents call for, or demand, recourse to audiovisual material which must be obtained or created. That is the objective of the 'Galilée' transmission. It brings scientific pictures, pictures from the economics and social world, pictures involving citizenship, ethical and aesthetic questions into the classroom. It allows students to see what cannot be seen in text books or generalist audiovisual programmes. Each subject is dealt with in 26 minutes from a selection of angles moving to and from between the students' familiar reality and the development of knowledge. There is an essential preoccupation running through the questions that are dealt with which integrates the transmission: the education of the citizen. For the first time, the copyright issue has been solved and teachers have the rights to record the video material directly form the television programmes.

One point is essential: the teacher must remain master of the situation. Every broadcast is produced so that the teacher can tie it in to his course: teaching guides are provided, before transmission, on the Internet and, in part,
on the termly CD-Rom which is a supplement to the Téléscope review. The video cassettes and their guidance
notes will be sold by the regional and departmental centers, and by mail order, two weeks after the programmes
are broadcasted, using contract payments available only to scholastic establishments, with relaxation of
copyright for use in classrooms.

In 1997-1998 the accent will be on the new contents for classes of the sixième and cinquième (grade 6 and 7),
and for the quatrième and troisième (grade 8 and 9), for which the programmes are already partially in
preparation for material that is not susceptible to later changes. From 15 September four items have been dealt
with during four weekday transmissions (of half an hour duration each):

• Monday: Science and technology (how are familiar things constructed; how do the tools we use work; how is
our daily food produced)

• Tuesday: Education for citizenship and for responsibility (discovering the world of work and the reality in each
professional area to start pupils thinking about where they are leading; learning the basic rules about life in
society and the values on which democracy is based; understanding the functioning of the human body and being
responsible for one's own health)

• Thursday: French and arts (mastering the different ways of discussing; decoding the language of images;
getting into the process of creation and understanding the process of production of a work of art; study a work
and study more works).

• Friday: Discovering the world (reading a landscape; understanding the organization of economic activities;
knowing the inhabitants of a country; understanding the interactions between different species in a given
environment and identifying the constraints which that environment exercises).

A Fully Integrative Web Service

For the teachers it is a matter of giving greater emphasis to the simple use of the new supports. Whether it is
about the programmes or the pedagogical organization, a teacher, a media manager or a college principal will be
able to obtain information about the products and services which are on offer. Everyone will have all the useful
information available, which is kept up-to-date on Cndp's Internet site (http://www.cndp.fr):

• Complete documentation on the new college. The official texts, the teaching programmes and their
accompanying documentation. Library references on major themes selected from the public and private
contributions by the review 'Cndp Choisir', as well as other data bases. The catalogue of written, audiovisual and
multimedia products edited and distributed by the pedagogic document centres (Cndp [National], Crdp
[Regional] and Cddp [Departmental])

• Specific services and productions. Information about the services and productions offered by the nearest Crdp
or Cddp within the framework of the 'Savoirs collège' operation. Specialised forums for dialogue with other
colleges and with Cndp. A link to other servers: educational servers at the regional level, Crdp servers and
others which have been selected by Cndp for their educational interest.

• Information about the 'Galilée' transmissions. The annual programme of these new television transmissions
which are coproduced with La Cinquième (mentioned above). The pedagogic guides make it easy to use them in
real time in the classroom.

• A termly CD-Rom. This is a supplement to the review 'Téléscope', complementing the Internet, or for those not
yet connected, which allows them to have available - at the media center of the school 'Centre de documentation
et information (CDI)', for example - all this information augmented by multimedia data. This CD-Rom will be
widely distributed.

• The national Cndp and Crdp reviews. They will offer access to information for those who do not yet have
informatic equipment available. This is the way that an out of series Téléscope was widely distributed when
schools restarted after the summer brake.
'Savoirs collège' an Attempt to Create a Suitable Toolbox for Secondary Schools

We know that it takes time for teachers to integrate technology (see Cuban 1986, Saettler 1990, Cuban 1993, Sandholtz & al 1997).

'Savoirs collège' will take part for three years in this new first cycle of secondary teaching. New products, services and experiences will come to enrich it. The mobilisation of the national network of regional and departmental centres (Crpd and Cddp) should allow 'Savoir college' to situate itself more and more within the practices of the establishments and their educational policies. Thus, while writing the article, operations are in a too early stage to advocate the success. Nervertheless, the ministry of education and Cndp are releasing some of the first evaluation results for the ED-media conference.

We can already assess some interesting indicators, even if they do not constitute a scientific evaluation. For the first three and a half months of the project (from september the 15th to december the 31st), the number of hits of our web site raised of 120 % from 8,300 to 18,300 hits per day. Of course our web site is not limited to 'Savoirs collège' but these requests represent approximately 55 % of the traffic and a global download of 70 Mo per day.

In addition to the national television broadcast, a serie of 76 videocassettes gathering the video programs of 'Galilée' has been launched on an annual subscription basis and at a low price of nearly five USD per cassette delivered every fortnight. Even though teachers have been able to record the programs free of charge when broadcasted the serie of cassettes has been subcribed for simplicity reasons.

At the beginnig of the operation, our target was to reach 10 % of all the lower secondary schools in year one. After only five months, 749 suscriptions were registered representing 100 % of our objective. We now expect to reach the number of 1,000 -i.e.13 % of the schools- before the end of the school year. A survey conducted with the first 500 suscribers shows little differences between the percentage of schools which have subscribed the video and the population distribution. This means that the number and the diversity of existing local resources, which varies with the size of the city, does not seem to interfere with the choice of subscribing.

Again we must stress that we do not consider these results as clear indicators of success but merely as encouraging hints. 'Savoirs college' is an operation in progress with new releases forecasted. But one can say that benefits are already on the records. It added cohesion in the inside of the Cndp organisation which employs diversified field specialists, associated teachers, televison producers, multimedia developpers. In the classroom, the integration of disseminated materials into a single toolbox cleared the role Cndp is able to play as an helper and a facilitator.

The main goal here is to give everyone, teachers and media workers, the ability to know about the media resources relating to their discipline or field of work. Teams in the schools should be able to discover the suitable tools which would help them with their work involving the major priorities of innovation -e.g. mastery of language, citizenship education, and education on orientation; on how to acquire methods; and on modes of adaptation of the teachers to the diversity of their pupils- and which would enrich their establishment project.

It would be quite naive to believe that this scheme would be, at the beginning, perfectly satisfying. Further developments will progressively improve it. Lack of bandwith for the schools which are hooked to the net through dial-up modems or even 64 kbps ISDN lines is a severe limitation for multimedia services delivery. To ensure the success, the access bit rates need to be enhanced. It may allow to play video on-line for preview and/or asynchronous use. Also, an accurate research engine associated to a validated data base is needed to ease teachers work. ‘EducaSources’ is the name of the one under construction in partnership between Cndp and the French Ministry of Education.

'Savoirs collège' aims clearly to put information and communication technologies at the service of teachers. Cndp hopes to raise the utilisation of these technologies in the classroom and to stimulate the educational multimedia market which is gestating in France.

Abstract

Elementary school students have difficulty in using link and may be disoriented when studying web-based courseware. Moreover, they may not be interested in reading courseware. In this paper, we devised a methodology to promote the learning motivation and to prevent navigation disorientation by using a multi-user game that integrated with web-based courseware. Experiments of our implemented game show that the game does improve the motivation of the students in practicing and learning. At the same time, the students do not have the problem of disorientation in using the game. Analysis and discussion for the effect of the motivation factors of the game is also presented. This information provides guidelines for designing instructional game script.

Introduction

World Wide Web is very popular and easy accessed so that a lot of teachers put their teaching materials on the web. However, students need to know how to use links. Moreover, the student should keep in mind the structure and access paths of the courseware to prevent disorientation. This may be not difficult for university or senior high school students. It may be not easy for K-9 students [Corrina et al., 1996]. On the other hand, K-9 students do not have difficulty in playing computer games. The students can soon figure out the script structure of the game and know how to play it and navigate in the game script. Besides, those students can sit and play games for a long period of time. On the contrary, it is not easy to keep them concentrate on the courseware for a short time if no interesting things is embedded in the courseware.

It may be a good idea that we integrate a computer game with learning materials. Since students likes to play a game, the students may have more motivation to learn. The students may be more willing and persistent to learn. At the same time, if we design the game script based on the learning hierarchy and flow of the courseware, the student may not be disoriented in learning. By showing the structure of the game script, which is easy to be comprehended by the students, the students will always know where he/she is and where he/she should go next.

Before the computer network becomes so popular today, most of the games are single user games. In a single user game, the player always fights with simulated enemies generated by the game program. Usually, the simulated enemies use a same strategy in a same situation. Hence, once the player overcomes a problem in a game. That part becomes no interesting for her/him. Besides, students may abandon if they are not able to play the game well in the beginning.

Owing to the popular of the computer network, games can be designed as multi-user games. A multi-user game provides an environment for players to fight with real persons or to compete and cooperate with other players. Even for same scenery, players still face an unknown situation because real persons will change their strategies. Thus, a multi-user game becomes a social environment and can keep on being interested in for players. Moreover, if a player/student has orientation problem, other player can assist the players that are in trouble when the game has the facilities and encourage players to do so. Therefore, we can embed learning materials into a multi-user computer game to improve the motivation of the students. And, the student can learn in a social environment.

The primary reason of embedding learning materials into a multi-user computer game is to promote the learning motivation of the students. Lepper and Malone [Malone and Lepper, 1981] investigated what makes a computer game fun. They [Lepper, 1988] [Malone and Lepper, 1987] [Stipdk, 1993] found that motivation factors can be divided into two groups: intrinsic motivation and extrinsic motivation. The motivation factors of a single user game are mostly related to intrinsic motivation. The intrinsic motivation factors includes: challenge, curiosity, engagement, autonomy and fantasy.
When Lepper and Malone studied computer games, most computer games are only single user games. Therefore, the factors considered in what make computer games fun are related to intrinsic motivation. However, in a multi-user game, extrinsic motivation factors should be included. The extrinsic includes: competition, collaboration, and recognition.

Another reason for developing a multi-user instructional game is that a multi-user game has the possibility of building a situated learning environment. The game simulates a social environment that students can learn and practice the learning materials in a real situation. Lave and Wenger [Lave and Wenger, 1991] presented their idea and proposed elements about situated learning. We list the some ideas of Lave’s situated learning: Community of practice, Periphery, full participation, identity, Opportunity, learn to talk, not learn from talk, and access.

In this paper, we describe a multi-user instructional game that can motivate and guide students to learn and practice courseware on the web. This game demonstrates a way to integrate games, internet communication facilities, courseware in the web, and database techniques together for assisting learning. Thus we can promote the learning motivation of the students and prevent the students from disorientation in navigating the courseware. Besides, experiments are done to analyze the effect of the motivation factors in the game.

Related Systems

Many ideas of our multi-user game come from Multi-User Dungeon MUD games. A MUD game is a text base game. In a MUD game, there are (1) levels of players and (2) communication tool such as talk and chat room. Each level in MUD has different privileges. Thus, it forms a player community. Because it is a text base game, it provides users imagination possibilities. However, it is not suitable for elementary school students. We adopt its ideas to form a community of practice.

WebQuest [Corrina et al., 1996] is a web based instructional game. The students ramble about in the game to find related information to pass a scene. When facing with problems, the students can invoke a web browser to find the answer. The students can design their own game. Experiment shows that the students more like to design a game than to play the game. They did not try to build a community of practice in the game.

Game Script and Learning Materials

selection of the style of the game

The first thing of developing a instructional game is to design a game script and put learning materials into the game. Since a learning material always has a learning hierarchy [Gange, 1968], the game script should follows the learning hierarchy. Therefore, we decide to implement our game as a role playing for the following reasons. First, role-playing games are the most popular games in Taiwan and this style of games allows player to explore and think. Second, a role playing game always has a hierarchical script structure. Thus, it is easy to design the game script according to the learning hierarchy so navigation disorientation can be eliminated. Third, a multi-user role playing game can form an environment to serve as a community of practice.

Arranging the game script according to the learning hierarchy to prevent disorientation

Figure-1 is a learning hierarchy for arithmetic skills. Each box represents a subskill. The arrow line represents the legal learning flow. The bar line represents an and join. A student should learn all the subskills connected to the bar line.
We can design a hierarchy of script scenery based on the learning hierarchy as shown in Figure-1. The text in italic form is of the game script. Each learning element or box is a scene or an act. In the scene, the background is a place in Taipei city with roles in it which give hints, asking question, and lecturing through page in world wide web. The player is trying to get scores and the token by studying courseware or practicing exercises.

Players should get enough score or token in order to get into another act or scene. The condition of passing is stored in the bar line in the above figure. The players are free to go to any scene if they hold enough tokens and scores. Since the game script is designed based on the learning hierarchy and flows, the players will learn and practice accordingly. There are different level of roles in the game to form a Periphery community of practice.

The game is designed based on client-server architecture. The clients side, which the student or teacher faces, handles the user interaction and graphic display. The client also communicates with the server so that other players' information can be shown in the game. Also, it also sends user's behavior back to the server side. Interesting reader can download it from http://db.csie.nceu.edu.tw/~sunny/myssgi.html (in Chinese). The server contains a game server and an educational database. The game server handles the communication among players. The educational database is to record the behavior of the students.

The game also provides a mechanism for players to query the whole scene hierarchy as shown in Figure-2. Thus, the players can know where they are and where they can go. Besides, the mechanism also shows all the players in the game and the location of each player.
Building a Situated Learning Environment to Promote Learning Motivation and to Prevent Disorientation

To form a situated learning environment, we must do the following things: (1) to build a community of practice, (2) to build a set of communication tool, and (3) to encourage collaborative and cooperative working.

To build a community of practice, the game will assign each player different levels of role with different privilege. The player can query information of other members in the game. Besides, the game also provides apprentice mode to let higher level role guide lower level one in playing.

In the community of practice, members of the community should be able to communicate. Therefore, we build a set of communication tools. The communication tools includes (1) querying players status, (2) calling learning companion, (3) testing a learning companion, (4) asking a learning companion to teach, (5) getting other players as an apprentice, (6) 1-1 talking, (7) discussion room, and (8) broadcast (shout). The game script is designed to encourage collaborative and cooperative working.

Experiment and Discussion

Totally, eight classes students had used this game. Six classes (NGCAI) students play our instructional game and fill the test questions. Two classes (NGCAI) students only read courseware, do practice, and answering question which are exactly the same as embedded in our game without the game elements. After reading the learning materials, they are asked to fill the same test questions. The period for each class experiment is two hours.

For the two classes which only read materials and do practices, most of them quitted in two to three minutes. They also do not know what to do next. However, for the six classes, which play the game, most of them, played two hours. They would like to play the game even after two hours. This shows that the game elements do promote the learner’s motivation. Moreover, the students do not have problem of disorientation.

The following are the records the student actions taken in the game which are stored in the database.

<table>
<thead>

comparison for self & another  1401  35.45
CAI presented  36  0.91
virtual people hint  759  19.21

Table-1 action statistics of students playing the game

From the above statistics, the most frequent events of a player is trying to know this/her and comparing with others. This shows immediate competition can improve the student’s motivation. The second frequent actions taken are getting good and virtual person hint. These actions are the main script of the game. They are all embedded with a practice. This shows that a game can attract students to do practices.

Students like to talk to others. It may be a new experience for the students to talk in a computer game. The students may just want to talk with others by computer. In the beginning, the game asks the name of the player. The students were excited when they saw their names shown in the game.

Because the test period is limited to two hours, not many students achieve the level for shouting and calling for chat room. However, the students achieved the level still like to call for a chat room talking. In the table-1, there are 57 times and 61 times for shouting and apprenticeship mode. It illustrated that recognized by others and controlling others are fun for students even though without rewarding for that action. Most students asked questions (65 ask out of 61 apprenticeship) for their teacher in apprenticeship mode. It does provide a way to help low performance students. Table-1 shows that the students seldom read CAI courses in WWW. The major reason is that (1) students are eager to pass each scene, they are reluctant to read the courses because it is slow for passing the scene, and (2) students more like to ask other players directly because it is more efficient.

The following table is to test whether the game can promote the motivation of students as they may expected. The test sheet is designed based on Likert Scale and t test. Each question has four degrees for each : very agree, agree, disagree, and very disagree. The elements are categorized based on the motivation factors.

</tbody>
</table>

Table-2 comparison of motivation factors

From the above table, it shows that our game meets the expectation of the students. After the students played the game, all motivation factors are improved. The rank in table-2 shows the ordering of degree of motivation improvement of our game. The first three significant factors are fantasy, cognition, and curiosity. Table-1 also shows that the students feel that the most interesting factors of the game are (1) challenge, (2) competition, and (3) curiosity. After they played the game, the most interesting factors become: (1) curiosity, (2) challenge, and (3) competition. This shows that the most interesting factors of a role playing game are (1) curiosity and (2) challenge. Although the students are very concerned about other players’ score that are shown in table-1, the major driving force of keeping working on games is curiosity and challenge.
In Table-3, we compare the motivation factors for high achievement students and low achievement students. The second column shows the motivation scores of the top one-third students in the class based on the arithmetic test score. The third column is the score of bottom one-third students. The result shows that low achievement students like the game more in every part of the game. It is easier to explain that low achievement students like cooperation more because they usually need help in answering the questions. About cognition and control item, it may be that lower part students have less chance to be recognized. The problems and game script structure may be easier for them to capture for high achievement students so that the curiosity score for them is lower.

**Conclusion**

We devised a method to promote learning motivation and prevent navigation disorientation of the students by using a multi-user game that integrates web-based courseware. Effects of motivation factors are also investigated. Experiment shows a game can promote the student motivation to do practice. Moreover, most students do not have the problem of disorientation by using the game. However, to promote students to read courseware by using a game is not easy. More work left to be done to investigate how to use a game to improve the motivation of reading courseware.

Investigation also shows that low achievement students are more likely to be attracted by a multi-user game. The element of cooperation in a multi-user game is important for lower achievement students. A learning game should be designed to meet different level of students. Thus, high achievement students can feel interesting and low achievement student do not feel upset.

Communicate through computer by Chinese typing is difficult for elementary students. Further work should be done to make communication on computer easier.

Abstract: Learning to be a designer of educational media now involves a new set of skills and insights: in addition to traditional topics such as designing video products and designing computer-based tutorials, students must also learn about designing WWW-based sites for learning-related purposes. What and how do we teach them? What are guidelines for the design of WWW-based sites for learning-related purposes? And, what are guidelines for teaching about such guidelines? In this paper, we describe how we use a mixture of WWW-based functionalities and new didactics to teach educational-technology students about the design of WWW-based learning environments. We identify the set of design guidelines that we teach, and show some of the ways in which we have designed our own WWW-based course to improve the way in which we teach our students about these design guidelines. We conclude on a meta-level: What are design guidelines for teaching about design guidelines for WWW-based learning environments?

1. What is our Content in Courses about the Design of Educational WWW Environments?

Our first task is one of content: what do we want to teach our students about the design of WWW-based learning environments? Designing and producing educationally effective WWW environments involves the integration of technical considerations and skills, user-interface design, instructional design, and management and organisational aspects. Thus many perspectives have to be addressed in courses in which students are being trained to become accomplished designers of WWW environments. One of the major strengths of WWW-based environments is their elasticity: an environment can be designed as a communication center, an information center, a collaboration center, a dissemination and publication center, and a presentation center, and combinations of all of these. A site can emphasize its hyperlinking capabilities, or it can emphasize its communication and information-organization capabilities. Thus trying to teach students about good design of WWW-based environments is challenging because the subject matter is so broad. We have chosen to focus on a set of design guidelines that have applicability across this broad variety of application forms for WWW-based learning environments. By design guidelines, we mean a 'statement of good practice', expressed as concisely as possible, ideally, so that it can be remembered. 'Keep it simple' is an example of a simple-sounding but complex-to-apply design guideline.

Many different authors are now publishing lists of design guidelines. For example, [Madhumita & Kumar 1995] have written about design guidelines for instructional design, [Park & Hannafin 1993] have published guidelines about interactive multimedia, and [Wilson & Jonassen 1989] have discussed guidelines for hypertext and instructional design. A small number are now beginning to focus on guidelines for WWW-based courses (see for example, [Eekma & Collis 1996]). Sometimes sets of design guidelines are built upon design guidelines for earlier media, such as for computer-based learning products or educational multimedia. Typically design guidelines can be grouped in clusters relating to presentation aspects, to content aspects, and to instructional-approach aspects, as well as aspects specific to the sorts of media involved (i.e., for video, audio, printed materials, hyperlinked multimedia databases, WWW sites, etc.).

Based on a number of years of investigation, we have developed a set of 21 design guidelines for educational WWW sites appropriate for use with our first-year students. Ten of this are shown in [Fig. 1],
organized according to level of abstraction. These guidelines are continually evolving; we fully acknowledge their incompleteness and occasional overlap. The complete set can be seen at the URL in [Fig. 1].

**Figure 1:** Design guidelines used as content for a course in which first-year educational-technology students learn about the design of educational WWW sites [Collis, Verhagen, & Gervedink Nijhuis, 1996, 1997]

But although it has not been too difficult to find lists of criteria for the design of WWW environments, and to translate those into design guidelines for educational WWW sites, in our own ongoing search of references we have not found any design guidelines for the meta-level: design guidelines for teaching about design guidelines... How do we teach about design guidelines for WWW environments to first-year students? In this report we will show our approach.
2. Teaching About Design Guidelines for Educational WWW Environments

The course "ISM-1" is a required subject for first-year students in the Faculty of Educational Science and Technology at the University of Twente ("ISM" are the initials of the department in this faculty that specializes in educational media). Approximately 70 students are enrolled, and the course lasts the entire academic year, divided over three trimesters. During each trimester, the students work in groups to design and produce different types of educational media products, for different purposes. These products include desktop-published print materials, educational videos, and WWW environments that include Java Script-based interactivity and multimedia resources made by the students themselves (for example, Quicktime movies made by the students and integrated into educationally oriented WWW sites, where questions and answers about the message of the movies are presented via different JavaScript constructions). WWW environments are part of each of the product sets during each trimester, so the students develop in their skill and experience in designing and producing such environments over the year. The course is organized about five traditional lectures per trimester, and these group projects. (For a full description, see [Collis, Verhagen, Gervedink Nijhuis, & Meeuwsen, 1996]. The entire course is supported by an integrated and complex WWW environment, about which much has been written (see for example, [Collis, Andernach, & Van Diepen, 1997]. The course can be visited at http://www.to.utwente.nl/ism/ism1-97/home.htm.

Our main strategy for teaching about the design guidelines is to use them as the way to integrate the theory and the practical aspects of the course. The design guidelines are developed week by week, in our study materials, used to shape the way students look at and evaluate WWW sites made by others, and used as the criteria for the students' own design work. In addition, and perhaps most powerful in terms of student motivation, the design guidelines developed in the theory part of the course are the basis for the mark given to the students when evaluating the WWW sites they produce themselves in the projects. [Fig. 2] shows a typical study page for a design guideline, including a link to an external site that illustrates the guideline in practice.

Figure 2: An example of study material relating to a particular design guideline.
[Fig. 3] Shows one of the on-line exercises that students do after each week's study about design guidelines.

Questions to submit

To answer the questions, type your name, your email address, a subject, and your message text. Once complete, press the "Submit" button. If you want to start over, press the "Clear" button to erase all the fields. You may answer in Dutch or in English, whatever suits you best.

Your full name:
Your group number:
Your e-mail address:

Question 1. Please name one of the guidelines of this week and describe how you want to use it for your own WWW site.

Guideline:

How I will use this on my WWW site:

Figure 3: A typical on-line exercise.

Parallel to this, the students apply the design guidelines in their own work. They do this by using them as the criteria by which they evaluate their own group's site, the criteria for peer review of the sites of the other groups, as criteria for the on-going and final evaluations of their sites by the course team, and as the basis of the final presentation and reflection that they must do about their work. [Fig. 4] shows a part of the results of self-evaluation.

BEST COPY AVAILABLE
Our site is a good example of:

10: Place navigational buttons on the same location on the screen throughout a program, so that the user can always find them in the same place.

Because:
De knoppen staan steeds op een rij onderaan de pagina en zijn dus altijd op dezelfde plek terug te vinden.

13: The user automatically generates a mental model of the web site....

Because:
Door de pagina's allemaal dezelfde kleur als de knoppen te geven weet de gebruiker waar hij/zij zit. De pagina's zijn ook op soortgelijke wijze vorm gegeven wat het geheel ook consistent mak, zodat er gemakkelijker een mentaal beeld te vormen is.

Figure 4: A part of the results of self-evaluation in which guidelines are used.

3. Issues Relating to Teaching about Design Guidelines

Although we have made significant progress in developing our instructional strategies for teaching first-year students about design guidelines for educational WWW environments, we are still concerned about a number of aspects and are carrying out research to investigate further how to design WWW environments to better support good teaching and learning about design guidelines for WWW-based learning resources [Winnips 1997]. Key among these concerns are:

1. How can our content in terms of the choice and wording of the design guidelines be improved?
2. How can we measure the students' growth in understanding about these design guidelines? (The students have indicated that the guidelines are so clear and sensible, that they can come to "know them" without much effort. How do we indicate levels of wisdom and insight in terms of applying a guideline such as "Keep it simple?" to the design of a WWW environment?]
3. How can we measure the impact of our own teaching strategies on this growth? In particular, how can we design and use our course WWW site as a powerful learning environment relating to these design guidelines?
4. How can we most effectively scaffold [Jonassen 1996] the students in the application of the design guidelines? How can scaffolding procedures be designed as part of our WWW-based course environment? How can we measure the impact of the different forms of scaffolding we are trying to use in our course?
5. Looking at the problem from the course designers' perspective: how do we design a WWW-based resource to help students learn design guidelines for WWW-based resources?
6. Finally, from an instructor's perspective, what are design guidelines for teaching about design guidelines with the support of WWW environments?

We conclude this paper with a brief reflection on the last question.
4. A Preliminary List of Guidelines for Teaching about Guidelines for WWW-Based Learning Materials

Based on our experiences with three years' of the ISM-1 course and the use of a WWW-based course environment as well as design guidelines in those three cycles, we offer the following provisional set of design guidelines for others who wish to teach their students about design guidelines for WWW-based learning resources:

- Provide many different ways to apply the guidelines, ranging from using them to categorise external sites, to criteria for evaluating the students' own work.
- Repeatedly give opportunities for articulating the design guidelines, using them to explain one's opinion about a WWW site [Vermunt 1992], ranging from memorising to creating one's own guideline (reflecting).
- Scaffold the explanation and examples, providing detailed comments to begin and also less-detailed points; scaffold the pedagogy, from explicit exercises to implicit appreciation.
- Find a measure of student progress, and collect data to show improvement.

NetTest: A General Purpose Web-Based Assessment and Teaching Tool

Donald H. Cooley, Jianping Zhang, Yun Ni
Computer Science Department, Utah State University, Logan, Utah, USA
cooley@don.cs.usu.edu

Abstract: With the advent of computers, multimedia learning systems, and the Internet, technology use in education has increased tremendously. As electronic delivery of educational material increases, the need for an electronic means to assess learning also increases. This paper describes NetTest, an Internet-based tool which can be used for multiple forms of assessment of knowledge or competencies. An important feature of NetTest is the breadth of question categories that it can deliver. In addition to multiple choice and true/false questions; matching, sequencing, fill-in-the-blank, graphics, essay, and performance-based questions are allowed. Along with a variety of question types, NetTest has extensive authoring, management, and security features. Since NetTest is Java-based, it can be accessed from any system with a Java-enabled browser. While NetTest was initially designed as an assessment tool, extensions to NetTest enable it to function for both assessment and teaching. Using author-enabled feedback, NetTest can teach as well as assess.

1. NetTest: An Assessment Tool

NetTest consists of four elements: a test taking/delivery system (TTDS); a test management system (TMS); a test authoring system (TAS); and a user interface. The TTDS controls user and author access to the test and statistical databases. This element also provides the multiple levels of security in NetTest that are critical for use in an educational environment. The TMS provides the means by which a manager or instructor controls access to the system and generates reports on student progress, performance, etc. NetTest's TAS allows instructors to create and edit tests for inclusion in the test database. The foundation for NetTest is a set of databases which contain student, test, and performance data. The test database contains all of the tests for NetTest. The student database contains student information for log on security, class status, test results, etc. The performance database contains information about overall test performance, question correct/incorrect rates, etc. The user interface runs under the student's Java-enabled browser. It is the means by which one navigates in NetTest and issues commands.

2. Test Taking/Delivery

NetTest is a Java-based Web-enabled system and hence, through the Internet, someone with a Java-enabled browser can access and use NetTest. Currently, because of browser incompatibilities, NetTest only runs under Netscape 4.0 or higher. The TTDS interfaces to the student and test manager components to assemble and deliver a test to a student. In order to access NetTest, a user must have a valid username and password.

Once a user selects a test, NetTest extracts from the database for that test a subset of the questions in the database. In building the test database for a particular subject, an author categorizes questions into sections. Typically, a section consists of a set of questions designed to measure a particular competency or skill level. At the time of authoring, one must also specify the number of questions to be selected from a section. For diversity among tests on a subject, the author should generate considerably more questions for a section than the number to be selected for an individual test. Using a possibly different number for each section, the system randomly selects questions from the database. These questions are then combined to form a single test. The order of the questions in the test is also randomized and for multiple answer questions such as multiple choice, the order of the choices is randomized.

At the highest level, NetTest allows for two general categories of tests; secured and not-secured, and three general categories of questions: pre-test, required, and general. A secured test is one which not only requires that the student be logged on with a valid username and password, but that a program manager also have generated
a request for a test for this student. Normally, this means that the student has identified him/herself to the manager by showing a valid picture id. For the not-secured test, the student only needs to log onto the system and select the desired test.

NetTest’s three question categories allow for testing of initial knowledge of the subject (pre-test); specific knowledge (required), and/or general subject knowledge (general). Using pre-test questions, it is possible to develop an initial knowledge or background test for a subject. In such a case, when a student enters NetTest and selects a test for a subject, they can choose to take a pre-test or a general test. If pre-test is selected, the system randomizes and delivers all of the pre-test questions for that subject. The author has the option to require or not require a pre-test. However, once taken, a pre-test cannot be re-taken.

When a student chooses to take a general or standard test, all required questions are selected, and then, based on the author-set section quantities, other questions are selected to produce a complete test.

### 2.1 Test Security

NetTest has several levels or types of security. They are: Log On, every user must log on with a valid username and password; Secured Test, a secured test can only be taken after a user has logged on, and a program manager has unlocked that specific test; Class Requirement, only a student registered for a particular class (or some other identification) is allowed to take such a test; IP Address, a test will be delivered only to the machine(s) with specified IP address(es); and Time Stamp, a test can only be taken on a specific day(s) at a specific time(s). These security levels are not mutually exclusive. For example, a test can be secured so that it is only delivered to systems with certain IP addresses, on a particular day, to students registered for a particular class.

### 2.2 Question Categories

Seven different categories of questions are currently allowed in NetTest. The categories or types are: true/false, multiple choice (one or more correct answers), sequencing (place the shown steps in proper order), fill-in-the-blank (up to 10 variations or spellings can be scanned and accepted), matching (match items in column A with those in column B), essay, and performance-based. Except for performance-based questions, all questions, regardless of type, have the same user interface. In addition to text-based questions, it is possible to have a graphic associated with each of the first six question categories. Figures 1 and 2 are examples of two such questions; namely, multiple choice and essay.

When a student exits a test, the questions in the test are automatically graded, except essay and performance-based questions. The student is also notified of their score, and the student and test result databases are updated. If enabled, the instructor will be notified (by e-mail) that the student has completed the test, the score they received, and the time the test was taken. Finally, also if author enabled, NetTest will give the student feedback as to the results for specific questions. It is its multi-level or extended feedback capability that represents one of NetTest’s most important capabilities. Rather than simply telling the student whether or not they have answered a question correctly, and possibly, what the correct answer is, NetTest can present a variety of additional information to assist the student to understand the answer. Such information may be textual, graphic, bibliographic, links to other web sites, and video/audio information such as specific feedback recorded by the instructor. For a class, this feedback could at least include references to the text where the tested material is presented. Answer feedback can also be set to be given only after a particular date/time. In this way the instructor can control security for question answers.

### 2.3 Essay Questions

Essay questions represent a special question category that the system is not able to automatically grade. When a student completes a test containing an essay question(s), the essay question answers, i.e. the student’s written responses, are stored in a secured database and an e-mail message is sent to the author assigned address of the grader. At their convenience, the grader can then enter NetTest and call up the student’s answer to read and
grade. Once grading is complete, the grader assigned scores for these questions are used to update the student’s
total score, and the student is also notified by e-mail of their score. In addition to assigning a score, through the
NetTest interface, the grader can add comments to the student’s essay to give additional feedback. Hence, when the
question is graded, the student receives not only a score, but an annotated evaluation of their essay. These comments
will be in addition to the more generic feedback that can be included as with other types of questions, i.e. locations
in the text where the subject matter for the questions is discussed, etc.

While not another question category, bundled essay questions are also allowed. In bundling, the author
develops 2-4 sets of essay questions. For such questions, NetTest will randomly select one question from each set
and then deliver all to the student as a single essay question with the instruction that they are to answer only one of
the set in the essay answer window.

2.4 Performance-based Questions

Like essay questions, performance-based (PB) questions are a special category. Upon completion of a test,
the results for these questions are also transmitted to an author-specified site for grading. PB questions represent a
powerful extension to standard CBT systems. A PB test is a set of PB questions associated with a particular
software tool or product. In order to execute a PB test, it is necessary that the host system have a copy of the specific
software on which performance is to be measured. For a PB test, a screen as in figure 3 will be displayed. Normally
PB questions are used in conjunction with a specific software product. For example, if an instructor wished to test
competency in the use of a word processor such as MS Word, they could do so most effectively using a PB test.

A PB test has three components: an environment, an initial state, and a sequence of PB questions. The
environment is the software product on which the PB test is given. This product may be a standard commercial
software product such as Corel’s WordPerfect, or it may be more special purpose such as a chemistry laboratory
simulation tool. The initial state for a PB test is typically an initial file. For a document processing PB test, the initial
state might be an initial document file on which students are to make changes, additions, corrections, etc. The PB
questions are those operations that the student is to perform. Answering such questions results in a change of the
system’s state. As an example, for a spreadsheet PB test, there might be a PB question such as *set the format of cell
B12 to currency*. Figure 3 shows the user interface for a PB test. The top portion of the screen is the actual product,
and the bottom portion is a set of PB questions. When DONE NetTest transmits the system’s final state, in this case
the modified file, to an author assigned location for grading. This form of question also allows for a much more
flexible assessment of competency. In this environment, when versions of a software product change, PB questions
need not change. This is because PB questions are couched in terms of the performance of a particular task not in
terms of how that task is performed. A question such as “What are the keystrokes needed to...”, is not version
independent.

The random selection process is also slightly different for PB tests. Normally, an author will create several
PB tests with associated initial state and PB questions. At time of test initiation, the system randomly selects and
delivers from this database a single PB test with its associated PB questions.

3. Test management system

NetTest’s test management system controls access to the test, user, and statistics databases. The
functionality of this part of NetTest is accessed through the various user interfaces.

3.1 Test Database

The test database is simply a database of tests, where a test is a set of test questions categorized by section.
Ownership for a test is assigned to the author of the test. A test owner can give that privilege to other authors to
allow for more than one person to edit a test. However, the more common security level is read/copy access. With
this level of security, an individual can copy another’s test; rename it, and then proceed to edit it under their own
authorship. Once a test is authored, an owner can revisit the test to edit, add, or delete questions.
3.2 User Database

In the user database is stored user information, such as user type, class registration (if they are a student), current status, i.e. tests passed to date, etc.

3.3 Statistics Database

This database stores most of the data used in the generation of test results. For example, in addition to data about test taking results, a record is maintained for every question in every test indicating the number of times it was answered correctly and the number of times incorrectly.

4. Test Authoring System

The test authoring system is that portion of NetTest that allows an instructor to create or edit a test for inclusion in the test database. The process of entering or editing tests is performed in a template fill-in environment and hence is relatively straightforward. Figure 4 is an example of such a template for a multiple choice question.

5. User Interface

Depending on the type and operating mode of the user, there are three user environments or interfaces. Specifically, a student interface, an author interface, and a program manager interface. As shown in the preceding figures, the interface is a windows-like environment with most operations performed in a point-and-click mode. Where specific input is needed, it is generally template fill-in.

Program managers are responsible for security, test management, and report generation. Instructors can also perform certain generation operations. Like the other interfaces, the program manager interface is a point-and-click environment. Program manager functions include creating or deleting student, manager, and/or instructor accounts; generating a report on the passing rate for a selected test(s); unlocking a secured test for a student; etc. There are also different levels of security for program managers. For example, a program manager can be given only test unlock privileges, in which case they cannot edit or remove accounts, etc.

Two of the most useful reports generated by NetTest are question pass rates (QPR) and student performance (SP). The QPR report lists all questions in a given test and the frequency with which they were answered correctly and incorrectly. Such a report is useful for question and test validity analyses. The SP report is much like a grade list. In fact, such a report can be saved to disk in spreadsheet format for use and editing by an instructor. Another important feature of NetTest is that all databases are SQL format. This means that with proper security clearance, someone can access this database to generate their own report(s). Currently NetTest uses MS/SQ and JDBMS for its database system. In the near future we will port it to an Oracle SQL environment.

Summary

While work on NetTest is on-going, it should also be recognized that NetTest is a real product. It is the goal of the multimedia research group at Utah State University to continue to expand the capabilities of NetTest, and to find applications for NetTest which will test and verify its utility. The authors believe that NetTest is one of the more powerful assessment tools currently available and as such, are working to establish relationships with potential users of NetTest.

When an instructor authors a test, if they spend the additional time needed to include resources for feedback, we believe NetTest can be an effective teaching as well as an assessment tool. The PB assessment capability of NetTest means that it can assess competency in the use of specific software tools such as word processing or spreadsheet programs. Furthermore, this capability means that when NetTest is integrated with specialized software, e.g., a laboratory simulation tool, it can be used for assessment in laboratory-based classes.
such biology, chemistry, or physics. Currently NetTest is being used for challenge examinations in US History and Economics. Beginning Fall, 1998, with the opening of USU's computer-based testing facility, NetTest will be used for campus-wide testing of computer literacy.

Figure 1: Multiple Choice Question

Question:
1. For copyrighted software with all rights reserved, which is not one of the rights typically reserved?
   A. You are not to copy or use the software without the copyright holder's permission.
   B. You are not to modify and redistribute the software more than one copy.
   C. You are not to make the software available for public use if the software is
      purchased.
   D. You are not to provide or distribute any software to anyone, unless you keep
      a backup copy for yourself.
   E. You are not to modify the software.

What is your choice?
- A  - B  - C  - D  - E

Dynamic Content
A New Model for Collaborative Learning Environments for Language and Culture Studies

Ellen Crocker, Foreign Languages and Literatures, Massachusetts Institute of Technology, Cambridge, MA, USA, ecrocker@mit.edu

Kurt Fendt, Foreign Languages and Literatures, Massachusetts Institute of Technology, Cambridge, MA, USA, fendt@mit.edu

Abstract: This paper investigates the potential of dynamic content structures in non-linear educational media. On the basis of a Web-based, collaborative hypermedia learning environment for German Culture and Language Studies, titled “Berliner sehen”, the presenters will explain the concept of dynamic content and the resulting new forms of student interactions. Authentic personal life stories in “Berliner sehen” in conjunction with a rich archive of relevant current and historical documents encourage students not only to explore the lives of Berlin residents and the multiple stories they tell about their neighborhoods, past and current events, places and people but also provides students with the capability to reconfigure at will the media contexts to create their own “mini-stories” and “mini-documentaries”.

The Project

The Berliner sehen project combines an interactive narrative approach with the genre of an interactive documentary to form a new hybrid: a collaborative hypermedia learning environment. Experimentation shows that this new hybrid genre provides students with a variety of ways to explore notions of culture through language from multiple points of view. Non-linear modes of accessing the material in Berliner sehen are supported by a narrative structure that is based on individuals’ life stories told by residents of both parts of the formerly divided city of Berlin.

The core video material, filmed specifically for the project, depicts nearly 50 residents of Berlin from all walks of life and in a variety of conversational constellations. Eight Berliners and their intersecting life stories in neighborhoods in east and west Berlin provide a common narrative structure in their conversations with family members, friends, neighbors, and colleagues. In these natural, non-scripted conversations and discussions the residents bring up a broad array of private, social, political, current and historical issues that pertain to their personal perspectives on cultural change as east meets west. One of the recurring themes is the changing face of the re-unified city that can be seen in city redevelopment projects and the process of gentrification. The hypermedia archives contain supporting documentary materials that provide a particular focus on such overarching themes in the core video material.

Pedagogically, we proceed from a model that combines the learning of culture through narratives and encourages students to investigate authentic contexts of language discourse. We do not follow a conventional top-down approach that would describe, explain or synthesize information about the culture in a thematic framework. The core video of conversations among Berlin residents provides the students with an insider’s perspective on life stories as they are embedded in the larger social context and cultural history of the city. The insider’s perspective
is doubled by the specific cultural context of life in Berlin today, a city in which two German cultures confront each other. West Berliners and East Berliners each provide us with an insider’s perspective to their respective German cultures as well as an outsider’s perspective to each other’s culture. By juxtaposing these perspectives students gain a unique position from which they learn about culture through the words and the original stories of the people who live in that culture.

The structure of the core video is based on principles of hypermedia rather than a linear or hierarchical structure. In such a structure there are multiple points of entry rather than a specific beginning or ending point. This structure allows for the units of content to be re-configured according to the user’s perspective rather than limiting the user to a fixed configuration. Since the order in which a user views a particular segment of the video material is not predetermined, each segment of the video has meaning as a separate autonomous unit and at the same time can easily be linked to other segments in a meaningful way. The narrative structure of the eight individual life stories of the Berlin residents provides a key relationship that connects all of the video segments. Narrative structure as a principle of hypermedia design serves here to orient the user without imposing a linear structure on the documentary.

The prototype of an interface component of “Berliner sehen” depicts the dynamically reconfigurable workspace with the so-called perspectives on the right. While in browsing mode, students can select any combination of persons and notions to display a permutation of media documents that provide a context for study:
The Concept

The concept of dynamic content builds upon the original idea of Hypertext, as it was first described by Vannevar Bush in "As we may think" [Bush1945] and later by Theodor Nelson in "Literary Machines" [Nelson 1987]. Bush argues that our current methods of storage and retrieval of information are inadequate:

“Our ineptitude in getting at the record is largely caused by the artificiality of systems of indexing. When data of any sort are placed in storage, they are filed alphabetically or numerically, and information is found (when it is) by tracing it down from subclass to subclass. It can be in only one place, unless duplicates are used; one has to have rules as to which path will locate it, and the rules are cumbersome. Having found one item, moreover, one has to emerge from the system and re-enter on a new path.” [Bush1945, 106]

According to Bush, the storage and the manipulation of data are operations that can easily be automated. Retrieving data, however, is a highly creative process that requires new approaches for it to be automated. Existing techniques of retrieving information, he argues further, heavily rely on relatively inflexible systems of artificial content structures that have no equivalent in human thinking:

“The human mind does not work that way. It operates by association. With one item in its grasp, it snaps instantly to the next that is suggested by the association of thoughts, in accordance with some intricate web of trails carried by the cells of the brain. It has other characteristics, of course; trails that are not frequently followed are prone to fade, items are not fully permanent, memory is transitory. Yet the speed of action, the intricacy of trails, the detail of mental pictures, is awe-inspiring beyond all else nature. Man can not hope fully to duplicate this mental process artificially, but he certainly ought to be able to learn from it.” [Bush1945, 106]

As a solution to the problem, Bush developed the concept for the so-called MEMEX, the memory expander, which - in 1945 - was a mechanical device. A closer look at how a user can interact with documents, already provides useful insights to the basic design principles for a system of dynamic content:

“The owner of the memex, let us say, is interested in the origin and the properties of the bow and arrow. Specifically he is studying why the short Turkish bow was apparently superior to the English long bow in the skirmishes of the Crusades. He has dozens of possible pertinent books and articles in his memex. First he runs through an encyclopedia, finds an interesting but sketchy article, leaves it projected. Next, in a history, he finds another pertinent item, and ties the two together. Thus he goes, building a trail of many items. Occasionally he inserts a comment of his own, either linking it into the main trail or joining it by a side trail to a particular item. When it becomes evident that the elastic properties of available materials had a great deal to do with the bow, he branches off on a side trail which takes him through textbooks of elasticity and tables of physical constants. He inserts a page of longhand analysis of his own. Thus he builds a trail of his interest through the maze of materials available to him.” [Bush1945, 107]

Systems that connect media documents through fixed links, e.g. the WorldWideWeb, share merely the connectivity feature of hypertext. The model of dynamic content on the other hand replaces fixed links with reconfigurable dynamic links. This paradigm permits a flexible and individualized approach to retrieving information without restricting the user by fixed ordering schemes. In conjunction with a provision for collecting materials, systems of dynamic content offer students a rich learning tool that fosters high-level thinking skills such as hypothesizing, application, analysis, synthesis, and evaluation. It further promotes cross disciplinary interactive approaches that enhance motivation by allowing users to influence the outcome, to follow
divergent paths, and to experiment with different interpretations of the material. A dynamic learning environment for cultural studies such as “Berliner sehen” lets student access the otherwise ‘hidden layers’ of a foreign culture by juxtaposing cross-cultural content and personal perspectives.

The integrated networking capabilities of “Berliner sehen” provide students with a collaborative workspace that can be shared flexibly across Intranets and the Internet. Whether students are in one location or in several culturally different regions, they can collaborate to reconfigure the core material in ways that reflect their respective views of specific cultural notions. Students offer ‘their’ interpretations of the “Berliner sehen” materials by publicizing them to the network. This approach permits learners unique insights in the process of culturally dependent interpretation.

The Technology

“Berliner sehen” as a model for a dynamic content system is built on top of a complex database structure written in Java. The content of the core archive consists of more than thousand video clips in MPEG-1 format as well as thousands of historical and personal photos and documents. The Berliner sehen archives, including all texts, images, audio and video, are stored in a hybrid local/ networked fashion. The core video material and other copyrighted documents will be distributed in a variety of formats: on high-density DVD-ROMs, via an INTERNET-2 connection, and on multiple CD-ROMs for upload to an Intranet server; depending on the institutional set up, all other material collections are stored locally, on Intranet servers, or can be accessed through the central project server at MIT. Developed in the Java programming language combined with the QuickTime media format, this approach takes advantage of the latest developments in media technology, without compromising the potential for distribution on a variety of low-cost computer platforms. Berliner sehen is constructed as an open system that allows students not only to expand the archives but also to collaborate on the construction of new collections that can be made available to other users over networks.

A Coordinated Browsing System

Abstract: Java is enabling Web applications to be richer and more interactive. It is now becoming feasible to build collaborative Web applications. This work focuses on a synchronous class of collaborative applications. A coordinated browsing system was built, which allows a group of users to “surf” the Web together (where users have the capability to be geographically distributed, possibly working on different platforms). In this environment when a user in the group loads a new document from a site, the same document gets loaded on all the other users’ Web browsers. The proposed coordinated browsing system works on any platform that supports a graphical Web browser with Java capability. Advantages are two fold: in our approach it is not necessary for every user in the group to have the same browser, nor do we modify the browser.

1. INTRODUCTION

The World Wide Web is growing exponentially, thus, making it an attractive framework for a wide variety of applications. Today the World Wide Web is the most cost-effective way to share information among geographically dispersed users. The graphical Web browser’s ease of use makes internationally distributed multimedia information accessible to anyone with access to the Internet. The Web seamlessly connects disparate hardware platforms running different operating system in diverse locations. With the advent of Java technology, Web applications can now support collaboration.

The focus of this work is to develop a synchronous class of Web based Java collaborative applications. More specifically, we are looking at coordinated browsing (co-browsing) which allows a group of users to “surf” the web together (where users have the capability to be geographically distributed, possibly working on different platforms). When a user in the group loads a new document from a site, the same document gets loaded on all other users’ Web browsers. Coordinated Web browsing, along with audio support, can be used effectively in many situations to increase productivity. Some example scenarios in a teaching environment are:
1. **Group of students**: Courses that are project oriented might require students to collectively research or explore information on the Web. For example, a group of students may be working together to write a report on the subject of computer security. For this, students may decide to research the material together to identify papers that they can use for writing the report.

2. **Group of students and an instructor**: When an instructor holds a recitation session with a group of students to explain or elaborate on some concepts discussed earlier in the class, an instructor may find it useful to use different media, such as animation and video available in a digital library, to explain a breadth-first search algorithm.

3. **An instructor and a student**: When a student wishes to interact with the instructor about a specific question, the instructor may find it appropriate to co-browse material from the lecture for that course.

Recently, many collaborative Web applications have been developed [Bhatia 97, Chen 97, Hoshi 92, Maly 97a, Maly 97b, Toye 94, Rees 93, Beca 97, Davis 97]. Most of these approaches either require modification of the browser or are based on the X Window System protocol. However, these approaches do not lend themselves easily to a group of users working on multiple platforms (such as Unix, Windows NT, MacOS, and Windows95) concurrently.

This paper describes an approach that works on any platform that supports a graphical Web browser with Java capability. Most new Web browsers, such as the Netscape and Microsoft Internet Explorer, have this capability. Also, in this approach it is not necessary for every user in the group to have the same browser. It is feasible for some users in the group to use Netscape while others use Microsoft Internet Explorer. Another advantage of this approach is that it does not modify the browser. Coordinated browsing can be integrated with audio to enable users to speak while browsing. However, this paper will only discuss the coordinated browsing architecture and its implementation.

The rest of the paper is organized as follows: Section 2 presents the architecture of the coordinated browsing system, Section 3 discusses the design and implementation issues faced, Section 4 describes the current prototype, and in Section 5 Conclusions and future work are detailed.

## 2. CO-BROWSING SYSTEM ARCHITECTURE

When a user in the group loads a document from a site in a co-browsing session, the same documents is loaded on all the other users' Web browsers. The main attribute that makes co-browsing possible is its ability to intercept a Web browser's request for a document and communicate it to other browsers in the session. The other browsers, on receiving this information, download the same document. We use a modified proxy server to intercept requests from various Web browsers in a co-browsing session. A Web browser, once configured to use a proxy server, sends the complete URL request to the proxy server. The proxy server, in turn, opens a connection to the requested URL Web server, makes the HTTP request, and then sends back the result to the Web browser. Traditionally, a proxy server has been used to provide Web services across a firewall, or to locally cache remote documents to reduce network traffic. Java applet technology has been employed to enable Web browsers in a session to receive information about document requests. Web browsers in a co-browsing session always have an applet running to receive these request updates. In addition, software is also needed which will keep track of the active Web browsers in a session. This software will communicate with the applets. Methods are also needed to allow a Web browser to join a co-browsing session.

The following is a description of the co-browsing architecture for a single group of client browsers. This system will be referred to as "the single-group architecture." The number of clients supported by a single-group architecture is determined by the hardware and software characteristics of the machines involved. A
discussion on how the single-group architecture can be extended into a hierarchy of groups to support large
number of users will follow. The objective of the overall design is to achieve cross-platform support, and to
allow for the use of standard web browsers and servers (without modification).

Single-group Architecture

The single-group architecture along with its various components and how they interact is shown in Figure
1. The co-browsing architecture consists of (i) a Central Proxy Server (CPS), and (ii) a Central Registration
Service (CRS) that consists of a standard Web Server (WS) and a Registration Server (RS). In this section
we look at the functional description of these modules and how they interact to support a co-browsing
session. In the next section we discuss the design and implementation issues for these modules.

![Diagram of Single-group Architecture](image)

**Figure 1:** Single-group architecture for co-browsing system.

To help illustrate the working of the co-browsing architecture the following example describes a situation
where a new user joins an ongoing co-browsing session of two users. To keep this explanation simple,
certain assumptions have been made: the user in a co-browsing session only download simple HTML
documents without any embedded images, the user never clicks a link with its target set to “main”. These
issues, along with their impact on the overall co-browsing architecture design, will be discussed in the next
section.
Step 1. The new user downloads a registration document served by the CRS-WS [Fig. 2]. This document has information about the existing users in the group. Once the user selects to join the group, she receives a two-frame web page. One frame of this web page is visually hidden from the user and contains an embedded applet along with a parameter containing the URL of the current document being viewed (http://www.some.site/doc0.html) by the group. The browser downloads the applet and runs it. First, the applet registers itself with the RS. Note, due to security restriction of Java applets, the RS and WS have to be on the same host. The Java applet security environment does not allow applets to communicate to any host other than the host from where it is downloaded. The applet registration process involves informing the RS it is active and the port number at which it will be listening. Upon receiving this information, the RS updates its table of active Web browsers in the session [Fig. 3]. Second, the Java applet downloads the current document being viewed by the group into its second frame. Recall that the URL of the current document is passed by the RS as one of the parameters to the embedded applet. The Java applet remains active until the user leaves the co-browsing session. Since all new documents are loaded into the second frame, the embedded applet remains active. However, the applet will stop running if a new document is loaded in the main window. This issue will be discussed in the next section.

Step 2. User-1 clicks on a link that points to the URL "http://www.some.site/doc1.html". User-1's browser sends the request to the proxy server, which performs the following two functions:

(i) it makes a connection with the host "www.some.site", gets the document "doc1.html", and sends it back to User-1's browser. It also caches the document for further distribution.

(ii) it passes the requested URL along with the requested Web browser information to the RS.

Step 3. The RS on receiving information from the CPS, sends the URL "http://www.some.site/doc1.html" to the applets running on User-2 and User-3's Web browsers. Note that the RS does not send the URL information to the browser that originated the request. The applets, upon receiving the URL information, issue a request to their respective browsers to load the new document in the second frame.

Step 4. User-2 and User-3's Web browsers send the request for "http://www.some.site/doc1.html" to the CPS. The CPS serves these requests from its cache. These requests are not forwarded to the RS.

Figure 2: A new user requests the registration document for joining a co-browsing session.
Figure 3: An applet registers with the registration server. The Registration server updates its table of active Web browsers in the co-browsing session.

3. DESIGN AND IMPLEMENTATION ISSUES

To build a working co-browsing system, the following design and implementation issues must be addressed:

- What happens if a user in a co-browsing session loads a complex HTML document that requires multiple HTTP requests by the browser?

- What happens if multiple users in a session concurrently try to load different documents?

- What happens if a user clicks on a link with its target set to the main browser window?

- What happens if one of the browsers is on a slow machine or on a slow network connection?

For a full discussion of these issues, please refer to [Davis 97].

4. PROTOTYPE

The current prototype implements a single group architecture. The prototype system was designed using the Java 1.0 development kit and is currently being updated to Java 1.1 in order to take advantage of any performance increases and additional features the new JDK might offer. Java is the language of choice for the Central Proxy Server and Central Registration Server because it is platform independent. The detailed implementation of the Central Registration Server, and the Central Proxy Server are discussed in [Davis 97].

5. CONCLUSION
This paper proposes a co-browsing architecture that allows a group of users to "surf" the web together. The proposed architecture works with any graphical Web browser that supports Java applets. The users may potentially be geographically separated and working on different platforms. The system was demonstrated by building a single group architecture that is able to support a co-browsing session for 100 users at any given time. The possibility of implementing a scalable hierarchical-group architecture is speculation at this time.

Features such as asynchronous support are planned for the future. Students and teachers will be able to create a scripted tour of several Internet sites and register this tour with the proxy server. Users can then access a series of pre-scripted WWW locations. Support for page annotations will also be included for the pages placed in a tour. Providing a means for asynchronous use will facilitate the creation of reusable courseware materials. It also allows greater flexibility for large groups of students working together whose respective time constraints (work, parenting, etc.) would otherwise prohibit traditional collaborative methods. Once the complete Java Media APIs are available, audio will also be supported with the co-browsing architecture. This feature will enable co-browsing participants to have simultaneous audio and web browsing potentials.

Abstract: World Wide Web (WWW) "home pages" are now ubiquitous for universities around the world. A university home page is the first place that many stakeholders will be visit for research on the university or for information on a variety of topics. It was hypothesised that the size and nature of universities and their investment in the staffing of WWW sites will determine the level of output of WWW sites. A WWW-based survey was conducted of Webmanagers at all universities in Australia. A response rate of 80% was achieved. The number of services provided, the number of pages made available and the number of pages that are changed on a regular basis were alternative measures of output. The hypothesised relationship between size and nature and output was not supported. There was limited support for the hypothesised relationship between staffing levels and output.

Introduction

This paper introduces an empirical analysis of the strategic development of the World Wide Web (WWW) by university management in the Australian context. The WWW has wrought major changes in the manner which universities communicate with students, faculty, and the wider community. Many universities worldwide and certainly every university in Australia have at least one WWW server and a "home page". The services provided by these sites range from relatively simple introductions to the institution to large and highly complex, multimedia institutional encyclopaedia. The home page has, in a very few years, become a core element of University public relations, information management and dissemination and to a lesser extent a snapshot of its teaching, learning and research activities.

Yet the development of the WWW in the university setting has been the subject of very little research. The research, which has been conducted, has been largely descriptive of the issues that have arisen within a single institution. An extensive literature search has not disclosed any published research that investigates the development or management of the WWW across a large panel of universities. The research described in this paper was designed to fill this gap in the educational technology research literature. The research also analyses the factors that explain the size, complexity and state of the university web sites. The remainder of this paper proceeds as follows. The next section sets out the background to the study and introduces the survey that is at the heart of this research. The following two sections analyse the model and the results of the survey. A summary and conclusion follow these sections. The necessity for and direction of further research in this area is explored.

The Study

An important development in information technology (IT) provision in universities recent years has been the arrival of the WWW site. For many external parties, such as journalists, potential students and academics from other institutions, the university WWW site is now the first and often only source of information. Faculty, staff
and students also use the WWW site for administrative, teaching and learning purposes. It would be unthinkable in the late 1990s for a university of any size whatsoever not to have a WWW “home page”.

University WWW sites varies in scale and complexity. Some provide little more than a quick snapshot of the university. Others are highly complex including information on current events, university handbooks, staff and student contact databases and interfaces to administrative applications. The management of WWW in universities is not a typical IT function as it involves elements of IT, public and alumni relations, student administration as well as input from faculties or schools and individual faculty and students.

At the same time as the WWW has arrived in the university, central university IT facilities are experiencing very rapid increases in demand for resources [McClure, Smith, & Sitko, 1997, Ellis & Debreceny, 1997a, Debreceny & Ellis, In Press]. IT managers feel that they are almost under siege as new classes of users demand a wide variety of services. As [McClure, Smith, & Sitko, 1997] note “a decade ago, fewer than 20 percent of our faculty, staff and students were active consumers of technology services and support. Today, almost all of them are, at least to some degree. ... The educational potential of the Web alone has unleashed a firestorm of support demands, not to mention escalating printing costs in public labs.” (p 2). Problems for central IT management include upgrading of computer networks, provision of adequate on-campus laboratories and off-campus connectivity [See CAUSE, 1997].

Despite the ubiquity of the WWW in the university sector, there is surprisingly little research on the management of the WWW. The literature has been descriptive in nature. It has either centered on the experiences of a single institution [Quinn, 1995, Hensarling, 1995, Callum, 1996] or has described the impact of the WWW on a particular class of university administrator [for example, Ryan, 1996, Meer & Fravel, 1996]. [Goldenfarb, 1995] provided a useful analysis of the critical success factors which determine the adoption of a WWW-based CWIS. An extensive literature search in traditional journals, relevant conferences such as ED-MEDIA and ASCILITE and on the WWW has uncovered no research, which has investigated the development or management of university WWW sites from a cross-institutional perspective. This research was designed to overcome at least in part this apparent gap in the research literature on educational and administrative information technologies.

The objective of this research was twofold. First, it was desired to build an understanding of the role and the challenges facing the university Webmanager. The second objective was to complete a profile of the output of the university WWW site, the tools used to build and maintain the site and the management strategies. An important element of the study is to gain an appreciation of the concerns and the plans of the Webmanager and of his or her team.

The Model

The dependent variable in this study is the level of output of services. Three measures of output were adopted. The first measure is the level of services provided. The survey sought information on the range of services provided as shown in Figure 1. For each service, the respondents were asked whether these services were provided by central Web services under the control of the Webmanager, by another server on campus or not at all. A score of two was allocated if the central web server was used for the service. A score of one was given if another university server provided the service1. There was, of course, no score if the service was not provided. The second measure of output was the number of pages on the central Web site. The third measure was the number of pages that were updated on a weekly basis.

1 A number of combinations of scores were tested in the reported models shown below. The results were essentially invariant to changes in relative scores.

**Figure 1: Potential Services Provided**

Three independent variables were adopted. The first independent variable was the size of the institution. Size should predict the level of service provided by the central Web site. The range of stakeholders (students, faculty, staff, prospective students, parents, employers etc.) for universities is not dependent on scale. While a larger university would have more student, teaching, administrative and research activities than a smaller university it is not a linear relationship. The cost of bringing information on these activities to the WWW has, however, a high fixed cost component and a relatively low variable cost component. For example, the cost of establishing a database of faculty research activities may involve several person-months as well as server and networks resources. Once the service is established and integrated into the university’s business processes, the marginal cost of adding research information to the new WWW database is low. Almost certainly, it will be lower than for the equivalent printed report. A larger university will, we predicted, have more stakeholders to absorb the fixed cost of development. It is hypothesised that the size of university is a determining factor in predicting the level of output of WWW services.

The second independent variable was the nature of the institution. Universities were categorised as regional or metropolitan and ex-Colleges of Advanced Education (CAE) and “traditional” university. The latter classification reflects the historical origins of universities in Australia. Prior to the late 1980s, a number of higher education institutions in Australia were “Colleges of Advanced Education” or “Institutes of Technology”. These institutions primarily had a teaching and learning mission. Following the creation of the so-called “Unified National System”, these institutions either merged with the then-existing universities or became universities in their own right. The student population of the ex-CAEs is more heterogeneous than those of the traditional universities. For example, they have relatively high proportions of part-time, adult and distance students. It was predicted that the ex-CAEs would be more likely to use the Web for communication purposes as their heterogeneous student populations can more effectively reach the WWW.

A third independent variable was the staffing levels within the central WWW services. It is with the staffing of the WWW unit, that universities explicate their priorities. The level of staffing is a second order variable.

**Survey Results**

The survey was distributed and the results collected over the WWW in August and September 1997. There were 33 useable responses to the survey, from a population of 412 universities. Analyses of different aspects of the survey results have been published in [Ellis & Debreceny, 1997b] and [Debreceny & Ellis, 1997]. The distribution of respondents by size\(^2\) and type of institution is shown in Table 1:

---

2 One university in the survey is managed as a federated institution. The campuses have a high degree of autonomy. Each campus was treated as a separate institution for the purposes of this study.

3 Size is measured by thousands of Equivalent Full Time Student Units (EFTSUs)

There was no statistical support for the hypothesised direction. Larger universities did not provide a greater range of services than those provided by smaller universities. As Table 2 indicates, some of the smaller universities (for example, those in the 5-10k EFTSU range) are providing a wide range of services. Not one of the three largest universities was in the fourth quartile and one was in the first quartile. A similar pattern was found for the number of pages on the central web site, as shown in Table 3. Two of the largest universities provided less than 100 pages of content. This is a trivial amount of content for such large institutions. Conversely, some of the smaller institutions were providing large quantities of information on the WWW. One of the universities in the group of 10-15k EFTSUs provides more than 20,000 pages of information with more than 200 of these pages changing on a weekly basis. The patterns that are disclosed in Table 2 were repeated when the nature of universities was investigated. The number of pages was somewhat different however. Regional institutions, even smaller regional institutions, are providing more pages than their larger metropolitan siblings are. This may be a function of the stronger distance education element at regional institutions.

---

4 While the number of observations is small (33), it constitutes a very high proportion of the population.
5 Employing both the Kruskal-Wallis non-parametric test and the Chi-square measure on Crosstabs.
The level of staffing provided a more interesting pattern. There was a high degree of variability in the level of staffing allocated to development and maintenance of the WWW site. Table 4 shows the equivalent full time staffing on WWW duties, by size of institution. It can be seen that even large institutions operated their central WWW site with the equivalent of less than one quarter of a person’s time.

The Kruskal-Wallis non-parametric test of ranks (mean ranks) for the effect of staffing on output is shown in Table 5. No pattern can be discerned for services provided, but statistically significant relationships existed for both pages on site and pages changed weekly.

Conclusion

Only limited support for the hypotheses on WWW provision, set out above, could be found in the analysis of the survey results of 80% of Australia’s universities. It was hypothesised, for example, that size of university would
be positively correlated with WWW output. To the contrary, a number of the smaller and medium sized universities had a substantial WWW presence. Some of the larger universities had a minimal presence. The level of staffing did however provide some predictive power. Perhaps more interesting, however, was the relatively low levels of staffing within most central university WWW functions. This is, perhaps, an indication that the WWW has not yet become a focus for university management.

This is the first large-scale survey on central WWW provision within the University sector. The research should be complemented by similar studies in other countries and by small scale and case study research which provides more detailed cross-institutional comparisons.

Abstract:
Many tools have been designed, prototyped or implemented for students' use in the acquisition of programming skills. We present a concise review and analysis of twenty-five systems developed to teach problem solving and programming. These systems are classified in three categories: programming environments, intelligent tutoring systems, and intelligent programming environments. A discussion of deficiencies and weaknesses of these systems is also included.

PROGRAMMING ENVIRONMENTS

Programming environments are systems used by programmers to develop and test programs. They are used by novices and experts, individuals and teams of programmers, and provide a range of functionalities. Traditional programming environments consist of tools that can be used in program construction, compilation, testing and debugging: editors, language compilers, pre-coded function libraries, linking loaders, parsers, tracers and debuggers. More current systems also include syntax-directed editors, code indentation, graphical user interface tools, dynamic compilation capabilities, powerful library systems and possibly code generators. This section examines only those environments developed primarily for teaching programming. An explanation of each reviewed system follows.

Pict [Glinert and Tanimoto 1984] is intended for Pascal programs that will be represented graphically. Pict is a purely iconic graphical environment and consists primarily of an editor where programming is done by selecting atoms, which are pre-written functions such as input, output, looping control, etc. that are represented/displayed as icons. The atoms are selected with a joystick and arranged in a flow-chart-like manner on the screen: with Pict, the keyboard is not used. The program syntax representation can be formed, and the user can observe the execution. The system detects syntactical errors, but does not assist in planning the solution.

PECAN [Reiss 1985], a language independent system, provides the student with multiple views of a program including representations of the program, its semantics, and its execution. PECAN consists of three main components: (1) a basic level support module that includes the command manager which provides the user interface, a general purpose parser, and an incremental compiler that consists of a control module and several special purpose modules which interpret semantic actions; (2) a mid-level service module that includes PLUM, a data structure support that provides data manipulation and database management, event management, and data structure monitoring and ASPEN, which provides program representation via abstract syntax trees; and (3) a higher level module that includes the various program views.

SCHEMACODE [Robillard 1986] addresses the issues of documenting source code and understanding flow control. The problem with documentation is that it is not systematic because it is not part of the programming language, and it is usually done after the program is completed (bottom up instead of top down). SCHEMACODE consists of two main components: (1) a schematic editor, where the programmer constructs the problem solution in Schematic Pseudo Code (SPC) and (2) code generation module, where the system generates the program source code in either FORTRAN IV, FORTRAN 77, PASCAL, dBase III, COBOL, or C.

The DSP system [Olsen 1988] is intended to encourage algorithmic thinking and to support modular programming. The DSP system is highly visual and allows for selecting, moving or copying predefined templates to avoid syntactical errors. The DSP system is designed to combine the advantages of application generators and traditional programming languages. Programs can be generated in Ada, Modula II, or Pascal. The DSP system
The University of Washington Illustrating Compiler (UWPI) [Henry, Whaley, and Forstall 1990] was developed to use program illustration or visualization to help students learn basic programming concepts. UWPI illustrates the data structures for simple program written in a subset of Pascal. A program illustrator works by watching for events through hookpoints, which are inserted into the program. UWPI inserts these hookpoints automatically. UWPI consists of two main components: (1) a conventional compiler/interpreter including an analyzer, interpreter and runtime-state parts and (2) an extended compiler core including an inferencer, two illustrators, layout tools and a renderer. The inferencer searches for the abstract data types within the code, chooses a layout plan, and passes the plan to the data illustrator, which, in turn, creates and updates the illustration.

BACCII's [Calloni and Bagert 1994] premise is that the best way to learn programming is by developing algorithms using icons, independently of syntax details. Students develop algorithmic flowcharts using icons selected from a menu without any regard to the programming language syntax. ASCII format code is automatically generated for Pascal, C, FORTRAN and BASIC. The current version enforces top-down design methodology and an object-oriented version is being considered. BACCII consists of two main components: (1) the iconic algorithm development module, which allows the students create solution logic by combining icons and (2) the code generation system allowing the students to convert the iconic algorithm into language syntax.

ASA [Guimaraes, de Lucena, and Cavalcanti 1994] is an environment designed to teach algorithms at the introductory level. It supports code execution, animated tutorials, and a program construction facility. ASA consists of two main components: (1) the lessons model, which presents information in tutorial form with animation of concepts and algorithms and (2) the constructor, which consists of a flowchart editor and an interpreter allowing for algorithms to be formed using menus and icons, and to be represented graphically using flowcharts. The student can also visualize the algorithm in pseudocode, Pascal, C, or Clipper.

SUPPORT [Zelkowitz, Kowalchack, Itkin, and Herman 1989] is a PC-based system intended for programming using a subset of Pascal. The goal is to create a self-sufficient system that does not require the student to deal with the operating system or even be exposed to language features that are beyond the scope of the first course. SUPPORT consists of three main components: (1) a syntax-directed editor to build the program; (2) a Pascal interpreter to execute the programs; and (3) a user interface module, which uses windows to communicate with the user.

STRUEDI [Kohne and Weber 1987] is a LISP STRUcture EDitior for novice programmers. The basic idea behind STRUEDI is to allow the student to select predefined language constructs from a menu in order to build the program. STRUEDI maintains control of syntax, provides for understandable presentation of code, and helps the student understand syntax and semantics by offering explanations. The number of predefined constructs is limited to those taught in a first year LISP course. However, the instructor can modify the number. STRUEDI consists of primarily of a sophisticated syntax-directed editor and a collection of predefined language-constructs that are selected from a menu.

Example-based Programming System (EBPS) [Neal 1989] combines the concepts of syntax-directed editors and software reuse. It was observed that novice programmers had problems with the terminology used in currently available syntax-directed editors. It was also noticed that programmers use previously written code, either from textbooks or their own code, when writing programs. The idea for this system is to use pre-written examples to aid the programmer. EBPS consists of two main components: (1) a syntax-directed editor and (2) an example library. The syntax-directed editor is supported with an editing and an example window. Example programs can be viewed, edited, or copied into the editing window.

Software Design Laboratory (SODA) [Hohmann, Guzdial, and Soloway 1992] is based on a software design model, and provides a "workspace" for each stage of the process. The system was developed to help students overcome serious difficulties in identifying problem modularization during the design process, and to integrate those modules in the proper order to form a solution to the problem. Its primary goal is to support the software design...
process. SODA consists of three main components: (1) a problem decomposition module, which provides reference to existing program solution techniques; (2) a composition module, which support the students in integrating solution parts; and (3) a debugging module to facilitate solution verification.

MEMO-II [Forcheri and Molfino 1994] was developed to address shortcomings in earlier tutoring systems developed specifically for learning particular languages and paradigms, and systems that promote learning programming methodologies, but do not aid students in solving problems. MEMO II consists of three major components: (1) a specification acquisition module used to build solution specifications using an editor and a verifier; (2) a reasoning mechanism, which proves the specification base; and (3) a direct implementation module that allow students to automatically translate specifications into code.

INTELLIGENT TUTORING SYSTEMS

Artificial intelligence techniques are employed in some tutoring systems to provide more sophisticated support for students learning programming. Such systems are referred to as intelligent tutoring systems and allow access to tutoring and testing material on language syntax. These systems offer adaptive instruction to individual learner needs and are able to analyze student responses and determine correctness; guide and interact with students; and provide feedback and advice. An explanation of each reviewed system follows.

The BASIC Instructional Program (BIP) [Barr, Beard and Atkinson 1976] is an independent, self-contained instructional course for learning the BASIC programming language. BIP was intended for students with no prior computer knowledge as a tutor or a supplement for learning computer literacy. BIP consists of five main components: (1) an enhanced BASIC interpreter which also collects knowledge about student performance and presents errors in a more readable fashion; (2) a database of 100 programming problems of varying difficulty; (3) a HINT feature which provides text help and text-based “graphical” problem solving hints; (4) the Curriculum Information Network (CIN), which through a series of error counters and self-reported student ability information will select problems for the student based upon skill set; and (5) a BASIC language student manual.

Goal-Restricted Environment for Tutoring and Educational Research on Programming (GREATERP), better known as the LISP Tutor [Anderson and Reiser 1985], combines a psychological theory of skill acquisition with artificial intelligence to create a teaching device for the LISP language. It was developed on the assumption that private tutoring is much more effective than classroom training. The tutor is intended for beginning LISP programmers in introductory courses, is written in LISP and runs on VAX systems. The LISP Tutor consists of three main components: (1) the domain expert, which writes LISP functions from problem specifications; (2) the bug catalog, which holds possible divergence from the ideal “expert behavior”; and (3) the tutoring module, which consists of an expert system used for instruction.

PROUST, a tutoring system for Pascal programs [Johnson and Soloway 1985], was developed with a two-fold goal: to provide students with their own “programming expert”, and to create a “pedagogical expert” that could interact effectively with students. PROUST consists of three main components: (1) a module to address the location and content of the bugs in a program; (2) a module to determine what the student intends to do with the code; and (3) a module, the most important, to identify misconceptions a student may have that explain the presence of bugs in the program.

The ACT Programming Tutor (APT) [Corbett and Anderson 1993] is a cognition-based tutor. The APT tutor is designed as a programming environment to help students complete short programming assignments, and based on an ideal student model using production rules as its knowledge base. The knowledge base currently supports LISP and Prolog syntax. APT consists of two main components: (1) the tutor interface, which presents the exercises for the students to solve and (2) the cognitive model, which consists of a set of rules for writing LISP code.

INTELLIGENT PROGRAMMING ENVIRONMENT

Intelligent programming environments combine the features of intelligent tutoring systems such as adaptive instruction, monitoring and assessment of students’ progress, and feedback and advice with tools that are used in the program development process. In addition to the domain knowledge base, the student model, and the tutoring agent, intelligent programming environments provide access to traditional programming environments utilities such as syntax editors, compilers and debuggers. An explanation of each reviewed system follows.

Bridge [Bonar and Cunningham 1988] is a "complete tutorial environment" for the beginning programmer. In addition to finding student errors, it also understands partially completed programs and student intentions for their code. The tutor is able to understand natural language specifications to problems and the syntactical solution.
Bridge consists of three main components: (1) solution specification module, which allows the students to formulate their ideas in English; (2) plan specification module, which teaches the students programming skills and allows them to translate from informal specifications to plan specifications; and (3) the syntax module, where students build the programming language code for the solution.

Graphical Instruction in LISP (GIL) [Reiser, Ranney, Lovett, and Kimberg 1989] was developed to construct explanations based on its knowledge of the problem and the solution and to use visual representations to aid the student in writing simple LISP programs. GIL consists of four main components: (1) a problem solver, which uses a knowledge base of reasoning rules and plans; (2) an explainer, which follows the problem solver's logic and explains its own reasoning; (3) a response manager, which responds to program errors, errors which are legal LISP expressions, but are not useful to the program, non-confirming strategies, and specific hint requests; and (4) a graphical interface, which allows students to build programs by connecting objects representing different program constructs into a graph instead of using LISP's traditional text form.

Intelligent Tutor, Environment and Manual for Introductory Programming (ITEM/IP) [Brusilovsky 1992] is an integrated intelligent tutor an programming environment for teaching the mini-language Turingal [Brusilovsky 1991], designed for this system's use. ITEM/IP was developed as an example of a system that provides functionality by integrating an electronic manual, a tutor, and a programming/learning environment. ITEM/IP consists of three main components: (1) the programming laboratory as an integrated editor/debugger; (2) the information kernel, which contains the student history); and (3) the pedagogical module, which controls teaching operations such as when to move on or repeat a lesson.

DISCOVER [Ramadhan and du Boulay 1993] is an intelligent tutor and programming environment designed to teach beginning programming. DISCOVER combines visualization and traditional programming environment features with intelligent tutoring. It consists of two main components: (1) the free phase module, which allows the students to construct programs on their own with no feedback from the system other than memory visualization and (2) the guided phase module, where students learn from a set of problems under the guidance of an "intelligent programming expert."

Episodic Learning Model Programming Environment (ELM-PE) [Weber 1993] is a cognition based intelligent programming environment designed for teaching the LISP language. ELM-PE is an example-based system designed to support students learning LISP through the use of analogies. ELM-PE consists of five main components: (1) a syntax-based structure editor, designed to reduce syntax errors by filling in LISP statement slots with appropriate insertions, allowing only valid LISP syntax to be constructed; (2) example-based programming tutor to teach LISP whose code may be modified and copied into the student's own programs; (3) a stepper module allowing the student to visualize the flow of data during the execution of the program, which can be stepped through line by line and stopped anywhere to allow the student to see mistakes made; (4) error messages delivery and explanation module; and (5) a cognitive diagnostic module based on the ELM theory.

Capra [Verdejo, Fernandez, and Urretavizcaya 1993] supports planning and implementation and combines features of programming environments and tutoring systems. The system helps the student understand and write elementary programs and provides tutoring based on students' knowledge. There are three steps to a programming solution: problem abstraction, relationship to a class of solutions, and refinement to produce a final answer as designed and stored in the system's knowledge base. Capra consists of three main components: (1) the tutor module, which presents the students with exercises to check concept comprehension; (2) the knowledge based debugger, which monitors students problem-solving activities; and (3) the interface module, which manages the system's multi-window interface.

INTELLITUTOR [Ueno 1994] is another example of an integrated intelligent programming environment that consists of three main components: (1) GUIDE, (2) ALPUS, and (3) TUTOR. GUIDE is a knowledge-based editor which assists the student in writing programs with built-in syntax knowledge. ALPUS is the portion of the system which attempts to "understand" the student's intentions based on an "algorithmic structure" knowledge base that contains possible solutions. It analyzes buggy statements and detects logical errors. It then "guesses" the intentions of the student and offers advice for fixing errors. The TUTOR subsystem receives information from GUIDE and ALPUS to build a model of the current user's abilities. TUTOR can then present the appropriate knowledge to the student to facilitate learning. The system does not, however, consider the student's knowledge level.

ANALYSIS OF REVIEWED SYSTEMS

Most of these tools are basically environments for coding and testing. Some of the tools support a broader, but still incomplete, aspect of the problem solving and program development process. A major shortcoming is an
intense emphasis on syntax. The student is led directly into the implementation stage, without any allusion to the problem solving activities. Research results [Soloway et al., 1982; Perkins, Schwartz, and Simmons, 1988; Shackelford and Badre 1993] have consistently uncovered student difficulties with programming beyond the scope of syntax. Despite this, the overwhelming majority of the tools continue to solely address the implementation stage of the software process. Even the tools that do not solely focus on the coding task devote a disproportionate amount of attention to this activity compared to other software process activities. The inadequacy of the user interface has also been criticized. Students must typically spend considerable time learning how to use the system, creating the need for tutorial support to overcome basic operational difficulties. With these systems, student dissatisfaction with the user interface is frequent [Eisenstadt, Price, and Domingue 1993]. Rules-and-Errors Knowledge Bases, such as those used in intelligent systems, are also problematic since they evaluate student programs based on comparison with stored "ideal solutions." A knowledge base of solutions, errors and rules is maintained for comparison and verification. Such a knowledge base is intrinsically incomplete because it is impossible to include a pattern for every solution and a complete list of errors [Haga and Kojima 1993]. Because the solution knowledge base is incomplete, students will inevitably propose correct solutions deemed invalid by the system [Sleeman and Brown 1982]. The simplicity of their examples is another concern regarding the problem solving approach of intelligent systems. As observed, this is inevitable given the limitations intrinsic to the rules-and-errors knowledge base essential to an intelligent tutoring system [Haga and Kojima 1993]. The tools actually address this incompleteness problem by the expedient of using only highly specified and simple problems for which reasonably complete knowledge bases can be developed. Thus, the very "problem simplicity" that enables the knowledge based system to behave as an expert simultaneously reduces its usefulness once the student is ready to move beyond the basics of the subject. The reliance on a limited number of teaching paradigms and simple examples makes these systems too restrictive to suit student needs, reducing their ability to provide significant experiences [Eisenstadt et al. 1993]. Evaluation of post-system deployment is an important assessment technique; however, little such evaluation has been reported. Those experiments that were done almost invariably report success and improvement in student performance but offer little supporting detail. An examination of the reported evaluations reveal a variety of problems with experimental design, including frequency of experiments, selection of course sections, number of subjects, the type of evaluation performed and the conclusions reached by the authors. To measure the impact of intelligent systems and programming environments on computer science education and the delivery of introductory courses, they must receive widespread acceptance. However, it is questionable whether these systems have been integrated into the curriculum. There is no evidence in the literature that true integration has taken place; by integration, we mean a system has become an important and integral part of the learning process and is regularly used by students and teachers to enhance the learning environment. Intelligent systems present the student with a simple problem containing a clear definition, specifications and constraints. The student is then led into finding the "ideal solution." The systems monitor student activity very closely and adapt to their responses, but never relinquish control [Marco and Colina 1992; Snow and Swanson, 1992]. Therefore, students often become dependent on the system's ability to lead them in solving the problem. Imposition of such barriers to creativity and the acquisition of higher order thinking skills undermine student cognitive development. This is a serious drawback, considering that these are the very skills the intelligent systems propose to teach. For example, it is often the case that a problem can be solved in a variety of ways. The problem solver may also explore alternative solutions to a particular problem. Students may identify correct solutions that are judged erroneous by the system because the solution is not within its domain.

Abstract: This paper examines differences in attention and knowledge representations for hypertext studied with three types of learning goals: factual learning, information application (problem solving), and information integration (interrelating text content). For all goals, readers focused on target content (content required for the goals), selecting this information most often and spending more time on this than other content. However, Fact readers focused attention more exclusively on target content than other readers. Integration readers selected target content as often as Fact readers, but spent less time on this content, suggesting a broader study focus. They also attended to organizational information about the units provided on a content map for information selection. Application readers were less systematic in their study strategies, and focused less on target content than the other groups. Attentional differences were reflected in text recall, with Fact and Integration readers recalling more target content, and Application readers remembering more introductory information.

1. Introduction

Instructional hypertexts provide an advantage over traditional textbooks in facilitating goal-directed text study. Because readers have some degree of control over the order, pacing, and content of their instructional material, they can focus on and organize relevant content to meet the requirements of their learning goal. [Dee-Lucas 1996b] found that readers alter their hypertext study strategies in a manner consistent with their learning goal. The current paper reports additional analyses from the Dee-Lucas experiment. These analyses examined differences in attention and knowledge representations developed with different hypertext learning goals.

Dee-Lucas compared readers studying a hypertext with goals emphasizing factual learning (answering factual questions), information application (using the text content to solve problems), and information integration (interrelating different portions of the text). The results indicated that readers are flexible in developing goal-specific study strategies for hypertext. For factual learning, readers used an alphabetical topic list to select information units for study (as opposed to a structured content map providing an organization for the units), and reviewed units extensively. This suggests a focused study strategy emphasizing understanding of a subset of the text content. In contrast, information integration readers preferred to select units from a hierarchically-organized content map showing unit relationships. They also took detailed notes, and reviewed the information units often. These findings indicate a concern with understanding both unit content and between-unit relationships. Information application readers did not show a preference for the content map or topic list, and reviewed units less often. These readers appeared to rely less on the available hypertext features and possibly more on prior knowledge to guide text study.

The three groups also exhibited differences in depth of understanding for the text. Readers with the simplest goals (factual learning), were unable to use the text content for higher-level tasks (information integration and application), but readers with the most complex goals (information integration) were able to complete simpler tasks (information application and answering factual questions). This suggests that the complex goals resulted more elaborated knowledge representations for the text information [Kintsch 1988].

Although readers exhibited differences in study strategies and text comprehension with the different goals, there were no overall differences in study time or text recall. There were no differences among the three groups in total study time, the number of units selected, the number of readers selecting each unit, or
Thus at a global level, the different goals did not appear to influence how thoroughly readers studied the text or the amount of content they retained.

This paper reports analyses of qualitative differences in attention and recall for different types of hypertext content with the three learning goals. Each hypertext unit was classified according to its relevance to the goals (i.e., target units, elaborative units, and introductory units), and the effect of learning goal on the processing and recall of these different types of information was examined. The extent to which readers used the topic list and content map to select units from each information category was compared to determine if the structural information provided by the map aided unit selection for some types of content. To investigate attentional differences due to study goal, text review and study times for each category were examined. Text recall was also analyzed to determine if attentional differences were reflected in knowledge structures developed for the content.

2. Method

The hypertext consisted of 17 content units (1, 2, and 3 screens in length) discussing the scientific measurement of length and time. Each screen had buttons for displaying the following: (1) the previously selected screen; (2) a topic list for selecting units; (3) a content map (also for selecting units); (4) the assigned learning goal (factual, information integration, or information application questions); (5) a screen for recording notes; and (6) a set of self-testing questions allowing readers to assess their understanding of the text.

Readers selected units for study by clicking on their titles on the content map or topic list. On the content map, unit titles were organized in a hierarchy indicating subordinate and superordinate relationships among units. The topic list presented the titles in alphabetical order with no information about how they were related.

The button for displaying the learning goals allowed readers to review the assigned goals at any time. The Fact goals consisted of three questions that involved paraphrasing information from the text. The Integration goals had two questions asking readers to compare and contrast different portions of the text. The Application goals consisted of three problems that required readers to use quantitative relations to derive new relations and solve problems. The learning goals for all groups dealt with the same units within the hypertext.

The participants were 60 undergraduates who had not taken any college level physics. Twenty participants were assigned to each of the three types of learning goals. Prior to studying the experimental text, all readers used a practice hypertext to familiarize themselves with the procedures for taking notes and studying the text. They then studied the experimental text with the assigned learning goals. All readers were given the assigned questions prior to text study, and could review them at any time. After they had finished studying the text, the readers completed the goal questions using their notes. They then completed the learning goals that had been given to the other two groups. They had not seen these questions prior to studying the text. Finally, they completed a free recall in which they wrote down everything they could remember. The free recalls were used to assess readers’ knowledge representations. To determine what was remembered, each unit was analyzed into its component propositions, and the recalls were scored for the number of propositions recalled from each unit.

3. Results

The hypertext units were classified into three categories according to their relationship to the learning goals. Six of the content units contained target information required to complete the learning goals. All learning goals required information from these units, but the goals differed in how the unit content was to be used. Another six units provided elaborative information which modified or expanded upon the target content. This information was related to the learning goals, but was not required to complete them. Four units provided introductory information. This was general information relating to the topics of the target units. One unit was an introduction to the text as a whole, and thus did not fit into any of these categories. Due to its special status as the superordinate unit for the hypertext, data for this unit were not included in the analyses.
3.1 Information Selection from the Content Map vs. Topic List

[Dee-Lucas 1996b] reported that Fact readers preferred to select units from the alphabetical topic list, while Integration readers preferred the hierarchically-organized content map. Application readers exhibited no consistent pattern. These results suggest that the structural information on the content map aided unit selection for Integration readers, whereas Fact readers were able to select the content they needed by scanning titles on the topic list. To determine if readers used different access facilities to select different types of information, an analysis of variance was performed on the proportion of unit selections made from the content map and topic list for each information category.

The analyses indicated that the Fact group made more unit selections from the topic list than the content map for all information categories, although this difference only reached statistical significance for the introductory content (for target content, p<.08; for elaborative content, p<.09). This suggests that the Fact readers did not find the organizational information provided by the content map to be useful or relevant for the factual learning goals. In contrast, the Integration group made more unit selections from the content map than the topic list for all categories, with significant differences for both the target and elaborative content (for introductory content, p<.18). This suggests that the Integration readers may have been basing their unit selections in part on the structural relationships among the units.

There were no significant differences in the use of the content map and topic list by Applications readers. This may reflect individual differences in the degree to which readers based unit selections on prior knowledge relating to the application problems. Research with traditional texts indicates that readers rely to a greater degree on prior learning for information application tasks than for goals emphasizing text recall [Kintsch 1988].

3.2 Attentional Differences

[Dee-Lucas 1996b] reported few differences in unit review for the overall text. There were no differences in the number of readers selecting each unit, or in the number of units selected. However, Application readers reviewed the units that they selected less often than readers with the other learning goals, suggesting less thorough text processing. To determine if there were differences in the amount of attention given to different types of content, analyses were performed on the number of times each type of information was selected, and total study time for each information type.

3.2.1 Information Review

An analysis of variance on the total number of unit selections from each information category indicated a significant interaction between learning goal and information category. All readers selected target content most frequently, followed by elaborative information, and then introductory information (with significant differences between all categories). However, Fact and Integration readers selected the target content more frequently than the Application readers, with no significant differences among the groups for the other information categories, see [Fig. 1]. These findings suggest that all readers concentrated their text study on the target content, but Application readers focused on this information to a lesser degree than readers with the other goals.
3.2.2 Study Time

An analysis of variance on the proportion of total study time spent on each information category also indicated a significant interaction between learning goal and information category. All groups spent more time on the target content than on the other information categories. They also spent significantly longer on elaborative than introductory content. However, Fact readers spent a significantly greater proportion of their total study time on the target content than readers in the other two groups, see [Fig. 2]. This is consistent with the unit selection data indicating that the Fact group concentrated text study on target content.

3.3 Text Recall

[Dee-Lucas 1996b] found that Integration readers were able to complete the simpler goals (fact and application) in addition to the integration goals that they had been given. This suggests that these readers developed elaborated knowledge structures incorporating a broad range of content. In contrast, Fact readers were only able to complete the fact goals, suggesting narrow knowledge structures focused on goal-related content.

To more closely examine knowledge structures developed with the different goals, an analysis of variance was performed on the proportion of text recall consisting of each information type with each goal. All readers recalled significantly more target
content than other information types, and more elaborative than introductory content. However, the recall of Fact and Integration readers contained proportionately more target content than recall of the Application readers. Furthermore, Application readers' recall included a significantly greater proportion of introductory content than recall of the Integration readers, see [Fig. 3]. These results suggest that Application readers focused on a wider range of information, and did not process the target content as completely as other readers.

Figure 3: Mean proportion of recall consisting of elaborative, introductory, and target content for each goal.

4. Discussion

All readers focused their text study on the target content, selecting this information most often and spending proportionately more time on this than other content. All readers also processed elaborative information more thoroughly than introductory content, indicating that readers were more concerned with acquiring an in-depth understanding of target content than a general information framework. Although all groups were consistent in their study focus, there were differences due to learning goal in the thoroughness with which readers processed target content. These attentional differences were reflected in knowledge representations developed with the different goals.

4.1 Factual Learning

The factual learning goals required readers to paraphrase information from the target units. Readers needed to pay close attention to the wording and content of the text, but did not need to make inferences or go beyond what was stated. Although all readers focused text study on the target content, Fact readers processed this information more thoroughly than other readers. They selected target units more often than Application readers, and spent more of their total study time on target information than readers with integration and application goals. This was reflected in more complete recall of the target units (compared to Application readers).

One factor contributing to the focused text study with the Fact goals was readers' ability to easily identify target units. Fact readers preferred to select units from the alphabetized topic list rather than the content map, even though the content map was more informative (i.e., grouped together related units). This suggests that these readers were confident about which units contained goal-related content, and did not find the additional organizational information to be useful for unit selection, or relevant for completing the learning goals.

[Dee-Lucas 1996b] reported that Fact readers were able to answer the factual questions they had been given as goals, but were unable to complete the information integration or application questions. This indicates that these readers developed knowledge structures limited to a literal understanding of the text, with little elaboration or ties to other knowledge [Kintsch 1998]. This suggests that the repeated review and long study times for the target content were devoted to developing a complete representation (i.e., incorporating all of the target content), rather than acquiring a deeper understanding. Fact readers' preference for selecting
units from the topic list also suggests that they processed the units in isolation, without trying to form an integrated text representation.

4.2 Information Integration

The Integration readers had to compare and contrast target content, generating relationships that were not explicit in the text. These readers required an understanding of the target content at a level sufficient for determining between-unit relationships. The results of the current research suggest that the Integration readers processed the target content at a deeper level than readers with the Fact goals. Integration readers selected target content as often as Fact readers, but spent less of their total study time on target units, suggesting a broader study focus. However, Integration readers recalled the same amount of target information as Fact readers. [Dee-Lucas 1996b] reported that Integration readers made extensive use of study aids provided in the hypertext. They took more notes than Fact and Application readers, and used self-testing questions more often than Fact readers. These findings suggest that Integration readers used study strategies that went beyond repeated text review in trying to achieve a relatively deep understanding of the content. This deeper processing would have facilitated recall of the target content. Additionally, the process of interrelating the text units in generating the between-unit relations required for the integration goals would also aid in target unit recall because memory for one unit would prompt recall of related text units [Dee-Lucas 1996a].

Integration readers preferred to select units from the content map rather than topic list, indicating that these readers found the organizational information to be useful. This information may have been used to guide unit selection, and/or to interrelate units in the manner required by the integration questions. [Dee-Lucas 1996b] found that Integration readers performed as well on the fact and application questions as readers receiving those goals in advance. Thus Integration readers mastered the content to the degree necessary to answer factual questions and apply the content to solve problems. This is consistent with the study strategy data indicating greater depth and breadth of processing with the integration goals.

4.3 Information Application

The Application readers had to use the target content to solve problems. While these readers needed to have a thorough understanding of the target information in order to determine how the content should be applied, they did not have to cover all of the target content. They could concentrate on the specific information within the target units that they needed to solve the problems. In the current research, Application readers as a group were less focused in their text study than readers with the other goals. Application readers selected target units less often than other readers, and spent less time of their total study time on the target units than Fact readers. Text recall for this group included proportionately less target content than readers from the other groups, but more introductory content than readers with the integration goals. These findings suggest that Application readers had a broader focus to their text study than Fact and Integration readers, and concentrated less exclusively on target information.

Even though readers with the application goals focused less on target content, they performed as well on the factual learning goals as Fact and Integration readers. Application readers may have concentrated on the information within the target units that was unfamiliar, so that they were able to answer factual questions about the target content even though their recall was less complete. Application readers did not perform as well on the information integration questions as the Integration readers. The Application readers most likely organized the text content around the application problems in goal-specific structures which were not useful for comparing and contrasting the content in the manner required by the integration goals.

Unlike Fact and Integration readers, Application readers showed no consistent preference for the content map or topic list when selecting units. These readers may have relied to a greater degree on prior knowledge to guide text study. Research with traditional text indicates that readers with learning goals requiring information application use prior knowledge to develop more elaborated knowledge structures incorporating both text content and related knowledge from other sources [Kintsch 1988].

5. Conclusions
This research found that readers studying hypertext with different types of learning goals alter their processing of goal-related information (i.e., target content) and organizational information according to the goal requirements. These processing differences were reflected in both the content of readers' knowledge representations and their ability to use the information to complete other tasks [Dee-Lucas 1996b]. These results are consistent with research with traditional texts showing that readers develop knowledge structures that reflect the nature of their learning goals [Schmalhofer & Glavanov 1986]. The extent to which this process is facilitated by the flexibility of hypertext depends on the match between the study goal and capabilities for goal-directed learning provided in the hypertext [Wright & Lickorish 1990].

Paradigm Change in Education in Conditions of Emerging New Information Technologies and Global Information Infrastructure Building

Yu. Demchenko
Associate Professor, CAD Dept., NTUU “KPI”, Ukraine
demch@cad.ntu-kpi.kiev.ua

Abstracts: Paper discusses general trends and problems of Education and Research development in conditions of emerging new technologies and Global Information Environment. New principles of Education in Information Environment are based on existing paradigm shift in modern education changing role of teacher from source to producer of information and role of students from passive information receivers to active knowledge accumulator. Possibilities of Internet for education and Research are considered. Discussed results are based on two years experience in active instructional methodology development in Kiev Polytechnic Institute.

1. New Trends and Technologies of the Information Age

Internet and Global Information Infrastructure (GII) development in the world changes the main paradigms in Education and Research and raises new tasks caused by mankind survive Information Revolution and start building Information Society which is defined as post-technological society.

The pace of revolutionary technology changes increases exponentially:

50000 years ago - primitive man started to speak and conceive discrete picture of the world operating with primitive concepts and images;

5000 years ago - literacy appeared giving first opportunity for acquiring knowledge in the form combining text and pictures

500 years ago - book-printing invented; great opportunity for knowledge acquisition and dissemination, involvement of many people into research and education

50 years ago - computer and communications give new possibility and tools for multimedia data acquisition, dissemination, processing and messages exchange

5 years ago - WWW was invented as hypermedia information presentation: information acquisition, processing, access and search in Global Information Environment.

Last mankind invention World Wide Web gives people tool for facilitation of the power of abstract thought because of WWW operates with mixed (multimedia) information very similar to real thinking process. Now WWW technology becomes basic for development of Knowledge Network operating with knowledge and information across the network and independently from the form of information presentation. The wonderful feature of the web technology is the possibility to model via its directory and hyperlink structure the model of information and knowledge presentation in the brain, as it was defined by Lev Vygotsky, Russian Psychologist: “The word (information) is its search” [Vygotsky 1995].

GII based on Internet and WWW technologies provides powerful tool for global knowledge integration.

On the background of global economy’s integration companies and countries survive global competition. In the knowledge based economy of Information Age knowledge and skills become the key factor of competition. Distinctive feature of modern Knowledge Based Companies (KBCo) is continues improvement of their products by integration and
attraction of knowledge and skills of developers, implementers and users via bug reporting, beta-testing and other approaches for knowledge absorption and skills involvement. The very existence of KBCo is based on constant technologies' development and change as well as on learning acquired skills.

Such picture of the world wide economy differentiation is not fatal but stress on the main factor of success in the modern world economy - the knowledge and skills that should be supported by lifelong learning and training. IT and GII were the main facilitator of forming Information Society and they are main base for doing in the knowledge based society.

In global information environment developing countries or countries with emerging technologies are suffering in general from the high technologies changing pace that does not correspond to the national economy development pace. These processes lead to forming "slow" and "agile" nations in respect to technology innovation and implementation [Kennedy 1993].

Complete globality of modern IT and possibility for its instantaneous dissemination via GII allows to make technological leap-frog for developing nations and countries with emerging technologies. But such trends should demand special concern and national policy in education and training areas.

2. Education in Global Information Environment

Education should respond on global challenges of forming Information Society in providing necessary background for successful people living in this new knowledge based formation:

- forming base knowledge and motivation for constant improvement of knowledge and skills
- forming moral principles of coexistence in open IS accepting of majority of truths and inadmissibility of harmful impact because of global impact of any actions in global information environment
- setting up of life-long learning motivation
- free access for learning materials and training materials.

On other side, IT provide efficient tools in education for tight interaction with external environment and facilitation of knowledge acquisition owing to global access to information (and knowledge) and possibility to increase number of experiments during learning.

The education area is becoming now the place where many technologies meet, converge and are tested by real practice and coexistence. Education area is becoming important part of general companies’ activity (notwithstanding the structural affiliation - to company or university). Education becomes a conductor and promoter of new technologies and area where new approaches and new social imperatives are forming now.

New aspects of education and research in networked information environment and IT usage are based on approaching assistance tools to the real process of abstract thought process

- facilitation and extension of abstract thought process by extension of it’s information and knowledge base
- providing tools for multimedia images manipulation and processing
- replacing and supporting information processing by information/knowledge access in growing structured information environment
- increasing contributive effect of education and training

New approaches in education and training should increase the assistance-to-contributive effect, i.e., education and training organisations should become the knowledge based organisations themselves and implement KBCo corporate model. Contributive effect in IT education should shift from secondary process to productive. Changing approaches in professional education should utilise the learning process (or it’s results) for creating information and knowledge base for teaching next generation of students and/or trainees.
Classroom integration into Internet will demand special approach for curriculum design and instructional methodology used that should be focused on reaching main teaching goals because of learners in such environment have real choice “to stay” in the class or escape into Internet surfing. Curricula have to take into account existence of such global information environment as Internet. Teacher must afraid that his/her students will be lost in the open global information space. Education and culture globalisation and internationalisation shall not impact on national cultures. In these circumstances, education at its initial stage has to inoculate national and cultural values to learners. (Students should accept priorities of national values in integration into the global IS). During education and further lifelong learning people should take over new global criteria (but not change values) applying and adopting them to the national values.

This approach can play constructive role even in the case of inevitable “brain drain” (physical and via teleworking) caused by growth of transnational corporations and global workforce integration and migration. In general, this process is inevitable because of objective development of transnational corporations that utilise and integrate the most important value of humankind - human intelligence. Conformity to international criteria in professionalism and skills will raise common professional and knowledge level among local specialists.

Development of GII and communication infrastructure will be facilitated by

- needs of distributed knowledge based workforce access and integration
- needs for national and cultural information resources access

Rapid technology changes and economy IT-directed restructuring in Ukraine (as country with emerging technologies) raise another problem with “professionally lost” generation. Wide demand of knowledge intensive qualified workforce in IT (and programming particularly) causes problems with completed professional education. Students that have at least initial knowledge in IT and programming are absorbed by many small companies for serving their IT needs. In difficult economical situation they are forced to earn money that, in general, contradict with needs for intensive learning according to curriculum. Young people of the third-fourth years in Universities go to professional sphere without formed professional credo that could affect their potentiality to innovative qualification growth in the future. Professional consciousness should correspond to the professional knowledge to secure constant and successive professional growth and knowledge acquisition but not only skills.

3. Paradigm shift in professional education

In modern networked information environment the main paradigm of professional education is sufficiently changed in actual roles of teacher and students. Old methodology was based on concept of the classroom as the ultimate place of knowledge receiving where teacher plays the role of source and transmitter of information and knowledge and learners play the role of receivers. Teacher could learn from his/her experience. But now with rapid technologies' changes very few teachers can teach from their own experience.

The problem for education is that competition between transnational industry leaders provide increased pace of technologies development and changes. Therefore, in current conditions the main paradigm of education is changed to cooperative and contributive learning in which teacher plays role of information producer and curriculum adviser but students act as information accumulators and knowledge acquirers. They become responsible for necessary knowledge acquisition based on curriculum experience but teacher has to manage education process and set up an appropriate motivation system, in other words, teacher will teach students how to learn and set motivation frame for successful and timely curriculum performing.

Teachers in the new instructional methodology have to satisfy the following demands

- have high level of initial knowledge and necessary experience in IT
- ability to work as project teams member and curriculum manager
- ability to organise project teams work in such way that all students accept proposed conditions
- dynamically manage curriculum establishing and adoption criteria and flexible motivation principles oriented on the final results.

Students are learning in cooperative project based environment oriented on producing final results that help them to acquire knowledge in adjacent areas of common project group competence. Contributive process of education in IT should work on developing meaningful information resources increasing national presence in GII.

The real challenge for Ukraine as country with emerging technologies in Professional Education on IT and IT based courses is Constructivistic instructional methodologies incorporating active position of teacher and students in tight interaction with global information environment:

**Project or Problem Based Learning (PBL)** that is effective in information and knowledge rich environment with developed infrastructure [PBL-1 1997, PBL-2 1997, Lenschow 97a].

or **Cooperative and Contributive Learning (CCL)** that is PBL adopted to the conditions of emerging technologies and developing communication and information infrastructure [Demchenko-1 97a, Demchenko-1 97a].

### 4. Main Principles of Teaching in Networked Information Environment

Existing experience acquired during implementation of elements of PBL and CCL instructional methodology in teaching Networking Information Technologies and Services at CAD department in NTU “Kiev Polytechnic Institute” allowed to formulate the main principles of education in Global Networked Information Environment.

These principles can provide real base for establishing active position of teachers and creative role of learners.

1. The new paradigm of education in modern Networked Information Environment should be incorporated into instructional methodology development
   
   *Learning from the Internet - Contributing to the Internet*

2. **Cooperative Learning Model + students' initiative.** Using Internet/Intranet technologies Teachers and Learners can mutually benefit from implementation and mastering new technologies. Key role in exploring this principle belong to educational projects and rely on Cooperative model of course management that effectively use students initiative in mastering new technologies

3. **Contributional Learning model.** In conditions of wide use of computers and multimedia technologies among students and rapid technology changes, teachers sometimes can not have strong benefits in practical technological experience. In these circumstances they should play the role of mentors and/or managers of educational process or curricula. Teacher can propose some idea of *contributinal learning* when students or student's groups work on the projects that will have real implementation in building Campus computer network, development of information resources or other Society’s meaning.

4. **Integration of traditional and distance learning.** New networking environment provided by Internet/Intranet eliminate differences between traditional and distance learning, however, stressing on interactive on-line (IRC, conferencing) and off-line (e-mail, mailing lists) communication between teachers and students.

5. **Concept of “active position”.** Complete implementation and full benefits from using Internet and New Information Technologies in Education can be reached only by using this principle that is very close to the idea of contributional learning. It is not enough to give students and teachers Internet access only. To use effectively Internet, faculties should start development of their own Internet resources and creation of its own Internet presentation.

### 5. Existing Experience
Pilot project on development of Educational Program and Instructional Methodology for Teaching Computer Networking and Internet Information Technologies has been started at Computer Aided Design Department in Kiev Polytechnic Institute in 1996. 17 students of the first group have successfully defended their Master theses in June 1997. All students were involved into development of complete educational course technical and information base.

The main intermediate results of pilot project realisation can be stated

1. Formulation and testing in real practice Cooperative and Contributive Learning Instructional Methodology in teaching Networking Information Technologies and Services
2. Creation and operation of educational server and development of technical base for cooperative work of tutors and students on educational and information resources development.
3. Development of training materials and information library for practical studying of Internet technologies that are used now both for students self-training and for users training courses
4. Involvement of students in pilot testing of instructional methodology, development of educational base and creation of WWW information resources of society's meaning was resulted in development of information content of two experimental servers
   • U'Pavilion - WWW Server on Historical and Cultural Heritage of Ukraine (http://www.park.kiev.ua/)
   • Multiling - WWW Server on Multilingual Applications in WWW/Internet (http://www.ml.kiev.ua/)
5. Creation of the critical mass of specialists and students involved in development of educational courses and correspondent research activities

Current experience allows to suppose that wide implementation of such instructional methodology and whole realisation of it’s potentiality in local conditions will affect teaching of another IT related courses at the Department and lead to their integration on the base of Internet/intranet networking and information technologies which were found to be very effective for re-engineering educational process and developing collaborative learning models.

6. Summary

Education and research in present rapidly changed environment caused by Information Revolution and GII spreading over the world has to challenge new approaches and paradigm shift. The importance of Education, particularly professional education, is increasing now as base for successful implementation of the new technologies.

Cooperative and Contributive Learning model was found as effective approach for developing new instructional methodologies in Education in Global Information Environment.

Professional academic contacts have to be established for cooperative development and wide dissemination of the new educational courses and instructional methodologies.

Evaluation of Educational Simulation Interface
Using the Graphical Jogthrough Method:
The “Network Simulator” Experience

S. Demetriadis, A. Karoulis, A. Pombortsis
Computer Science Department, Aristotle University of Thessaloniki
[sdemetri, karoulis, apombo]@csd.auth.gr

Abstract: This paper reports on the application of the Graphical Jogthrough method in evaluating the interface design of the “Network Simulator”, a simulation program that enables users to virtually build a computer network, install hardware and software components, make the necessary settings and test the functionality of the network. Graphical Jogthrough is an expert-based interface evaluation method modified by the authors so that evaluators’ ratings can produce evidence in the form of a graph presenting estimated proportion of users effectively using the interface versus the time they had to work with it in order to succeed effectiveness. The modified method along with the results of the evaluation session are presented and concluding from their experience authors argue that Graphical Jogthrough may be useful for locating interface design deficiencies in educational software and the extend of this usefulness strongly depends on two factors: the evaluators’ expertise and the tasks selected for evaluation.

1. Introduction

Any simulation is a software medium that utilizes the interactive capabilities of the computer and delivers to the learners a properly structured environment where user – program interaction becomes the means for knowledge acquisition. The structure of the simulation (actions that users are allowed to perform and experiences they are guided to have) creates a cognitive world that users enter in order to acquire knowledge of the subject matter. Characteristics of interface design such as intuitiveness (use of proper metaphors) and transparency (not interfering with the learning procedure) [Roth and Chair 1997] must and can be evaluated using various methods depending on the production phase of the software.

We have designed and developed a first prototype of an educational simulation program that we call “Network Simulator”. This software enables users to virtually build a computer network, install hardware and software components, make the necessary settings and test the functionality of the network. For a first evaluation of the interface design we have chosen to use the Cognitive Jogthrough method since it is intended for evaluation early in the development phase, has been reported to be a valuable information source during a system design process [Aedo et al. 1996], is relatively cheap to apply and has also been applied for the evaluation of educational interfaces of a certain kind [Catenazzi et al. 1997]. Wishing to produce evidence of interface quality that would take into account the user’s gradual familiarization with the interface tasks we modified the standard Jogthrough method by introducing a special graph for recording and presenting expert evaluators’ ratings. We call this modified version “Graphical” Jogthrough.

2. The Network Simulator Interface

“Network Simulator” may operate in either of two modes: (a) Stand alone as any typical simulation program or (b) in communication with “ISTOS” [Demetriadis et al. 1997], an interactive learning environment where a cognitive apprenticeship module enables users to work with Network Simulator, design their proposed network solutions and submit them to the module for further assessment. Users of Network Simulator manipulate a network much as word processor users manipulate a written document. The “New” menu command enables users to activate on the screen a specific topology or network architecture selecting from the various supported in the simulation. An activated topology is a properly structured grid consisted by a number of cells where the hardware components of the network may be placed.
User’s first action is to place the appropriate nodes, communication media and active elements of the network (computing machines, printers, network cards, cables, bridges, routers etc.) and proceed later on to install the necessary software so that the initially empty grid becomes a fully functional computer network. “Network Simulator” extensively utilizes the Select – Carry – Install metaphor. Users may select the component they need from the toolbox, carry it to the desired cell and install it by clicking on the empty cell [Fig. 1].

![IBM Compatible Diagram]

Select: User is ready to select the IBM Compatible Machine icon from the component inventory

![Carry Diagram]

Carry: User has selected the IBM Compatible Machine (indicated by cursor), has carried it to the proper grid cell and is ready to install it

![Install Diagram]

Install: User has clicked on the cell and the IBM Compatible Machine icon appears. Cursor remains in “IBM” mode denoting that an “IBM Compatible Machine” item is continued to be carried and may be installed in another cell.

Fig. 1: The Select – Carry – Install Metaphor used in Network Simulator

3. Interface Evaluation Using the Graphical Jogthrough Method

Walkthroughs and the Jogthrough Version

Interface evaluation of a software system is a procedure intended to identify and propose solutions for usability problems caused by the specific software design. A usability problem may be defined as “anything that interferes with user’s ability to efficiently and effectively complete tasks” [Karat et al. 1992]. The main idea in expert based evaluation methods is to present the tasks supported by the interface to an interdisciplinary group of experts who will take the part of would be users and try to identify possible deficiencies in the interface design. Evaluator use an appropriately structured questionnaire to record their ratings. The original Walkthrough method [Lewis et al. 1990] is a substantially slower proceeding method since all the recording is done manually. In the Jogthrough version instead [Rowley and Rhoades 1992] a video camera is used for recording evaluators’ comments and proposals, thus speeding up the pace of the session. One should have in mind that Cognitive Walkthrough is a method originally designed for the evaluation of “Walk Up and Use” interfaces [Wharton et al. 1992]. Users therefore are supposed to be basically novices or infrequent users working with relatively simpler interfaces (e.g. information kiosks). The method though has been applied to more complex interfaces [Wharton et al. 1992] in an attempt to identify needed refinements and augmentations that could turn it into a useful evaluation methodology even under these circumstances. The Jogthrough version has also been implemented for educational software.
evaluation [Aedo et al. 1996], the kind of software that users may gradually become familiar with through repetitive usage.

The Graphical Jogthrough Evaluation Session

We applied the Jogthrough method for the evaluation of the Network Simulator interface. Our session lasted about 4 hours. During this time length 6 tasks (and a total of 20 actions) were evaluated. Two members of the design team guided the session. The first author acted as the “Moderator”, presented the tasks and actions, commented on the design principles followed and guided the conversation trying to succeed in time management so that opinion expressing and record keeping could be accomplished for all the tasks according to the pre-planned timetable. The second author played the role of the “Recorder”, recording the videotape time code at moments when something interesting was brought up by the evaluators. Would be users of the simulator were described as having limited experience with the “Windows 95” environment, knowing the basics of a word processor and a spreadsheet and having introductory knowledge of basic programming languages such as BASIC and/or Pascal.

Evaluators Profile

We invited four experts to act as evaluators in the Graphical Jogthrough session:
- a) Evaluator A: Multimedia Expert (Multimedia Educational Systems Analyst),
- b) Evaluator B: Subject Matter Expert (Network Manager, Aristotle University of Thessaloniki),
- c) Evaluator C: Multimedia Expert (Multimedia Programmer-Producer and Educator (High School Informatiqs Teacher)),
Our evaluators were very experienced in multimedia software programming and development and one of them in the subject matter. None of them though had any special cognitive science background.

Selecting the Tasks

The tasks selected for evaluation were representative of the complete set of tasks available in Network Simulator [Fig. 2]. Each task was analyzed into a series of actions the user had to perform for completing it and these actions were defined both in terms of user goals and interface actions that had to be executed (see analysis of Task 1 in [Fig.2]). So we tried to define user goals at the granularity of individual interface actions although this is reported to cause problems in certain cases [Wharton et al. 1992]. The reason for doing this was the poor Cognitive Science background of our evaluators. Since they were unfamiliar with the method we believed it would be helpful to see user goals and interface actions tightly bound, avoiding thus getting involved in considerations that might lead to session delay and failure of completing the evaluation in the time available.

| T.1.) Activate a New Network Grid |
| a.1.1) Start the procedure for activating a New Network Grid (click on “New” icon on the Toolbar) |
| a.1.2) Determine the general kind of Network needed (click on appropriate button on the displayed menu) |
| a.1.3) Determine the specific topology or architecture to be used (click on appropriate button on the displayed submenu) |
| a.1.4) Confirm the Selection (click on the “OK” button) |
| T.2.) Install a Computing Machine |
| T.3) Uninstall a Computing Machine |
| T.4) Install a hardware component (Network Interface Card (NIC)) on a computer |
| T.5) Uninstall a hardware component (NIC) |
| T.6) Connect a NIC to a cable |

Fig.2: List of the Evaluated Tasks
Questionnaire

Evaluators were handed a booklet that contained the forms to record their ratings. The form displayed the five basic questions that the evaluators had to answer. These questions were:

(Moderator describes the action)

a) How many users will think this action is available?
b) How many users will think this action is appropriate?
c) How many users will know how to perform the action?
(Moderator executes the action)
d) Is the system response obvious? YES NO
e) How many users will think that the system reaction brings them closer to their goal?
(after presenting complete task)
f) Do you find the task useful? YES NO

If NO then how can it be modified to become useful? Comments / Opinions

The above questionnaire had to be answered for every action of each evaluated task. In a typical Jotthrough session such as those described in [Rowley and Rhoades 1992; Aedo et al. 1996] evaluators answer questions a, b, c, and e by using a simple arithmetic code: 0=very few, 1=less than half, 2=more than half, 3=nearly all, NS/NC=Doesn't Know/No answer. Their ratings therefore define a number of potential users without considering the process of user becoming experienced with the interface after repeatedly having completed the various tasks. We instead wanted to capture in the evaluators’ ratings exactly this gradual increase in user understanding of the interface. For this purpose we designed an answer form appropriate for a more complex environment where users may start as novices and gradually become experienced. We asked the evaluators to estimate the above numbers of successful users in four distinct phases of user familiarization with the interface: the first time users try to perform the task, after having performed it few (2 or 3) times, after enough (4 or 5) times and after more (>6) times [Fig. 3].

4. Results

Ratings for the Network Simulator Interface

In [Fig. 4] evaluators’ ratings are presented after they have been coded (1=None, 2=Few, 3=About Half, 4=Most, 5=All) and statistically elaborated to obtain the mean scores across all the evaluated tasks. We interpret this final graph as a kind of quality “fingerprint” displaying visually an estimate of how fast the majority of the users would be effectively working with the specific interface. The curves indicate the increase in number of users who (according to the evaluators) could successfully understand actions as available, appropriate, getting them closer to their goal or know how to perform them versus the times they would actually have to perform the tasks in order to achieve this level of understanding. A first observation is that a great number of users (~ 60%) is expected to effectively understand the availability, appropriateness and way to perform the actions even from the first time. Even more users (~ 90%) will understand the first time that system responses are getting them closer to their goals. The overall result indicates that evaluators expect the majority of users (90%) to be able to completely understand the task performance after they actually perform the tasks for a few (2 or 3) times. One can see that “Closer to Goal”
curve is distinctly higher than the three others. We believe that this might be an indication of evaluators having strongly connected the user understanding of getting closer to his/her goal to the perceptual alteration of the system state (obvious when an action was executed).

Fig. 4: Evaluators' Ratings for the Network Simulator Interface

Evaluators' Opinions and Suggestions

Evaluators made several remarks concerning many perceptual interface characteristics such as appearance of windows and buttons, buttons functionality, consistency of the alternative options in relation to the options generally supported by the operating system etc. More important they almost always offered solutions and alternatives that the design team could later implement. The select – carry – install metaphor was generally positively commented and a suggestion was made that altered cursors (indicating carrying an item) might better be icons of the item instead of letters denoting it. There was a case where one of the evaluators proposed that selection of a specific network interface card might well be inactive when the user chooses a network topology where this card is not used and so have the interface support user’s decisions by limiting the available options only to the accepted ones. This suggestion was rejected since it was in contradiction with our pedagogical approach to allow users make mistakes that in the real world would be possible to do. We believe that it is pedagogically correct not to have interface options guide user’s decisions but offer constructive feedback after a user follows a path of action that may lead to unaccepted proposals.

5. Concluding Remarks and General Guidelines for Applying the Graphical Jogthrough Evaluation Method

The benefits of the method may be seen as resulting from two mutually completing sections: a quantitative one including ratings recording and a qualitative where designers listen to evaluators' remarks and comments and discuss with them.

In the quantitative section of our modified procedure the graph presented in [Fig. 3] was the main instrument for ratings recording. The use of this graph is judged as successful. After a short introduction by the moderator, evaluators were able to comfortably use it and denote their ratings by checking on the proper boxes. In the qualitative section the comments and suggestions that evaluators made helped us understand
how to apply a better design on various interface aspects. Evaluators focused more on the perceptual characteristics of the interface but this was only natural since their main background was on multimedia programming and development.

Task selecting and analysing is a point of great importance especially since the Walkthrough or Jogthrough methodology itself does not provide guidance on this point. Tasks should be representative of the overall available tasks and at the same time not too much extended and time consuming when evaluated. Analysing the evaluated tasks so that user goal granularity would be the same as interface action seemed to work alright but one should be cautious to avoid possible pitfalls [see Wharton et al. 1992], i.e. cases where actions might not be quite well mapped on user goals. We believe that our approach (having task actions described both as user goals and interface actions) helped evaluators proceed in a faster pace since they found user goals already connected to interface actions.

Concluding from our experience we argue that the Graphical Jogthrough interface evaluation method may offer useful feedback to designers provided that they clearly understand interaction between the two main factors of the session: evaluators’ expertise (human factor) and selected tasks (system factor). The results (quantitative and qualitative) that the session produces are strongly biased by the characteristics of these two factors. Designers should keep in mind that the specific expertise of the evaluators will inevitably lead them to focus on certain aspects of the interface design neglecting others. It is their responsibility to identify the priority of other factors (e.g. the pedagogical approach) and reject the evaluators’ proposals in case they misleadingly suggest redesign of certain interface aspects. Reflecting on the session we conducted we summarize as follows: aspects of Graphical Jogthrough that worked well include identification of perceptual interface design deficiencies, discussion with evaluators (helped us develop a more clear opinion about the way possible users might work with the interface we designed) and use of the graph we introduced in order to capture indication of novice-becoming-expert pace. Aspects to pay attention to include evaluators’ background (it constitutes the human factor and will define the area of useful conclusion drawing), selecting the tasks (it is the system factor and should be a satisfactory trade off between adequate system representation and time length of the session) and designers’ clear understanding of the human and system factor (it is the relationship between these two factors that defines the specific usefulness of the evaluation session).

INTRODUCTION

For the student of Haematology the ability to correctly identify normal and abnormal blood cells is an essential skill. To interpret the morphological changes and variations that occur in diseases of the blood and arrive at a clinical diagnosis is very difficult and conventionally takes many hours of study using a microscope. In a haematological disease such as Chronic Myeloid Leukaemia, for example, the morphology of the white blood cells changes dramatically as precursor cells normally found only in the bone marrow enter the peripheral blood stream (see Fig. 1). At the present time the only meaningful way a student can learn to identify these cells is to have one-to-one tutorial help at the microscope.

BACKGROUND

At Curtin University of Technology in the School of Biomedical Sciences, Haematology is taught to students enrolled in the Medical Science degree course. There are -
- 80 first years
- 60 second years
- 30 third years (major Haematology unit)
These students have access to only 20 microscopes and very little tutorial time. A major problem for the students was finding extra time when the microscopes were not in use, to study their blood cell morphology. It became apparent that a solution to this problem could be met by the use of the capabilities of interactive computer based multimedia.

STUDENT SURVEY

Before embarking on such a project a survey of second and third year students was performed to assess the extent of the problem. Following is a summary of some of the survey questions:

Do you find the class tutors’ help with cell identification satisfactory?

- YES - 56%
- NO - 44%
Not enough time - too many students
Too shy to ask questions
Just wasting tutors time
Just guess at odd cells
Don’t understand initial concepts

When you have finished assessing a blood film do you have difficulty in forming a conclusion?

- NO - 20%
- YES - 80%
  - Not enough time
  - Miss an important cell or inclusion
  - More than one abnormality
  - Can’t relate abnormality to the disease

Do you have difficulty in relating and interpreting blood count results/histograms from automated cell counters, to the morphology on the blood film?

- NO - 55%
- YES - 45%

What do you perceive as the major difficulties in cell identification?

- Not enough time with tutor
- Abnormal white blood cells and precursors
- Atlas doesn’t have full lineage
- Variations of normal and abnormal cells

Do you find tutorials using the video helpful?

- YES - 99%
  - Get feedback on what we were supposed to see
  - Reinforcement
  - Clarify cell morphology
  - What cells are significant
  - Much better to "see" than be told
- NO
  - One person too shy to ask questions

Although the video tutorials were deemed most useful, sometimes a period of 1 to 2 weeks elapsed before the student could get this type of feedback on their interpretation of the blood cell morphology.

INTERACTIVE MULTIMEDIA AS A SOLUTION

I. The student would not need access to a microscope.
   - The student would not need a tutor as immediate on-screen help with cell identification and access to the correct diagnosis would be available.
     - The student could work at their own pace.
     - Other information could be incorporated, such as a fully illustrated patient history, further laboratory test results, normal values and a glossary.
II. The students progress could be monitored either in a learning mode or in an assessment mode.
III. Initially, only one blood film per case study would be required to digitise the blood cell images onto the computer. This would be a major advantage in gaining access to rare blood cell disorders.
CURRENT METHODS OF TEACHING

Currently students are given a report sheet with a brief patient history, blood count values and a stained blood film (see Fig. 2).

![Figure 2: Report sheet and blood film](image)

The blood film is assessed, using a microscope and the student performs a differential white blood cell count, using a "diff. counter". This involves counting 100 white blood cells and differentiating them into their different cell types (see Fig. 3). After also examining the red blood cells and platelets the student is expected to write up a conclusion and suggest a diagnosis. This may include suggesting further laboratory tests to aid their diagnosis.

![Figure 3: Using a "diff" counter at the microscope](image)

NEW PROPOSALS USING INTERACTIVE MULTIMEDIA

It was decided to enhance the educational value of the teaching material by using realistic haematological case studies, as seen in a clinical laboratory, rather than just an "atlas" type package. At the present stage of development, the program includes the following features:

1. The patient history includes "hot text" with which the student can interact and actually see the features and clinical appearance of the patient. (See Fig. 4)

![Figure 4: The Patient History screen](image)

2. A glossary is also available on every screen for the student to access the meaning of unfamiliar terms or abbreviations. (See Fig. 5).
3. Full blood count results from printouts (see Fig. 6) from automated haematology analysers (see Fig. 7) were obtained and scanned using a Umax Vista-S8 flatbed scanner. The student is then be able to interact with these results and learn to relate the appearance of the graphical representation of the cells with the microscopic appearance. (See Fig. 8).

4. On appropriate screens the student has access to normal values or images of normal cells, to compare with the patient results. (See Fig. 9).

5. At any stage in the white blood cell differential, if the student can not identify a cell, access to a cell identification protocol is available. (See Fig. 10).
6. The cell identification protocol has a step-by-step interactive approach to the identification of each white blood cell whereby the student must select specific morphological criteria to identify the cell. As on other screens, access to the correct answers is always available. (See Fig. 11)

7. The correlation between the red blood cell morphology and the graphical representation from automated haematology analysers also allows for student interactivity, to enable a better understanding of these concepts (see Fig. 12). Similar screens are available for platelet morphology.

8. The final Case Summary (see Fig. 13) correlates all the previous screen input from the student, which then enables them to reach a tentative diagnosis.

9. In most haematological case studies, to come to a final diagnosis, confirmatory tests are often requested. Again by interactivity, the student has immediate access to further relevant laboratory test results for the patient (see Fig. 14).
Figure 14: The Diagnostic Tests screen

10. On the final screen the student is required to reach a diagnostic conclusion (see Fig.15). At this stage the student may choose another Case Study or access a more "in-depth" review of the current case which would include references for further study by clicking on the Case Review icon (Fig. 16).

Figure 15: The Final Conclusion screen

Figure 16: The Case Review screen

In summary, this is a totally new and unique approach to teaching haematology. By working at their own pace, with the high degree of screen interaction and tutorial help available at every step, students can develop their own deductive reasoning skills. They are also able to reach a conclusive diagnosis and gain confidence in their ability to correctly diagnose haematological diseases.

DEVELOPMENT

Initially 6 months was spent in designing the storyboards. It was decided to incorporate the conventional method of examining a blood film and therefore the navigation is fairly structured, with the interactivity occurring within each screen. By nature the diagnosis of any clinical disease state has to be approached in a systematic fashion. For haematological disease the following protocol is generally accepted (Dacie & Lewis, 1995) (see Fig.17).

Figure 17: Diagnosis Protocol for Haematological Disease
This format was adopted in the designing of the storyboards and formed the basis of the navigation map (see Fig.18) which can be accessed from any screen via the HELP button.
AUTHORING ENVIRONMENT:

The Haematology Tutorial was developed in SuperCard 2.0, an environment very similar to HyperCard, but with the addition of built-in 8-bit (256) colour and the facility to add scripts to graphic objects. The scripting language SuperTalk is a super-set of HyperTalk, and the conversion of HyperCard stacks to SuperCard stacks is provided within SuperCard. Some minor “tweaking” may be necessary with some HyperCard commands which are not directly supported in SuperCard.

The most critical aspect of this project was the requirement to display digitised images of blood cells on the computer screen equal in quality to that seen through a microscope. This meant that 16-bit colour (32768 colours) was the minimum in terms of colour quality, and that colour balance and image density had to be accurate and consistent over the 500 images captured and processed for each case study.

Early prototyping revealed that the QuickTime video format would provide the required image quality in the SuperCard environment, and at the same time allow transparent compression-decompression and rapid retrieval of the images. A decision was made to purchase a high-resolution triple-CCD video camera to ensure optimum colour fidelity and balance at a sufficient resolution. The camera was adapted to fit an Olympus BH-2 microscope, and the images were digitised through a PowerMacintosh 7100 AV computer (see Fig. 19), supplied through a local Apple University Development Fund grant.

IMAGE PROCESSING

Images were captured in two magnifications from the microscope. The “low power” views were captured with a 60x objective and the “high power” views were captured using a 100x objective with oil immersion. The standard Macintosh AV program, VideoMonitor was used to capture the images as PAL "half-screen" (376 x 288 pixels) single frame PICT files, which were then manipulated with Adobe PhotoShop to produce a set of base images ready for conversion to QuickTime format. Images are displayed in the program in two sizes: 376 x 288 pixels and 188 x 144 pixels. The larger half-screen size is used for the differential count (see Fig.10), and for red blood cell and platelet morphology screens. The smaller size appears in other screens as a cropped area without any scaling (see Fig.11).

PROGRAM DESIGN AND STRUCTURE

The Case Study module of the Haematology Interactive Teaching program is essentially data-driven. It is designed as a series of template screens on which different images and data relating to each case study is presented to the student. The selection of the particular case study may be decided by the student or may be selected, either sequentially or randomly, by the program itself, depending on the mode required.

An important part of the design was to enable the program to be used in “author” mode to generate or modify and save case study data without the necessity for a programmer. For example, the Cell Identification screen (see Fig.11) requires the student to select characteristics describing the displayed cell, and then to check their identification. In author mode, the same screen can be used to select the correct characteristics (with alternative
selections) and save this data to the case study data file. The program may then be switched immediately to "student" mode to check the data from the student perspective.

Other screens may be used in author mode to position screen "hotspots" and link these to images (see Fig. 8), enter patient history information and data (see Fig. 4), or even proceed through a complete differential count on screen (see Fig. 10) and save the results in the data file. The main advantages of the author mode is that additional case studies may be created without technical programming assistance, and case study data may be verified and/or modified while the subject expert works through the program.

PROGRAMMING CONSIDERATIONS:
An initial prototype of the differential count used a database of screen coordinate hotspots for each cell in the particular frame being displayed. As the mouse was passed over the cell, the cursor changed to a "magnifying glass" icon to indicate a high-power view was available for this cell. Similarly, in the high-power view, when the mouse was waved over a cell, the cursor would change to a "question mark" icon to indicate a link to the Cell Identification protocol screen. This method was effective in terms of the interaction, but presented difficulties with the complexity and amount of data required for implementation. A further problem with this method was that the program was unable to determine in a multiple cell view, exactly which cell the student was considering when they pressed an F-Key to identify and count the cell. A possible solution was to have the student click on the particular cell first, then press an F-Key to count the cell. A cell selected in this manner could not be highlighted by an overlay of a graphic, since the QuickTime display occupied the highest layer on screen, except for the cursor.

A different approach simplified the data structures and decreased the program's response time. A small arrow was overlaid on each multiple cell frame in the sequence to indicate to the student the current cell under consideration. Frames with multiple cells were simply duplicated and the arrow moved to a different cell in each duplicated frame. This meant that there was one frame for each cell in the blood film regardless of multiple cell views. The student could now view the frame and press an F-Key to identify the cell indicated by the small arrow (see Fig. 9). Pressing any F-Key also automatically advanced the view to the next frame, saving a number of keystrokes. If a higher magnification of a cell is available an "OIL objective" icon appears which the student can click on to access the image. The Review Errors procedure was also vastly simplified by this technique. In this mode, the program could easily locate incorrectly identified cells, and display these sequentially for the student to review. A displayed count-down of the number of incorrect cells left was also now possible.

REFERENCES

ACKNOWLEDGEMENTS
This project was made possible by two grants from the Committee for the Advancement of University Teaching (CAUT); one in 1995, and one in 1996 for Stage 2 development. The graphic design was by Jud Kieran, honours student, School of Design, Curtin University of Technology, and Bayer Diagnostics kindly permitted the use of printouts from the Technicon I instrument.
Beyond the Information Arcade™: Next Generation Collaborations for Learning and Teaching at the University of Iowa

Barbara I. Dewey
University of Iowa Libraries, Iowa City, Iowa, 52242, USA
tel: 319-335-5871, fax: 319-335-5900, e-mail: barbara-dewey@uiowa.edu

Abstract: Since 1992, the University of Iowa Libraries' Information Arcade has been a spring board for developing new collaborative technology-based services to support teaching, learning, and research. This paper describes next generation developments underway in applying learning technologies as well as issues and challenges, including development of media user education programs, technology training programs, and building "Arcade-like" facilities across the campus. Issues and challenges found in these new collaborative efforts will be discussed as well as "third" generation scenarios to come.

1. INTRODUCTION

In 1992 the University of Iowa Libraries opened the Information Arcade, a unique, ground-breaking facility designed to support the use of electronic resources in research, teaching, and independent learning, and founded on the philosophy of collaboration between librarians, faculty, and information technologists [Lowry, 1994]. Over the past five years the Arcade was the focus of intense worldwide attention including winning the ALA Library of the Future Award. Five years after its opening new campus-wide technology-based services are being developed to support learning, teaching, and creative research. This paper describes next generation developments in advancing collaborative learning and teaching environments in the Libraries and throughout the campus, building on experiences gained from developments in the Information Arcade.

2. ADVANCING LEARNING TECHNOLOGIES THROUGH THE INFORMATION ARCADE

Progress towards integrating computer-based multimedia programs, Internet resources, and other networked information resources by teams of faculty, librarians, and information technologists is evidence of Iowa's assimilation of the "Information Arcade" philosophy at the University of Iowa - collaboration, creative risk taking, and integration of services and staff expertise to support innovation in teaching and learning throughout the curriculum.

Elements of this experience may contain useful models for other institutions seeking to create dynamic and effective learning environments. Major issues facing research library staff and other players in the university committed to the integration of learning technologies into the curriculum are also considered.

2.1 THE WHITE CITY AND MORE: REAL APPLICATIONS WITH EXCITING RESULTS

Development of a physical space such as the Information Arcade, visually and actively demonstrating action based on an education philosophy (interactive learning combined with rich connections to networked information resources), remains a critical element in the success of current initiatives and the future developments of others. Established with a $750,000 grant from the Roy J. Carver Charitable Trust.
of Muscatine, Iowa, the Arcade consists of an electronic classroom with 24 dual platform high end workstations and an instructor's station. Beyond the classroom are clusters of multimedia workstations and information stations. All workstations are mounted on an ethernet network allowing for superior connectivity making possible the creation of the LWIS (Libraries-Wide Information System) and the Gateway to the Internet, a specially selected collection of direct links to databases, documents, image collections, WWW home pages, and other materials arranged by subject, type of information resource, and institution ([http://www.lib.uiowa.edu/](http://www.lib.uiowa.edu/)) [Lowry, Soderdahl, Dewey 1996].

The creation of the Information Arcade provided a dynamic way for librarians to work directly with early innovators on campus such as English Professor Brooks Landon who taught a course, “Literature and Culture of Twentieth Century America.” Central to the course was the profound implications of the 1893 World's Columbia Exposition in Chicago. When taught in the Arcade's electronic classroom, the course was transformed into a hypertext-guided tour of the fair using documents, images, and photographs. The end result is a dynamic and continually emerging database Landon calls “The White City.” From the research library perspective the Information Arcade provided a focus for bringing together the expertise of librarians in information resources needed for a course such Landon's with faculty who would use the facility for developing interactive learning environments and other new approaches to their courses. What occurred was a fundamental change in the way librarians and faculty worked with students and with each other. Important for librarians, the facility provided a new way to use their expertise to integrate information resources (in all formats) into courses, along with the information seeking and problem solving skills needed to sort out and apply the vast body of information resources available to students now and in the future. And, the opportunity to experiment with emerging learning technologies and creating information resources for research and teaching with Arcade technology and staff expertise was a major advancement (even prior to widespread web use). Lofty goals but doable over a relatively short period (five years) with the existence of a splashy, high profile and expertly staffed facility, the Information Arcade, and with a strong emphasis on partnerships.

3. IF WE BUILD IT THEY WILL COME

Why were librarians at the University of Iowa so interested in learning technologies to the extent that we truly believed “if we build it they will come,” a famous saying from the Iowa movie Field of Dreams? Obvious reasons include the fact that research libraries are already immersed in the application of technology from purchasing indexes, books, and research materials in digital formats to carrying out library operations in an online environment (processing, reference, communications). For the UI Libraries it became a major way to pursue our primary goal -- “to maintain as a top priority the development and delivery of instructional programs and materials to assist students, faculty, and staff in acquiring the skills and knowledge to achieve information literacy in order to secure information needed immediately and throughout their lives [University of Iowa Libraries 1995].” And, building the Arcade enabled us to visibly address the concern that technology, in and of itself, become the driving force of advancement in the learning and teaching process.

Stephen Ruth accurately remarked in a recent EDUCOM Review article that technology-based learning is not about the medium but it is all about how the technology is leveraged [Ruth 1996]. Or, as a recent Pioneer Seed Corn Company television ad noted (Iowa has plenty of corn producers) we are seeking “Technology that Yields.” Thus, librarians’ role in working with faculty to incorporate research skills within courses in new and dynamic ways, and with networked information resources, is a natural progression of the more traditional roles of simply housing and providing access to library materials. Not only does technology “yield” under this model, but it provides mechanisms for major transformations in learning environments.

3.1 BUILDING “ARCADE-LIKE” FACILITIES THROUGHOUT THE UI LIBRARIES SYSTEM
Using the Information Arcade as a model, the Libraries, in collaboration with academic colleges and departments, have built or are planning similar facilities throughout the campus. The Information Commons, a 5,000 square foot electronic information and multimedia teaching facility at the UI Hardin Library for the Health Sciences, opened in August 1997 [Duncan 1996]. The Commons provides faculty and students, primarily from the health sciences colleges, with access to health sciences databases and computer-based learning as well as multimedia technologies that support faculty and staff in creating specialized interactive technologies. Truly a collaborative effort, use of the Commons as an instruction site has skyrocketed and it has proved to be a fruitful physical location for instructional and research-related partnerships with faculty. At this writing plans are underway for an expansion of two additional electronic classrooms (http://www.lib.uiowa.edu/commons/).

ARTIC, The Advanced Real Time Information Center, is an electronic teaching facility located in the Marvin A. Pomerantz Business Library. ARTIC’s purpose is to incorporate state-of-the-art technologies for all kinds of dynamic (real time) business information sources, especially global financial trading markets, into a teaching venue for College of Business Administration faculty and librarians. ARTIC extends the collaborative and innovative philosophies of the original Arcade concept by providing an actual space for librarians and faculty to improve students’ ability to compete in our real time global information-driven economy through effective navigation of business information sources.

Ongoing building projects for the Engineering Library and the Biology Library include Arcade-inspired smaller electronic teaching facilities within their walls. These facilities will provide greater access to electronic multimedia resources so important in these disciplines and bring together more students and faculty in subject-specific interactive learning environments. The facilities, planned in close collaboration with the College of Engineering and the Biological Sciences Department, provide yet more venues for dialogue with faculty regarding collaborative ventures for integrating electronic resources into their curriculum.

4. STAFF TECHNOLOGY TRAINING

Getting beyond the first wave of success the Arcade generated was a major challenge. A critical part of the University of Iowa’s success in extending the Information Arcade concept was a concerted effort to broaden the technical expertise of library staff from throughout the system. This was accomplished through a variety of staff training sessions covering topics from web page creation to desktop publishing, digitizing and imaging. In order to whet staff appetite for such training as well as minimize fears, technology training days are set aside devoted to hands on experience with the latest software and hardware available for application to user education and learning technologies. The staff technology training series has resulted in an exponential growth in the number and variety of user education programs staff provide on a regular basis for the University of Iowa’s 28,000 students and over 2,000 faculty.

5. INTERACTIVE AND “VIRTUAL” USER EDUCATION

Librarians trained to use, not only the electronic classroom in the Information Arcade, but other facilities around the campus, are able to integrate appropriate software and hardware solutions for the creation of interactive general discipline-specific user education sessions on library resources. Newly constructed venues and innovative technological applications have definitely added value to more traditional lecture-based modes of classroom instruction. Thus, the physical space (an electronic classroom) becomes a dynamic learning environment capable integrating information resources into truly interactive courses.
ranging from Engineering to English, History to Mathematics and throughout the Health Sciences curriculum.

Extending our reach to thousands of students in a large university setting is simply not possible in classrooms (electronic or otherwise) or regularly scheduled educational sessions held in the library. Although engaged in user education programs for some years, it was clear that we were not reaching large numbers of students and faculty. For example, in 1990 a total of 393 user education sessions were held reaching 6,678 students. By 1996 the number of sessions increased to 628 reaching 12,087 students. However, this falls far short of the campus population of 27,500 students. And it was also clear that faculty and students had ever increasing needs in learning how to effectively use the more expanded, more complex, and more numerous information resources available at a large research university [Dewey 1997]. These two obstacles ranked above lack of hardware, software, or even available funds. In fact, a research project funded by the Council on Learning Resources found that a population of 1000 faculty from four research universities identified two major obstacles to increased use of electronic information technology: (1) lack of information about databases and resources and (2) lack of training in their use [Adams and Bork 1995].

One way we can hope to expand user education programs in a truly exponential way is through the implementation of broadly accessible web-based tutorials and information packages which may be used 24 hours a day by many individuals at one time. Library Explorer, developed initially as a hypercard program, now web-based, is a computer instruction program designed to help students learn to choose information sources and finding tools appropriate for their work. Using the book as a metaphor, Library Explorer directs the user to a variety of "chapters" and allows them to search the Libraries' online catalog at any point in the program (http://www.lib.uiowa.edu/libexp/). A specialized information package, Engineering Reference Assistant, provides students "virtual" assistance locating Engineering information resources appropriate to their needs and class projects. The Engineering Reference Assistant can be accessed via the Web and available anytime the student needs help (http://www.lib.uiowa.edu/eng/robo/robo1.htm). Other digital information packages for subject domains are in the planning stages at the University of Iowa Libraries.

5.1 TWIST AND SHOUT

A major issue continues to be identifying effective ways to systematically expand our reach effectively to large numbers of students through the curriculum. Thus, an initiative began in the summer of 1996 called TWIST (Teaching with Innovative Style and Technology). TWIST is a three year project funded by a $370,000 grant from the Roy J. Carver Charitable Trust. TWIST's primary goal is to design a model instructional program to assist faculty to incorporate new technologies and information resources into their courses. During 1996/97 faculty from the Department of Communication Studies worked with TWIST staff as an initial target audience for development of materials and instructional sessions. This particular group of faculty were recruited because they represent a wide variety of interdisciplinary interests within one department, providing a broad testing ground for application of a model for humanities and social sciences (http://twist.lib.uiowa.edu). Initial TWIST projects included: assisting a Latin American media scholar to construct a web page for two courses -- U.S. Media in Latin America and Cultural Imperialism -- providing students with information about traditional and electronic information sources, and working with a cross cultural communication scholar to develop an experimental course -- Intercultural Communication Course -- using electronic communication tools to link students from Iowa to students at the University of Jyvaskyla in Finland.

As with user education programs described earlier, reaching large numbers of faculty, and consequently students in courses via the faculty was unrealistic through traditional methods. Thus, TWIST staff also are in the process of completing web-based tutorials that can be used at the faculty's convenience or point of need (http://twist.uiowa.edu/tutorials/). Topics included: Guide for Beginning Researchers at the UI
During the 1997-98 academic year TWIST is focusing on developing partnerships of librarians and faculty in a program called TWISTed pairs to explore the use of web-based learning environments for specific classes. A general process for implementation of the TWISTed Pairs model is that TWIST staff: 1) meet with the librarians and show options they can use with faculty; 2) survey the librarians involved to determine current skill levels and develop a training needs assessment; 3) meet with librarian/faculty pairs to develop individualized plans; 4) continue training librarians (and faculty); and 5) work directly with faculty offering assistance as needed (http://twist.lib.uiowa.edu/projects/).

Pairs are in place with faculty from African American World Studies, American Studies, Italian, Pharmacology, Journalism, Geography, Asian Languages, Communication Studies, English, History, Rhetoric, Art History, Comparative Literature, Spanish, and Film Studies. It is hoped that this work, along with the web-based tutorials, will result in a model transferable to other academic communities.

5.2 nTITLE: A CAMPUS-WIDE INITIATIVE

TWIST staff and other librarians have begun an important collaboration with the University’s Center for Teaching and Information Technology Systems (ITS) to plan and implement a state-funded program called nTITLE (new Technology in the Learning Environment). A total of 96 professors from across the campus were selected by their college deans to participate in 3.5 day 1997 summer workshops planned and taught by the Center, the Libraries, and ITS in the Information Arcade classroom. Each participant received a grant of $3000 for equipment to be used for technology-based improvements in their teaching (http://www.uiowa.edu/~ntitle/).

6. NEXT GENERATION ISSUES AND CHALLENGES

Next generation advances are naturally accompanied by major issues and challenges. The political difficulties of forging constructive alliances with departments across the campus such as libraries, information technology services departments, and academic departments can be a major barrier to productive collaboration. In today’s fast-paced environment there is no time to smooth over philosophical differences or achieve consensus on every detail. All parties must be willing to take risks and move forward. This is the only way to make projects happen. Issues of copyright and other legal concerns can be paralyzing, but should not be barriers to development. Staff training and development is critical to the success of next generation initiatives because of the need for technical expertise, not to mention the necessity of adequately maintaining the hardware and software behind the new learning technologies. Expertise in instructional development and computer-based design is also essential. Also, administrators must consider when to create from scratch or when to implement models taken from other institutions. Basic training of faculty and students in the new technologies is a major need which should not be taken for granted. For example, we found in a pilot needs assessment of beginning University of Iowa freshman, that only 30% were using the Libraries' web-based systems. Therefore, the need for ongoing evaluation and assessment is critical. Recognition via the promotion and tenure system found at the University of Iowa (and most colleges and universities across the U.S.) remains a major issue among faculty who are considering spending time applying learning technologies or developing multimedia research projects.
7. A THIRD GENERATION IS ON THE HORIZON

Advancing the Information Arcade philosophy of transformation through collaboration and creative use of learning technologies and networked information resources to another level is essential for the Libraries’ efforts to remain relevant and central to the teaching and research missions of the University. Increasing partnerships and collaboration with faculty and students will become more and more integrated into daily work. Without this kind of major transformation I believe we would not be major players in planning for next steps in the University’s advancement of its teaching and research missions. With the groundwork laid by the Information Arcade implementation and development we are an essential part of the University and the State of Iowa’s new emphasis on integrating instructional technology into all aspects of university life ensuring that graduates will have the tools they need to function effectively in the next information age and beyond.

8. REFERENCES

Acknowledgments

The author wishes to thank Sheila D. Creth, University Librarian, for her enthusiasm, vision, and leadership in support of the efforts described here and to Michael McNulty, Associate Provost for International Affairs, for financial support from the University of Iowa Committee on International Travel to attend the conference. All staff responsible for next generation efforts in teaching and learning are heartily thanked as well because without their excellent efforts none of the advances described in this paper would exist.

Abstract: This paper describes a web based training system which has been used as a working prototype to assist teachers in lecturing since fall 1997. The main goal of this system is to provide an integrated environment for both students and trainers. Lecturers can use it to create, maintain and offer courses and also administrate student affairs. Rich communication facilities extend the advantages the system provides to students. Apart from university areas the system is also designed for usage in companies to train its employees.

1. Introduction

Due to faster development cycles in science and industry, life-long learning has become a key factor for everybody who wants to continue being successful in a job - or even in private life. Great efforts have been put in the task to ease knowledge transfer, make it more pleasant, or simply automate it to become more efficient. Over 30 years ago computer based training (CBT) was introduced as a supplement to traditional classroom courses, with these goals in mind.

The advantages have been that students can decide where, when and how fast to learn; a lot more students can be reached; and learning can even become fun (particularly) if a CBT course makes good use of multimedia. The disadvantages are that CBT students often suffer from a 'tunnel syndrome' because they are restricted to material stored on the CD-ROM, and they don't have the possibility of getting answers to any questions that were not foreseen within the original design of the course system. There is essentially no support for communication between students and a teacher or tutor who might help them. Another major disadvantage is that the generation of a good, comprehensive course is very expensive.

A possible solution to these problems is a Web based training system that provides good communication facilities and even better reachability, through use of the Internet (or an intranet) combined with powerful tools to generate, maintain, and offer courses. The following documentation concerns such a system, based on Hyperwave [Maurer 96a], called GENTLE (an acronym for GEneral Networked Training and Learning Environment) [Maurer & Dietinger 97].

Note: Whenever we speak about the 'Internet', 'students' or a 'campus', this doesn't mean that this system is restricted to university applications. It can also be used effectively within local network systems by companies that want to train their employees!
2. GENTLE knowledge management system

Traditional CBT and even WBT systems have the problem that they not only isolate the students from each other, but also from the courseware authors and course contents they have created. GENTLE provides mechanisms to automatically store and maintain courses; this helps to increase reusability and thus reduce course creation time and cost.

The module repository and the course wizard

Each course, which is stored in a course library, consists of several course modules which again are stored in a module repository. Each module is characterized by a set of attributes and keywords to ease re-use when looking for already existing lessons to include in the development of new courses. Courseware authors can decide to physically copy a module and make their own changes to the module afterwards, or they can just link a module to their course (logical copy). In the latter case modifications to the module can only be made by the original module author - not by the author of the course who wants to include the module. The advantage is that any update or changes to a course module, by the module author, are immediately reflected in all courses where this module is included. If wanted the Hyperwave billing mechanism can help in establishing courseware-module markets, in contexts where modules can be sold or exchanged.

The authoring tool that supports the creation and administration of learning modules is called the course wizard. It also assists in creating new courses that follow clearly predefined pedagogical guidelines by suggesting a consistent structure.

Each new course includes an introductory page that has to be publicly readable (even if attending the course is not free) and contains the following information:

1. overview/aims/content
2. prerequisite and course level(s)
3. how to use this course
4. time required to master the course
5. references
6. samples/highlights

In the first section an author should give a short abstract about the course content, its aims and how a student would benefit if completing the course. The prerequisite section has to describe the required knowledge background of the student and the difficulty levels in each case. Alternatively, the system could offer an introductory questionnaire upon course enrollment wherein the existing skills of the student are tested and this information is then used to generate an adaptive course, customized to that individual. In the same way, the student's learner type could be taken into account and thus provide a maximum adaptation to the student's individuality. Please note that this does not mean that a special version of the course is created for each student, but that the system dynamically decides upon retrieval which student should get which course page in what way!

In the third section the author can state whether this is a computer-assisted instruction course that supports a traditional lecture, or if it is a true Web-based training course, without physical presence of a teacher. This can also be the right place for including links to the teacher and the supporting staff (possibly automatically generated by the system). In addition, the system automatically creates a link to an 'introduction to the WBT system' lesson (which is included in every course and publicly readable).

Another quite important piece of information is how long the students could reasonably expect to take in completing the course. This of course depends on their own knowledge background and abilities - and thus might be re-adjusted after they have done the first lesson!
'References' is a link to the course's background library - including all relevant material that complements the courseware content; like full online books, descriptions of traditional books, or links to other interesting pages on the Web.

The last section could show a few highlights out of the course to whet the appetite, give an overview of the course style or quality, and also work as an advertisement (especially for courses that students have to pay for).

Apart from the introductory page a course also consists of course modules. Each module should address each topic treated, described in a short introductory page within that module, and may include frames and chapters, or subchapters that combine several frames. A frame can be composed of any document type like text plus images, audio, video, animation, simulation, tests or of a mixture of these elements. It is recommended that at the end of each lesson the author should add a self-test for the students, to let them evaluate whether they have understood the content completely. The course should suggest a specified set of frames to redo if necessary. Note that because this test is not used to assign grades, students are given the means to be able to decide for themselves whether or not they have solved a problem correctly. There is no need for 'artificial intelligence' to check answer for correctness.

The course environment

Whenever an author creates a new course using the course wizard, it will also automatically generate a course environment that provides the following features:

- navigational aids (table of contents, next/previous frame, last page visited)
- several ways of student/student and student/teacher communication
- systems to support the inclusion of private notes
- search routines for the background library

Due to the features of the Hyperwave server, no extra programming (apart from layout-specific features) is required to provide a table of contents at the beginning of a new chapter, or to update the 'next' and 'previous' frame function. The last page that a learner visited can automatically be accessed on any later occasion, after interrupting a course session, in order to guarantee a smooth continuation of learning.

To reduce the tunnel syndrome, both synchronous communication (like online chat), as well as asynchronous communication (like discussion forums) are supported. Annotations serve a special role in GENTLE. Students can either make private annotations (as personal notes to a special point within a frame) or public annotations of several types. Annotation types are

- comment
- supporting argument
- counter argument
- question to the teacher (private and public), or to other students (public only),
- answer
- teacher 'hints'

Annotations can be created by the students either identified or anonymously, or by the teacher. These types can also be used in the discussion forum and are visualized using different icons. If students have posed new questions to the teachers, those teachers will be notified by an email.

The course environment also provides a powerful search function; with the capability to restrict the search scope, to the background library, the entire course content, or the complete courseware server.
Delivery tools

GENTLE can either be used online, where the students are connected to the server all the time (useful in PC-laboratories or in student residences that have a direct network connection), or offline. For primarily offline use the whole course content, including the background library, can be extracted from the courseware server and put on a CD-ROM. Hyperwave functions like searching are emulated using Java applets, requiring only an ordinary Java-capable Web browser. To prevent the 'tunnel effect', annotations and intermittent links to discussion forums are supported. The students simply have to go online occasionally for a short period of time to synchronize their data with the server and to fetch new answers or annotations. The course environment is slightly different because additional online functions (synchronize feature) have to be added, but it generally appears the same to the students either way they use the system.

Course Evaluation tools

Due to the fact that GENTLE is based on the connection-oriented protocol of the Hyperwave server, user-tracking and even student-modeling become possible. This can be used together with pre- and self-tests for improving the overall quality of the courses as well as fitting the personal needs of the students during the dynamic customization process (of adaptive courses).

Students management

Whenever new students enroll at the courseware server, they will have to answer a few questions to inform the system about their knowledge background and their aims. This information can be used to automatically determine what courses (e.g. additional optional subjects) students should take and automatically suggest them. At the university level a customized study plan for each student can be generated. Commercial companies could use this feature to design a career plan for each employee (of course the decision process can be influenced by relevant authorities).

To sum up all the features of GENTLE: It is not only a network-based CBT system, using the Web simply as a transport medium for static courseware, but can be more clearly seen as a dynamic and comprehensive knowledge management system.

3. GENTLE from the student's point of view

Although certain features are also available to anonymous users, full benefit can only be granted to identified users. Each new user has to fill out some form to specify at least a few personal details. For a student this could be name, registration number, area of studies, intended outcome, etc. This questionnaire can also be extended to become a so-called profiler, where the students answer some test questions to find out their level of background knowledge, learning habits ('learner type' according to Meeker) and cultural background. This information can later be used in the formulation of adaptive courses which dynamically adjust their content and style according to the students' profile. In this way a very individualized training environment can be offered, of a sort which otherwise can only be found in a single-teacher/single-student relationship.

Upon completing these questions, users will get a personal working area on the server called "locker". It contains the following elements: Courses Suggested, Courses Enrolled, Courses Taken and Private Working Space.

In the 'courses suggested' section, students will find all courses that the system thinks would be appropriate for them. In the most trivial case, all courses available would be listed here. In the more advanced versions it would depend on the user's detailed profile whether or not a course will be listed here. This is also the place where students will select which course they would like to enroll in. If the user has registered for a course (using the course registration) it will be listed in the 'Courses Enrolled' collection which serves as the entry point for the course itself. The collection 'Courses Taken' may be used for administrative purpose, but can also
function as a private area for the student to maintain their own overview of any courses they have already mastered and how well they did. The 'Private Working Space' may be used as a working area for doing exercises or to store e.g. personal pages.

The course environment

After signing up for a course, each student will experience the course through access to the following functions: 'start', 'next/previous page', 'search', 'annotate', 'discussion forum', 'online chat', 'continue' and 'exit'.

Navigational aids

Whenever the students enters a course they will automatically arrive at the last visited page (or the introduction if this is the first visit), so that it is easy to continue after an interruption. To come to the next/previous page the user has to click on the 'next/previous page' button, 'start' will lead to the introduction page of the course and 'exit' will leave this course and bring the student back to the locker.

Searching in the background library

With 'search' one can query either a customized background library, the whole course content, the discussion forum, or the whole server. The background library is automatically generated during the course-creation process, based on the guidelines of the courseware author.

The annotation facility

Annotations can be placed within an HTML page using various annotation types; they are be visualized with different icons that appear within that page upon its delivery from a Hyperwave server. These annotations can be made by either participating teachers or students; in either 'identified' or 'anonymous' mode (in the latter case, no information about the creator of the note will be stored on the server).

Note: The annotating document as well as the annotated document can (theoretically) be of any type (audio, video, whiteboard, etc...). However only with text documents serving as a base all features are available.

The discussion forum

Another form of asynchronous communication supported by the system (besides annotations) is a discussion forum, where each thread is hierarchically visualized. This is tightly integrated with the annotation facility, so that it is possible for an annotation to become the main starting point for a new discussion thread. Again a discussion contribution may be any document type, and the same combinations of annotation and user types are allowed. A discussion forum can be moderated (posted notes being checked and afterwards released to public by a moderator) or unmoderated (every contribution will be visible, according to the individual access rights, immediately after posting).

The online chat

The online chat can be used if two or more people are online at the same time. Students can chat amongst themselves, or even with the teachers within their office hours. Text may be augmented by drawings on a whiteboard, but in theory any document type is allowed (especially audio documents, as an alternative to text). A possibility to archive chat sessions (especially student-teacher chats) can be made available (and such sessions are afterwards treated like an asynchronous discussion).
4. **GENTLE from the teacher's point of view**

The systems provides good tools to make learning easier and more efficient, but students can only benefit from them if teachers use the system for their courses! To increase acceptance the system has implemented a number of wizards and assistants to simplify several tasks. (These wizards are accessible when entering the courseware collection, if a teacher has the necessary access rights to create a new course.)

**The course wizard**

This is the main tool if a teacher intends to use the system to create a new course. The spectrum of possibilities starts with auxiliary support for a traditional lecture and ends at a self-contained Web Based Training course, where the teacher needn't physically meet the students at all.

Upon launching the course wizard, the teacher will be asked a few questions by the wizard:

- information about the teacher (name, image (to be uploaded or existing URL), office address, office hours, email address, home page, phone number etc.)
- if the system is supporting a traditional lecture: lecture hours and place
- title of course, table of contents and short introduction into course objectives, additional information (like special keywords categorizing the course content for the course manager) if necessary
- the teacher may select supporting material (from the online library) for the background library. If the online library is really huge, the teacher may specify the subject area using keywords to reduce the list of available books and choose the appropriate ones.

The fields for information about the teacher are preset and need to be filled out only if something changed since the generation of the teacher's profile. After filling out all fields in the form, the course wizard will create a course skeleton including the discussion forum, the background library, the 'introduction to course and instructor' chapter and placeholders for empty modules (according to the table of contents).

Even if a teacher does not want to invest more time, the students now have information about the course and the teacher electronically available. In addition, the course will automatically be supported by a discussion forum and a background library (if the instructor selected some books during the course creation process). Of course the students would benefit much more from the system if the teacher decided to create more detailed online course content. For this purpose the instructor may use the page wizard:

**The page wizard**

The page wizard helps the teacher to design and create a new course page or to edit a pre-existing one. When creating a new page, the author can choose from several different templates (e.g. a template for material to accompany a traditional lecture, or some chosen template for a pure online course, etc.) and then change the style and color according to their own taste.

After creating a new page the teacher may use the wizard to access editing tools to rework the page. The integration of many editing tools (HTML-editor, HM-card, Macromedia Director etc.) is configurable to support whatever tools are in common use at this campus (campus-wide software), or special ones that correspond to the author's preferences.

**The module manager**

The module manager is important if there are a large number of course modules (each course consists of modules) that are stored in the module repository. The module manager can be used to categorize each module, in order to simplify administration. One can thus automatically generate a completely new course out of existing material, just by specifying some keywords. The manager will then suggest a list of modules that fit
these categories. If access rights permit reuse, the author may link these modules in the new course or make a
physical copy and rework the module according to the new requirements. The billing mechanism of
Hyperwave can even be used to establish a global 'trade' in courseware modules.

The course manager

The course manager is used to automatically assign courses to students (in the 'courses suggested' folder).
Decision criteria for this might be the syllabus, a career plan etc.

The offline wizard

This tool will be used to create a special offline version of a course that works without the WBT server.
Nevertheless should key features as searching and adding private annotations will still be supported by the
offline version.

A more powerful version could also support going online from time to time, to synchronize the offline content
with the server (very important for discussion forum and annotations!).

Abstract: This paper describes a virtual class which is based on the principles of CSCW (Computer Supported Cooperative Work) and ICAL (Intelligent Computer Aided Learning) systems. The virtual class proposed allow to a group of learners to participate in training sessions of an adapted tele-teaching system or adapted virtual class; this system takes into account progression rhythm differences inside a community of remote learners. The virtual class allows to adapt the teaching system in a flexible, individual, and collective way. This system also allows the implementation of a pedagogical method: the cooperative learning. This implementation is being developed in a distance education context using the Internet and Java. The OMT (Object Modeling Technique) methodology is being used to specify architecture of the adaptable virtual class.

I Introduction

The principle of the architecture proposed for an adapted training service is to allow the adaptation of knowledge transmission from a teaching function managing a virtual group of learners by a communication system [figure 1]. Teaching functionality’s are distributed taking into account the participation of teachers, system, resources and learners in some cases (when a learner has the knowledge or experience necessary for playing the teacher’s role).

![Figure 1: General architecture for each adapted training service.](image1)

The majority of learning telematic systems developed do not or rarely enable the system to control the teaching module. In general the teachers control this function, in the same way as traditional classrooms. In this paper, we propose for each adapted training service that the system allow to distribute the teaching functionality with the participation of teachers, learners and resources in a virtual class system. We take into account two kind of sites in a multi-site environment for distance education [figure 2].

a) The central site which provides a set of reusable SITB from a server.
b) The decentralized sites, which allow to learners to participate in an adapted training class.

![Figure 2: A multi-site environment for distance education.](image2)
II General architecture

In the multi-site environment of tele-teaching, we propose that any training site must be represented according to the ARESFED (In french: "Architecture pour la Reutilisation et l'Exploitation des Services de Formation dans le contexte de l'Education à Distance") [Hernández 95d]. This architecture is composed of three layers: support layer, layer of a set of reusable SITB (Service Independent Training Building Block) and a cooperative service layer [Hernández 95d] [figure 3].

In this way, the representation of each training site is simplified and standardized. Thus, we must specify only an architecture: the ARESFED (in portuguese it is called ACVA: “Arquitetura de uma Classe Virtual Adaptativa”).

II.1 Support Layer

It represents a set of frameworks from which the training architecture is built: Information Space, provides information management services relevant to the courseware developed (for example: an object-oriented database management system stocks all the reusable objects).

Communication Space, supplies services supporting a distributed system and network service.

II.2 Layer of a set of Reusable SITB

This layer is represented by a set of functional, independent, and reusable components. These components will be shared and reused for creating a new service. We have identified with a participation of educationalists two kinds of resources: didactic (teaching activities) and information resources (“bricks of domain”) [Canut 94], [Vincent 94]. From reusing of these types of resources a training service can be specified as a dynamic training service.

II.3 Cooperative Service Layer

This abstraction level represents the two kind of cooperative training services provided by this architecture. We consider two kind of adaptable services [Hernández 95c]:

a) global level represents a virtual class composed of a set of remote learner groups and
b) local level represents a particular learner group, each remote learner group is classified by a knowledge level.

These two classes of cooperative services must be adaptables to learner's behavior in a training session. The composition criterion of virtual class takes into account a pedagogical context, this pedagogical context is based on the cooperative learning [Doyon 91]. A virtual class will be composed of a set of heterogeneous groups, each group allows to a set of remote learners to participate to a training session. In a traditional class the homogeneity of knowledge level is not always assured. Some cases, this homogeneity of knowledge level becomes very superficial. For solving this problem, we consider a first level of adaptation to learner's educational needs, this
level correspond to take into account a composition of a virtual class from heterogeneous groups. These groups have a variable composition [Hernández 95d]. Each heterogeneous group corresponds to a different level of knowledge allowing characterizing a group of learners with the same level of knowledge about a particular domain. However, inside a group of learners is possible to find different behaviors of learners according to progression rhythm of each learner. The second level of adaptation is taken into account into a group of learners. A particular knowledge level associated to a group of learners may also become superficial and not adapted. For preventing this problem, we propose to consider the behavior zones into a group of learners. In this case, it is necessary to allow and manage the change of behavior zone of a learner inside a group (inter-group change) for assuring an adapted knowledge level of learners inside a particular group (local view). For assuring an adapted virtual class (global view) also is necessary to allow and manage the change of group (intra-group change).

II.3.1 The Adapted Training Service of a Virtual Class Architecture

The adapted training service of a virtual class has as principal objectives:

a) managing of progression of a set of remote learners,

b) controller of the VCTS (Virtual Class Training Service) takes into account a pedagogical, structural and adaptable control of a virtual class.

An initial composition allows creating a set of heterogeneous groups, this initial composition is based on a learner evaluation. However, for preventing that the initial distribution becomes static and not adapted during a training session, we must consider a logical mobility of learners. This logical mobility must respond to learner's educational needs according to behaviors detected of a group of learners during a training session. So, two levels of distribution of learners have been considered: variable groups corresponding to level of class and inside a group of learners, that is a set of behavior zones have been established [figure 4] [Hernández 95c].

II.3.2 Group Training Service (GTS)

A controller of a Group Training Service (GTS) must adapt a training session to learner’s educational needs. The actors considered in a virtual class are remote learners, teacher and shared didactic resources (didactic and domain entities).

Activating didactic interactions represents a local didactic strategy. The controller of a GTS manages these didactic interactions.

The controller of a GTS must establish a dialogue with the controller of the virtual class. This dialogue allows indicating either a learner may change of group or a learner has a problem or a learner send a request (when he wants to express a problem or point of view).

We established with educationalist team three behavior zones inside a group, these behavior zones represent three types of possible progressions: normal, intermediate and critical zones [Hernández 95c]. The control of behavior zones represents a fine adaptation to knowledge level and to learner’s educational needs.

The architecture for each controller of a group training service (GTS) was specified in [Hernández 95d].

![Figure 4: The distribution of learners in the virtual class.](image)
III Specification Object-Oriented of the Adaptable Virtual Class

The first step of the OMT (Object Modeling Technique) methodology [Rumbaugh 91 et al.] is concerned with devising a precise, concise, understandable, and correct model of the real world.

III.1 Global view of the ACVA ("Arquitetura de uma Classe Virtual Adaptativa")

In the case of ACVA we represent each layer of architecture as a subsystem [figure 5]. In this way, the global view of ACVA is represented by an object model, which takes into account the three subsystems of the ACVA.

III.2 Server of reusable SITB (Service Independent Training Building Block)

This server represents the layer of reusable SITB [figure 6]. The coordinator of SITB must control the interactions with GTS (Group Training Service) and VCTS (Virtual Class Training Service) coordinators, and the recovery interaction with a learner or teacher.

III.3 Group Training Service (GTS)

A Group Training Service belongs to cooperative service layer [figure 7]. The coordinator of Group Training Service has to manage: - the communication with the VCTS (Virtual Class Training Service), - the reuse interaction with the server of SITB and - the didactic control taking into account a didactic strategy. One coordinator of GTS allows considering the behavior of group by behavior zones (which were specified in [Hernandez 95d] and two kind of profiles: learner's profile and profile of group [Hernandez 95d]).
III.3 Virtual Class Training Service (VCTS)

The VCTS also belongs to cooperative service layer [figure 8]. The coordinator of VCTS has to manage: - the communication with each group, - the reusing interaction with the server of SITB and - the pedagogical control taking into account a pedagogical strategy. The coordinator of VCTS takes into account the behavior of each group and virtual class by two kind of profiles (profile of group and profile of virtual class).

IV Conclusion

The architecture of the virtual class proposed is a response to traditional virtual classes, which are not adapted. Works are in progress for implementing a server of reusable SITB in the object-oriented domain. This server will be implemented using of Internet and Java; the access to server will be analogous to a learning environment. The same server will be also used for reusing a set of reusable SITBs and adapting them in a virtual class by Internet. A tutoring system also is being developed (using Java) to reuse a set of reusable SITBs from the server.

Value, Cost and Evaluation - It is a Matter of Perspective: Justifying the Allocation of Resources to Develop a Specialised Interactive Multimedia Package in a University Setting

Brian Ducie
The Faculty of Business
Edith Cowan University
Perth, Western Australia
b.ducie@cowan.edu.au

Abstract: Since the development of interactive multimedia (IMM) and its application to course delivery in universities and schools much research has been conducted into the pedagogical validity of IMM, its development and evaluation. A small amount of research has attempted to quantify the costs and benefits of IMM as a curriculum tool for the purpose of accountability and the justification of resources used to develop the IMM software. Incomplete definitions of value and cost have resulted in this work being viewed with suspicion, resulting in a general unwillingness to incorporate such techniques in the evaluation process. This paper seeks to establish a framework to more correctly identify and quantify the expected value of a proposed IMM product and suggest how the utilisation of willingness to pay techniques may result in a more comprehensive and acceptable definition of value.

Introduction

The introduction of computer based education into the university environment for the purpose of instructional delivery has triggered much debate about the costs and benefits of technology in the learning process. The development and introduction of interactive multimedia products has added fuel to the debate about pedagogical performance verses educational efficiency. Literature on interactive multimedia evaluation has emerged in two distinct streams. The majority of discussion centres around the evaluation of interactive multimedia on pedagogical grounds, spending much time defining development methodology which results in the best educational outcome. A much smaller contingent of researchers have centred their attentions on the cost/benefit issue, with much of the attention given to quantifying cost and justifying interactive multimedia in a cost per student framework.

It is important to justify the allocation of resources in interactive multimedia on pedagogical grounds and important to quantify the costs of development, production and operation of the product but the value of the product also needs to be quantified to complete the information set for the purpose of accountability. Comparing cost and value has its foundation in economics where the allocation of scarce resources should be conducted in a manner that maximises the collective benefit of the community. In efficient markets willingness to pay directly relates to the value an individual places on a resource and forms the basis of resource allocation. There is much debate about multimedia products and how one should evaluate their pedagogical "correctness" but overarching all of this is a quantifiable cost limitation and the desire to achieve the best value for money. How do you quantify value? This paper seeks to introduce some ideas about quantifying the educational value of interactive multimedia and stimulate further discussion in the area.

This paper has four purposes. The first, is to establish the need to quantify the value of interactive multimedia courseware within a traditional economics of education framework. The second, is to explore the question of how to value interactive multimedia courseware. To answer this the beneficiaries need to be identified and their value criterion examined. The third purpose is to review the current literature on the cost and benefits of interactive multimedia and the arguments for and against the need to quantify benefits. Fourthly, introduce the concept of "willingness to pay" and the contingency valuation method as a means of quantifying the student's perceived value of an interactive multimedia package.
A Need for the Economic Justification of Interactive Multimedia Educational Software

Blauge [Blauge 1989], conducted a review of the then current literature in the economics of education and despaired that the topic was "dead in the minds of the professional economist and professional educator." Whilst these comments were made in relation to ongoing discussion about the economic justification of education itself, they do reflect a hole that has largely been ignored in interactive multimedia (IMM) literature, the economic justification for the allocation of resources into the development of IMM software.

Traditionally education can be justified in economic terms where the perceived benefits to the wider economy justify the cost. In this respect education is considered to be a community investment, where the long term benefits or returns on the investment must be greater than the up front costs in order to justify a public subsidy which directly only benefits the few. Cohn and Geske [Cohn and Geske 1990], described education in the United States as a gigantic industry. Pursuing this analogy, an educational institution can be described as a company in this industry that traditionally operates with the sole purpose of maximising benefits to its stakeholders. All investment undertaken must be justified in a cost/benefit framework. The cost/benefit framework has to be applied at all levels of the education hierarchy and in a university setting this equates to the allocation of resources between faculties, within faculties the allocation to courses and within courses the allocation to unit materials and mode of delivery.

Expenditure on IMM can be justified if you demonstrate its value. This is not an easy task and the next section attempts to classify the stakeholders which stand to gain value from the introduction of an IMM product into a university setting.

Defining value

The stakeholders in a university are the university itself (represented by the needs of its academic and administrative staff), the students and the wider community. Each benefits from the operation of a university in a different way and hence each stakeholder will have a different perspective of the value of the education delivered. The aim is to allocate the resources in a way that maximises the stakeholders' collective benefit. The cost of developing an IMM package for the delivery of curriculum can be justified if the benefits to the institution, students and community are greater than the costs and that the collective benefits are higher than those achievable if the resources were used in another way.

For a university, the benefits received from the introduction of IMM courseware are directly and indirectly observable. If the use of IMM simply replaces a component of the teaching process such as lectures, tutorials or workshops, freeing up facilities and lecturer time for other purposes, the impact of IMM is directly observable with the costs and benefits easily quantified. If the introduction of IMM enhances and improves delivery within the same facilities and the same use of lecturer time the task of quantifying value becomes more difficult. The source of value for a university may be that the educational program delivers a better quality of student, enhancing reputation in teaching excellence and attracting more students (and hence more dollars) into the university in the most cost effective way. In this respect it is hard to place a precise dollar value on a particular IMM package. As a result, developers rely on justifying effort and expenditure through the use of education evaluation techniques, demonstrating enhanced delivery and implying value to the university on those grounds.

For the student, investment in education involves the development of human capital to be more productive and to improve future earnings potential [Cohn and Geske 1990]. A student should only invest in education when the long-term benefits exceed the cost. It is reasonable to suggest that a student is mindful of the long-term benefits when evaluating and selecting a university or course of study but the focus of a student is more short-term when valuing a mode of study within a unit. In this respect the benefit is an operational one, recognising that whilst attending university the student's most scarce resource is time. To better manage time the student needs curriculum delivery that is more flexible and effective therefore improving the student's learning efficiency. The utilisation of IMM in education is built on this foundation and should be valued according to the ability to deliver greater choice of when to learn and how to learn in addition to the usual requirements of quality education.
If, through the introduction of IMM, a student becomes more employable, this has obvious benefits for the student and for the university but not necessarily for the community. For the community, value is added when, as a result of education a student's contribution to the community is greater and the collective community quality of life is enhanced. How the student goes on to better utilise scarce resources as a result of their educational experience is the community test of the value of that education.

It is the author's view that the university and the student stand to receive the greatest value from the introduction of IMM courseware, where the community's benefit is only residual. All future discussion of value will focus on the university and student benefit.

Cost/Benefit Analysis for the Educational Use of IMM - Discussion to Date

The research literature is quite rich in the area of assessing instructional design and the impact of computer based instruction on the delivery of education, and developing in the area of evaluation of multimedia and other software. The general thrust of the instructional design literature revolves around development, implementation and assessment. The evaluation focus is on the operational and pedagogical aspects of instructional delivery, incorporating formative evaluation during the design phase and summative evaluation upon implementation.

With the introduction of IMM into the education environment assessment of course specific IMM has paralleled the instructional design assessment path. Most of the evaluation has been conducted on pedagogical and operational grounds with recent papers on IMM design discussing in length how to conduct formative evaluation of multimedia (MM) software. Taylor Northup [Taylor Northup 1995] indicates the need to widen this view in the case of MM evaluation, suggesting it is time to shift the MM focus toward "the instructional product itself and the process used to produce it." Taylor Northup examined the use of rapid prototypes as a means of early feedback to indicate the likely success of MM design. How do you define success? This question is typically left out of the MM development process in the literature. In addition, the cost of developing MM, defined in dollars, is usually omitted from formative and summative discussion, which usually justifies the final product on the grounds of educational benefits alone.

Reeves [Reeves 1994], asks the question, “what really matters in computer based education (CBE)?” and goes on to describe fourteen pedagogical dimensions. Reeves explains that one of the reasons for the lack of systematic evaluation in CBE is "because the process has often been reduced to a numbers game" and that decision makers allocate resources based on data that is easy to collect, rather than seeking a true measure of what practitioners are trying to achieve. This highlights why there is resistance to any attempt to quantify the benefits of CBE and the need to develop valuation techniques that are acceptable to policy makers and developers.

It needs to be recognised that there are much wider aspects of value that need to be captured here and in the case of IMM, given the discussion above on stakeholder definition of value, quantifying benefit is not easy and in the past has been largely ignored. At most, it can be claimed that quantifying the value of IMM in education has been conducted very poorly with very blunt instruments but to retreat to the pedagogical high ground ignores the basic need to reconcile cost and benefit in similar measures for the purpose of accountability. Whilst it is naive to believe that all costs and benefits can be quantified it is equally naive to try and dismiss the need for harder measures of performance (predicted or otherwise) in an environment of increased competition for scarce development funding.

In recent times papers discussing MM courseware development issues have added more dimension to the evaluation discussion. Blalock [Blalock 1995], makes the statement "everyone in interactive multimedia should be fluent in the language of return on investment (ROI)" and although the article primarily relates to MM training in an industrial organisation context, the lesson should not be ignored in academia. Blalock develops a ROI model, which elegantly captures the essence of investment decision making.
For a MM investment to be acceptable the ROI must match or better a minimum return criterion.

\[
\text{ROI(\%)} = \frac{\text{Benefits} - \text{Costs}}{\text{Costs}}
\]

A number of authors have examined the cost of producing IMM. Marshall [Marshall et al. 1995] proposed a framework for measuring IMM development effort and, expressing effort as a proportion of learner time, came up with a workable definition of IMM productivity. Tan and Ngyun [Tan & Ngyun 1993] examined lifecycle methodology in the costing of IMM for an Australian Institution. Lifecycle cost is the total lifetime cost of an IMM package and includes development and recurring costs. Cost efficiency is affected by the number of students using the package every year and the number of years the package is expected to be useable, resulting in a cost per student schedule similar to the one graphically represented below in figure 1.

![Figure 1: Cost per Student Diagram](image_url)

The total number of students equals the number of students per annum multiplied by the number of years the IMM package is used.

Tan and Ngyun compared three types of IMM from low cost, low educational value to high cost high educational value and then all three types to the normal instructor led delivery. As part of the analysis, possible savings in the instructor’s time were included. The conclusion was that high quality courseware can be justified if used by large populations of students.

Canale and Wills [Canale & Wills 1995], looked at the difference between anticipated costs and actual costs in the management of an IMM project. They discovered cost overruns in both project management and IMM development. As part of their conclusions the following important implication was stated.

"Projects are rarely considered to be outright failures. It is common for expectations to gradually diminish during the life of a project as difficulties compound over time. The gradual erosion of expectations means a resetting of goals to lower levels of acceptability. Quality is compromised because time and funding are fixed."

In order to measure the success of an IMM package, it may be prudent to compare actual verses anticipated value, as well as actual and anticipated cost. Pre project, defining anticipated cost and value is necessary for three reasons. Firstly, to demonstrate that the project is likely to be a worthwhile exercise on its own merits. Secondly, to facilitate the project selection process where there are a number of possible projects and limited funds. Thirdly, as a self assessment tool for developer performance to see if the product meets their original expectations.
Blalock and Tan and Ngyun have attempted to capture the value or benefits of developing IMM software and whilst it is a step in the right direction, they both opted for obvious and easily quantifiable values such as reduced instructor time. As discussed above herein lies the fault of existing valuation methodologies which leaves them wide open to criticism from the pedagogical purists, the measure of value is too narrow and targeted at one stakeholder only, the university. The next section discusses how it may be possible to capture the IMM value from the student’s perspective.

Using “Willingness to Pay” to Determine the Value that Students’ Place on an IMM Package

Discussion above has established there is need to estimate the likely value of an IMM package prior to development and production in order to determine an appropriate amount of resources to allocate to the development of that product. The value of the IMM product is a function of the value gained by the University and the students. As suggested above, quantifying the value to the university is straightforward where the introduction of the product results in better utilisation of facilities and academics’ time but there are potentially other residual benefits for the university which are harder to quantify. The stakeholder that stands to gain more value from the introduction of an IMM package into the learning process is the student. Whether the intention is to sell the final product to the student or to provide the product free of charge, we need to establish a willingness to pay to know what value the student puts on the product to insure we do not over invest in its production. How can we estimate the value of the product, where no formal market exists and therefore no market price information is available? The answer potentially lies in a technique called the Contingency Valuation Method (CVM).

What is the Contingency Valuation Method?

CVM is a technique used by economists to value resources with no observable price. The technique parallels methods used by marketing groups to establish the likely sale price of a product in the embryonic stage of its development cycle.

The principle behind CVM is to use survey methodology to determine the price individuals are likely to be willing to pay for a product contingent on a hypothetical market situation. This price information is used as a proxy for the value of the product or amenity and the range of responses used to sketch out a hypothetical demand function. If the hypothetical market described is plausible and closely resembles the conditions under which the product or amenity is to be introduced, the price given by the individual under hypothetical conditions will mirror their true actions if the market actually existed.

Wilks [Wilks 1990], states that the CVM was first applied in 1963 in the area of recreational planning and has principally been used to value a host of public goods and sensitive environmental amenities such as recreation, toxic waste dumps and goose hunting permits. To date the technique has been used primarily to value environmental goods but the question of willingness to pay and the determination of an appropriate measure of value, where true value is not readily observable, is an problem shared with the developers of IMM products albeit on a smaller scale and potentially can be addressed by the use of the CVM.

There is some evidence of research into willingness to pay for education generally. For example, Gertler and Glewwe [Gertler & Glewwe 1989] modelled a demand curve for user-pays education in Peru to determine how people would respond to such fees and whether or not the general population believed there would be value in developing educational facilities and programs.
CVM – The Process and Possible Application to Assess the Perceived Value of IMM courseware

Wilks [Wilks 1990], reviews the CVM and describes a general procedure that uses a survey instrument administered face to face, over the phone or by mail, to establish the price at which an individual will no longer be willing to purchase the good or amenity, determining maximum willingness to pay. As suggested above the nature and presentation of the survey instrument has to be carefully controlled in order to elicit meaningful responses. The survey instrument can take many forms but generally consists of three components.

A comprehensive description of the good or amenity is provided in order to establish a plausible and relevant scenario from which the respondent can form an idea of value. One concern commonly raised is the inability of the respondent to comprehend all the issues presented and therefore make an informed and appropriate decision. This may be a problem when asking about complex and sometimes abstract environmental issues but if the sample group to be questioned are existing and past students of the unit who have experience of the current format and delivery, their ability to comprehend the likely benefit of introducing a tangible IMM product will be quite strong. The use of students can also minimise the concern that a hypothetical scenario will result in a hypothetical response because the context in which the product is to be used is quite real to them.

Once the contingent market is established, questions are asked, designed to determine the individual’s maximum willingness to pay. The form the questions take vary but common techniques include simulating an auction and bidding the price up or down until the individual decides to buy, an alternative approach the placing of prices onto a card and then asking the individual to select one. Another method involves presenting one price only and asking for a yes/no response, the responses are then aggregated to determine a response profile at each price.

Questions are then asked to establish the profile of the respondent and used in later analysis to gain some insight into reasons why particular responses occur. In addition to the usual age, sex and income questions it may be useful to ask questions that expose how the student utilises their non study time, such as work, sport and social activity in order to establish the potential opportunity cost of allocating time to study.

CVM as an IMM Project Development Management Tool

CVM has the potential to be used as an integral part of the product development process. The survey will be cheap to administer with a high response rate if you use existing students to generate the data set and capture your sample by conducting the survey in class.

The success of the procedure depends on the quality of the market scenario created by the developer. Creating the product description forces the developer to carefully consider the purpose, context and goals to be achieved by introducing the IMM package and then presenting this in a clear and understandable way. The process of defining the product may help in achieving a compromise between pedagogical prowess and practical outcomes, highlighting the difference between the developer’s value set and that of the student.

The result of the contingency valuation survey can be integrated into project funding submissions, providing a monetary value argument and directly justifying anticipated costs. Once the contingent value of the IMM project to the student has been established it can be combined with the anticipated benefits to the university and a total value estimate calculated. If the project cost is less than the anticipated value, the project it is viable.

Once funding is approved and the project moves into the development stage, the product description can be continually revisited through the development process to ensure the promised product quality is not compromised. This directly relates to the concerns of Canale and Wills [Canale & Wills 1995] quoted earlier. Post production and implementation, a similar survey can be conducted as part of the evaluation process.
Conclusion

Quantifying the value of interactive multimedia courseware needs to be given more attention by researchers and developers. This area has only attracted small interest in the past and has been treated with a degree of suspicion by product developers and educationalists because of blunt measurement devices that do not capture the true value attributed to an IMM product. It is not enough to justify an IMM product on pedagogical grounds, there is a need to explore ways of better capturing total value so that developers and educationalists can use this information to add an extra dimension to the justification of proposed projects.

This paper has attempted to set the framework for examining the issue of quantifying value. Three stakeholders are identified, two of which, the university and the student, directly stand to gain value from the implementation of an IMM product into coursework delivery. To date quantifying value to the university has been attempted by estimating the potential cost savings achievable if an IMM product is incorporated into the curriculum. To date, quantifying value to the student has been ignored and until a method is introduced that can adequately estimate the likely benefit to the student of an IMM product, any attempt to quantify the true value of a package is likely to result in an underestimation.

Willingness to pay is presented as a possible solution, incorporating the use of the contingent valuation technique. CVM has the potential to capture the expected value an IMM product will deliver to the student and greatly improve the total estimation of value. This value can be used to justify funding application and satisfy the developer of the market worth of the IMM package.

Encouraging Lifelong Learning with Learner-constructed
Web-based Performance Support Systems

Joanna C. Dunlap, Ph.D.
School for Professional Studies, Regis University, U.S.A.
jdunlap@carbon.cudenver.edu

Abstract: Influenced by generative and intentional learning environment strategies and
tools, a Web-based tool has been developed to empower learners to build their own Web-
based Performance Support Systems (WPSS) to support their learning, professional
development, and performance within a domain. Enabling learners to develop their own
WPSS accomplishes two goals: (1) people learn about the domain while they are locating,
evaluating, and organizing resources to support their work activities and/or their intentional
learning activities; and (2) once the WPSS is completed it can be used to support
performance and further professional development while working in that domain. In this
way, the WPSS not only enables learners to build a learning and performance resource that
will provide them with immediate support and guidance, but also helps them develop
structure, strategies, and skills for subsequent lifelong learning activities.

In a climate of rapid change, increasing innovation, emerging technologies, and proliferating knowledge,
lifelong learning is a necessary professional development objective. In order to keep current, people have to be
willing and able to continually "retool" their knowledge and skill base. The need to be a continuous learner is
especially apparent in domains influenced by scientific and technological advances; these advances cause
knowledge and skills to become obsolete overnight. Yet, employers need personnel who possess contemporary
skills and knowledge, and are willing and able to proactively update their abilities to meet the ever-changing
needs of the organization. Employees who are able to keep up with the information explosion are valuable
assets; employees who fail to "grow with the flow" are restructured out of their positions. Therefore, lifelong
learning is essential to staying current, competitive, productive, and innovative in today's workplace, and
therefore employed and in-demand.

Following the prescriptions of the intentional learning methodology which promotes the development of
metacognitive and self-directed learning skills, a web-based development tool was created. This tool was
designed to help people generate their own, individualized web-based performance support systems (WPSS) to
address the concerns described above by encouraging and providing a supportive structure for lifelong learning
activities.

Lifelong Learning Defined

The knowledge explosion requires professionals to engage in lifelong learning if they intend to stay
current — let alone evolve, advance, and remain competitive — in their profession. Therefore, lifelong-
learning skill development is imperative if people are expected to learn over the full expanse of their
professional lives. Unfortunately, some of the people that most need lifelong learning skills — those with
careers in ill-structured, complex professions — are not developing them during their formal education.
Regarding the lack of lifelong-learning skill development in schools, Walton and Matthews [Walton &
Matthews 1989] state, "Some [professionals] from...schools with the usual type of curriculum behave as if they
had been immunized against further learning, and many [professionals] often do not continue to learn
sufficiently." In order to better prepare people for lifelong learning, learners must be exposed to learning
activities that require them to take on and develop many of the responsibilities normally afforded to educators.
"We teach most effectively when we help our students learn how to learn...not what to think and make and do
in [the current year]; but how to think and how to learn for those years of life and profession than lie ahead"
To achieve this requires moving away from a view of learning that is controlled outside the individual — by a teacher, trainer, instructional designer, or subject matter expert — to a view of learning that is internally controlled by the individual [Overly et al. 1980]. The ability to engage in lifelong learning, therefore, is based on the development, and subsequent successful application, of two skill areas: metacognition and self-directedness.

**Metacognition**

Von Wright [Von Wright 1992] defines metacognitive skills as "the steps that people take to regulate and modify the progress of their cognitive activity: to learn such skills is to acquire procedures which regulate cognitive processes." Glaser [Glaser 1984] describes metacognitive or self-regulatory skills as knowing what one knows and does not know, predicting outcomes, planning ahead, efficiently apportioning time and cognitive resources, and monitoring one's efforts to solve a problem or learn. Metacognitive skills include taking conscious control of learning, planning and selecting strategies, monitoring the progress of learning, correcting errors, analyzing the effectiveness of learning strategies, and changing learning behaviors and strategies when necessary [Ridley, Schutz, Glanz, & Weinstei 1992]. Because metacognition involves these self-regulatory skills, it can have a positive impact on problem solving ability and the transfer of knowledge across domains and tasks if developed during instruction [Bereiter & Scardamalia 1985] [Bransford et al. 1986]. In fact, if not developed, students have difficulty recognizing when they have failed to adequately meet learning goals or complete tasks [Bransford et al. 1986]. Since these are skills utilized by successful practitioners and experts [Chi, Feltovich, & Glaser 1981] [Bransford et al. 1986], adequately developed metacognitive ability is needed in order to engage in effective problem solving and reasoning activities.

**Self-directedness**

To be successful, students must develop the self directed learning skills needed [within the domain]. They must be able to develop strategies for identifying learning issues and locating, evaluating, and learning from resources relevant to that issue. [Savery & Duffy 1995]

The domain of medicine provides a perfect example of self-directedness. When dealing with real patients, the doctor has to begin assessing the patient's condition before having all of the data necessary to evaluate, diagnose, and treat the patient. Characteristically, the patient provides the doctor with fragments of information ("My stomach hurts. I can't hold any food down. No one else in my family is experiencing any problems."). The rest of the information needed to solve the patient's problem comes from the study of a variety of other resources: patient and family history, laboratory results, x-rays, other doctors' opinions, past experiences, similar cases in the case file, and current research findings on new diagnostic and treatment procedures. The doctor has to determine what information is needed, what resource should be used to acquire the information needed, how to use the resource effectively, how to come to terms with opposing or contradictory information, and how to apply the information acquired to the problem to achieve a solution for the patient. These skills are described as "self-directed learning skills" [Barrows 1985] [Barrows 1986]. Barrows [Barrows 1995] defines the process of self-directed learning as utilizing the following skills to solve a problem or fulfill a learning requirement:

- the ability to identify and define a problem/learning need;
- the ability to identify, find, use, and critique resources for solving the problem or meeting the learning requirement;
- the ability to capture and apply information from resources to the problem or learning need; and
- the ability to critique information, skills, and processes used to solve the problem or meet the learning requirement.

Staying abreast of new innovations, research, techniques, and information is a prerequisite for successful decision-making and problem-solving on-the-job. Therefore, professionals need to develop lifelong learning skills, specifically metacognitive and self-directed learning skills, if they intend to stay current in their fields.
Organizations and Professional Development

Although employees' ability to engage in lifelong learning has a direct impact on an organization's effectiveness in today's ever-changing marketplace, the development of the skills needed to engage in perpetual learning activities has been neglected by many employers. Unfortunately, many organization's rely on short-term solutions, such as conventional training and performance support tools.

The Conventional Training Solution

How are professional development activities typically addressed? We often see trainers imparting knowledge and procedures to trainees using canned, inflexible instructional materials which often do not reflect the true complexity or the current reality of an ever-changing work environment. [Unfortunately, this is the case whether we are describing an instructor-led environment, computer-based training (CBT), or Web-based training (WBT) (which is often just CBT repurposed for the Web).] After the training activity is over, employees struggle with applying what they learned from their training experience to the demands of their jobs. Not only did the conventional training solution not accurately represent the on-the-job performance requirements, but it did not prepare the employees to:

- transfer the knowledge and skills to their specific job requirements,
- extend the knowledge and skills presented during training to address increasingly complex job requirements, or
- update the knowledge and skills presented during training when their job requirements change or the knowledge and skills change.

In other words, what is missing from the equation is the development of domain-specific lifelong learning skills so those employees can actively transfer, extend, and update the knowledge and skills acquired during training. So, employers have looked for other professional development solutions that address this problem. One solution that has presented itself is electronic performance support systems (EPSS).

The Electronic Performance Support Systems Solution

Although redefined and revised over the last few years, the term electronic performance support system refers to an integrated database of information, tools, learning experiences, resources, and guidance/advise designed to help people learn how to perform a task just-in-time or on-demand with limited conventional training support [Gery 1991] [Raybould 1995]. Addressing the failings of conventional training, electronic performance support systems have been utilized as alternatives and supplements for conventional training solutions.

However, the problem with conventional training is also, in part, the problem with EPSS. EPSS products are typically developed by instructional designers or performance technologists working with content experts. All of the tools, references, job aids, and tutorials are created to meet the general and generic needs of all the individuals who will access the EPSS; assuming that everyone who needs to access the EPSS has the same performance issues, learning needs, and learning preferences, EPSS limits individualization. In addition, like with conventional training solutions, all of the higher-order thinking, problem-solving, and decision-making that goes into creating the "content" of an EPSS — all of the activity that helps people develop domain-specific lifelong learning skills — is done by the development team. So, again, the issues of transfer, extension, and updating are not effectively addressed by EPSS.

Instructional Methodologies for Developing Lifelong Learning Skills
In order to develop lifelong learning skills, the learners — as opposed to the instructor or development team — need to be directing and driving the learning process and activities based on their learning and performance needs. Two instructional methodologies that specifically address the development of lifelong learning skills are generative learning and intentional learning.

**Generative Learning Environments**

Instead of accessing information from the system that was input by someone besides themselves (such as a teacher, subject matter expert, or instructional designer), a generative learning environment requires students — individually and collaboratively — to be responsible for creating, elaborating, and representing domain knowledge in an organized manner [Cognition and Technology Group at Vanderbilt 1992] [Hannafin 1992] Scardamalia et al. 1989] [Scardamalia & Bereiter 1991]. Some generative learning environments provide students with a context or situation requiring them to take action (e.g., a problem that needs to be solved or a case that needs to be analyzed). Other types of generative environments require students to determine what it is about a particular content area they wish to know, and then take responsibility for answering their own questions through research and synthesis and representing the acquired knowledge in an organized and accessible way. It is through this process of "generating" knowledge, instead of passively receiving information, that help learners develop structure, strategies, and habit for lifelong learning.

Generative learning environments require students to take responsibility for determining what it is about a particular domain they need to know, and then direct their activities accordingly to effectively research, synthesize, and present their findings. Schank and Jona [Shank & Jona 1991] describe a generative learning environment in their discussion on the research method of teaching. Under the research method of teaching, students are asked to research a particular topic and then present their results to others (the class, a collaborative group, etc.). In this way, students are taking over the responsibility of information gathering and synthesis and dissemination/presentation from the teacher.

For this teaching method to lead to successful learning, students need to be allowed to select their own topics to research and report on, so that they have a real interest in proceeding with the assignment and have more control over their learning. Because the learning is student-directed, where each student makes choices and takes responsibility for those choices, the learning is more meaningful; "...in general, material that is organized in terms of a person's own interests and cognitive structures is material that has the best chance of being accessible in memory." [Bruner 1961]. In addition, because students are responsible for selecting a topic, developing a question to research, making decisions about how to gather information, analyzing and synthesizing information, etc., they are engaging in activities that help to develop high-level thinking and problem solving abilities.

**Intentional Learning Environments**

Intentional learning refers to the "cognitive processes that have learning as a goal rather than an incidental outcome" [Bereiter & Scardamalia 1989]. When employed in a learning environment, intentional learning encourages students to take "an intentional stance toward cognition" [Scardamalia & Bereiter 1991], which means that learners must learn how to monitor and be aware of their own learning processes, and take responsibility for pursuing desired and/or required learning outcomes. Intentional learning is learning that is actively pursued by and controlled by the learner [Resnick 1989]. Palincsar and Klenk [Palincsar & Klenk 1992] describe intentional learning as an achievement resulting from the learner's purposeful, effortful, self-regulated, and active engagement. By encouraging students to take "an intentional stance toward cognition", intentional learning helps students learn how to not only monitor and be aware of their own thinking and learning processes (i.e., metacognitive skills), but also to take responsibility for pursuing individually-determined learning goals (i.e., self-directed learning) — the "cognitive processes that have learning as a goal rather than an incidental outcome" [Bereiter & Scardamalia 1989].

An example of a computer-mediated, intentional learning environment is the Computer-Supported Intentional learning Environment (CSILE). The goal of CSILE is to support students in the purposeful, intentional processing of information [Scardamalia et al. 1989] [Scardamalia & Bereiter 1991]. Using CSILE, students are supported in the construction of a shared knowledge base, representing and organized the domain...
in ways that can be understood and utilized by others interested in the domain. In other words, instead of accessing information from a pre-existing database that was structured, organized, and filled in by someone else, students engaged in CSILE create their own knowledge base based on what they want to learn and on how they want to structure and organize the information to be an effective resource for other learners.

Generative and intentional learning environments encourage students to construct their own meaning, perception, understanding, and knowledge. Through the process of creating, elaborating, and representing their own knowledge, these learning environments utilize instructional strategies such as collaboration, knowledge construction, reflection, and self-directedness to promote the development of lifelong learning skills and strategies, as well as a predisposition to lifelong learning activities.

**Learner-center, Web-based Performance Support Systems**

Influenced by generative and intentional learning methodologies as well as the EPSS technology, I have developed a Web-based tool empowers learners to build their own Web-based Performance Support Systems (WPSS) to support their learning, professional development, and performance within specific domains. Similar to electronic performance support systems (EPSS), a WPSS uses the Web to provide on-demand access to integrated information, guidance, advice, assistance, training, and tools to enable high-level job performance. In fact, using the Web to create performance support systems is a perfect fit because the Web is actively used by professionals as a forum for the distribution of current and up-to-date references, instruction, and guidance. By creating a structure that supports individualized and collaborative knowledge building by the people who will actually be using the knowledge, the higher-order thinking, problem-solving, and decision-making regarding the selection and utilization of appropriate learning materials and performance support is done by those who can get the most out of the process. Enabling employees to utilize an easy-to-use tool to develop their own WPSS accomplishes two goals:

1. they learn about the domain while they are locating, evaluating (which requires utilization of resources), and organizing resources to support their job performance activities and/or their generative and intentional learning activities; and
2. once the WPSS is completed it can be used to support performance and further professional development while working in that domain.

In this way, the WPSS not only enables learners to build a learning and performance resource that will provide them with immediate support and guidance, but also helps them develop structure, strategies, and skills for subsequent lifelong learning activities.

**Overview of WPSS Development Tool Components**

The WPSS development tool helps employees — collaboratively and as individuals — organize, assess, and utilize Web-based resources. In order to build an effective WPSS, the development tool enables employees to organize Web resources into a variety of self-determined categories. Categories may include:

- cue cards: brief definitions, reminders, directives, job aids, best practices
- computer-based instruction: tutorials, case studies, practice activities
- wizards: intelligent demonstration/application functions; assistance
- coaches: response sensitive correction and feedback
- mentors: individualized responses to questions from experts in the field
- practitioner forum: access to other practitioners in the field
- examples
- tools
Animation Shareware

**Level:** Intermediate

**Description:** This site provides shareware that you can use to display animations.

**Strengths:** There are several players including the AAWIN which I demonstrated on Monday. I also found an advanced program (PowerFLic) which has many more features than AAWIN. I you have any interest in multimedia animations for your WBI, this is a must see site.

**Weaknesses:** It has very little supporting information, but if you can get the shareware.

*Anthony Mostek, created 10/11/1997*

Microsoft's NetMeeting

**Level:** Beginner

**Description:** Microsoft NetMeeting is a web-based communication tool for people who are deaf or hard-of-hearing. You can use NetMeeting 2.0 to communicate more effectively in real-time with others in the workplace, the classroom, and the home—gaining substantial benefits over using traditional TTY devices. Read all about our benefits for users who are deaf or hard-of-hearing.

**Strengths:** It's free, and it is a great communication tool that can be used for web conferencing, online seminars, real-time classroom instruction. Has chat-like and whiteboard-like features. Allows people to show each other documents and work on them together.

**Weaknesses:** I'm still thinking about it.

*Joni Dunlap, created 10/8/1997*

---

**Figure 1:** Sample categories and corresponding entries

In order to build a WPSS that meet individualize, specific learning and job performance needs, employees engage in a number of generative and intentional learning activities including:

- determining their learning needs and goals
- developing a plan for action for finding resources to help fulfill those goals
- researching Web resources that meet the appropriate needs
- utilizing Web resources in order to evaluate usefulness, difficulty level, strengths and weaknesses
- updating links to Web resources when appropriate
- responding to other learners' comments regarding WPSS contributions
- developing Web resources via HTML pages and threaded discussion forums

In other words, employees practice and develop the very skills and strategies needed to engage in lifelong learning activities while they are learning domain-specific content and skills needed for their jobs.

California State Univ. WebQuest - Tools, Templates,
Training
Level: Intermediate
Description: This site provides a lot of useful information in all three
areas: Tools, templates and training. This site may prove to be useful for
our Project 1.
Strengths: This site provides the following:
1) Strategies and tactics for on-line teaching and learning
2) Document preparation for on-line courses,
3) On-line student learning activities,
4) Growing an on-line learning community, and
5) Management of on-line course resources.
It is very well organized and appears easy to use.
Weaknesses: I am looking for them. Maybe too much information?

Comment: I started taking the on-line course to see the format, content,
etc. and found something interesting relative to the Professional
Development Center. They had chats with experts and then summarized
the information.
Check out the URL http://edweb.sdsu.edu/clint/chat.html
to see how they did it.
Sherri Lancton, 9/22/1997

Figure 2: Example of a threaded discussion and commenting on others' contributions
Examples of the WPSS in Use

Although still in a formative stage with enhancements being added all the time, there are a number of examples of the WPSS tool in action. These WPSS examples can be viewed for examination purposes only via the following URLs:

- Domain: Designing Distance Learning for the WWW
  http://www.cudenver.edu/~jduanlap/wpss.cgi/5990
- Domain: Multimedia Authoring with HTML
  http://www.cudenver.edu/~jduanlap/wpss.cgi/5600
- Domain: C++ Programming
  http://www.cudenver.edu/~jduanlap/wpss.cgi/cplpl

To experiment with the tool, access to a sample site is provided at:
http://www.cudenver.edu/~jduanlap/wpss.html

[Note: In order for the WPSS to function properly, your browser must accept cookies and have JavaScript enabled.]

Conclusion

Because lifelong learning is now such a critical success factor for professionals in business and industry, learning environments that help promote the development of lifelong learning skills and strategies are in high demand. Influenced by generative and intentional learning environments, a Web-based development tool was designed to enable employees to develop their own Web-based performance support systems. The activity of building a WPSS helps employees learn about a domain, construct a knowledge base to support their future performance and professional development in that domain, and develop the skills, strategies, and structure needed to engage in the type of lifelong learning activities that will help them stay current in their professions.

Abstract: Adaptive link annotation is a new direction of research within the field of user-model based interfaces. It is a specific technique in Adaptive Navigation Support (ANS) which aims to help users find an appropriate path in a learning and information space by adapting link presentation to the goals, knowledge, and other characteristics of an individual user. More specifically, ANS has been implemented on the WWW in the InterBook system [Brusilovsky, Schwarz & Weber, 1996] as link annotation offering four states: Ready to be learned, visited, not ready to be learned, and unknown. In this paper, we present preliminary results from an investigation to determine the effectiveness of user-model based link annotation on learning outcomes for a group of twenty-five second year education students, in their study of databases and spreadsheets, using sections of a textbook on Clarisworks, which had been authored into the InterBook program. Through the use of audit trails, questionnaires and test results, we show that while this particular form of ANS implemented in InterBook initially had a measurable negative effect on student's learning, it appears to have been beneficial to the learning of those students who tended to accept the navigation advice, particularly initially when they were unfamiliar with a complex interface. Discussion and suggestions for further research are provided.

Introduction

Adaptive annotation of links is a new and promising technique for adaptive navigation support in educational hypermedia. This technique was suggested in Brusilovsky, Pesin, & Zyryanov [1993], and in de La Passardiere & Dufresne [1992]. The idea of adaptive annotation technology is to augment the links with some form of comments which can tell the user more about the current state of the nodes behind the annotated links. These annotations can be provided in textual form [Zhao, O'Shea & Fung 1993] or in the form of visual cues using, for example, different icons [Brusilovsky, Schwarz & Weber 1996; de La Passardiere & Dufresne 1992], colours [Brusilovsky & Pesin 1994; Brusilovsky & Zyryanov 1993], font sizes [Hohl, Böcker, & Gunzenhäuser 1996] or font types [Brusilovsky, Schwarz, & Weber 1996]. Link annotation is known as an effective way of navigation support in hypermedia [Zhao, O'Shea & Fung 1993]. Annotation seems to be a very relevant way of adaptive navigation support in educational hypermedia. Annotation can be naturally used with all possible forms of links. This technique supports stable order of links and avoids problems with incorrect mental maps.

Adaptive Navigation Support in InterBook
InterBook is a system for authoring and delivering adaptive electronic textbooks on WWW. All InterBook-served electronic textbooks have a generated table of content, a glossary, and a search interface. Each electronic textbook is based on knowledge about the subject domain represented in a form a network of concepts. Each node of the domain network is represented by a glossary entry. Likewise each glossary entry corresponds to one of the domain concepts. All sections of an electronic textbook are indexed with domain model concepts. For each section, a list of related concepts called the spectrum of the section is provided. The spectrum of the section can represent also the role of a concept in the section (each concept can be either an outcome concept or a background concept). The knowledge about the domain and about the textbook content is used by InterBook to serve a well-structured hyperspace. In particular, InterBook generates links between the glossary and the textbook. Links are provided from each textbook section to corresponding glossary entries for each involved background or outcome concept. Similarly from each glossary entry describing a concept InterBook provides links to all textbook units that can be used to learn this concept. It means that an InterBook glossary integrates features of an index and a glossary. These links are not stored in an external format but generated on the fly by a special module that takes into account the student's current state of knowledge represented by the user model. InterBook uses coloured bullets and different fonts to provide adaptive navigation support. Wherever a link appears on InterBook pages: in the table of content, in the glossary or on a regular page, its font and colour of its bullet will inform the user about the status of the node behind the link. Currently four colours and three fonts are used. Green bullet and bold font means 'ready and recommended', ie., the node is ready-to-be-learned but still not learned and contains some new material. A red bullet and an italic font warns about a not-ready-to-be-learned node, while white means 'clear, nothing new', ie., all concepts presented on a node are known to the user. Violet is used to mark nodes which have not been annotated by an author. A check mark is added for already visited nodes.

The literature on the evaluation of adaptive link annotation in educational hypermedia is limited and sometimes characterised by anecdotal evidence from a variety of less formal experimental designs. Further, the evaluation of adaptive hypermedia systems has generally been noted by writers in the field as a much under-investigated area. Existing studies have tended to focus on the use of audit trails to provide information about the effectiveness of link annotation in terms of improving browsing or learning efficiency. A survey of the literature on adaptive navigation support in educational hypermedia reveals just a few empirical studies, or at least papers with a non-trivial evaluation component, that serve to set the context for the study reported in this paper. de La Passardiere & Dufresne [1992] conducted experiments with MANUEL EXCEL focussing on the value of history-based mechanisms such as a three-stage footprint [unseen, partially seen and completed] and the use of adaptive advice. Their work pointed to the value of an adaptive history-based mechanism as a means of navigation support. Brusilovsky & Pesin [1995] conducted one of the earlier studies with the adaptive link annotation and hiding mechanisms of ISIS-Tutor. This was an important piece of work which reported some positive results with ISIS-Tutor which used colours and symbols to adaptively mark the links on a page to related pages. This environment used annotations of "not ready to be learned", "ready to be learned", and "in work". As another extended "with and without" experiment conducted at The University of Moscow, it was found that "...the overall number of navigation steps, the number of repetitions from concept to concept and from index to concept are seriously less for [adaptive hypermedia]" [Brusilovsky & Pesin, 1995, p. 222]. In a recent study using ELM-ART-II, Weber & Specht [1997] compared the mean number of pages and tests that visitors to the ELM-ART-II Web site made [those who made a non-trivial visit], both with and without adaptive link annotation and adaptive curriculum sequencing. It was found that there was a statistically significant effect of adaptive curriculum sequencing at p<0.05 but no significant difference in link annotation. Here, it is the ability of these adaptive interface tools to motivate the users to proceed that is being evaluated. Further, Weber & Specht [1997] report that adaptive link annotation had no significant effect on the number of navigation steps. Weber & Brusilovsky [submitted] used the ELM-ART system to test the effect of both adaptive curriculum sequencing, as mentioned, and link annotation. No significant effect on the number of navigation steps was found through the use of adaptive link annotation. There was some evidence that the adaptive component was useful for beginners, but the small effect faded as the users became more familiar with the system.

**Empirical Study**
In a study involving 25 undergraduate teacher education students in an educational computing elective at the University of Technology, Sydney, students were exposed to two chapters of a textbook [Rubin, 1996] about Claris Works databases and spreadsheets, and used the InterBook system both with and without adaptive link annotation. The goal of this experiment was to assess what impact, if any, user-model based link annotation would have on students' learning and on their paths through the learning space, in this realistic situation. The experiment was aimed to investigate both the effect of link annotation on learning and the effect of link annotation on user paths. The hypothesis was that adaptive link annotation would provide students with a more efficient path through the knowledge space with improved learning outcomes. Tests of knowledge were carried out, audit trails and questionnaires were gathered and the results analysed. The experiment took place over a four-week period. In the first two-hour session, students were introduced to InterBook and its features explained to them. They used the system for an hour, and answered a questionnaire about its features. This questionnaire showed that almost all students were familiar with what each of the buttons and annotations meant. They were then free to use the system at any time during the following week. In the second session, students were randomly divided into two groups of equal size, one group receiving the link annotation, while the other group did not. They were allowed access to the chapter of the textbook on databases which had been authored into InterBook and they completed a questionnaire. Students had access to the database chapter for the following week. In the third session, students took a multiple choice test on the database section of the textbook. They were then allowed access to the spreadsheet section of the textbook in InterBook which they could access for the following week. This time, the group that did have the adaptive link annotation for the database section now did not receive it, and vice-versa for the other group. In the final session, students took a multiple choice test on the spreadsheet section and completed a questionnaire. The audit trails from the sessions were extracted, and analysed along with the test results and the questionnaire responses.

Results

Questionnaires were used to assess the functionality of each of the key interface features of InterBook, the results showing that all the features were working as expected, quite uniformly across the group. The students' test scores were then used as a measure of their learning of the material in each of the sessions. Adequate reliability and performance of all test items were established by discarding some of the test questions or individual distractors. In this way, each of the test questions was constructed to be an adequate predictor of how a student would score in the overall test, as is desirable in a norm-referenced test. At the conclusion of the experiment, alphas of 0.75 and 0.82 were obtained for the database and spreadsheet tests respectively, and these very acceptable values were interpreted as establishing adequate reliability for the tests to be used in this and any subsequent experiment. A two-sample t-Test was performed on the test results, and a t value of -0.3667 showed that link annotation had a statistically significant negative effect at the p<0.05 level on the database section [the first session], and no effect on the spreadsheet session [the second session]. This unexpected initial result suggested that further investigation was required.

To exclude students who learned less from the system than from other sources in the study, two subgroups were introduced, the first based on spending a 'reasonable time' with the system. This consisted of those students who spent a reasonable time using InterBook over both sessions, as it became clear from the audit trails that a number of students relied heavily on either their previous knowledge of the content, or on the printed version of the Claris Works book. For both the database and spreadsheet sections, two-sample t-Tests showed that there was no significant difference at the p<0.05 level in the test means for those with ANS and those without ANS. Separate audit trails for each of the two time periods were generated, to examine how users navigated through InterBook with and without ANS. For each user these trails showed the number of times they selected a link with a green ball and also a red ball, as well as their use of all the other features of the interface. The non-annotated 'continue' button was used more than all other interface features put together. This button takes the user to the next node in the courseware as sequenced by the author. Certain unexpected behaviour was immediately apparent for a small group of students, who were purposefully and continually selecting nodes which were not recommended. More generally, it was noted that just because link annotation was evident in the interface for one group, individual students within that group were accepting it to vary extents. Just because a student was offered link annotation does not mean...
that they were accepting or making profitable use of it. A measure of the student’s acceptance of navigational advice was calculated from the audit trails, taken as the number of green ball hits minus the number of red ball hits divided by the total hits.

A clear correlation of 0.670 was found between the agreement rate and score in the database tests: The more students agree with system’s suggestion, the better is the score [for the group receiving link annotation]. This positive correlation in the first session on databases suggests that while link annotation may be a distracting complication to an interface, it is helpful to those that choose to follow it in terms of improving their knowledge of the content. We also examined the paths of each group through the hypermedia, and found that those with link annotation had more exploratory, less linear paths, although this difference was marginal. This reflected their trust in the system’s suggestion and the support that they were offered by link annotation to do something other than press the ‘continue’ button.

**Conclusion**

These results suggest that ANS is a feature which is initially useful in improving comprehension for those new to a complex interface who are prepared to accept it. However, it adds another option to an interface: a cognitive overhead which may distract users from the content. This was reflected in the fact that the overall group who received ANS initially performed significantly worse in the knowledge tests. User model based link annotation seems to be of value to those that agree with it, those that accept and follow the annotations. They take advantage of the fact that the content has been examined and structured for them, and they make use of both the implicit structure of the knowledge that the courseware embodies in its static form, as well as the individual link annotations which hint at the domain structure relative to the current path of the learner through the user model. The experiment offers firm evidence that adaptive link annotation has a significant positive effect on student learning in an educational system. However, once users with minimal hits on the system were excluded, numbers in each of the two groups with and without annotations was a mere 8 and 9 respectively, and this is one of the severest limitations of the experiment. This study also suggests that the existence of ANS in the interface has an effect on the linearity of a user’s path through the learning space, with those users experiencing link annotation being prepared to use those annotatable links more often than those who received no link annotation. As a result, their paths through the material were less linear, more exploratory, as they selected more "real links" and exhibited less use of the Continue button. In some ways this is hardly surprising, and again reflects the learner’s trust of the system’s annotations. If a link is annotated, a user has more confidence about the relevance of the material behind it than under a non-annotated link. In a non-annotated InterBook interface, the safest option for users was the repeated use of the Continue button.

Abstract: Reusing pre-existing electronic information in the design of educational software has become a new perspective able to reduce the development costs of such systems. This approach has to face the problem of organizing and structuring this pre-existing information in a way that ease users' understanding and assimilation. Formal Concept Analysis (FCA) Theory is proposed as a technique to extract and organize the domain information contained in the reused information and as a suitable method to implement different interaction techniques. Therefore, FCA can be used as a complementary tool in the production of systems with educational or help purposes.

1. Introduction

Due to the advent of Internet and the massive dissemination of bibliographic collections, software libraries and multimedia repositories, the amount of electronic information available has rapidly grown. In many educational contexts reusing all this knowledge to provide tutorial or help support would avoid constructing this kind of systems from scratch and it will reduce their final production costs. Reusing this knowledge leads us to solve the problem of how to make useful for users this information that was originally created without educational purposes. To obtain this educational aim we propose to structure and to organize this pre-existing information in a way that ease users' understanding and assimilation. With this goal we propose to integrate in the same educational system different organisations of the domain information (based on different techniques) that allow multiple kinds of interactions with users. We applied this approach to the construction of assistants for complex software applications [Fernandez-Manjon 98, Fernandez-Manjon 97].

Frequently, educational applications are built around some kind of conceptual network (knowledge base) representing experts' view of the domain that is used to organize the information. Gathering experts' knowledge identifying what are the domain key concepts; what are their attributes and what are their interrelations is an essential and difficult phase in the software design process [Winkels 92]. This is usually done in a manual way and it is difficult to apply in complex domains. Also, there is no perfect structure for a concept map (or a single view for a domain) and it can always be discussed, improved or adapted. To cope with these problems we propose to integrate the manual approach with other complementary techniques. In many real scenarios the main objective is to face the problem of extracting, organising and structuring automatically the domain information in order to build low cost, pragmatic and "easy to access" conceptual networks.

In this paper we focus on an approach to the automatic construction of conceptual networks based on Formal Concept Analysis (FCA) Theory and its application in the development of help tools. We think that FCA can provide the basis for educational tools that use a conceptual network as a learning tool, as a navigational support (e.g. giving access to a rich multimedia documentation), or even as a method for designing educational applications. This theory is especially suited to areas where there is a large number of objects that can be described using a rich set of attributes. FCA theory allows the construction of a conceptual network whose (formal) concepts are automatically extracted from the objects and attributes of the domain. We choose the Unix operating system as a complex and well known domain to exemplify our approach.

The rest of the paper is organized in the following way. First, we present what is necessary to turn the pre-existing information into an effective educational medium. Then we introduce the basics of the formal concept analysis theory and how this theory can be used to support design and production of educational software. Finally, we present some conclusions of our approach.
2. Information Reuse, Organisation and Interaction in Educational Systems

We understand the construction of educational software (and more specifically of help systems) not only as a process of software development but also as a process of organizing, accessing and structuring pre-existing electronic information oriented to obtain useful and effective assistants. The information reuse approach proposed leads us to solve the problem of how to extract, organize and structure the domain knowledge embedded in a set of documents whose final objective is to be presented to the user in a comprehensible way. Also, the application should allow different and "easy to use" interaction methods (e.g. information retrieval or browsing) to simplify the access, relation and understanding of the information presented.

Usually the help systems are accessed by the user in a free learning way (not in a driven learning way) to retrieve some items of interest, to obtain complementary information or to explore the related contents of the domain [Winkels 92]. In this situation it is appropriate to organize the domain information into some kind of structure that could be explored by the user in a simple and "browsable" way [Wasson 92].

The idea is to merge structuring and browsing methods in order to provide user with a flexible way to interact with the domain knowledge without knowing precisely how it is organized or what are exactly his learning goals. The main difference between browsing methods and the more classical accessing methods based in information retrieval techniques is that browsing allows a "free" examination of the indexed information without any preliminary knowledge of the domain while most of the information retrieval methods make necessary a previous knowledge of the domain in order to construct queries able to specify the user's needs [Salton 89]. Also, when applying information retrieval techniques users can not directly explore the structure of the domain knowledge and, as a consequence, the learning component of the system is reduced due to it not being possible to view similar or related concepts at first sight.

The domain knowledge in such a navigational educational or help system should be arranged in a conceptual network (or hierarchy) permitting the user to easily move around and examine concepts. Within this network similar domain concepts should be clustered allowing direct accessing to other related concepts. The construction of such networks is usually done manually by human experts that select and index the main concepts of the domain. Concepts obtained and arranged following this approach may be perceived to be similar in many senses and the corresponding mapping to a specific conceptual network may often turn out to be quite arbitrary, depending on the subjective judgement of the expert. Systems created using this approach are expensive and very difficult to maintain. Also, besides the conceptualization difficulties, attempts to provide efficient network navigation are hindered by visualization technical problems. In order to fully exploit the conceptual network created and not to overcharge the user with extra information the browser interface should allow to make a partial exploration of the hierarchy.

Our approach to the construction of educational software reusing pre-existing electronic information is supported by the (complementary) use of FCA theory. FCA suits the needs of the organizing-navigational paradigm presented above due that it can be understand as a technique able to extract and organize the domain knowledge embedded in a document collection within a structure suitable for browsing. As FCA is an automatic method, the development and the maintenance costs of systems based on this approach are competitive.

3. Formal Concept Analysis Theory: Formal Concepts, Contexts and Hierarchies

FCA provides a complete set of mathematical tools to analyze and to obtain conceptual hierarchies [Wille 92]. Here we introduce in an informal way the main notions of FCA without using the mathematical formulation of the theory (as previously done in [Wolff 94]) that can be found in [Wille 92, Davey 90].

The central idea is the formal concept which is a mathematical abstraction consisting of two parts, the extension and the intension. The extension covers all the objects belonging to a concept while the intension comprises all the attributes valid for all those objects. When the objects and attributes of a domain are fixed we called this a formal context. For a better understanding of the idea of formal concept we propose the following example. [Tab. 1] shows a context where some Unix commands are described by some keywords or descriptors (obtained from the command documentation). In this case the objects are a subset of Unix commands, the attributes are a subset of keywords used to describe the commands and the crosses in the table hold a "has a" relationship between a Unix command and a specific descriptor. An empty cell in [Tab. 1] indicates that the corresponding descriptor does not describe or does not apply to the corresponding command.

The basis of the most widely understanding of a concept is the function of collecting individuals into a group with certain common properties. Keeping this idea in mind we will consider the attributes corresponding to the object "lpr" and ask for those commands (within the context) which share attributes with the object "lpr". We
can see that no object shares all the attributes belonging to "lpr" but the objects "lpq" and "lprm" share the attributes "printer" and "job" with it. Hence we get the set A consisting of {"lpr", "lprm", "lpq"}. This set of objects is closely connected to the set B consisting of the attributes {"printer", "job"}. It is possible to conclude that the set A is the set of all objects having all the attributes of B, and B is the set of all attributes which are valid for all the objects in A. In FCA each of these pairs (A, B) is called a formal concept.

Table 1: Formal context produced by seven Unix commands and their descriptions

Concepts of a given context are naturally ordered by the generalization-specialization relation (subconcept-superconcept) producing a hierarchy for the given context. At the top will be the more general concepts that have a smaller intent and larger extent that any of the more specialised concepts below. If we look again at our example we can see that the concept A1 = ({"lpr"}, {"printer", "job", "send"}) is a subconcept of the concept A2 = ({"lpr", "lpq", "lprm"}, {"printer", "job"}).

Particular kind of formal concepts are those concepts generated by an only attribute or object belonging to the context. These concepts are called attribute and object concepts respectively; they are useful because an object concept represents the smallest concept with this object in its extension while an attribute concept represent the largest concept with this attribute in its intension. In our example, the concept ({"lpr"}, {"printer", "job", "send"}) is an object concept and it can be considered as the most specific concept with the object "lpr" in its extension. On the other hand, the concept ({"rm", "lprm"}, {"remove"}) is the attribute concept corresponding to the attribute "remove". This attribute concept is the most general concept with the attribute "remove" in its intension.

Moreover, hierarchies of formal concepts can be represented graphically by line (or Hasse) diagrams. These diagrams are composed of nodes representing formal concepts and links representing the subconcept-superconcept relationships (notice that this hierarchy is not limited to be a tree). Object concepts are named with the object that produces the concept; attribute concepts are labeled with the attribute that generates the concept. A diagram contains all the context information; an object has an attribute if and only if there is an upwards leading path from its object concept to this attribute concept ([Fig. 1] shows the diagram of the Unix example). That means that most of the FCA applications can be supported by graphical representations that simplify the presentation of information and the interaction with users.

4. FCA as a Learning Tool: Information Retrieval, Browsing and Application Design

There are several learning alternatives that can be implemented to exploit the organization of the information around the domain formal concepts provided by the FCA. We analyze three different uses: information retrieval, browsing and application design.

The domain structuring provided by FCA can be used to support an easy and effective retrieval of information. For instance, in the Unix example, the problem of a user looking for information about a specific command can be focused to FCA terms as a process of helping users to obtain the smallest concept that has this command in its extension (i.e. the object concept).

As FCA gives us all the formal concepts of the domain and their organization within the conceptual hierarchy it is possible to implement different retrieval interactions with the following common characteristics. The user does not need a previous knowledge of the domain, it is not necessary to know the keywords or structure used to index the information and; the searching process is driven in a quick and incremental way. In order to construct the "queries" that define the search path to the object concept requested two kind of interfaces may be implemented: a table based interface and a hierarchy diagram based interface. Table based interfaces show a set of selectable descriptors that the user can incrementally choose in order to describe his needs; as another separate
column the interface presents the set keywords selected by the user and; as a third column, the interface shows the items selected by the system as possible objects to be retrieved. This way of presenting hierarchical information allows the user to obtain at least one object in his searching process [Lindig 95].

An example of this approach is presented in [Tab. 2]. In this example the user needs to find information about the commands used to change the working directory in Unix. To do his first choice the system will present as selectable descriptors all the descriptors available in the conceptual network allowing the user to select the keyword "directory". Then the system will show as possible items to retrieve the objects "rm", "ls", "cp" and "cd" and it will update the list of selectable descriptors to those keywords related with the attribute "directory" (i.e. "copy", "remove", "file", "change", "display"). Next interaction will refine the searching path adding the descriptor "change" to the incremental query. This last selection drives the search to the object concept {("cd"), ("directory", "change")} that will be used to retrieve the information related with the command "cd".

<table>
<thead>
<tr>
<th>Step</th>
<th>Selected Descriptors</th>
<th>Commands</th>
<th>Selectable Descriptors</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>--</td>
<td>all</td>
<td>all</td>
</tr>
<tr>
<td>2</td>
<td>directory</td>
<td>cd, cp, ls, rm</td>
<td>copy, remove, file, change, display</td>
</tr>
<tr>
<td>3</td>
<td>directory, change</td>
<td>cd</td>
<td>--</td>
</tr>
</tbody>
</table>

Table 2: Incremental query construction where the user specifies the keywords "directory" and "change". The commands and the descriptors compatible with the partial query specification are also shown.

On the other hand, a second approach to the construction of information retrieval interfaces based on concept networks is to present the hierarchy diagram in a graphical way. This approach would arrange the formal concepts around a graphical diagram where users could access directly to the indexed information. In this case, if the domain were complex, problems could arise making very difficult the visualization of the complete set of concepts. Solutions to this problem should avoid presenting the whole diagram focusing the view in the sub-hierarchies related with the user's interests [Carpineto 95] or merging the tabular representation with a graphical representation of sub-hierarchies. The above approach to graphical concept hierarchy representation is closely related to a domain browsing approach.

Domain browsing is an approach to the exploration of indexed domains that allows the user to interact with the domain without knowing precisely the contents of the domain or the way it is organized. Relations between concepts obtained using FCA define structures suitable for browsing. Conceptual networks appeal to the
browser's intuitive notions of distance, closeness and dimensions clustering similar concepts within the concept diagrams. Also, browsing methods not only can be used in a domain exploration way but also they can be exploited as powerful learning tools that allow users to solve their direct needs of information (short term learning process) and finally acquire a global view of the domain where browsing is applied (long term learning process). This is the reason because the way browsing is going to be done and how it is going to present the domain concepts and their relations are going to clearly determine the domain users' learning process.

We will explain a typical browsing session within a conceptual network implemented using FCA and we will try to observe how the learning process is going to be done. Coming back to the Unix example, suppose that the user explores the domain in order to obtain information related with the commands used to manage the printer. He will browse to the node "printer" unfolding the part of the domain corresponding to the subdiagram shown in [Fig. 2]. This subdiagram only contains as object concepts those related with printing actions such as "lpq", "lprm" and "lpr". The selection of a specific descriptor reduces the number of navigational concepts within the diagram to those concepts that are especialisations of the attribute concept "printer". The application of a browsing technique over the concept hierarchy makes that the system does not show commands such as "ls" or "rm" that are related with typical file and directory actions but that are described by the keywords "display" and "remove" respectively. As a consequence, the user's attention will concentrate only in the information that he wants to know about and, at the same time, he will acquire a global notion of all the commands that can be used to manage a printer in Unix by inspecting its electronic information related. The following user's interactions will refine the learning objectives browsing down in the diagram in an incremental way until the browsing process obtain an object concept.

![Subdiagram](image)

Figure 2: Subdiagram corresponding to the user's selection of the keyword "printer".

Finally, FCA can be used as a previous step in the design of educational applications. The automatically extracted formal concepts can be latter refined by the domain experts in order to manually construct the definitive conceptual network. The number and the quality of the concepts obtained by FCA are variable because it depends on the objects and the description of these objects (that is the formal context). But we have the warranty that all the information is indexed.

Also it is necessary to notice that FCA permits a more labored analysis of the data and even to create different views of the same domain as described in [Wille 92, Wolff 94, Godin 95]. One of the possibilities is that the analysis of the domain can be done taking into account which are the relationships between the attributes and not only considering those as a simple and independent characteristics. For example, we could also include in the analysis of the domain the experts' perception that the "display" and "list" actions are particular instances of a more general action that is "inform". That will also produce an automatic organization of the domain information but taking into account the experts' view of the area.
5. Conclusions

In this paper we have introduced formal concept analysis as a tool to develop educational software reusing pre-existing electronic information. Systems that implement this technique have low development costs and are easy to maintain. This is possible due to FCA feature able to process the electronic information automatically.

We have compared FCA with other approaches used to construct the same kind of systems and we can conclude that the conceptual networks created using FCA may improve the effectiveness of hierarchy navigation for interactive searches and the general learning process of a specific domain. The main reason is that concept relations generated by FCA theory provide a conceptual structure that can smoothly integrate different methods to manage and to present information without changing the domain structure created. We do not propose AFC as an information extracting and structuring standalone method. Nevertheless, conceptual networks usually have no relevant or nonsense concepts that should be discarded by a domain expert. FCA should be understood as a first step method able to create a first organization of the domain that considerably reduces the efforts and costs of developing the structure of a domain from scratch.

Presently, we are using FCA as a tool to unfold the domain data supporting the construction of better user interfaces. We are applying this approach not only in the Unix domain but also in a different application for teaching text comprehension in a second language. The next step of the project is the evaluation with real users of the interfaces produced using this technique.

Abstract: The current development Internet tools enables the appearance of new challenging fields of applications for global network. A particular technology, the WWW, has been acted as the central explosion spot for new application areas and better system integration using the Internet infrastructure and tools. One of these new auspicious fields is teleproductics, which is the remote access and control of industrial devices/facilities through a telecommunications network, in this case the Internet. This paper describes the project, design and development of an Internet supported teleproductics system aimed for interactive distance learning of mechanical engineering. The current result of this project was the implementation of a virtual mechanics laboratory, used to demonstrate the Internet technologies applied to teleproductics.

1 Introduction

The subjects described on this paper are built around the teleproductics [Firmeza 1997] concept. Teleproductics is the interaction among industrial facilities, shop floor devices, computer systems and telecommunications networks. The main idea of application of teleproductics system, is the remote control of self-contained highly automated industrial plants. In despite of the apparent concept’s limitation related to more wide application fields, in fact, many applications can be imagined. An example is the projected and developed system, designed to be applied to teaching mechanical engineering by using virtual laboratories (enabling cost reductions due to the overcome of multiplication of similar facilities), using the Internet benefits such as accessibility, easy of use and globalization.

Figure 1 illustrates the concept of teleproductics applied to IDL [Minoli 1996].

![Figure 1: Teleproductics applied to IDL concept.](image)

System's Design And Architecture

From this point on, this paper will describe the project and implementation approach of a Web based teleproductics system, developed to demonstrate the capabilities and potentialities of the general concept. On our particular design, the system will have the following main modules:

- A virtual Control and Operation Platform, designated COP.
- A Manufacturing Integration Platform, designated MIP.
- The Manufacturing Platform, which includes a shop floor containing its specific devices and custom industrial network.
- Feedback circuits, which includes return video data and alarm/event notification.

The next figure presents a simplified diagram presenting an architecture obtained from this specific design:

![Architecture of an Internet based teleproductics system.](image)

2.1 The Control and Operation Platform

The control and operation platform includes applications for shop floor simulation, CAD/CAM tools and a container for all the tasks related to remote device control, operation and configuration.

In this design proposal, this container is essentially an HTTP\(^1\) client. Obviously, we are talking about an ordinary Web browser, such as Netscape Navigator or Microsoft Internet Explorer. In fact, these are currently the only two solutions available which fill the system’s requirements (JAVA support, installable plug-ins, etc). The use of a browser as the container for the user interface improves the architectural independence of this important module, allowing users to access the virtual laboratories using different machines and operating systems. This feature is a key role on the system’s portability and accessibility.

When thinking about a Web browser acting as the virtual interface to the system, we may think that everything was built using the HTML\(^3\) language. Although HTML is used, it has a minor paper on the interface functionality, since it was implemented mostly by using virtual reality models constructed using VRML\(^4\), and JAVA applets to do the “real” job of operating the system.

To better understand how the system is remotely accessed, using the Web browser, let’s look at the operations from a top-down perspective (Figure 3):

---

\(^1\) HTTP: HyperText Transfer Protocol
\(^3\) HTML: HyperText Markup Language
\(^4\) VRML: Virtual Reality Modeling Language
When a user accesses the system by using the Web browser, we get a VRML 3D model of the virtual laboratory, allowing him to "walk" inside it just by using a pointing device (usually the mouse). When approaching the model of a lab's element or manufacturing device, the user can access a page allowing him to operate or configure the specified device, just by clicking it.

After completion of control data modification, user returns to VRML model, allowing to operate/configure another device. The complete user interaction process is represented on the following diagram (Figure 4):

![Diagram of user interaction process]

**Figure 4: User interaction's top-down diagram.**

All the configuration and state data is stored on a database placed on a lab's server. This database has an essential role on the entire system, since it acts like a common point of access for both the user modules, and the control and operation services running on the lab.

### 2.1.1 Control and Operation Modules

These modules can be implemented either by using HTML forms associated with server CGI applications or ISAs\(^5\), or by using JAVA applets with remote database connectivity.

On the first approach, all the processing and database access occurs on the lab's side, by remotely launching specific database access applications on HTTP server. Their functions are retrieving device configuration or state data, and modify specified parameters. The second solution conducts to a more distributed system, since the clients connected to the system do part of the processing work. This JAVA based solution, remotely accesses the database managed by a SQL server placed on the lab, using, for instance, a JBDC\(^6\) connection [Thomas 1996]. This solution conducts to a more user-friendly system, containing better features and functionality.

\(^5\) ISA: Internet Server Application. Microsoft's standard for HTTP server applications, built over the Internet Server API (ISAPI).

\(^6\) JBDC: JAVA Database connectivity
2.1.2 Device's Native Programs Upload

Most of the available manufacturing devices need to be programmed to do a specific job. Many allow users to load manufacturing programs, either by using a storage media, or by communicating with the device using a communications network. In the case being studied, we need to upload programs to manufacturing devices remotely over the Internet, using the browser. One of the solutions for this problem, and the one being adopted, relays one more time on using JAVA applets. Their task is to upload a user's manufacturing program into a lab's server, and then notify a server's service to deliver the code to the specified device.

![Program file upload process](image1)

Figure 5: Program file upload process.

2.1.3 Additional Modules to the Control and Operation Platform

Integrated, or coexisting with the Web browser, the user needs some additional features. On systems like this one, two additional modules are quite important: an alarms & events reception module, and a video reception module [Wolf 1996].

The alarms & events module is needed to receive alarm messages generated on the lab whenever abnormal or error situations occur on the real manufacturing process.

The video reception module is needed to show the real flow of the process, using monitoring cameras installed on strategic placed spots of the lab.

![Video and alarms modules](image2)

Figure 6: Video and alarms modules.

2.2 The Manufacturing Integration Platform

The Manufacturing Integration Platform (MIP) is one of the main system’s components. Its mission is to place a bridge between the control and operation clients connected to the lab and the lab itself, comprising its manufacturing devices and equipment.

On a logic approach, the MIP must contain a set of services, allowing the setup, control and monitoring of the labs shop floor.

A general MIP usually contains several communication interfaces, like the interface to the connected users (the Internet), and interfaces to specific devices (MAP[7], serial, Ethernet, etc), to support the data flow to all its inner services.

The Figure 7 represents the logic architecture of the MIP.

2.2.1 The Lab: A Windows NT Based System

At the lab the interface everything will be implemented through a server (Figure 8). This server, that we’ll call Lab’s Server, will provide access to text files containing HTML and VRML scripts. Additionally the server is used to store specific applications required to manage the processing of data received from the configuration forms, and other applications such as monitoring and communication tasks. Some of those applications are CGI applications, which are launched by the HTTP service.

Coexisting with the services and associated applications, this machine (or another machine on lab’s network) will be the host for a database. The function of this database is the storage and management of the configuration data of the production unit’s components. On the proposed implementation this database is based on a SQL Server, for increased functionality and modularity of the system.

To enable the coexistence of all those services, the operating system to be used on this server must be a multitask operating system, with integrated network support. The proposed solution is based on Windows NT Server, which includes the entire network functionality required embedded. Furthermore its version 4.0 includes also the IIS\(^8\) which includes an HTTP server with support for CGIs, direct access to databases and an API called ISAPI\(^9\), that allows to write applications for the WEB service, with some advantage over CGI applications.

Using the Microsoft SQL Server for Windows NT the connectivity and access to the database problem is also solved.

This machine also hosts a service to process and transmit/receive the control data from/to a central control unit which direct controls specific devices, and also a service to handle the feedback video signals, including its transmission to all the connected management and operation units.

\(^8\) IIS: Internet Information Server, from Microsoft Corporation

\(^9\) ISAPI: Internet Server Application Programming Interface
2.2.2 Device Control Service & Interfaces

Manufacturing devices can present several types of external control interfaces, being the most common serial, MAP/MMS\(^{101}\) [Messina 1994] or Ethernet interfaces, excluding some proprietary solutions.

A clear issue arises when comparing these and other kinds of interfaces: The addressable ones, and the non-addressable ones. In the first case fits MAP or Ethernet, while serial fits the second case.

The main differences between these two cases are relating to the delivery process to a specified device. While data on addressable devices is kept attached to messages or commands transmitted or received encapsulated on the network protocol used, on non-addressable devices we must have an additional module responsible to data delivery from/to specified devices.

The device control module, named Central Control Unit (CCU), is implemented as a Windows NT service that runs on the server and is always listening to changes on the system's database. Whenever a user on a control and operation platform performs a database modification, this service receives a message from that client containing a device's identifier. Then, this service requests a SQL database query reading the specified device configuration and state. Finally, using that data, the service constructs a frame and delivers a message to the device using the appropriate physical connection, and data encoding.

2.2.3 Lab's Integration

With such architecture, we walk to true manufacturing integration, with a common interaction point on the entire process, accomplished by the shop floor server. This is an open architecture allowing to distribute the several processing modules over several machines on the lab's network, including the SQL database. All the remote COP's input/output is accomplished by tunneling data to the lab's server. (with the eventual exception, depending on the implementation approach, of the video delivery service).

The following figure represents an example of the concept of shop floor integration with a common point of access.

---

\(^{101}\) MMS: Manufacturing Message Specification
3 TELEPROD: A Demonstration Laboratory

TeleProd is the name of a demonstration project, created to apply and test the architecture and some of the techniques developed. TeleProd project consists of a virtual laboratory built using some resources and devices, such as light bulbs, sensors, actuators, step-motors and cameras, available at the project's work lab. Although these devices may not seem the most appropriate ones to simulate a real mechanical engineering lab's shop floor, they are suitable for testing the most important issues of the system, like remote database interaction, control and monitoring services and global system's integration. This system includes all the main modules and platforms described on the proposed architecture, although having some limitations related to the work environment present on the lab, like the lack of real programmable manufacturing devices.

On this prototype demo, the control and operation platform was completely built over a Web browser. Users can access the lab by navigating on its 3D model, built using VRML, then they can access each of the individual controllable devices by clicking the mouse. On each case, a specific control page containing remote database access JAVA applets is downloaded from the lab's server. Alarms and events are received using a JAVA reception module that uses TCP/IP sockets. Even the feedback real time video acquired from several sources is presented on the browser client area.

Figure 10 shows the general look of the virtual lab graphical interface.
On the middle left frame we can see the lab's 3D model, live video is presented on the right frames and on the bottom frame we can see an alarm reception applet.

Each of the device types is associated with a control applet allowing controlling and changing its parameters. These applets do their job by querying and changing corresponding device's configuration parameters on the database, and then sending a message, using TCP/IP, to a service running on the lab's server.

On the real lab, all control data and messages are managed using a central control unit (CCU) built using a PC with several I/O cards, which is connected to the lab's server using a serial RS-232 connection. On this demonstration system, the CCU has two main functions:
1. Receiving all the messages from the server, decoding them and then sending control commands to specified devices.
2. Listening for alarms and events. When one of them occurs, a message is sent to the lab's server.

The next diagram represents the main TeleProd lab modules and its relationships:

![Diagram of TeleProd Lab modules](image)

**Figure 11: TeleProd Lab modules.**

### 4 Conclusion

Current information and communications technologies built over the Internet, enable the development of new distance learning applications that may contribute to wider information access/diffusion and substantial cost reductions to institutions: staff costs through the possibility of reusing infrastructures by remotely control existing facilities and investment costs through the capability to increase resource's sharing.

Teleproducts is a potential example of this, because it will enable remote access to expensive manufacturing laboratories, used in most cases to teach mechanics and manufacturing related engineering.

This paper discussed how current technologies could be used to implement a Teleproducts system based on the Web, presenting a running project related to a specific area of application. The system under development is focused to implement virtual laboratories for teaching mechanical engineering.

Abstract: This paper reports the results of observation skills training via an interactive multimedia training program for preservice teachers. The training program provides multiple videos for users to practice six types of observation methodologies, comparisons to "expert" data, and on-line access to procedural information. The study provides an analysis of audit trail records, user surveys, and pre/post testing of observer reliability to ascertain relationships between prior computer experience, prior classroom experience, learning strategies, engagement time, and program efficiency.

1 Background to the Study

The purpose of this study was to examine the effectiveness of a multimedia training program to develop proficiency in classroom observation skills of preservice teachers. The training program was delivered through an interactive videodisc format which offers multiple videos for teachers to practice six types of observational methodologies: event recording, duration recording, latency recording, interval recording, time sampling, and A-B-C analysis [Fitzgerald 96] [Semrau 96]. For each video-based practice, the computer program controlled the start and stop frames, provided a timer, and provided user control over practice sequence. Users entered their observation results into the computer program and compared their data to that of "experts." Two unique features in the design of the multimedia training program are: 1) one video is "saved" to provide a constructivist experience for the user to define behaviors for each of the observational methodologies, and 2) procedural information for the six observational methodologies is available on-line for easy review.

Training in classroom observation skills is a complex and time-consuming process. To learn to code behavior reliably, an observer must learn to identify behaviors accurately, watch and code multiple behaviors in real-time, and apply these skills to varied and dissimilar settings. The usual training method involves an apprenticeship model where a teacher explains the procedure, demonstrates via videotapes, provides practices through videotapes and field assignments, and undertakes reliability testing with tapes, if at all. It is not feasible to spend the necessary amount of practice time for classroom observation training within most teacher education programs; thus mastery of methodology or reliability is rarely documented [Fitzgerald, 1995].

Interactive multimedia training provides one solution to the problem of observation training, practice, and reliability testing. Through repeated practice with videos and "expert" comparisons, a novice can practice until proficient and establish coding reliability. With the capability of accessing procedural information regarding observation methodologies, a novice can review procedures if questions arise during practice. Since a hypermedia format allows users to make personalized decisions regarding practice sequences and strategies,
the format may provide an effective training alternative to the typical apprenticeship model in observation training.

2 Description of the Multimedia Training Program

This screen introduces the user to the particular observational methodology to be practiced. In this example, the user is practicing Event Recording. A brief description of the methodology provides general information necessary to begin the practice. If the user requires further information, he/she may access procedural information from the on-line resource section of the program. A sample table gives the user an example of how event data are recorded. The user chooses from three possible videos for practice, two which include expert observation results and one that does not. The observation practice "Do Your Own" can be used as a constructivist activity for defining behaviors of interest to the user.

After the user runs the video and collects his/her observation data, the data entry screen appears. At this step, the user can elect to run the video again or enter the data which he/she has collected into the program. The computer screen provides the exact length of the observation period to enable the user to compute rate data for the observed behavior. These data entry screens are matched to each type of observation methodology which vary in the number of children and behaviors observed and the method for computing rate data.

After the user enters his/her data into the computer, the expert comparison data screen provides comparative results. The screen displays both the user's results and the results of experts who observed the same observation video. Information at the top of the screen explains how the user can compute his/her "percentage of agreement" (reliability) between the two sets of data. At this point, the user may go back and practice this observation segment again, select another segment to practice, or return to the main menu and select a new methodology for practice.

Audit Trail

The program records embedded data paths that are invisible to the user. These paths collect information such as the overall length of time the user engages in the program, the length of time spent in each methodological
section, the number of times a video is accessed, and the observation results entered by the user for each practice. For example, in the above practice, the computer records the frequency and rate data entered by the user for that particular practice semester. The audit trail provides a cumulative record of all practices and observational results and enables the researcher to examine factors which may relate to successful learning.

3 Description of the Research Study

3.1 Research Questions

The study was designed to address the following research questions about the use of hypermedia-design practice materials for learning classroom observation skills:

1. What effect does a hypermedia-designed practice program have on performance outcomes for preservice teachers learning classroom observation skills?
2. Do performance outcomes for preservice teachers relate to differences in prior computer experience, prior hypermedia experience, prior teaching experience, learning style preferences, or semester?
3. What practice strategies predict successful performance outcomes for preservice teachers learning classroom observation skills through a hypermedia-designed practice program?

3.2 Methodology for Implementing the Multimedia Training Program

The observation training program was integrated into special education methods courses during three semesters at Lincoln University. Following pre-testing, the instructor provided instruction in observation skills prior to the students' use of the multimedia program. The instruction included content and procedural information and a demonstration of each methodology. During these introductory sessions, students could ask questions about the observation procedure and clarify the required observation steps. Students were then required to practice the observation methodologies using the multimedia training program in the computer lab. The basic expectation was that each student use all available practices with the suggestion that practices be repeated if the user's data did not match the expert data by 80% agreement. Students received extra credit for their participation, but their level of proficiency was not used in computing the course grade.

3.3 Participants

Subjects included 29 preservice teachers enrolled in special education methods courses. All students were undertaking foundational coursework prior to student teaching; students in the summer session had prior knowledge of special education methodology; fall and spring session students had little prior knowledge. Demographic information was collected via user surveys and served as independent variables.

Prior Computer Experience. All but two participants had a moderate level of experience using computers across a number of areas of computer applications; the remaining two had minimal experience. Based on a scale where students rated their experience from 0 = "no knowledge" to 9 = "expert knowledge" on 9 categories of computer applications (total score possible = 81), the mean prior computer experience score = 29.7, standard deviation = 14.6, range = 2 to 53. Most students had never experienced hypermedia, and those that had, indicated they had limited knowledge of hypermedia. Using the sub-scale for rating experience with hypermedia (item score possible = 9), the mean prior hypermedia experience score = 0.9, standard deviation = 1.4, range = 0 to 5.

Prior Teaching Experience. Since the subjects were enrolled in an initial teaching certification program, few had direct, salaried, classroom teaching experience. Of the seven with teaching experience, they had been primarily employed as teacher aides or substitute teachers. The mean years of prior teaching = .88, standard deviation = 2.03, and range = 0 to 7 years.
Learning Styles. Participants represented a mix of learning styles as assessed with the Kolb Learning Style Inventory (McBer & Company, 1981). Using the 4 learning style types defined on this instrument, there were 9 students identified as assimilators, 9 as divergers, 8 as accommodators, and 3 as convergers.

Semester. Participants were included in the study over a three-semester duration. The numbers of students for the semesters are: summer = 7, fall = 16, and spring = 6. There were some implementation differences across the semesters particularly affecting the duration of practice time prior to post-testing.

Data Collection for the Dependent Variable

The dependent variable for the study was observation proficiency measured by pre- and post-testing on two different types of observation methodologies—event recording and interval recording. Matched pre- and post-tests were administered using original videos controlled by the computer to standardize test administration. In the event recording test, subjects watched 5-minute videos and recorded the frequency of occurrence of a defined behavior. In the interval recording test, subjects watched 5-minute videos and recorded on-task in each of 50 six-second intervals. Percentage of agreement scores (reliability) were computed for each of the pre- and post-tests.

Path analysis data were compiled from the on-line audit trails and user practice logs. Through these logs, practice strategies were examined by analyzing each user's number of repeated practices, total practice time in the program, number of times the procedural information module was accessed, total time spent reviewing procedural information, and proficiency on two related observation practices: interval practice #2 and time sampling practice #2. These two internal practices were used to ascertain proficiency of users during practice.

Data Analysis, Results, and Interpretation

5.1 Question 1: Performance Outcomes

A paired t-test was applied to the pre- and post-test results to determine the effect of the hypermedia-design practice program on observation skill proficiency. The scores represented the percentage of agreement (reliability) to expert data. Pre-to-post test results were not significant for event recording (t (24) = .959; p = .35) but were found to be significant for the interval recording methodology (t (24) = 3.88; p =.001). Table 1 displays the means and standard deviations for the reliability scores.

The small variation found in pre- and post-scores for both event and interval tests suggests the difficulty level of these tests is not high enough to provide accurate assessment of observational ability by the participants in these areas. In addition, the narrow range of scores exhibited limits the effectiveness of the regression analysis. In the future, more robust pre/post measures might ensure greater assessment of proficiency.

Further recommendations include increasing the number of practices available to users within the program. The ability to check one's scores with the results of the "experts" is an integral and essential part of the program; however, once these results are seen, repeat practices are compromised, essentially allowing for only two "unique" practices in each observational method. Additional practices would increase the amount of unique experiences available.

5.2 Question 2: Relationships between Post-test Outcomes and Learner Differences

Simple regressions were run to evaluate whether outcomes of the observation training program were related to learner differences. Table 2 presents the regression results for the post-test outcome scores related to three independent variables. No significant relationships were found to indicate that prior computer experience, prior hypermedia experience, or prior teaching experience with children predicted the outcomes for learning observation skills.

Table 3. Relationships between Outcomes, Learning Style Differences, and Semester

The subject pool for this study exhibited a high level of homogeneity in prior computer experience, prior hypermedia experience, and prior teaching experience. As a whole, most subjects had a moderate amount of computer experience, minimal hypermedia experience, and little, if any prior teaching experience. This limited range of experiences negatively impacts the effectiveness of the regression analysis. The small number of subjects also limits accurate evaluation, particularly with regard to subjects' learning styles. Further studies, therefore, would greatly benefit from a larger and more diverse subject pool.

5.3 Question 3: Relationships between Outcomes and Practice Strategies

Path analysis data were used to examine relationships between successful learning outcomes on the interval post-test and strategies used during practice on the multimedia program. Simple regressions were run to evaluate whether outcomes of the observation training program were related to differences among the subjects in how they utilized the program capabilities, amount of practice time, and proficiency levels during practice on the more rigorous methodologies. Table 4 presents...
the regression results pertaining to audit trail data. No significant relationships were found to indicate that different ways subjects utilized the program affected their performance outcomes.

The number of practices and amount of total time spent in the program exhibited a better distribution among the subject group. However, both were found to be insignificant to successful learning outcomes.

The available review section in the hypermedia program was largely unused by the subjects because of the amount of procedural knowledge provided by the instructor. This reduced the importance of such a knowledge source in the hypermedia program. Therefore, it is recommended that hypermedia developers consider the environment in which the program is to be used and determine the necessity of such a

Table 4. Relationships between Outcomes and Practice Strategy Differences

6 Summary

Interesting questions emerge regarding the effectiveness of an interactive multimedia training program for developing observation skills. Because the program allows users nonlinear access to practice segments, expert comparisons, and access to procedural resource information; the learning strategies of users differ. The findings from this study provide multiple data points from audit trail records, user surveys, and pre/post testing in observation skills to examine the correlates of observation proficiency: prior computer experience, prior classroom experience, learning strategies during training, and total engagement time with the program.

Students utilizing this program appeared to learn observation skills equally well, regardless of different learning styles or their prior experiences with computers or in the classroom. Given the limiting factors of a small and homogeneous subject pool, this study nevertheless suggests that a hypermedia-based practice environment minimizes the effect of learning style and experience differences between users in terms of overall outcome of observation proficiency. This study therefore lays the groundwork necessary for further study of the equalizing potential of hypermedia-based learning.

The study is important in establishing how preservice teachers utilize an interactive multimedia learning environment for observation skills training, the resulting outcomes for observation proficiency, and overall training efficiency of the multimedia program.

E-mail: lfwong@fa.ied.edu.hk

Abstract: The study will utilize two empirical research directions: applied and basic researches. It offers sample strategies for experiencing art teaching in a classroom based on multimedia settings. Both the classroom section and the foundation section focus on the following objectives: 1) to ascertain which instructional methods and technologies have the greatest effects on the artistic learning; 2) to look at the theoretical way of how multimedia and critical inquiry accelerate perceptions and analytical capacities in art teaching; 3) to explore the feasibility of using Human Computer Interaction Methodology approach as they relate to Instructional strategies for metacognitive development; 4) to address the transformation of Eastern and Western Educational Reform in Context by suggesting a Constructivist category and framework; 5) to examine how Eastern and Western beliefs and value assumptions can suggest vigor applications for future research initiatives in comparative multimedia studies.

Toward An Authentic Metacognitive Learning Approach

This paper involves a variation of a conceptual sequence of methodological strategies: It is built as related IMM to the particular art criticism sequence instruction. It also stressed to bring the students to be accompanied the sequential addition of the concepts of metacognitive learning processes. To explore how these processes are affected by theme and strategy variables from three perspectives: 1) knowing with feeling; 2) feeling of knowing; and 3) feeling with knowing. These three empirical models are correlated to one another. In the three studies, students received almost the same media presentation but through different instructional objectives, contents and pedagogy. Besides sequence of pictorial cues and art critical dialogue, a comparison of the three models may be made by the different treatment of Description Stage: The treatment without description stage; description is not the first stage of the treatment; description is the first stage of the treatment.

New Hypothesis of Cognitive and Cultural Self in Current Context

New social and technological structure has introduced a new metaphor for thinking of the self. It not only reconstructs meaning, but also reconstructs the definition of identity. As a multiple, plastic and permeable system, multimedia instruction may offer new avenues and context for self-understanding. Such understanding is always challenged by the cultural accumulation that we belong to. In respect of Chinese Confucian and Taoist philosophy, they both emphasized on the sentimental intuition correlated with the artistic rhythm of mind and learning behavior. The neo-Confucianist, had even figured out the power of inner thoughts in driving actions. However, they all left a methodological gap between knowing and practical intelligence.

From the point of view of Structuralism, the “art of the intelligible” indicates that the activity of creating and recognizing intelligibility. It is a matter not only of theory but also of praxis, that no formal program or effective procedure will generate it automatically. It arises out of acquaintance with cases and consequent insight (namely, “cognitive intuition”) into problems. It is a case of structural transformation that all understanding, no matter how variable, to the subject who understands, is somewhere along the same continuum [Caw 1988, pp.7]. Psychologically, the matrix will include the inner world of teaching by transforming self-doubt into self-confidence. As regards
Zen Mental shock appeal, it was usually to the student's intuition faculty rather than to his reasoning mind. Being entranced by external cues, inner awareness is inspired by a sudden, striking realization the phenomenon, the learners awake to their identity. Calm sympathy with the world of nature was very characteristic of both Taoism and Buddhism. Their theories when applied to education, words are used as symbols or blinds. Either see the world with pure eyes or open the third eyes, to arouse the creative imagination, was the main purpose of instruction.

This study emerges a view that internal consistency in learning is not enough. It raises a methodological note in the pattern of relationships between outer clues and inner consciousness. On the instructional and psychological conceptions, a person's cognitive self would actively transformed by the interactive rhythms of discussion and revealing connections with how the peers perceive. Expanding Polanyi's theory (1964), the IMM instrucational design will develop strategies based on a principal hypothesis: Through the interaction sequence consists of art criticism stages, learners can combine the subsidiary factors (formal, affective, manipulative, expressive, conceptual, and technical categories) with the focal aspects (confidence and sense of the whole)of an experience [Moustakas 1990, 21]. When both of them are in rhythm, converging true intelligent thinking and behavior, along with cultural belief and value, students can construct their own identities and narratives.

The Study's Design: Methods and Strategies
I have designed three modes of traditional Chinese painting inquiry: the intuitive, the normative, and the anthropological. It will focus on the microethnographic study built on the continuous case instruction in the classroom designed for In-Service Part-time Course for Training of Teachers in Primary School (ICTT) students in the Hong Kong Institute of Education. The length of the course was ten hours. Five two hours class sessions were held once a week during December 1996 to January 1997. In both systemic and systematic process, my research methodology consists of three phases: descriptive, experimental, and theoretical. Descriptive research includes longitudinal and cross-sectional observation. Experimental research is about what will occur under controlled conditions. I shall collect data through questionnaire, note-taking and tape-recording. Coding will occur by sorting data into conceptual categories. I shall use both semiotic and heuristic approaches for visual and dialogue analysis to form tentative insights. Collected from various data sources, I shall conduct internal and external comparison of concepts and theories. Findings will compel possible and meaningful research questions in arts education by philosophical and psychological evaluation.

This paper describes only the evaluation process of Model 1 (Knowing with Feeling, KWF). Unstructured observation of written and verbal records will be used for prescriptive analysis. This Knowing with Feeling instruction method is based on new insights from instructional psychology and Chinese philosophy. Monitoring the presence of sequential matrix makes its methodological analysis. Such matrix is displayed in the learner's art criticism categories. The results will suggest that self-regulated learners should construct their own self-chosen sequence as a learning strategy via the teacher's instructional design matrix.

Observation Analysis
This phase focuses on comprehensive record of a classroom journey between causality and continuity of the multimedia environment; and a practical experience of the multiple and contradictory "self" and "no-self" in artistic and cognitive classroom context. It will suggest an Art IMM instruction that pushes students to produce or to perform by clearly defining the paths.

Media Statics and Natural Calm Sympathy--Aesthetic Cues in Mindlessness process
This step tries to generate hypotheses, to see how the presence of minimal forms setting brings to intuitive inquiry; how the manipulated and structured media environment provides an cue encounter to convey existential validity to the viewer. Being located in a quiet and static visual environment of a slide show, the learners could access the overall information regarding the target theme and medium without any direct instruction for about five minutes. The considerations try to make apparent that the appreciation of the simple Chinese landscape painting is not merely sensory qualities. Toward
pure aesthetic attraction, a tacit message would come to the learner's mind in the pattern beyond words. The preparation of mind in inner quietude and harmony was ready for mental or spiritual purification before the early stage of heuristic processes. It functioned like many painters and calligraphers in Chinese tradition, they used the inkstone grinding the ink, intended to focus their thoughts, to loosen their body, and to be free from any external disturbance.

*Initial perception* When the learners start from what and where they are, they would naturally shape their interactive way towards a world of senses and images which experience itself is initially rooted. Students would find it easier to start learning from simplicity and innocence. The problem is, a typical Chinese painting is not a record of a particular experience. Its form refers not only to human subjectivity but also to human development of spiritual knowledge as a whole. Art is only a kind of means, postures of practice toward the inner nature of persons. The paintings fill with symbols which the artists alone are capable of understanding. Although the students seemed confident of being surrounded by the calm environment, they might continue to leave it “bland” and bring nothing to mind. At that time the learners might experience the media phenomena from a particular centrist and egocentric view. From philosophical dimension of Buddha nature, such “thus-ness” or “such-ness” will prevent the learners from seeing into the reality.

*Media Flexibility and Internal Locus Control-- Methodological Cues in Responding Process*

*Initial Attention* The second instruction focused on a logical exposition of variables related to collective approach. Students were required to distinguish various strokes they encountered in the painting, and illustrated them into classified groups by drawing activities. Based on structural sense of visual elements, some of the semantic differential was showed. They successfully sketched an analogy. The pictorial cues stood out and attract immediate attention of the learner.

*Interactive motivation* This analogy was developed to be a conceptual view of information as hierarchy during class discussion. Participants tried to guess various features by the accessible words. The elements of perception entered into *conscious awareness* for its “addressable” quality. In the class I observed, such hierarchical clues helped students to attribute elements to proper categories. It supported an analytic inference and thus associated the focal sense of the wholeness.

*Initial impression* The choice of black and white copies from model Chinese paintings increased clarity and readability of contour line drawing or cun (strokes depicting various geographical features commonly used in Chinese landscape painting). They were utilized for practical understanding underlying properties, based on nonanalytic inference, in applying stenciling and collage techniques.

*Observative concentration* The computer assisted transparencies interfaced with processes of analytic criticism was eventually lead to an interior landscape emerged. On the basis of clues accumulated during the initial stages of search and retrieval, the transparencies were easier to apply different colours to facilitate discrimination between the functional areas on the painting. Eye fixation could be restricted to a certain part of the painting. A hidden pattern presented in the media flexible and multiple structuring and re-structuring demonstration. The dialogue further encouraged visual structuring of ideas and signs. Many students could speak out the different effects and functions of the lines, and jotted down the characteristics of the space. They yielded the categories of concrete and abstract sequences, visual and invisual connections, and obtained new aesthetic experience of natural and coherent movement actualized in every single stroke.

*Media Dynamic and Cognitive Focal Factor -- Cultural Cues in Determining Process*

*Dynamic attention* Interpretation criticism was drawn by the sequential motion of the computer assisted animation. On the comprehension of presented form fragments, students were able to view the different aesthetic ideas of Chinese and Western painting in abstract and structural patterns. They were aware of cultures code knowledge in perplexing and *Tension State*. With the visual support presented on the screen, students could see how forms in Chinese painting were related and gave birth to each other. The aesthetic balance could be judged by the drifting and dynamic equilibrium within the painting, not the reality. The instruction gave new meaning of making form: The multiple perspective structure of Chinese landscape painting conveyed an authentic sense of inner structure. It was different from the objective and psychological sense of western idea of space.
Transformations of executive processes and skills  Setting out to a computer-assisted producing package, the first step was to identify the objective. It targeted to integrate Chinese and Western ideas of space into 2-D Pattern Design. The students were required to join the two dynamic structures of cultural view in multiple harmonies. Selecting the appropriate stroke structures from the colour copies did it firstly. The form was then determined by specific requirements of the computer learning environment. In the evaluation criticism, I observed that productions were organized by what was adapted to the situation constraints imposed by the task. When interacting with computer software, logical procedures of cut and paste, drop and add, structure and restructure were temporary attended. The student who benefited from this method was capable of improving judgments and decisions in variety of choices. In situations of uncertainty, this process convinced students that they could be able to regulate their self-chosen sequence of producing. Most of the learners facilitated the acquisition and creativity of skills. But it had moderated affective aspects of personality. Many works were controlled by rationally combining the two different cultural logic.

Preliminary Conclusion
The interplay of the two mental activities: affective and cognitive intuition has not really been investigated in existing researches. This study is not just a correlation but evidence of an empirical based, causal connection between feeling and knowing. Although the students would find it hard to create meaning from a Chinese landscape painting, but they could cluster the intuitive categories, not just with a pure form but with the structural sense of the forms. The forms structure in a sense a metaphor. It directs cultural continuity and certainty between the painting and the viewer. The exposition and comparison of criteria of intent will give the right encouragement of multimedia teaching. It has created new awareness and understanding of the transcendent thought of the artifact. Students will see more the philosophical value behind the visual sitting, thus internalize their human consciousness, explore and reaffirm their own webs of philosophical values and beliefs.

The analyses are based on a suggestion that the learners' concept and knowledge is inferential and heuristic in nature. My tendency is to depict the CAI based upon human perspective. Participants' responses indicated that the awareness aspects of their metacognition were related to media exhibiting. The better various combinations of art criticism stages could also evidence better self-regulation habits. Based on feedback about their production, metacognitive control was evidenced as a "reactive" thinking process in this study. This research will go on validating the quality of people's feeling and belief about their proactive control. What do they feel before or when they know: They feel they know or they feel they should know. If students believe that they know, believe what they know were proved to be motivating to actions, what would make such subjective feelings valid in learning performance? The research will be a continuous process, which is designed flexibly influenced by any changing dimension of independent variables. Consequently, it will achieve its real potential when it is utilized toward an integration of both externally paced instruction and internally paced instruction. The subjective conviction will contribute significantly to students' learning achievement, by adhering to the following instructional shifts:
1. A shift from Mindlessness to mental shock, processing to Metacognition determining;
2. A shift from Sensory to Control Dimension, toward intelligible Dimension as a whole;
3. A shift from the technical, to the reflective activities of Form, Metaphor and cultural context.

Abstract

World Wide Web sites have become a common mechanism for instructional management and resource distribution. Tools to authenticate the source and validity of multimedia information is vital, especially in the case of distance learning. Multimedia signatures1 are hidden and encoded information signals inserted in a media document (e.g., an image, video, or audio file) for the purpose of copyright protection and proof of ownership. This paper considers multimedia signatures as a mechanism for legal protection of educational resources.

1 Introduction

There has been a vast proliferation of educational World Wide Web sites which are now being used for a multitude of applications: supporting a traditional printed text, providing communication among students and teachers, supporting lab and library functions, and providing additional teaching and research support. In parallel, there has been a growing use, and also abuse, of digital materials on the Web, with extensive “borrowing” of Web documents, especially images.

Enforcement of copyright laws in this environment is a growing problem. Digital materials are extremely easy to copy, and copies can be modified with very simple techniques (e.g., brightness adjustments in images) so that the copying is not detectable using simple file comparisons.

Multimedia signatures are a new enabling technology that can help in establishing ownership of originals and derivations for digital media. Signatures are an imperceptible but robust signal added to existing data, allowing owners of digital media to prove the origin of copies and modified copies of their work. While not preventing theft of an image document, signatures promote the idea of an ethical and honorable Web by building the power of proof into documents.

Similar methods are also being used with detectable signatures. IBM’s “visible watermarking technique” [Gladney et al. 97] [Mintzer et al. 96] and the built-in watermarking feature of the Hyperwave next-generation World Wide Web system [Hyperwave] add perceptible but difficult-to-remove patterns to images. Although not as secure as imperceptible multimedia signatures, visible watermarks have the advantage of giving users a readily apparent notice about the status of a particular image. The combination of visible watermarks with multimedia signatures can be quite powerful. A visible watermark provides a straightforward way for users to identify a document’s source and copyright status.

1Some authors prefer the terms “labels”, “digital signatures”, or “digital watermarks” for multimedia signatures. We prefer the term “multimedia signatures” because, respectively: it suggests more focus on security than “labels”; it is not as easily confused with cryptographic signatures as “digital signatures”; and it does not seem to imply easily perceptible changes in documents, or a limitation to digital images, as “watermarks” may.
while accompanying multimedia signatures can give distributors some assurance of proving misuse even if malicious users remove all visible watermarks.

Applications of this idea include proofs of ownership, traces of distribution paths, and inclusion of public information like copyright notices or private information like copy prohibition tags in a "format-independent" way. Podilchuk and Zeng use the terms "destination-based" and "source-based" to distinguish signatures used for tracking different copies of a document after distribution from those used for authenticating the source of a particular document. [Podilchuk & Zeng 97]

2 Multimedia Signatures

The problem of inserting signatures is conceptually simple: encode an undetectable signal in an existing media document (generally an image, audio, or video document in digital format) in such a way that it is recoverable only by parties in possession of its “key”. All signature techniques work by introducing a signal that appears as noise into a media document. In some techniques, this signal only resembles noise as a side effect; in others, the signal is deliberately designed to resemble “natural” noise. Unfortunately, the task of devising signatures that are robust to compression, common document manipulations, and outright attacks is not easy. The signature signal should resist degradation, both from ordinary media manipulations and from purposeful efforts to erase it.

Multimedia signatures are similar in spirit to traditional paper-based watermarks: both are intended as nearly imperceptible superposings of additional information on a document. The difference is that traditional watermarks are attached to a particular document, while multimedia signatures are attached to the information itself. Traditional watermarks are not transferred by most copies—whether a scribe’s copy of an ancient manuscript, or a photocopier’s copy of typewritten document on watermarked paper. Multimedia signatures, referred to simply as “signatures” for the remainder of this paper, are designed to be transferred by all copies.

Multimedia signatures are a sub-area of steganography, or data hiding, in which secret signals are embedded into public ones. The defining factor is the lack of secrecy concerning the existence of the signature signal, or “covert channel” in the terminology of the cryptographic community. Since it is not assumed to be known only by those using it, ensuring the robustness of the signal is as important as hiding it well. [Cox & Miller 97] [Zhao 97] The general intention is to make the signature signal inseparable from the data it accompanies, at least without special knowledge initially available only to the signature’s creator.

Existing signature techniques, despite sharing the same basic goal, exhibit tremendous variety in their design. These differences can make direct comparisons difficult. There are, however, some basic issues that all methods must address. This paper gives an overview of the constraints and technical issues in applying this technology to educational Web sites. We consider the need for multiple methods (Section 3), issues of integration and ease-of-use (Section 4), and potential difficulties with using multimedia signatures to prove ownership (Section 5). A survey of existing techniques for multimedia signatures can be found in [Ford, Makedon, and Owen 98].

3 The Need for Multiple Methods

The fundamental nature of the media is important in the design of a signature technique. A technique that works well for images may not necessarily work well on video or audio. Furthermore, a given technique should ideally be insensitive to specific document formats within its media type. We present in this section the two primary media considerations.

Inserting signatures in temporal media—media that change with time, like audio and video—is a newer and more challenging area in multimedia signatures. There are important considerations in designing signature algorithms for temporal media that make them more complex than algorithms for static media. For example, since digital video can be viewed as a sequence of static images, it might seem natural to apply image signature techniques to each image in the sequence. The problem with this approach is that small changes used to encode a signature in a single image may become much easier to find when other images in the sequence are available to provide statistical correlations. Also, signatures
Figure 1: Key plus original detection. Encoding uses the original document (optionally) and a key to generate a multimedia signature, which is combined with the original document to produce a new version for distribution. Detection uses the original document to extract a potential signature from a suspected derivative of the distribution version; this is then analyzed with the key to determine if it is the expected signature.

Figure 2: Key only detection. Encoding uses the original document (optionally) and a key to generate a multimedia signature, which is combined with the original document to make a distribution version. Detection uses only the key to determine if a document contains a signature corresponding to that key.
in temporal media need to be resistant to additional transformations; for example, interpolation between video frames may eliminate signatures encoded using image signature techniques on each frame.

In general, it is not possible to insert signatures successfully in different media using the same algorithm. The degree to which a given document transformation affects perceptibility in one domain may not correspond to its effect in any other. A signature designed to survive image transformations may not have the same success in the audio domain, where the effects of transformations on perceptibility is different. For example, time expansion or dilation of audio without shifting its pitch is a common audio transformation that has no obvious analogy in images.

The necessity of having multiple methods for inserting multimedia signatures into different media does not have to affect ease-of-use, as covered Section 4.

4 Integration and Ease-of-Use

As discussed in Section 3, inserting digital signatures into different media requires different techniques tailored to the media to be effective. In order to prevent this requirement from burdening users of multimedia signatures, different algorithms can be integrated into a single package that will use the correct method to insert each signature.

We envision a “smart” web server like Hyperwave [Hyperwave] being used to provide multimedia signatures transparently to content providers. The system could automatically add identifying signatures appropriate to the system, institution, and/or publishing individual when that person adds a document to the server. Under this arrangement, users never need to deal with signatures directly, other than to provide the server with any identifying information they wish to have included in the signatures it inserts. Hyperwave presently provides this service for automatic visible watermarking of images.

Content providers often desire to have some indication of who has made copies of their materials. Using the World Wide Web for dissemination of information makes this difficult. Even if users are authenticated and tracked, there is no way to distinguish a Web client that downloads an image for viewing and then discards it from one that retains a copy. Tracking all accesses is difficult for this reason, and may be objectionable to those accessing the material as well. One solution is to modify the server to provide lower-resolution, smaller or shorter versions of multimedia documents without signatures by default. Clients that wish to download full-quality versions can then do so, with the expectation that their access will be tracked and digital signatures will be inserted.

5 False Positives and the Invertibility Problem

An important legal problem for any inserting signatures system is the degree to which a signature it encodes can be “trusted”. For example, if the odds of a particular signature pattern occurring by chance are not acceptably small, then the system may suffer from “false positive” detections of signatures that were not inserted. Systems can be tuned so that false positives are not a likely explanation in any proof of ownership, but the best way to rule out the possibility of false positive detections will be to have multiple simultaneous documents where multimedia signatures can be detected.

The “invertibility problem” presented by [Craver et al. 96, Craver et al. 97] is a high-level problem with signature authentication. If a signature can be encoded with an easily reversible transform, and if there are no restrictions on the format of the signature, then anyone can claim any random noise in any data is a “signature” by simply computing the inverse of the signature encoding transform on that noise.

The problem can be minimized (eventually to an acceptable level) by requiring non-random signature strings and by increasing the complexity of the encoding: this reduces the fraction of combinations in “signature space” that are legal encodings. Another alternative is to require using an official registry of signatures if they are to be admitted as legal proofs [Craver et al. 96].
6 Conclusion

The trend towards the distribution of digital media documents stimulates research towards the development of methods for protecting copyrights. Multimedia signatures are a promising technology for ensuring that these rights are protected. There have been many approaches to digital signatures, and new ones are introduced regularly, but all techniques need to address certain core goals and concerns to be useful in education. Similar requirements will apply for multimedia signatures used in related areas like museums, which are gradually making many exhibits available to the public through the World Wide Web.

Abstract: The Learning Engines model is about the integration of rich learning activities into the WWW. It is concerned with the practical design, educational value and re-useability of software components. The model is focused on the academic teacher who is in the best position to conceive and apply novel learning objects to meet particular discipline learning requirements. A key component of the model is the ability to engage the learner in tutorial-style dialogue. By incorporating into this other content resources and customised interface objects, the learning environment can be effectively extended. Learning Engine objects operate within an open, scalable technical framework that provides mechanisms for inter-object communication, database management, delivery and authoring.

Background

The University of Melbourne is, like many other institutions around the world, re-thinking its approach to teaching in the light of changing economic and societal factors. There is a particular focus on restructuring whole curricula, supported in part by funding incentives for projects integrating educational technology into courses. The Multimedia Education Unit plays a central role in this process providing academic and technical support to departments and faculties. It is from this position that we perceive a need to enhance the often rather didactic delivery of information often associated with the World Wide Web (WWW). We are particularly interested in developing conditions for the active involvement of students, the process of 'doing', reflecting and of iterative adjustment of understandings. In this light we are seeking to extend the conversational nature of the teaching-learning process with some form of dialogue between the student and teacher, in this case by way of intermediary WWW-based software objects. The purpose of the model is not to provide the complete on-line interactive system. Rather, it is a practical opportunity for teaching staff to add rich and customised activities to their courses to complement existing on-line and traditional modes of learning. There are many solutions already available to efficiently deliver banks of multiple choice questions for example. The activities we are proposing however, with careful design and application, do have the potential to provide the student with a more engaging experience than might otherwise occur.

Despite an expanding collection of interactive WWW resources such as visualisations, simulations and tutorial systems, we see the continued need to customise on-line activities to meet the cultural, institutional and pedagogical positions of local teaching staff. From the technical development viewpoint, many challenges also remain. Appropriate cross-platform development systems are few in number and relatively immature, the foremost contenders being Java and Macromedia Shockwave. In the light of the traditional CAL approach within the University environment, we have initially employed, but are not restricted to, Shockwave for Director. Shockwave objects operate within a standard WWW browser page by way of an extension 'plugin'. They can offer a high degree of interactivity, control over various forms of media and are compact in size making them ideal for on-line delivery [Macromedia 1997].
The Learning Engines model

The Learning Engines (LE) model is an object-based approach to thinking about, constructing and interconnecting educational objects. By 'object-based' we mean here modular software objects that can be independently developed to certain technical and functional standards and set up to operate collaboratively. The model is not dependent on any single object, any object can be replaced, with the value coming from the combination. This value is both in effectiveness of learning and the ability to reuse resources in different teaching contexts.

Four broad classes of object in the LE model have been described [Fritze & McTigue 1997]. These include client-side visualisations such as animations, hyperlinked data sets, movies or other representations of information. Simulations may be pieces of virtual equipment or graphic representations of more complex relationships in which parameters can be adjusted, providing a higher degree of intrinsic feedback and in which there are multiple 'dimensions' for the student to explore. For both these types of resource, consideration should be given as to how they are employed in teaching. Unless a learning context is made clear, the student experience may well be one of knowledge reception or simply unfocussed exploration, rather than constructive engagement in learning activity. This context may be established by direct involvement of the teacher, by integrating the resource into other classroom activities or by providing guidance in some form of supplementary instructions. In the LE model, we introduce the idea of constructing an on-line dialogue between the student and the resource using a third class of object, the dialogue shell. A dialogue can be constructed by each teacher to provide an extended sequence of tutorial-style learning interactions to guide the student through a graded set of activities, provide immediate remedial feedback and give the teacher indication of problems and progress of the student. The 'shell' object is configured with content information by the teacher using a separate script template described below. Input or interface objects can extend the capabilities of a dialogue shell with customised and novel forms of interface to the subject matter. They could, for example, provide virtual 'pens' and 'papers' optimised for different subjects. It is worth briefly describing the main dialogue shell object and how it can be applied to other LE objects to create rich learning activities.

The Tutorial Itemset - a dialogue shell

The Tutorial Itemset is an instance of a dialogue shell with which we can create a sequence of question items for the student [Fig. 1]. It is based on the TutorialTools instructional authoring system used since 1993 to create over 80 hours of undergraduate CAL workshop materials for the School of Chemistry [McTigue et al 1995]. An earlier version of the WWW dialogue shell was described in [Fritze 1996]. It supports a variety of question styles and multiple levels of student feedback. Students can also register comments at any stage. Multiple assessment criteria can direct feedback according to subtleties in a student's response and the interaction styles have been extended to address the difficulty of open-ended responses.

![Figure 1: The Tutorial Itemset object displaying one of a set of question items](image)

In this example the Itemset object is operating as an independent object, under the direction of a question script. The real power of the LE model is in being able to extend this interaction with other LE objects to provide a richer and more customised environment. This has been described in [Fritze & McTigue 1997] and [Kennedy et al 1997] but it is worth summarising with two examples.
The example in [Fig. 2] illustrates how a very simple resource in veterinary anatomy can be used as the focus of a tutorial dialogue. The WWW page contains two LE objects, on the left a simple object, essentially a digital video of a leg that the student can position to various angles, and on the right, the regular Itemset dialogue object. The first question item requires that the leg is moved to full extension, subsequently the position of the leg is read by the Itemset as the answer to the question. The next question item not shown here will physically position the leg to a particular angle and pose a standard multiple choice or text entry question based on the indicated circumstance. As a simple visualisation of a body function the Leg resource is probably of limited value by itself. By using it as an extension interface to the Itemset, we have the ability to more fully explore the issues concerning this particular body system.

Figure 2: Objects combined to created a tutorial dialogue centred around a simple visualisation

The Interactive Graphing Object in [fig. 3] is another example of an interface component that extends the capacities of the general purpose tutorial object [Kennedy & Fritze 1997]. With this the student can sketch a curve on 'graph paper'. The attempt is also classified using a three point Bezier interpretation and reported to the Itemset. The Itemset can also specify curves to be plotted in the graph. In the example below, the Itemset and Graph object have been combined within a WWW page. A curve has been displayed on the graph as directed by the script of the Itemset. The student's sketched response has failed one of the Itemset criteria conditions which returns an appropriate comment in response. The level of detailed question and response using such combined objects is potentially very high and applicable across a wide variety of disciplines.

Figure 3: Graphing Engine input device as focus of a tutorial dialogue
Additional components under development in 1998 include interfaces and objects for open-ended text, simple algebraic input, image labelling, constructing images from picture elements, concept mapping, simple film storyboarding, a virtual dog for veterinary anatomy, a digital video front end and various language exercises.

Design Issues

The main focus of LE object design is directed at the educational level, but supported by an underlying technical and broader course-level framework. This focus addresses most directly the curriculum requirements and it is our intention that the content teacher plays a central role in the conception, functional design, implementation and evaluation of these objects. There are a number of reasons why the LE approach makes this practical. Firstly, as relatively simple resources or extensions to the dialogue shell, LE objects are finite in their functionality. Their purpose and operation are clearly understood by teaching staff who can discuss their requirements with programmers without the need for involved software development or detailed technical specifications. Secondly, the delivery of LE activities and navigation through the course is handled by broader scale WWW course delivery systems, whether a basic WWW server or a commercial delivery system such as WebCT, CREATOR or TopClass. The focus of the teacher remains on the 'coal-face' learning interaction. Thirdly, the construction and operation of LE objects is supported by an underlying communication framework and a library of standard software functions described below.

With smaller, modular constructions has come the opportunity to create objects suiting the purposes of multiple disciplines. The graphing object for example has applications in medicine, economics and the sciences. Techniques for working with open-ended questions apply across all faculties. Consequently we have been conscious of the need for a design methodology to draw together educational ideas and requirements from a wide range of interests. This has involved discussion and negotiation with academic staff from different discipline areas. Although it is beyond the scope of this paper, we draw attention to the technique of scenario-based design. This software design approach is centred on the use of brief descriptions of representative usage sequences as a catalyst in this process. This form of documentation is concise, couched in plain English and can represent the ideas from those with even a minor interest in a project. For more details refer to [Carroll 1995].

We have also found that the attempt to translate existing standalone tutorial exercises into the new Web-based object format, despite an apparent similarity of function, has highlighted differences in the nature of the two approaches. Most obviously, current WWW browsers struggle to run the on-line components as quickly and as seamlessly as their standalone counterparts written in HyperCard, ToolBook or Director etc. Despite having scrolling windows, browsers running on small monitors make it difficult to organise screen layout, with the increase in modularity and generic function also leading to a loss of ability to fine tune and optimise the display. The time to load a page and associated objects across the WWW can be highly variable and is generally much slower than the standalone. Activity grain size is something that should be considered in examining the dynamics of a student's passage through the course materials. In the case of LE components, we have found it most satisfactory when a page contains an extended sequence of activities, rather than just a single question.

Learning Engines Technical Structure

While the main thrust of this paper has been to present a teacher's view of the model and nature of LE objects, a brief summary of the technical structure is given here in terms of the supporting communications framework, the object content script and software core libraries.

Communication Framework

At present LE objects are Director Shockwave movies embedded within an HTML page. Each object has the ability to receive and send commands to and from other LE objects, to report a student response, set a simulation to a particular state or to demonstrate a correct answer. There are two methods in which this is implemented. Initially communication between LE objects as Shockwave movies was achieved using
preferences files of the browser plugin and simple JavaScript functions. A more scalable communication framework is now employed which is described elsewhere [IP et al, 1997]. The VA framework provides the lower level mechanisms for inter-object communication, server database connection and management of object scripts. A key component here is the VAmessenger in the form of Javascript on the enclosing browser page which directs messages between objects, even those created in different development systems, for example, in Shockwave, Java, Javascript or ActiveX. This underlying framework also provides the glue for integrating LE objects with Web servers, databases and independent course delivery systems.

LE script

Many objects such as the Itemset can be pre-configured with content data. These objects can parse an external script file to update their structure [Fritze, 1996]. The script can be loaded either from a local file or remote database during startup, providing a means of separating and storing content data and for basic authoring. Each object has its own 'vocabulary' of commands and parameters but follows a common syntax. Currently two script formats are supported. The original version is illustrated by the following script extract from the above charting object:

```
graphset
    plot "Plot 1"
    curve "Curve A", "type=growthl, y2=40"
    plot "Plot 2"
    curve "Curve B", "type=line, x1 = 50, y2=50, x2 = 100, y2=100"
...
```

The object is therefore able to be 'authored' in relatively plain English language, couched in terms of the teacher's view of the object. In adopting the VA framework as mentioned above and in anticipation of a move to Extended Markup Language (XML) as a standard for WWW communication, we are adapting the parser to the VAscript format described in [Ip & Fritze 1998].

LE Director Core Libraries

LE objects are currently constructed in Director 'Lingo' using an object orientated programming approach. The artefacts seen on screen and the underlying information structure are in fact created at runtime, as the content script is parsed. The software to support this exists in a library of core behaviours common to all LE objects. Creating an entirely new LE object then is greatly simplified and focuses on the creation of parent scripts and special behaviours for the new sub-components of the object. In the above example this would involve the parent scripts for the 'graphset', 'plot' and 'curve' sub-objects, defining their properties, behaviours and screen rendering characteristics. In addition to the parser, the core libraries support inter-object communications and other standard interface functions.

Future directions

The LE model has evolved out of the experiences of working with a number of projects in different disciplines including Physiology, Psychology, English, Chinese, Dentistry, Pharmacology, Economics and Commerce, Genetics, Chemistry, Veterinary Anatomy, Medicine and others. It is intended that departments will use the pool of LE objects as a shared resource and be able to develop at least simple additional objects to meet their own requirements. Evaluation of LE content materials for a number of these projects is being undertaken.

Administrative supports such as improved authoring tools, feedback and progress reports are being developed in conjunction with the VA framework and will be extended as the projects are implemented during 1998. The development of authoring layers with which components can be more easily configured by teaching staff remains a top priority and the subject of current work.

Integration into WWW-based courseware systems will provide more generalised solutions for whole course delivery, computer mediated communication, administration and assessment etc. We will be able to report
progress on work with MelbourneIT and their CREATOR course delivery system to incorporate LE components and the VA specification as extensions to that particular delivery system.

Institut für Rechnergestützte Wissensverarbeitung
University of Hannover,
Lange Laube 3, 30159 Hannover, Germany
{froehlich, nejdl, wolpers}@kbs.uni-hannover.de

Abstract. Educators are currently investing much effort into the conversion of their text-books and lectures into hypertext documents. Within our KBS Virtual Classroom project, we have recently developed a data-base oriented method for systematically designing such hyperbooks.

However, converting theoretical material into a hyperbook is only the first step towards a modern, project-oriented, computer-supported learning environment. To realise such an environment, the static course materials (regardless whether they are printed textbooks or hyperbooks) should be replaced by an open hypermedia information system, to which both the educators and the students contribute. In this spirit we have redesigned our hyperbook modeling technique to make it suitable for both capturing theoretical lecture material and providing a structure for the student projects.

Introduction

In our KBS Virtual Classroom Project we work on providing students with complete teaching and learning environments for several subjects of computer science (artificial intelligence, software engineering and introduction to computer science I (CS1)). To encourage project-oriented education, our lecture notes consist of a complete project accompanied by the necessary theoretical background. The structure and content of these lecture notes are described by a set of hyperbook data models forming a skeleton for the presented project and the accompanying theoretical background and providing a documentation of content and structure of our hyperbook. Additionally, these models serve as a skeleton for the student projects, leading to an open hyperbook knowledge base which is continuously enhanced and extended each year by student projects.

Previous Modeling Approaches

The most frequently used approach to hypermedia modeling is to use no models at all. Web pages are written and hyperlinks are hard coded among them. Hypertext documents designed in this way have a poor structure, in which users get lost quickly. Recently, the structured design of hyperbooks (and hypermedia in general) has received increasing attention. We identify two research directions relevant for the design of educational hyperbooks:

1. Systematic object-oriented modeling techniques developed for generic hypermedia systems like web servers and database front-ends. The Hypertext Design Method (HDM) [Garzotto et al. 93], the Relationship Management Methodology (RMM) [Isakowitz et al. 95], and the Object-Oriented Hypermedia Design Model (OOHDM) [Barbosa et al. 96] are the most prominent examples. These methods structure a domain into a set of types or classes and their relationships. By classifying the pages into these types, navigation links can be inferred automatically from the relationships.

2. Specific approaches for educational systems have been investigated by the adaptive hyperlink community [Brusilovsky et al. 96a,b], [Kay et al. 94], [Dale et al. 96], [Cleary et al. 94]. Usually the lecture pages, which can have an arbitrary structure, are indexed by the high level concepts of a user model. The knowledge derived from the user model can either modify the basic navigation structure of the document, e.g. the
system proposes suitable pages for the student; or it can be used to annotate the navigation structure. An overview of the different techniques used can be found in [Brusilovsky et al. 94].

Our own previous work [Fröhlich et al. 96a,b,c] can be seen as an instantiation and extension of the approaches under 1. for educational purposes. Let us now assess the suitability of the above approaches as the basis of an open hyperbook system. In principle, being offsprings of object-oriented design methods, the approaches under 1. support extension and maintenance of hypermedia by their systematic models, in particular by automatically deriving links from relationships between several objects. On the other hand, the approaches under 2. usually lack declarative domain models. Indexing book pages with user model concepts has the advantage that the book structure itself is not affected. Any book can be turned into a hyperbook using these techniques.

However, we think that this paradigm does not provide enough guidance for the students. If the student projects can be documented in any form and are then simply indexed by the topics of the lecture, the resulting book will not stay coherent and consistent. Furthermore, without an explicit domain model students have more difficulties to become aware of the structure of the domain. Our framework in KBS-HYPERBOOK for designing open hyperbooks for education is less strict than the formalisms under 1. but nonetheless provides the structure for student projects by an explicit domain model. Its very rich domain modeling language allows to structure the domain of a hyperbook in a meaningful way. As we will describe in detail in this paper, the domain model provides the basic structure both for the theoretical material and for the student projects, but does not dictate the actual relationships between the pages.

Domain Modeling for Educational Hyperbook Systems

Our KBS-HYPERBOOK domain modeling language provides the hypermedia designer with the full expressiveness of an object model based on the widely used Object Modeling Technique OMT [Rumbaugh et al. 1991]. Its concepts are domain objects, relationships and attributes, inheritance, instantiation, and aggregation. In contrast to software engineering there is no distinction between the different concepts of meta-class, class and object are meaningful, because all domain objects are finally implemented as pages. Each modeling concept has a semantics which is documented in a meta model that consists of a conceptual model accompanied by rules and constraints.

In this section we will motivate each concept and the semantics we assign to it. We will also introduce a part of the model for our CS1 lecture, in which all our domain modeling and navigational concepts are used. The lecture consists of a simplified software process and an introduction to the JAVA language as well as a large Java programming project which serves as example for the application of the language and our software process. As their course work, the students work on a similarly large programming project in groups of 3 to 4 students.

As in most object-oriented software engineering methods, we start designing our domain model for the hyperbook by identifying domain objects relevant to the application e.g. Java Applet or Applet User Interface. Existing documents can support the construction of the domain model e.g. software engineering books for our software process domain model or the Java reference manuals for the CS1 Java lecture. Having identified the domain objects, we move on to the identification of relationships among them. Our domain modeling language supports a wide variety of relationships, as shown in [Fig. 1].

The is-a relationship conceptualizes the specialization of a concept e.g. the user interface is a specialization of a Java applet. The instance-of relationship denotes that a concept or object is an instance of a more abstract
concept or object (-class). Although instance-of relations are less common in software models, we found this concept indispensable for all educational hyperbooks we have designed so far (CS1, software engineering and (a small part of) artificial intelligence). Especially in software engineering and artificial intelligence it is often the case that the lecture talks about abstract concepts (like „software process“ in software engineering or „reasoning“ in artificial intelligence) and then moves to some prototypical instance (like waterfall model as an instance of software process or diagnosis as an instance of reasoning). The KBS-relation qualifies the relation of two concepts therefore providing the ability to connect (and link) two otherwise not related concepts. We provide the ability to link to WWW-pages outside the hyperbook by using the external-relation concept.

![Diagram](image)

**Figure 2:** Small part of our CS1 domain model

[Fig 2] shows a small part of the domain model for our lecture CS1. The domain model consists of a short introduction to software engineering concepts and the object oriented programming concepts in Java. The hyperbook we are currently writing contains both the theoretical knowledge needed, as well as a one semester programming project. The student groups (we have currently 21 groups of 3 to 4 students) implement another project, whose solutions will also be included in the hyperbook. Additionally, student groups add hints concerning the concepts discussed during the course, which are also included in the hyperbook.

**Systematic Navigation Support**

The hyperbook contains several pages describing each object in the domain model. We distinguish two kinds of pages:

1. **Concept Pages** are pages which provide theoretical background, give practical hints, etc. concerning the domain object.
2. **Instance Pages** are instances of the domain object, e.g. a method declaration from a student project is an instance of the domain object "method declaration".

The navigation among pages belonging to the same domain object is made possible through the instance directory. This is a listing (menu) which contains all pages for a given domain object in some user-configurable order (based on attribute sequences).

To avoid spaghetti structures, the navigation among pages belonging to different domain objects is restricted by the domain model. A hyperlink may only exist between two pages, if the corresponding domain objects are connected by a relationship. A concept page, e.g. a theoretical explanation of a topic may (or may not) refer to a dedicated concept page explaining a related topic. Other concept pages under the related topic can be reached via the instance directory.
To see how the domain model explained so far defines a skeleton for the book, consider the scenario in [Fig 3]. Some pages have been added: Each domain object is described by a theory page. For the Java Applet concept there is a longer example on a separate page. The student group 1 has contributed an example, consisting of a User Interface page and an Applets&Threads page. Student group 2 has created a project page for a user interface and a hint page for Applets&Threads. Note how the links (lines between the pages) represent the several different relationships.

The domain model provides the core structure for the book and the possibilities of navigation. The actual hyperlinks between the pages must obey the constraints imposed by the domain model. As we described in [Fröhlich et al. 97a], KBS-HYPERBOOK is embedded in a deductive database environment. This environment allows to specify hyperlinks by deductive rules based on attributes of the pages, e.g. we let the system automatically link a page for an activity to all corresponding student group documents.

Visualization of Pages

The domain model describes the semantic relationships between different domain objects and thus the possible links. It serves as a guide to the whole book, both for the authors extending the book and for the readers by giving them a coherent and consistent navigational structure. Note, that the domain model specifies the possible links between two pages. The actual links are a subset of these plus links between pages connected by the instance directory.

Each page is displayed as a WWW page and associated links. The links have a uniform appearance: 1:1 links (like the normal relationships) are displayed as page1 related-to page2, where page1 is the page title of the current page, page2 is the title of the linked page, and related-to is the name of the relation. 1:n links (like is-a or instance-of relationships) are displayed as page1 related-to, followed by a vertical list of the page titles of the referenced pages. The page title of the referenced page can be accompanied by a short page description.

A trail is an arbitrary sequence of pages connected by relations or an instance directory. Additionally, a set of pages can be included by using a query on the attributes and type of the pages. A page can belong to more than one trail. The user follows a trail using dedicated next/previous buttons. At any point of the trail the user can leave the trail using any of the links present on the page, and can return to this trail by using a back button. The user can view all trails which include the current page and switch to another one of these trails. A set of trails covering the book completely can be used to obtain a sequential version of the hyperbook which can be printed. We are currently implementing a function, which displays (part of) the domain model or the link structure centered around the current page. This aims to provide a spatial concept of where the user currently is, and to provide the possibility to jump to other pages visualized on this display.

User Model

As space is limited, let us only note, that our full hyperbook system architecture also includes a user model. Within the user model, we specify topics and their relationships. These topics partially overlap with domain objects. Not all domain objects need to be included as user model topics, and not all topics are present in the book as domain objects (e.g. prerequisite knowledge). Additionally, a page may be relevant for more than one
user model topic and a topic can be discussed on more than one page. Therefore we have a m:n relationship between user model topics and pages.

The relationships specified in the user model represent the learning dependencies using Bayes' nets. Grading projects (which are similar in structure to examples and programs within the hyperbook) are classified similarly. Finally, the knowledge vector describing each user consists of a set of user model topics (and their values such as knows-nothing, knows-a-bit, knows-much, knows-all).

The performance of a student on such a grading project can be represented by assigning the appropriate value to each concept needed for this project. Using the update procedure of Bayes' networks, the knowledge vector of the student can be upgraded appropriately (both for these specific concepts and related ones, as specified by the learning dependencies within the user model). Using the values for the concepts within the knowledge vector the system can adapt the presentation of pages and links to specific users.

![System Architecture](image)

**Figure 4: System Architecture**

**Current Status**

The KBS-HYPERBOOK architecture described in this paper has been implemented in a first prototype. [Fig 4] shows the system architecture which is based on standard components complemented by a server-side JAVA program (Servlet) and the deductive database manager Concept Base [Jarke et al. 95]. The Concept Base system stores the hyperbook structure while the actual web-page content is referenced by the database objects and stored in the server's file system.

The user navigates the hyperbook by activating links. Via the HTTP-Get method the links cause the servlet to query the database. The database is queried for the fragments of the page representing the domain object and its navigational links. The JAVA program constructs a user specific page from this information and returns it as a WWW page. We are currently writing the lecture notes for our course “Introduction to Computer Science I” using the KBS-HYPERBOOK.

**Summary**

We have discussed our hyperbook system KBS-HYPERBOOK focusing on how to construct and use a domain model for a hyperbook. We think that the methodology described in this paper is the first one which is expressive enough to describe both contents and structure of an educational hyperbook without enforcing a database-like link structure on the hyperbook. Our approach contrasts to existing methodologies and systems, which either describe only the contents of a book (such as adaptive hypertext systems) or specify all links in a database like domain model (like RMM or OOHDM). The first results are very promising, and we hope to have a complete set of lecture notes (including student projects) for our CS1 course on the WWW at the end of this semester.

Abstract: In recent years, the number of non-Japanese learning Japanese has increased. Japanese characters are divided into three types: hiragana, katakana and kanji (Chinese characters). Kanji are the most difficult to learn; the number of kanji is great and their glyphs are complex. What we have developed is software for kanji learning software with vector and stroke speed evaluation capability.

1. Introduction

Multimedia--the synthesis of text, pictures, sounds, etc.--has become a widely-used term as information technology progresses. This is not an exception in the field of education, for much research is being conducted in making use of multimedia in computer-assisted learning (CAL) systems.

For many non-East Asians, learning kanji in their study of Japanese can be a difficult experience because of the sheer number of kanji; while the Latin alphabet has only about 50 characters, a Japanese twelve year old is expected to have mastered over 1,000 kanji. Another factor is the complexity of kanji glyphs (see fig. 1).

For a student of Japanese to learn kanji, repetitive drills similar to those conducted in Japanese elementary schools is often considered necessary. However, such drills are tedious and it is often difficult to allocate needed time in classroom situations. We feel that by utilizing multimedia we can create an improved method of kanji learning.

Writing kanji beautifully is difficult even for those who have mastered Japanese. The following are important factors in writing kanji beautifully:

- Correct stroke order
- Suitable part balance
- Distinction between leaps, stops, sweeps, breaks and curves (see fig. 2)
Kanji recognition system technology has shown progress and many reliable techniques have been developed. Our system, which we have named "Terakoya-Kanta," is based on vector and stroke speed evaluation.

There already exists software for kanji instruction; however, these tend to evaluate kanji characters by comparing written kanji with type. While this method may have the ability to evaluate glyph balance, they cannot evaluate stroke order, leaps, sweeps, breaks, stops or curves. Our system evaluates stroke order, leaps, breaks, sweeps, stops and curves to make possible higher accuracy in online kanji instruction.

2. System scheme

"Terakoya-Kanta" has two interfaces: one for making exemplary data and the other for learning.

2.1 Making exemplary data mode

Necessary data is prepared automatically when the user writes a kanji. The user can create data by scanning a piece of paper with a kanji written on it and tracing over the scanned graphic (see fig. 3). This will be help for making good exemplary data.
2.2 Learning mode

When the user finishes writing a kanji and clicks the mark button, the system starts evaluating the input kanji. We have prepared four learning modes based on user level.

Beginners can select Tracing Mode. In this mode, an exemplary animation sequence is shown in the example window while the first stroke is displayed in the input window. When the user traces the first stroke, the system displays the next stroke (see fig. 4). The user can learn correct stroke orders and we feel this is a good way for beginners to get used to kanji.

The next level is Seeing Mode. As in Tracing Mode, the system displays an exemplary animation sequence; however, the user is expected to write kanji in a blank input window without being shown an example. In this mode the user can learn suitable glyph balance.

For advanced users, there is Without Seeing Mode. In this mode, the system does display an exemplary animation sequences. Instead, the system displays type in the example window; no information about stroke
order is displayed and many times the user is asked to write kanji of which type and handwritten glyphs differ. In this mode the user can learn good kanji handwriting.

Experts can select Kanji Quiz Mode. In this mode the user is shown only the meaning of a kanji and is expected to remember the glyph. This mode calls for mastery of kanji.

In all modes sounds and pictures help create an enjoyable learning experience.

3. Evaluation and Direction Classification Method

3.1 Preparation for Evaluation

Before evaluation, input data must be converted to appropriate form. The following is an explanation of our system's method of data preparation.

3.1.1 Normalization of input field

The input data written in the input window will vary in size. Because of this, the system unifies the size of input data before evaluation. Input data is converted to 256 x 256 pixel size while retaining the aspect ratio. While it is possible to fix the input window at a certain size, this approach was avoided because the resolution of users' monitors will vary.

The system cannot evaluate kanji correctly if the written glyph deviates from the center; to avoid this, the system will correct such deviations.

3.1.2 Normalization of scattered data

Input data written by a mouse or a graphic tablet will contain noise, while a user who writes slowly or a user with a high-performance computer will cause blurring. Since noise will cause evaluation inaccuracies, the system normalizes scattered data. The system does this by first analyzing coordinate information of the input character. Then, the system calculates the average coordinates of a few successive points, and saves such data while deleting others. Analyzing filtered data reduces evaluation errors and makes it possible to minimize the amount of the data to be evaluated.

3.2 Evaluation routines

The system evaluates written kanji in accordance with the following factors. These evaluation routines are now being reexamined and further developments are expected in the future.

3.2.1 Stroke evaluation

The system checks each stroke the user writes. Checkpoints are as follows:

- The start and end positions of the stroke
  The system checks the distance between exemplar and data written by the user about the start and end positions.

- Vector direction
  The system checks the direction of the each vector, with emphasis on the start and end vectors. These are calculated by the cosine theorem.

- Stroke length
  The system checks stroke length.
  If the input data differs greatly from the exemplar data on the basis of these three checkpoints, the system judges that the user wrote the kanji in the wrong stroke order.

- Distinction of breaks and curves
  The system finds curves and breaks by evaluating the vector and the stroke speed of the stroke (see fig. 5). When a vector direction of a stoke changes, if the speed of that point is almost zero, the system judges that it is a break, and in other cases, the system judges that it is a curve. And the system checks their angle.
- Distinction of leaps, stops, sweeps.

At first, breaks near the end of the stroke are regarded as leaps. The system checks the stroke speed of the end of the each stroke, and distinguishes between stops and sweeps. If the stroke speed is faster and faster, the system judges that it is a sweep, and otherwise the system judges that it is a stop.

![Speed-time curve of a stroke](image)

**Figure 5:** Speed-time curve of a stroke

### 3.2.2 Glyph balance

A kanji with its strokes written accurately does not suffice as a beautifully-written kanji. Glyph balance is an important factor in good kanji writing. A kanji glyph consists of line segments that can be divided into parts, which in turn can be classified into basic strokes (see fig. 6). The system checks the balance between the glyph and its parts.

Checkpoints are as follows:

- **Position of the center of gravity**
  - The system compares the center of gravity of the glyph and its parts with exemplary data

- **Aspect ratio**
  - The system compares the aspect ratio of the glyph and its parts with exemplary data.

![Separation of a kanji into basic strokes](image)

**Figure 6:** Separation of a kanji into basic strokes
4. Conclusion

Many non-Japanese have studied Japanese and many have mastered hiragana and katakana; however, only a small number have mastered kanji. To master kanji, repetitive drills are usually considered necessary. Because of the large number of kanji and the complexity of the glyphs, this kind of learning is not only very difficult, but also tedious. We feel computer software utilizing multimedia can be effective in making kanji learning more enjoyable. However, the number of satisfactory software is limited; extant software may offer sounds and/or pictures but many can evaluate written glyphs only roughly. We feel such software cannot teach kanji correctly. The system we have developed not only makes use of multimedia but is also interactive. Our system can also offer appropriate advice based on vector and stroke speed evaluation -- in short, it can act as a virtual Japanese teacher. A student using our system can master correct and beautiful kanji writing enjoyably. (Our system was rated highly by the Portland State University.)

5. Future plans

To allow wider use, we are preparing a version for use on the World Wide Web. This system will be implemented at the Japanese Language Center of Waseda University and also at Portland State University for further modification.

Abstract: This presentation discusses using an Internet/World Wide Web-based conference environment called WELL Engaged as a tool to take the place of traditional peer editing groups in an on-line version of an advanced business classroom. A pedagogical objective of using the Internet conferencing environment is to emulate the group interaction that grounds classroom-based peer editing groups. A second is to encourage and enable spontaneous on-line student conversations about writing issues without the direct intervention of the teacher.

There are several tentative findings. First, many students report that they benefit from the on-line discussions about writing. Second, students say that the feedback from group members helps their writing improve, although there may be an adjustment period as students adjust written communication. Third, students find that they can easily adapt to interacting about their writing in an electronic environment. Finally, outcomes in the form of test scores, writing quality and course evaluations compare with those of the traditional classroom, which supports the idea that online conferencing environments are viable teaching tools.

Introduction

This paper discusses using an Internet/WWW-based conferencing environment called WELL Engaged as a tool to take the place of traditional peer editing groups in an on-line version of a business writing classroom.

The primary research questions are these: what are effective uses of Internet conferencing as a vehicle for creating on-line group interaction and peer writing evaluation and feedback? And, how do the educational outcomes of courses characterized by these on-line practices compare with outcomes in traditional classrooms?

The author's traditional business writing classroom is structured around groups interacting with writing in various stages of execution, driven pedagogically by what are generally called process models of writing. A primary objective of using the Internet conferencing environment is to emulate online the sort of group interaction found in classroom-based peer editing groups.

While many people are using electronic conferencing for discussions of course material and topics, it is less common to use conferencing for student groups to interact with each other directly about their writings-in-process. This leads to the second pedagogical objective, that of encouraging on-line student interactions about meta and local writing matters without the direct intervention of the teacher.
Setting

Golden Gate University is a private university in San Francisco that provides education in law, tax, liberal arts and business, from undergraduate through doctoral level. Our students are diverse, ranging from international and traditional students to working professionals, ranging in age from the early 20’s up. Most students are working toward degrees and certificates; many of them attend school in the evenings, and during intensive weekend programs.

The University offers courses at a number of satellite campuses in California. On-line courses are of particular interest to the University because they offer the opportunity to increase enrollment; for students, they offer a degree of convenience, particularly to complete courses that are regularly taught at the San Francisco campus, but may be rarely offered at other campuses. For teachers, on-line education is (for some) challenging and exciting; however, competition from other institutions that offer on-line coursework as well as pressure from the university’s accrediting agency require that on-line education be carefully considered so as to be considered viable for students, teachers, and administrators.

Instructor Background

The researcher is an Assistant Professor in School of Technology and Industry; until January of 1997, I held the same position in the School of Arts and Sciences. I have strong interest and some experience in using technology in the classroom and as a medium for distance teaching and learning. My current interest is to continue to successfully translate traditional face-to-face course materials and approaches into high quality on-line formats, and to make the on-line experience as substantive and satisfying to my students as a high quality traditional classroom experience.

The course under discussion in this paper is titled English 120, Advanced Business Writing, which I’ve taught traditionally and online. The course is a required junior-level course that is writing intensive, so translating the process-oriented components of a contemporary writing classroom (prewriting, drafting, revising, peer editing/reviewing and feedback) into the on-line format is important.

The instructional medium

English 120 has been taught traditionally for years, and more recently via two electronic formats, SoftArc’s First Class conferencing software, and, currently, in a World Wide Web environment. The writer has taught the course twice in the First Class environment and once in the Cybercampus / WWW environment.

First Class is a conferencing system that can provide a graphic interface whether used on campus or through an Internet connection. It uses the familiar desktop/folder metaphor, familiar to most people who use Macintosh and Windows machines. From our student point of view, the software is ubiquitous, and is used primarily as a campus email and public communication system. From an instructor’s point of view, First Class provides ease of use and management, along with reasonable security. A teacher can easily create a hierarchically-arranged set of folders to contain class material. Given the proper permissions, the teacher is able to control overall access of students to course material, as well as to determine particular students’ access to folders, for facilitation of group activities.

During the Fall of 1997, an entity named Cybercampus came into being, dedicated to creating instruction in a World Wide Web environment. Using a conferencing environment named WELL Engaged provided by San Francisco’s The Well, university instructors are offering a variety of classes in Management, Computer Information Systems, Business, Public Service and English. Fewer instructors are using the First Class environment, although they can if they choose.

Course materials for all Cybercampus courses are created and posted on World Wide Web pages, all of which feature common design features such as logos and interactive links. Moving from the University’s Cybercampus
environment to the Well Engaged conferencing environment requires an electronic jump to another server and system, but it is designed to appear relatively seamless to the student.

**WELL Engaged and on-line conferencing**

The Well is an Internet Service Provider that has been a pioneer in providing an open electronic conferencing environment on a variety of topics.

A prominent feature of their service is a conferencing protocol called WELL Engaged. WELL Engaged provides a discussion environment which people can enter at will, can control viewing of entries and can create and participate in discussions of new topics. Spellchecking and hyperlinks are supported.

In the Cybercampus/WELL Engaged environment, topics within courses can be created by the teacher and/or students, depending on access level and purpose. Topics are characterized by numbers of entries posted by each participant. The entries appear in linear order, giving the sense of a conversation, and they can be "scribbled" (removed by the writer) or "hidden" (archived) by the teacher. This allows a reasonable degree of control and a sense of communication, although currently topics cannot be easily rearranged, nor can entries be removed.

Since WELL Engaged operates in an HTML environment, it is also possible to include and follow hypertext links. This flexibility is helpful for students because it does not require a particular software; all class interactions can occur in the World Wide Web environment, which means that the Web can become part of the class.

English 120 students enter the classroom environment by connecting to the Cybercampus course site (illustration #1). All students have access to course overviews, but actual course syllabi or assignments are password protected. After entering, registered students can view and download assignment and syllabus material.
To enter the WELL Engaged conference area, students choose a Conference link, and must again provide a password. Upon entering the Well Engaged area, participants can see a number of topics, which will differ according to the instructor’s and students’ needs. (illustration #2). In the illustration, the Hoo’s Hoo? area is for student biography material, Practice is intended for cut-and-paste practice, Read Me First is for news and feedback, and the weekly course material is found in appropriate folders. Groups are also found under the Week area.
Figure/Illustration #2

Taken together, the topics in the English 120 WELL Engaged environment provide discussion areas that allow the students to find out about each other, to practice cutting and pasting skills necessary to interact in groups, to find out about work in progress, to get weekly assignments, and to interact in their groups and with the entire class. More traditional means of communication such as the telephone, email and face-to-face contact can be utilized as well, but accessing assignments and interacting in groups, the two major parts of the English 120 course under discussion, occur in the conferencing environment.

The Cybercampus and WELL Engaged environments have a consistent look and feel, so students report that the environment feels comfortable to them. From an instructor's point of view, the Cybercampus/WELL Engaged overall design provides ease of use, barely adequate flexibility and a reasonable amount of security, at the cost of a moderate learning curve and some experimentation.

**Structure of the Online Advanced Business Writing Class**

When students enter the English 120 conference section of the course from a Cybercampus “front end” page, they see their topic list containing topics as weekly assignments, hints for success in online classes, classmate biographies, and group folders. Currently, group folders are open to all students; a premise of peer editing is that students will have a safe group to interact with, so it was anticipated that having non-secure folders might be an issue, but students do not seem to be bothered by the open environment. It is within the group folders that students interact in the online peer editing exercises.
Course materials are highly structured as to expectations and due dates. Mini-lectures direct students to text materials, and they complete regular quizzes that are submitted via email. Letter writing and a research proposal assignment form the bulk of the course work, although a proctored in-person midterm is given to address concerns of security, and to allow the instructor to meet those students who take the course on the San Francisco campus.

The major paper of the course is a research proposal that attempts to solve a specific problem encountered in the students' work environment. This assignment carries a substantial number of points and completion is required to receive credit for the course. There are a number of checkpoints and discussions about the paper as it progresses during the trimester, many of which are carried on via email. A formal draft is submitted during the 11th week, and the instructor and student then conference via phone or email to discuss the paper.

The overall course is designed around a simulation in which students and the instructor work for the hypothetical XZY Corporation. A student can "work" in an area that reflects his or her real job, such as management or sales. If the student does not work in real life, he or she can choose a generic job that reflects the student's interest. Thus topics for the research proposal reflect contemporary business matters such as choosing a business database, using email effectively or introducing a new product in the marketplace. In addition to researching a topic, students are expected to place the topic within an effective, persuasive proposal.

While the proposal is not subject to group interaction in the same way as the letters, students in groups tend to extend their peer-editing and information sharing relationships to extensive discussions of the proposal.

**Peer editing in online groups**

At the beginning of the trimester, students are placed in an on-line group consisting of two other fellow students and the instructor, who participates in all groups.

The letter writing assignments follow a 3-step process. Assignments in the form of memos and letters are presented in a weekly assignment area in Well Engaged, accompanied by a mini-lecture and perhaps a quiz. Students then create drafts of these assignments; they usually have about a week to do this.

On a designated date, students post letters or memos to their group topic area, with a heading indicating clearly what the work is, such as this: Jones/draft/good news. During a 3 day period, other group members and the instructor interact with the draft, providing on-line feedback on the work. Each student enters the conference, enters the proper group, cuts-and-pastes group members' work into a word processor, provides feedback, and then reenters the feedback into the group area with an appropriate heading: Smith/feedbackonJones/good news (for an example of feedback, see illustration #3). Currently WELL Engaged supports only all caps for text formatting, so group members' feedback is limited to that feature.

**Beginning of Illustration #3:**

Dear Ray,

I would like to take this opportunity to congratulate you on your new sales manager position with XYZ Corporation. We are all very pleased that you accepted the job and I am sure you will be very happy working for this company. You came very qualified and with strong recommendations.

I have been with XYZ Corporation for 16 years and have enjoyed every moment of it. Our company has a strong relationship with our employees and an open door policy which we like to stand by. There are two
main company functions which the company TRY USING ANOTHER WORD BESIDES COMPANY, YOU'VE ALREADY USED IT ONCE IN THE SENTENCE, CONSIDER DELETING THE FIRST COMPANY puts on SPONSORS? to show their thanks for all our hard work, the Christmas party in December and the summer BBQ at the CEO’s home in July. CONSIDER SPLITING THIS LONG SENTENCE IN TWO.

There are ALSO a few non-company sponsored sport leagues, if you are interested please contact me for the names of the organizers.

I am sure you are anxious to begin your employment with XYZ Corporation, so I will see you at 8:30 am Monday October 20th in my office in building 2 on the 3rd floor, to finalize the mandatory company paperwork i.e. benefits. I look forward to meeting you in person.

Sincerely,
Carl K. Banks
Vice President of Human Resources

CARL, THIS IS AN EXCELLENT LETTER! THERE REALLY IS NOT MUCH TO SAY ABOUT IT. HOPE MY FEW SMALL COMMENTS HELP. MOSTLY IT'S JUST STYLE MATTERS! TOM.

Figure/Illustration #3

At the end of the feedback period, students are then given several days to revise the letter before submitting it. Letters are submitted to the instructor by fax, so that formatting can be considered in evaluation. There are 5 letter/memo assignments during the trimester, ensuring that group members experience at least that many sets of formal group interaction.

**Managing online groups**

Managing online groups for success requires several things of the teacher and participants. It is necessary to clearly state the purpose and structure of the groups in the initial course material; to encourage use of the group, the teacher should communicate with group members in the online environment. This should not preclude personal, phone or email communication, but there are many interactions that can be done online, particularly those that affect all members of the group.

During the initial assignment, the teacher will probably spend time modeling online responses for group members. Some students tend to be confused about the multistep cut-paste process, and the teacher will have to spend encouraging group members until everyone is up to speed.

Group members are required to participate in their groups. The objective of using the group is to provide an online peer-editing community, and students should be directly encouraged to be active members. Although I don't require a number of interactions, students are expected to interact with each others' work at least one time per assignment, and a minimal number of assignment points are taken away for those who do not. This requirement is clearly stated in the course syllabus, and is enforced consistently. However, if a supportive atmosphere is created early on, students do interact consistently on their own initiative.

**Conclusions, suggestions**

There are several tentative findings regarding the use of groups online. First, many students indicate that they benefit from the on-line discussions about writing. They enjoy the process of having a group and working within it, although if students are not sympathetically paired, the group experience is less satisfying. Many enjoy (or learn to
enjoy) the freedom of discussing writing online, and, overall, group members tend to create positive environments that last for the duration of the class.

Second, students overall report that the feedback from group members helps their writing improve. The nature of the feedback can be different than that overheard in face to face sessions. Depending on the students’ personalities and natures, written feedback can be considered somewhat harsh, although students can be seen modulating the content of the interchange much as they do in speech, in an attempt to adjust to the needs and comfort levels of other group members. For example, they may begin a conference entry with a straightforward discussion of another’s writing, and end with queries about possible weekend activities and trips, much as people do in face to face environments.

Third, students can adapt to studying about, talking about, practicing, editing and proofreading their writing and general coursework in a variety of ways in an electronic environment. Because writing is so personal, I had questioned whether, even with a high degree of interaction, such an environment would encourage students to meaningfully discuss the many problems that are exhibited in business letters. To my surprise, students discuss writing matters, the text, the relationship of course material to real life, all of those elements we take as signs of successful learning in a traditional class.

This has been a surprising finding to the researcher. I originally doubted that a university level writing course could be effectively taught on-line; having taught Advanced Business Writing in bulletin board and Internet environments, I now believe that it is possible to teach an on-line hands-on writing course whose curricular quality and student outcomes match that of the same course taught face to face (See Schutte for a control/pilot study on a similar topic).

Finally, the role of the teacher changes substantially in the electronic classroom. Teaching takes on a new role, directed more toward participation and facilitation than delivery. For teachers who view themselves as in some way controlling the writing growth of students, this may be disconcerting. For others, being a director and facilitator, as well as a true group member, can be comfortable.

**Web-based conferencing as an instructional tool**

The subjective elements of the electronic learning space are important factors in the success of this particular environment. The Cybercampus/WWW environment has been professionally designed, with links to other University sites and support information. It has a “look and feel” that is carried through all pages at all levels, extending into the conferencing environment. In short, this particular virtual environment seems like a real place, at least to contemporary students who are comfortable interacting online.

Students are responding favorably to the Web courses, and that dynamic, combined with the consistent growth of the University’s Internet/Intranet, suggest that conferencing-oriented classes offered via the World Wide Web are the wave of the future at this University. Indeed, during the first semester of Cybercampus’s existence, 13 classes were offered; during this, the second trimester, over 30 are offered, and it is projected that during summer of 1998, nearly 50 classes will be offered online. Certificates are being offered, and degrees offered entirely via online courses are in the planning stage.

After acknowledging the additional learning curve of working on the web, and as an ongoing participant in the process with a group of like-minded educators, the benefits of membership in the seemingly larger community afforded by the Web environment are becoming more tangible to me; even in virtual space, Web locations can be made to offer many of the interpersonal elements that humans expect of their communicative experiences.

The electronic conferencing environment appears to have the potential to be an effective analog to its face-to-face counterpart. As one of the processes in learning to write, working in community environments, regardless of whether they are online or face to face, seems to assist the development of writing skills for many university-level adult students, and also to address their learning needs. Electronic conferencing as part of a carefully designed online course appears to provide an effective tool that can support learning in the contemporary educational environment.
References

Abstract: The WorldView system proposes a new way for merging and sharing information in workgroups for educational purposes. It offers universal web browser access and complete user interactivity based on interesting information structuring concepts and access permissions. It supports the common document and pictorial information but innovates by offering extended representation and interaction capabilities for users. This system shifts the focus from hypertext documents and hypermedia presentations to a workgroup system allowing interactive users to manage general information items. The user can insert or delete information items but he can also interactively edit, reference, relate and annotate any number of objects. These interactions are kept in a logical structural organization with individual user, workgroup and generic folders. Authenticated users can view, insert, modify or delete objects over the internet relying on an account and security administration. A database engine is used to store, index and search the data. We take advantage of the best ideas from database storage and searching, unix accounting and security, windows directory structure, hypermedia anchoring and linking and some structuring and object extensions of our own to offer a significant improvement in workgroups. The system can be deployed on its own or as a workspace system in any database repository.

1. Introduction

Information exchange and collaborative work are important domains of application for modern database systems [Silberschatz 91]. These applications became especially attractive due to the availability of the Web and the possibility of accessing a database from anywhere using a simple browser. We refer to systems with a large quantity of data that can be shared among people, especially semantically rich data such as pictorial data. Many interesting examples of such usage can be given. A virtual museum can keep images of art objects together with annotations and explanations about the objects. Digital libraries, satellite imaging, medical imaging databases are other examples.

A subset of those applications would benefit from group work and controlled user interaction over the information items so that authenticated users interactively build a information repository. WorldView is a research project in knowledge structuring and hypermedia tools for information merging and sharing. The system described in this paper resulted from the real needs of different professionals in our community to intuitively integrate and share a wealth of information in their group work and from the educational institutions needs to intuitively build and share educational material in their organizations. The common facilities from file systems with information retrieval capabilities, databases and hypermedia authoring tools are applied in an integrated way. The conjunction of database retrieval and hypermedia browsing allows the user to either search or browse and link the information. A prototype of the system will be used in a history department where student and research teams search for all available information on ancient monuments and paintings to reveal their history. They progressively insert their findings in workgroup spaces and decide what to share. A similar system could be deployed in a medical imagiology environment to insert and share image analysis and diagnostics.

WorldView offers a base structure to guide users organizing the information they insert and comprehensive user permissions and object privilege features to allow them to control the access in the web-based system. The basic features of document and image viewing and linking are extended to more general objects called information items. Information items can be inserted, deleted or edited depending on authentication. When integrated into the repository, pieces of documents or pictorial data can become interesting objects on their own. This is called information items within-component referencing. These components or information items can be related to other objects in the database possibly originated from other data sources. The system allows users to reference, link or annotate any information item. The information is all kept in a directory-like structure. The system deals with the necessary security issues and establishes groups to enable users to choose the scope of the audience for their information. It is scalable to serve a community of any size and provides an extended database system which can be applied on top of a regular schema database with application in, among others, the educational, scientific, medical and art domains. The paper is organized as follows. Section 2 shows related work, Section 3 describes the system and Section 4 makes some commentaries about the application prototype. Section 5 concludes the paper.
2. Related Work

The system described here conjugates the philosophy of hypermedia collaborative work with complex semantically rich databases. Hypermedia systems organize and access multimedia information in a very intuitive way, linking all types of information. For a possible taxonomy of Open Hypermedia Systems please refer to [Osterbye96]. Hypermedia models such as the HAM model [Campbell 88] or the Dexter model [Halasz 94] have helped laying the foundations for these systems. For example, the HAM model divides those systems in three functional layers: a storage layer providing persistence, an application layer providing the functionality and a presentation layer for user interaction. Nodes, links and composites are important components of those systems which allow complete information linking. A database engine is used in many of those systems to efficiently implement the storage layer. Systems like HyperStorm [Bapat 96] or HyOctane [Buford 94] use an OODBMS to render hypermedia functionality. A general application framework for hypermedia documents on the VODAK ODBMS of HyperStorm can be seen in [Wasch 95]. WorldView extends typical hypermedia systems features by providing a base structure and access policy to allow users to freely create and integrate information and provides a web browser based access to users.

3. Overview of the System

The WorldView project builds applications incorporating many distinct parts that are assembled to work as a whole. It encompasses the following parts also illustrated in figure 1.

- **Users/Groups** - the persons accessing the system. They form workgroups.
- **User Accounts & User and Object Privileges** - logged users can manage their objects and those from groups they belong to.
- **User Interface and Access Structural Organization** (folder directories, user/group/generic workspaces,...) - this flexible system provides an important base structure to organize information.
- **Extending Metadata Objects** - referencing, Relationship objects, their specializations. Annotating objects.
- **Information Items & Schema** - documents, images, arbitrary pieces of both, objects from an existing database schema and database objects inserted by the user.
- **Database Storage & Searching** - a database engine implements the actual storage and indexing.
- **Support External Files & Handling** - information can be stored externally or in the database. SGML documents can be converted to corresponding document image objects and back to files.

![Figure 1- Overview of the WorldView System](image)
The information items and the corresponding database storage and searching capabilities provide the basic functionality to store and retrieve documents and images and to reference external documents. SGML documents can be converted to document image objects by the external files handling part and back to files using a metadata format file. The schema represents possible particular application domain objects. For operation purposes, the information items, schema and extended objects are handled in the same way.

From now on we focus on the new significant parts which provide the facilities for user interaction.

3.1 Information Items

Information items are pieces of information like documents, images, document components (chapters, sections, etc) or video frames. They can be stored as database objects, their URL simply referenced or stored and referenced from the file system. The system offers the tools for referencing, relating and annotating those information items. It also provides the means to interactively define and reference within-components of information items, transforming those components into information items on their own. Image objects are within-components of images and their spatial coordinates or contours build referencing objects. Document anchors are another example of referencing objects. Sets and lists are also important objects. Sets are used to implement the WorldView folders which are the basic structural unit. Lists will be used in the future to create another type of folders called “sequence folders” which keep information items in a specific sequence. Besides those object types, users can also create database objects and relate those objects or objects from a preexistent schema to the information items.

3.2 Data Storage

The information items are stored in a database schema. Images and documents can be stored as BLOBs or simple references to external documents or images can also be stored. The Annotation is another base type. To achieve hypermedia and extended functionality, referencing and generalized relationship types have been added. The referencing object type is further specialized for referencing specific types. These specialized object referencing types include image region contours, image location pointer, text region and text anchor. The generalized relationship type relates any number of objects. One of its specializations is the familiar Hyperlink, but it also relates any number of objects. These relationships are useful when a user is viewing an object and wants to access the objects which are related to it, generalizing the hyperlinking mechanism to any objects.

3.3 Access Interface and User Security Enforcement

The access structure plays an important role in WorldView. The interface configuration is based on the following premises:

- Information items are placed in folders;
- Providing some structuring enforcement and at the same time allowing a reasonable degree of information items handling flexibility;
- The system can be accessed by anyone through a web browser;
- The access structure must be associated with a user accounting and security policy;

Figure 2 illustrates the base structure. Registered users organize information in nested folders according to groupings, subjects or whatever is important. There are three base folders corresponding to possible useful repositories. The “all” folder is a generic workspace for everyone. The “group” folder contains any number of restricted access group folders for group workspaces. It is optionally administered by a user with all privileges over the specific group. Finally, the “user” folder keeps individual optional workspaces for registered users. The folders marked with an “S” label show only one type of information item for direct retrieval of information of a specific type.
Specific groups can only be created by the administrator. Figure 3 shows some group folders access in the prototype implementation. Each group can be public or restricted by default, but members can always access and extend them. User workspaces are private by default.

Figure 2 - WorldView root folders

Figure 3 - Screen capture showing group folders

Users can assume several roles, depending on authentication. There are unlogged users, registered users, logged users, the administrator and specific group administrators. Users accessing the system are “unlogged users” until they submit a username and password, which they can do at anytime. A new account proposal is automatically mailed to the administrator for the first login. A user becomes a registered user if he owns an account. By default he will have a certain quota which is adjustable by the administrator. If the user has an account and enters a valid login he becomes a “logged user”. Logged users can belong to many user groups (group administrators evaluate the applications). Every object has a owner (the creator), a group and a set of

---

1 The prototype is an adapted version for historical monument and painting studies. The examples are displayed in Portuguese but the important points are annotated with an English legend to clarify their meaning.
access permissions for user, group and other. Only the owner and the administrator (or group administrator) can change those permissions. Figure 4 illustrates the notation for object permissions. Access refers to viewing (which includes opening a directory), change refers to editing or modifying. Extending refers to inserting new objects, referencing, relating or annotating and the meaning of delete is immediate.

**Figure 4 - Object permissions**

Default object privileges are applied according to workspaces, as illustrated in Figure 5. Both the administrator and owner of an object can change its privileges. Unlogged users do not belong to any group, so they have "other" privileges. According to default privileges, they can access the information in the "all" workspace (public information) but cannot change anything. Logged users can insert information items, reference, relate and annotate objects, but only the owner and the administrator can delete objects. Figure 6 illustrates relating an image with a document URL.

**Figure 5 - Default Objects permissions**

**Figure 6 - Relating an image with a document**
Figure 7 shows the image retrieval screen. It allows the user to search, annotate, relate to any object, create points and regions of interest. The user can also view related information items.

4. WorldView Applications

The WorldView project is currently under progress. From it resulted a first workgroup application to share the material from studies of ancient monuments. This application uses only some features from the system and is centered around images. The administrator installs the WorldView data schema by running an SQL script in any database engine. The JAVA application then uses JDBC to access any database engine.

5. Conclusion

This paper presents the WorldView project. The system proposes a convenient way to share information. It presents an innovative user interface with information organizing structuring elements, user authentication, user and object privileges. It uses any database engine as its storage layer, which is accessed in standard SQL. The system provides the means to integrate any kind of information items. The research and implementation work is still under way to build a system supporting all the intended features.

Abstract: Activities carried out in project TEN aiming to start up a pan-European system for distance learning supported by a satellite communications network and the use of VSAT technologies are described here. As a major outcome of this project a pilot experience has been carried out involving remote classrooms in 6 different European countries, 30 lecturing courses, and over 700 participants.

1. Introduction

In the very origin of project TEN there is a very simple idea that at the same time can explain in a very easy way the system that was developed. This idea also constitutes the base of any training or learning model, that is, the existing asymmetry between the information flows going from teacher to students and viceversa.

Although from teacher to student this flow is featured as with huge information content, permanent during the whole class time, and being multi-point; in the opposite direction, from each student to the teacher, the information flow is instead small, occasional and point-to-point.

458
Figure 2: Information flow going to the lecturer

Trying to translate this theoretical communication model into a telematic system, we finally arrived to a technical working scheme that assigns communication resources asymmetrically and according to the information flow to be transported in each sense. Such scheme consists of a star-shaped VSAT network with the teacher classroom in the central node or hub station broadcasting through the satellite and remote stations connected by a return channel at lower speed so that students are allowed to interact on-line and remotely with the teacher.

2. Project TEN within the Telematics Applications Programme

In September 1995, a consortium formed by fifteen universities, companies and institutions from eight EU countries submitted a proposal to the open call in the Telematics Applications Programme within the Education & Training sector. After all evaluation and selection phases, that proposal finally became project TEN (ET 1022) that started in January 1, 1996 and is scheduled to finish in March 27, 1998. There is a web page in Internet where visitors can get more extensive information on the project (http://www.fundesco.es/ten).

During this period the main achievement of TEN has been the creation of a pan-European network for tele-education, based on satellite communications, and with seven nodes scattered over six EU countries. The network has been used to give pilot courses in order to show the system working. This has allowed on the one hand to improve the performance of the initial version and on the other hand to observe the level of user (teacher and learner) acceptance and verify its learning effectiveness.

3. Technical description

The system uses the Co-operative Data Exchange (CODE) network technology that had been previously developed jointly by two partners in the consortium TEN, SIRE and Unisource Satellite Services, for the European Space Agency (ESA). The CODE network is a Very Small Aperture Terminal (VSAT) system that provides interconnections between Local Area Networks (LANs) and remote stations via satellite.

The topology of the system is configured as a star-shaped network where a 512 kbps outbound carrier is used to broadcast through satellite the courses from the hub station or teacher’s classroom to all remote stations.
In order to allow students in the remote stations to participate during classes asking questions to the teacher on-line, the system provides a return channel that can be implemented either with a 56 kbps inbound carrier through the satellite, or with ISDN videoconference at 128 kbps, or with a PSTN connection via a modem. And finally it is also given the choice of a receive-only remote station without return channel, which could be useful in certain applications.

CODE provides the end user with a standard Ethernet interface to a TCP/IP transport which gives it the flexibility to provide other services such as database access, electronic mail, WWW and in general all services supported by Internet.

These are some of the main features of the system implemented by TEN:
- Satellite/Terrestrial Integrated Network: Broadcast/Point-to-Point/Circuit Switching
- Scaleable Stations
- VSAT/ISDN, Full VSAT
- Trunk Network TCP/IP LAN to LAN
- Data Network Interconnection & value-added data services
- Internet Connectivity (FTP, VT, E-mail, WWW, etc)
- Virtual Classrooms, Desk-Classroom
- It integrates and experiments with New Multimedia Developments: enhanced interfaces and facilities, emerging standards (Indeo-PCWG, H.261)
- It integrates and experiments with Distributed Multimedia Applications and Models

Another advantage offered by the system is that it does not need any kind of external help by studio technicians or specialists in its normal working during a course. To work with the TEN multimedia application is very easy to learn and this is based on the development of a friendly teacher/student interface.

The following features are available in the current release of the multimedia tele-education application:
- Full-duplex audio. In the communication between two stations the audio is full duplex, that is, there are two audio channels fully independent between the two stations. In a third station there is a switch that will be dynamically chosen between the different audio signals coming and only one of them will be reproduced. Whenever one of the audio signals is the teacher's one this will have priority over the others. In case of audio from remote stations it will be reproduced the one that first comes.
- PowerPoint viewer interface. This application includes the PowerPoint viewer to show and manage the slides of the presentations. The interface is the standard PowerPoint viewer interface. All the stations will have the same interface and the possibility to take control over the slides when they are interacting.
• Up to two remote stations interacting at the same time. It is possible to have two remote stations (apart from the teacher) interacting (audio, video and control) at the same time. The other stations will be watching and hearing the interaction among the two remotes and the teacher (not only the image and sound of the classrooms/participants but also the presentation slides, drawings, etc).

• Scanner. The application allows the integration of a scanner in the teacher and remote stations in order to show some last-minute information during a session. This information in printout copies can be digitised and sent to the other stations. Also drawings utilities are available to work over the scanned image.

• Use of videotapes. It is possible to broadcast videotapes from the teacher’s station. Image and audio coming from the tape during the video play will replace the teacher’s.

• VGA resolution. The display resolution used by this application is VGA (640x480) and high-density colour (16 bits). This resolution allows showing the application screen in a big size format without the need to utilise expensive video projectors in the classrooms.

• Application for managing courses and presentations. At the teacher station the software package includes one specific application to manage the presentations (insert, modify, delete, etc.). It offers two management levels: course and session (lecture), thus one course can contain several presentations.

• Teacher Simulator. Within the application software package, it is included an application that simulates the teacher interface in a remote station. Thanks to this a teacher being near a remote station is offered the possibility to have some training locally before the live satellite sessions (the hub station is in Madrid).

The teacher/student interface is the appearance of the screen that can be seen by the teacher in the computer from where he gives his course, and by all students in the big screens or electronic blackboards existing in every classroom connected to the system. This interface is defined in the same application that was developed in project TEN, and it is based on the most usual standards for PC (Windows 95, PowerPoint, TCP/IP).
By clicking the mouse on this interface (application toolbar) the teacher can give a presentation made with PowerPoint and students can see an image of his face in a corner while following his lecturing. He can also occupy the whole screen with his image in order to have all the attention of his students focused on him (possibility to change between small / big size of the teacher image). He can give permission to one or more remote stations to intervene in a discussion during the lesson time, he receives signals indicating that someone in a remote classroom wishes to participate, he can see in every moment which remote stations have logged on, and so on.

4. System validation

As it was said before, the network that was installed in project TEN has been used continuously from December 1996 to February 1998 to give 30 pilot courses, with more than 300 hours of system usage and about 500 students attending them and coming from the countries and areas where the remote stations are located. Students did not pay for attending the TEN courses.

The contents and subjects of the courses have varied a lot, depending on which institution among all the participants in the project was responsible of preparing them. Courses dealt with issues that were considered as interesting for small and medium-sized enterprises, but also with academic subjects and with training of trainers. In any case it was not the case that those courses were prepared having the TEN system in mind, but they were adapted from other systems or platforms to be provided through the TEN network. Furthermore courses were independent from each other and lasted no more than three sessions lasting 150 minutes each, and this was another setback for students that might want longer courses and also structured in a modular way. Our main goal at this stage was just to demonstrate the technical feasibility of the system and to check its pedagogical capabilities.

Future validation plans for the system are included in a project extension scheduled to start before July 1998. In this new phase five new remote stations will be installed in Poland, the Czech Republic, Hungary, Russia and Kazakhstan. Those new countries are going to receive funding from the International Co-operation (INCO) Programme of the European Commission and their participation will be co-ordinated by UNESCO.

Since the purpose now is to validate the idea of using the system for distance learning it has been adopted a completely new approach. First, courses are no longer free and therefore attendants will have to pay fees. In this sense we are increasing the value of the courses to the eyes of the students and also their interest. Second, contents are going to be designed according to students' needs and wants. Academic matters as astrophysics or dynamics of cardiovascular fluids will be dropped, and business administration or software applications in SME's will be preferred. Also it will be followed a modular approach in structuring the courses. Two or three main master courses will be prepared by European institutions of prestige but having the contents organised in totally independent modular courses, so that students are not forced to pay for a whole 9-month master course when they can only attend during three or four weeks a shorter course. Original plans are to start preparing the courses and looking for students in July 1998, and to start classes in October 1998 and until June 1999. Course materials will be provided through Internet and the TEN system will be used in sessions for groupware, tutorials, lectures, and so on, with the purpose of highlighting the contents of the courses.

5. Exploitation costs of the system

System TEN shows several clear advantages over competing solutions, such as how fast a network can be installed or re-configured, not depending of the situation of the local communication infrastructure, and not being limited in terms of the number of remote stations that can be connected to the system.

Furthermore, when we compare its exploitation costs with those of a 384 kbps ISDN videoconferencing system, that can be picked as an example of technological solution alternative to the one proposed in TEN, the advantages of the later can be seen immediately.

While the exploitation costs of a traditional videoconferencing system over ISDN at 384 Kbps increase proportionally with the number of remote classrooms connected to the system and with the number of usage hours, exploitation costs of system TEN are much more unresponsive to fluctuations of both variables, above all if it is considered the particular TEN solution that implements return channel in remote stations via ISDN at 128 Kbps. In this way it is only necessary to connect with the hub station when a question is to be asked to the teacher, therefore, minimising communication costs.
6. Conclusions

Summarising, project TEN is attempting to demonstrate the applicability of satellite communications, and more specifically VSAT technologies, in the area of distance learning and training. The proposed solution offers a great flexibility and adaptability to a lot of different learning environments (university education, training in the workplace, vocational training), and at the same time it constitutes a highly cost effective alternative.

Abstract: An unintended effect of Internet-delivered courses is a type of gentrification of the student population into technological haves and have-nots. It is the responsibility of universities and colleges to provide student access and training for the technology required to take these courses. Educators and researchers have been hard at work posing possible solutions to problems of access. Three categories of solutions have resulted from their efforts: public remedies, programs implemented by colleges and universities, and advances in the technology itself. Colleges and universities must also bear much of the burden to equip students to take advantage of new educational delivery methods. According to experts, they should design and test instruments that measure the technological skills of entering freshman students of color and economically deprived white women; design, develop, and instruct an interdisciplinary, introductory course in communication technology that will enhance students of color and women's information processing skills by increasing their computer performance abilities, reduce their technophobia, and increase their critical evaluation of the role of technology in their lives, and design a system for tracking the performance abilities of these students.

Introduction

A minor revolution is taking place in higher education: more and more students are completing courses using the Internet and other distance learning technologies (Corrigan, 1995). Entire online universities have been created to provide learning opportunities for students. For example, the Western Governors' University is coordinating hundreds of courses offered to thousands of students throughout the world (Educom, 1997). Institutions such as the University of Phoenix, University of Colorado, Denver, and Metropolitan State College of Denver are moving much of their curricula online. Corporate America is getting into the act, with companies such as IBM and Ziff-Davis offering online courses (ZDNet University, 1997). These delivery methods offer undeniable benefits, including convenience, increased access in many cases, and the opportunity for a richer learning experience (Germann, 1996). Many educators believe that this trend will continue and that in the near future, all or part of most college courses will incorporate technological components (Corrigan, 1995).

An unintended effect of Internet-delivered courses, however, is a type of gentrification of the student population into technological haves and have-nots. According to the Rand Corporation, "E-Mail is most likely to be used by wealthy, well-educated whites, while those most at risk include people without
college degrees, those with below average household incomes, and ethnic minorities—especially Hispanics, African-Americans, and Native Americans" (Rand, 1995).

This paper will examine the problems created by online courses—problems of access, educational disparity, economic disparity, and cultural bias. It will then look at some preliminary data from two area colleges, and finally recommend some possible solutions.

Problems of Access

There is no question about the impact of technology on society. Automated teller machines, cellular telephones, pagers, and other devices are ubiquitous. More and more individuals and businesses are turning to the computer and the Internet for education and training as well (Schrum, 1996). Many organizations support the spread of this technology.

We find that use of electronic mail is valuable for individuals, for communities, for the practice and spread of democracy and the general development of a viable National Information Infrastructure. Consequently, the nation should support universal access to e-mail through appropriate public and private policies. (Rand, 1995).

Unfortunately, that universal access is more talk than reality. The Rand Corporation study continues:

An information elite still exists, made up of those with access to and knowledge about computers and e-mail. And as e-mail becomes more pervasive, as more commercial and government transactions in the US take place online, those information haves may leave the have-nots further behind, unless we make concerted efforts today to provide all citizens with access to the technology.

Other researchers have found that many people, regardless of the problems of access, don’t have the necessary computing skills and abilities to take advantage of the new educational delivery methods. Krupa (1996) states that minority students are particularly at risk. "An Educational Testing Service Survey conducted in 1993 disclosed that minority K-12 students were considerably less skilled in computer competencies than white students. In particular, Hispanics and African American students registered fewer computer competencies than their white peers" (p. 38). Other research echoes this notion. Stickles (1988) states that many students of color (non-Asians) and poor white women haven’t learned communication technologies in their K-12 studies.

Many people denied access to online education simply can’t afford the computer, Internet access, and training required to take advantage of the new educational delivery methods. Resta (1992) reports that the average incomes of most families able to purchase a computer for the home is $35,000 while the average income of Black families is $16,786 and Hispanics families $19,027. Shields (1994) also writes that many students of color and white women cannot afford to purchase the technology.

In addition, research also indicates that some cultures hold a bias against computers specifically and technology in general. Stickles (1988) states that there is a strongly held negative prejudice among the black community toward computer technology. He reports that this negative attitude is a result of the perception that technology is a "white male power tool."

The overall effect of this lack of access, educational and economic disparity, and cultural bias is that large numbers of students—often students who could most benefit from the technology—are being denied those opportunities.

Internet-Delivered Courses—Some Preliminary Data

Although there is a large body of research available concerning educational technology in general, there is much less research concerning Internet-delivered courses. This is probably because most institutions only recently have began offering courses via this delivery method to large numbers of students. Front Range Community College is the largest two-year college in Colorado and has been offering online courses since 1994. Data from that college tends to support the conclusions of much of the research cited above. Specifically, in a study of 484 students who completed online courses between 1994 and 1996, data indicates that

--African American, Hispanic, and women students are underrepresented in online courses
--Asian students are not underrepresented

The report indicates that the data has not been checked statistically for significance, that no data was available concerning student income, and that more research is needed (Computer online course data,
In addition, limited, preliminary data from Metropolitan State College of Denver echoes these findings.

Some Recommended Solutions

Educators and researchers have been hard at work posing possible solutions to these problems. Three categories of solutions have resulted from their efforts: public remedies, programs implemented by colleges and universities, and advances in the technology itself. The Rand Corporation wrote that widespread public initiatives need to be undertaken to reach the disadvantaged student:

- Policy interventions should give priority to widespread home access. In addition, and not as a substitute, multiple options for network access located in convenient places (including, for instance, libraries, schools, public buildings, hotel lobbies, business centers, and the like) are important auxiliary access sites. Such common facilities could be considered good locations for help or training centers as well.

The Rand study also states that institutions need to study creative ways to make terminals cheaper; to have them recycled; to provide access in libraries, community centers, and other public venues; and to provide e-mail "vouchers" or support other forms of cross-subsidies.

Schuler (1996) estimates that some 600,000 Americans are now being served by community-based organizations that provide entry to the "information superhighway" at little or no cost. Some of this work is being supported by the Commerce Department's National Telecommunications and Information Administration which has spent $60 million on community initiatives during the past two years.

Colleges and universities must also bear much of the burden to equip students to take advantage of new educational delivery methods. According to Krupar (1996), schools should:

- design and test instruments that measure the technological skills of entering freshman students of color and economically deprived white women at Metro; design, develop and instruct an interdisciplinary, introductory course in communication technology that will enhance students of color and women's information processing skills by increasing their computer performance abilities, reduce their technophobia, and increase their critical evaluation of the role of technology in their lives, and design a system for tracking the performance abilities of these students...

She goes on to write that colleges need to provide technology role models for minority and women students. These could come in the form of computer course instructors and computer lab assistants.

Other institutions are offering other programs. The University of Minnesota--Crookston, (University of Minnesota, 1997) Waldorf College, and others are providing notebook computers to all students, and Hunter College is offering a special course for students without previous computer experience, most of them women and minorities (Epstein, 1993).

Finally, computer and related telecommunications technology is becoming cheaper and easier to use. Alternative devices such as "web-tv's", which allow users interact access through their televisions, went on sale recently. Network computers, which cost less than full featured versions but allow Internet interaction, also recently became available. And inexpensive handheld computers and attachments to video game machines is making access available to a broader audience. In reality, it will take initiatives such these, and many others, to insure a wide access to Internet-delivered courses and other types of educational technology.

Template-based Web Authoring for Language Teachers

Robert Godwin-Jones
Department of Foreign Languages
Virginia Commonwealth University
Richmond, Virginia, USA
rgjones@vcu.edu

Abstract. There are currently many possible approaches for creating Web sites for instruction. This paper describes the option of creating Web pages for language learning (or other disciplines) by using one of the many template-based authoring tools now available. Such an approach provides a quick and easy way to create course Web sites and to add interactivity such as discussion forums and drill and practice. A course recently taught by the author using "Web Course in a Box" (WCB) will be demonstrated, along with the WCB authoring tools. WCB has the advantage of creating a highly student-centered, active-learning Web site and allows for a surprising degree of flexibility and creativity in the use of the Web in language instruction. WCB is free to higher education.

Language teachers traditionally make extensive use of handouts in their teaching, in order to extend textbooks and provide a more personalized and customized approach to learning. Creating Web pages out of those handouts is simply an extension into cyberspace of what we all have been doing for a long time. The advantage over paper is the possibility of adding multimedia and interactivity; putting learning materials on the Web also allows for remote and off-hours student access as well as easy updating. For that to become possible for most faculty, however, there needs to be a quick and easy way to author, maintain and post Web documents, as well as to create interactive Web pages. HTML editors and text editors with HTML macros make the process of creating basic Web pages nearly as easy as normal word processing. However, with many of these programs teachers still need to know the basics of uploading files with FTP as well as of setting UNIX permissions for Web access. Macintosh and Windows servers streamline this process considerably, allowing server volumes to be mounted directly on the user's desktop.

An encouraging step in the direction of ease of use is the emergence of a group of products designed to make it much easier for teachers to manage and create Web pages and other Internet-based learning tools. Some are high-end commercial products such as Lotus Notes' Learning Space or those available through the Web tools in Asymetrix's Toolbook II. These products go considerably beyond the creation of course Web pages and use of collaborative tools -- adding, for example, sophisticated management and tracking capabilities -- but at the cost of some complexity in their use as well as of the required purchase of expensive proprietary software.

Another route has been taken by a number of universities -- the creation of inexpensive Web-based course creation and management tools. Most of these tools were initially developed for in-house use, but a number are being made available (or sold) for external use as well. This include such projects as WebCT (British Columbia), WEST (Dublin), the Instruc-tional Toolkit (Virginia), CyberProf (Illinois), WISH (Penn State), Virtual-U (Simon Fraser) and POLIS (Arizona). They vary considerably in their capabilities and approaches, and some are still in beta testing.
Another of these tools is one co-created by the author, called *Web Course in a Box* (WCB). As with most such authoring tools, using WCB does not require any knowledge of HTML nor does it require from the user any additional software beyond a Web browser. However, instructors who have learned HTML can use that knowledge to customize their pages beyond the default formats supplied. Using WCB involves entering text into form fields on Web pages, either through typing or copying and pasting, then sending the data to the Web server (by clicking on a button) where it is saved and formatted for the Web. As with other template-based systems, WCB allows customization of the look if the pages created, but does not allow absolute control over formatting and display options.

![Figure 1: Sample course home page created with WCB](image)

Typically, there is a short learning curve in learning to use such authoring tools, since users are working in a familiar medium, not learning a new environment. Updating pages once they are created is as easy as creating them in the first place; when forms are called up, the current values for each form field are automatically displayed for the instructor to verify and edit.

Such tools ease the process of creating Web pages in another way. Normally after creating HTML files, the user must then send, or upload the files to the Web server. Since typically the Web server is a UNIX computer, this necessitates learning FTP (file transfer protocol), maneuvering the UNIX directory structure and setting access permissions (with UNIX command line codes). Using WCB by-passes this procedure by saving the files in a predetermined and established directory for each course. Saving the files in the proper directory with the correct setting for Web access is accomplished automatically through submitting the WCB forms. In addition, the instructor can use the WCB forms to set up access control for course Web pages. This allows restricting access of course pages by requiring students to use logins and passwords. Access control is particularly useful if interactive Web pages such as discussion forums are being used, so that users can be tracked and their contributions registered.
Using WCB enables the instructor to integrate many types of files into an on-line course. Any type of file, including graphics, audio or video can be copied from the instructor's personal computer to the Web server, automatically uploaded and linked into the course pages. WCB does not create multimedia files, but it can help organize those files for student use. One of the greatest strengths of the Web is the ability to use the standard hypertext interface of the Web page to integrate seamlessly local resources with those located halfway around the world -- from the student's perspective are all just a mouse click away. Using file uploading and linking, instructors can make available not just text files, but also previously created learning materials such as HyperCard stacks or other language learning programs.

One of the main goals in creating WCB has been not just to ease the process of creating and maintaining basic Web pages for classes, but to enable the creation and to encourage the use of interactive Web pages, to help instructors move toward an active-learning, student-centered approach to the use of Web-based learning materials. Especially popular at VCU and at other institutions using WCB have been the threaded discussion forms. An example of the format of the forums is shown below:

![Class Forum](image)

**Figure 2:** Sample discussion forum

Multiple forums can be created for each class, which allows instructors to assign specific discussion or assignment topics to each forum. Instructors can also use a workgroup approach to the discussion forums, creating sub-groups in classes which then have exclusive access to workgroup-specific forums. Group projects can be done collaboratively in this way and then shared with the rest of the class in an open forum. The forums also allow attaching files, so that students can exchange and work collaboratively on files such as word processing documents.
The forums also can be archived, which when selected creates a snapshot of the forum at that point, putting all the posted messages and replies into one large file, which can then be viewed, downloaded and/or printed to provide an overview or review of the discussion in its entirety. Instructor-enabled forum management allows individual instructors to delete unwanted messages by author, by date, or by message thread.

Another option being added to the discussion forums is the ability to display thumbnail images of the original poster of a discussion thread next to the title of the message. The Web, as an electronic environment, is impersonal -- personalizing the environment in small ways can help towards humanizing somewhat the medium, as well as contributing towards building a community of learners, an especially important effort if the course is being exclusively taught over the Web. At VCU we will be linking to an already existing database of student images created for student identity cards, which are already in electronic format.

An additional interactive feature of WCB is the ability to create self-correcting quizzes and exercises. These can be created by typing in questions and answers or by importing text files containing exercises. There are a variety of formats available. Below is a short a newer quiz.
Of particular interest to language teachers is the fact that any character set can be used (as long as it is supported by the operating system the student is using). Feedback can be provided based on not just right or wrong choices but also on anticipated wrong answers, with in-context remediation help provided based on student performance. Student performance can be optionally monitored and scores reported. Content files -- whether text, graphics, audio, video or Java applets -- can be linked to the exercises or displayed side by side in a separate window (as shown in Figure 4). The next step will be to move toward an increased student-centered approach by asking students optionally to choose feedback, display and remediation options.

Using Web Course in a Box as a method for creating course Web pages makes sense for faculty who are not terribly interested in learning the mechanics of Web page creation and management but who want to create Web pages quickly. For faculty who want maximum control over the design and structure of their Web pages, creating Web pages from scratch with a text or HTML editor may be the best choice. However, even for those faculty, using a tool such as WCB may provide a good starting point. Or they may simply want to use WCB for key features such as access control, creation of discussion forums or interactive quizzes, and use the file upload capability to make available Web pages (or other files) created manually.

Web Course in a Box is an add-on to Web servers running under UNIX, WindowsNT or Macintosh operating systems, is free to higher education, and is available from http://www.wcbinfo.com.
Introducing Flexibility into Educational Programs: The Macquarie University Experience

Maree V. Gosper and David C. Rich
Centre for Flexible Learning, Macquarie University, Australia.
Email: maree.gosper@mq.edu.au / david.rich@mq.edu.au

Abstract: Macquarie University's vision is to provide flexible learning options for all students. This will involve the dual development of resource-based curricula and information technology (IT) capacity across the University. This paper highlights major issues underpinning the design, development and delivery of flexible learning and how these relate to the Macquarie context. It introduces a three-stage IT-based developmental model which accommodates both curriculum redesign and the wider institutional changes needed to ensure the delivery of high-quality flexible learning.

1. Introduction

Flexible learning embodies the principles of student-centred education by catering for individual needs in a mass higher education system that is expanding to accommodate an increasingly diverse student body. Flexible learning can provide students with real choices in when, where, how and what to study. Flexibility can be introduced in several ways. Flexibility in time allows students to study when it is most convenient to them, rather than being restricted to a set schedule of classes. Flexibility in place allows students to choose the location of study; learning materials can be accessed from different locations, either on-campus or off-campus at home, work or even the local library. Provision of a range of different learning resources and teaching methods allows students to choose what or how to study. Lastly, flexibility in pace allows students to progress through an individual course unit or a whole program of study at their own speed to match their own circumstances.

The vision for flexible learning at Macquarie University is to provide flexible learning options for all students. This paper highlights major issues underpinning the design, development and delivery of flexible learning and how these relate to the Macquarie University context. It introduces a three-stage IT-based developmental model which accommodates both curriculum redesign and the wider institutional changes that are required to ensure the delivery of high-quality flexible learning options.

2. Flexible Learning: The Macquarie University Context

Australian higher education has experienced major change since the early 1980s, with increasing student numbers, closer alignment to national political objectives, increasing government control, growing emphasis on 'quality' and 'value for money', organisational restructuring affecting all levels from system-wide to individual departments, and accelerating moves to recover costs from individual students. Policies introduced by the current Federal Government have encouraged competition between universities, with their growing differentiation an emerging outcome [Rich et al. 1997]. Among its responses to this increasingly challenging environment, Macquarie University has developed a Flexible Learning Plan, which is not only an attempt to respond to changing patterns of student demand but also reflects evolving conceptions of student learning.

Limited flexible learning opportunities have long been available to some students through a well-established distance education (external) program offered for some, but not all courses. This program runs in parallel with on-campus (internal) programs but is administratively distinct. Historically, students were required to enrol in one or the other; it was not possible to combine elements from the distance and internal programs. Students could not, for example, receive instructional resources available to distance students and
also formally enrol in on-campus tutorials or laboratory groups designed for internal students. This limited flexibility of study patterns and restricted use of learning resource materials to those students who chose to enrol in the distance program. Demand for more flexible options now, however, goes beyond this group. Although the distance program was established to provide education for non-metropolitan students, it is increasingly used by local students who, for family, career and other reasons have difficulty in accommodating on-campus class schedules. Administrative and educational distinctions between the two groups have gradually been eroded. All students, not just the traditional distance education group, are now potential users of flexible learning programs.

Pedagogically the content of distance and on-campus programs is usually similar, but the learning experiences are varied. In some units of study, there is little distinction between learning resources and teaching methods, while in others they can be very different. On-campus students generally attend lectures, tutorials, seminars and laboratory sessions. Although traditionalists consider the skills of academic discourse are best learned through small-group discussions, Bates [1995] challenges the reality of this, claiming that small-group face-to-face interaction is quite rare in post-secondary education today. For both on-campus and distance students, by far the largest part of their study is done alone, interacting with books and other media. The difference is that for distance students this fact is acknowledged and learning resources are designed to provide opportunities for interaction.

Distance programs typically employ a resource-based approach to curriculum design [NBEET 1994] which uses teaching and learning strategies based on instructional resource materials designed so that study is largely independent of real-time contact with staff. Numerous technologies are available to deliver resources including printed matter, audio and videotape, computer-based learning applications, interactive video (disk and tape), audio- or videoconferencing, broadcast TV and radio, and computer-mediated communications. At Macquarie, however, instructional resources are still primarily delivered using the early technologies of print, audio and video. Little use has been made of newer multimedia, Internet and computer-mediated communications. Taking this into account, along with Bates’ observations, we can surmise that upgrading instructional resources in the distance program and the use of such resources in internal programs can benefit all students.

Individual interaction with instructional materials, while crucial to the learning process, is only one element contributing to the complexity of learning and understanding. Cognitive development is strongly linked to input from others. Interaction among learners as well as between learners and teachers, whether through conversation or collaborative exercises, is an important strategy that should be embedded in any teaching program [Slavin 1997]. On-campus students have usually had more opportunities for communication between staff and students, both individually and in groups, than have distance students. However, modern communications technologies provide new ways for learners to interact at both a personal and instructional level that can partially equalise these opportunities. The selective and effective use of electronic collaborative learning exercises, virtual tutorials, bulletin boards and individual email conversations between staff and students has been shown to produce learning benefits [Katz & Lesgold 1993]. This provides, as never before, the opportunity to break down the barriers and isolation that many distance students experience. Likewise, in an environment of rising student:staff ratios and increasing class sizes, on-campus students could well benefit from these new avenues of communication.

The emerging reality is that it is now possible to provide similar learning experiences for on-campus and distance students by using instructional resources that exploit the interactive and communications capacity of modern technology. Incorporation of such resources into curriculum design not only facilitates the convergence of educational programs but, according to advocates, can produce other strategic and educational benefits. Well designed instructional materials can make students more active and independent learners; provide safety nets for students who are falling by the wayside in the more traditional mode of teaching; offer economies of scale where student numbers are large; reduce unproductive travelling time for part-time students; cater for student diversity; reduce pressure on teaching staff; and ease overcrowding of teaching space [NBEET 1994; Brown 1997].

The Macquarie University vision of flexible learning is to capitalise on these benefits to provide flexible learning options for all students, not just those enrolled in distance education programs. It aims to provide more choices by bridging the gap between on and off-campus students through the provision of similar curricula and learning experiences for both groups. In effect, this will result in a convergence of distance and internal programs which, for all intents and purposes, will mean academic staff will be teaching one program,
not two. The benefits for students are threefold: on-campus students will have access to the comprehensive resources currently available to distance students; off-campus students will have greater opportunities to communicate and collaborate with staff and the entire student cohort; and most importantly all students will have the choice of studying either on or off-campus or a combination of both, according to their individual needs at a given time.

3. The Introduction of Flexible Options into Educational Programs

3.1 Design Issues

Underpinning the design of flexible learning options is the curriculum design concept of resource-based learning. The enabling factor making it possible to use different resources in flexible ways is IT and its capacity to access information, deliver content and facilitate communication. Consequently, IT in general and the World Wide Web in particular have a pivotal role in the design and development of curriculum materials as well as in the delivery and management of flexible programs. At its simplest, the Web can be used to coordinate, and manage the learning experience through the provision of course outlines, teaching schedules, news bulletins and communication facilities. At its most sophisticated, the Web can provide a virtual learning environment that: handles enrolments; disseminates administrative information such as course outlines and teaching schedules; records student progress; delivers content and supports interactivity; facilitates communication and collaborative learning; provides assessment and feedback to students; and administers student evaluations of teaching.

Within the foreseeable future, a unit of study with flexible learning options would have a range of learning options equally accessible from on and off-campus. A Web interface would manage learning by providing course information, suggested scheduling of the content to be covered and the learning resources and interactive opportunities available to students. Specific resources may be delivered through the Web or may be in print, CD-ROM or disk format. A mixture of on and off-campus activities could be available; for example, students could choose between a face-to-face seminar session or an electronic discussion group; live lectures may be available or alternatively videoconferencing or audiotapes could be accessed. Other resources could include electronic quizzes, computer-based learning packages, simulations, group learning exercise and textbooks. Communication between participants could be facilitated through the Web using email, bulletin boards, conferencing options or, for students on campus, consultation hours could be available. Assignments could be submitted, marked and returned on-line. The role of the teacher would change from that of an expert delivering information and knowledge to one of an expert coordinating and managing a range of learning opportunities. Students would no longer be classified as internal or distance with restrictions on study options but would select from a range of learning resources or events, whether on-campus, off-campus or a combination of both.

3.2 Developmental Issues

Developing flexible learning options, as well as enhancing existing offerings, will require time, resources and energy. For students and staff it will be a new experience and infrastructure and support facilities will need to be developed to accommodate the change. From an educational perspective, the change will require the dual development of a resource-based curriculum and IT capacity. The term IT capacity is used in this context as an all encompassing term including physical infrastructure such as networks, hardware and software, and the technical skills and knowledge required to design, develop, implement and manage IT-based teaching resources as well as the supporting technical systems.

Neither curriculum expertise nor IT capacity, especially the ability to integrate new technologies into teaching programs, is evenly distributed across Macquarie University. This is not unusual in the Australian higher education system as evidenced by a recent study of the expected adoption of computer-mediated communication in university teaching which revealed that “there was little evidence of a consistent move towards an informed use of new technologies for teaching, with most developments being related to individual enthusiasts or small groups with expertise” [Hesketh et al. 1996]. Consequently, any institution-wide move
towards introducing flexible options must be coupled with the development and maintenance of the necessary human, physical and technical resources. A recent report on Quality in Resource Based Learning [NBEET 1997] identified these as including: the design and development of instructional resources, with more emphasis needing to be placed on instructional design to ensure there is a focus on active student-centred approaches and recognition of cultural and educational diversity; the development and maintenance of technical infrastructure; staff development to ensure confident and committed staff with new competencies; sustained and committed leadership; informed planning and management of resources; the provision of effective and efficient administration systems and services; support for learners; provision of adequate access for all clients; evaluation mechanisms to ensure continuous improvement; and new benchmarks for accrediting courses.

4. A Web-based Model for Introducing Flexibility

4.1 The Model

The Centre for Flexible Learning at Macquarie University has developed a three-stage model to facilitate the introduction of flexibility (Tab. 1). This Web-based model guides the development of on-line study programs within a framework that accommodates the institutional developments listed above. The model:

- recognises that flexible learning is underpinned by resource-based curriculum design;
- recognises that the Web is pivotal in coordinating and managing flexible learning programs;
- recognises that a variety of other media will also be used, depending on the particular teaching context;
- emphasises the active involvement of participants in the design, development, implementation, evaluation and maintenance of resources and programs;
- recognises and accommodates the need to develop institutional capacity to support flexible learning;
- recognises that institutional capacity requires coordination at all operational levels; and
- provides a practical context within which to develop, evaluate and refine products, supporting policies, strategies, and technical, administrative and managerial structures.

4.1 Stage 1: Developmental

Stage 1 is largely a developmental phase to orient staff and students to an on-line environment and to develop the structural mechanisms, skills, curriculum content and administrative procedures needed to deliver education through the Web. It commonly involves maintaining an existing curriculum structure and teaching resources but developing a homepage for the course unit or program involved, as a supplementary, not compulsory, resource. It might provide some or all of the following: administrative information, curriculum outlines, assessment requirements, lists of additional learning resources, a bulletin board or links to Internet sites, professional bodies or special interest groups. Initially, open (public) access to the homepage is recommended.

The Stage 1 homepage serves several purposes. It orients students to using the Web as a communication and information resource. For staff members and departments, homepage construction requires involvement in the development process and is an opportunity to gain an understanding of the scope and nature of the changes needed to accommodate Web-based teaching. Most importantly, this concrete experience is a basis for developing, evaluating and refining policies and strategies to deal with curriculum and management issues associated with resource development; technical, physical and human infrastructure support; access and equity issues in regard to computer ownership and Internet access; support and training for students; and staff development.

4.2 Stage 2: Partial Flexibility

In Stage 2 computer use becomes compulsory for at least one component of study, so that all access and equity arrangements, technical infrastructure, and student and staff support mechanisms must be operational. Typically, as knowledge and skills grow in Stage 1, new learning resources are developed using the Web environment’s special features to cater for both on and off-campus students. Such resources may include
compilations of relevant Internet links, quizzes, simulations, computer-based learning programs, practice exercises with hints and feedback, gateways into research or commercial databases, and communications facilities such as email, listservs and bulletin boards that can facilitate collaborative learning or individual communication. In Stage 2, the range of such resources often increases and they are fully integrated into the curriculum.

Only when the transition to compulsory computer use has been made can staff and students critically evaluate the initiatives. This stage can thus be seen as the trialing phase, which provides the opportunity to evaluate and refine resources, policies and procedures. At the same time there should be ongoing infrastructure, staff and resource development taking place. The internal and external curricula should be subject to continual review and restructuring with the aim of convergence to a common curriculum. It is often desirable to protect the increasingly valuable intellectual property embodied in the learning resources by a system of password protection, making them available only to enrolled students; as in Stage 1, organisational material and any content likely to promote the course unit or the University can be left available to the public.

4.3 Stage 3: Full Flexibility

Stage 3 is typically reached when there is sufficient confidence in the curriculum resources, access arrangements, technical capability and support structures to offer the program with full web-enhanced flexibility, although the transition from Stage 2 is not always clear-cut. Computer use is compulsory from either on or off-campus and again it may be desirable to password-protect key learning resources. The entire program of study is available flexibly to all students and is managed on-line. It is important to reiterate, however, that full flexibility does not imply that all components of teaching and learning are delivered through the Web. Rather, it is used to create a virtual learning environment which acts as a point of communication to coordinate and manage the learning experience which is provided through a range of resources in several different media.

Table 1: An IT-based model for introducing flexible learning into the curriculum

5. Using the Model
Sequential progression through stages is particularly useful for programs with little or no expertise in the Web or in computer-based teaching. Most activity at Macquarie University is still at Stage 1 where expertise is being developed or Stage 2 with partial flexibility. While the University has flexible offerings in the form of traditional distance education programs, very few are operating at Stage 3 of the IT-based model with on-line management and coordination of students' learning. For Schools with existing learning resources, the conversion to full flexibility is often a process of integrating those resources and management systems within a Web-based environment: essentially a movement from Stage 2 to Stage 3.

The first programs to offer full Stage 3 Web-based flexibility followed this approach. Emerging from the School of Earth Sciences, the flagship was a first-year unit, GEOS114 Global Environmental Crises [Earth Sciences 1997; Rich et al. 1997] catering for 400-500 students. Before the emergence of the Web, a resource-based curriculum akin to Stage 2 was developed employing a computer-based multiple-choice quiz (available on-campus only), an interactive CD-ROM, a textbook and live or audiotaped lectures. The unit moved to Stage 3 and full flexibility with the development of a Web interface to guide study patterns, manage the use of learning resources and integrate communications facilities. New IT-based resources were developed, including an Internet Resources kit and two interactive learning programs. Alongside these, lectures and print materials are still used.

For existing distance education programs running parallel with internal programs one pathway to Stage 3 flexibility is to initially retain existing materials, but merge the programs by developing a Stage 1 Web presence to serve both, introduce computer-mediated communications and gradually develop new resources accessible on or off-campus. An example is a first-year law unit, LAW113 Jurisprudence Law [Law 1998]. A Website supports both on-campus and distance students; course unit content is identical for all students but different instructional options are available, for example a choice of lectures or audiotapes. A key feature is the ability to use structured and unstructured discussions via email and bulletin boards as an alternative to on-campus seminars. The program has currently reached Stage 2. While trialing and evaluation are taking place, a safety net for distance students without computer access is operating through the availability of traditional on-campus block teaching sessions. Once development and strategic issues identified in the model are resolved, Stage 3 flexibility can become a reality. At this stage, all students will be required to have computer access to enrol in the unit.

These are two of many examples of how the model is being applied, both representing initial units of degree courses. Both evolved from supportive foundations: strong IT capacity in one case and an existing distance program in the other. A major challenge lies in developing flexibility where neither of these foundations exists. In such a context, the three-stage model provides a framework to guide the sequential development of flexible learning, as an alternative to what can otherwise seem the insurmountable hurdle of achieving full flexibility.

6. Concluding Comments

The three-stage model is powerful because it actively involves staff in the development process; it accommodates different teaching contexts and levels of design and technical expertise; and it provides a framework for staff development, and for policies and strategies to develop IT infrastructure. Introduction of flexible learning into the curriculum will, for some, involve workplace changes as well as adjustments of personal philosophies of teaching and learning. The staged approach provides the time and space necessary to deal with such structural and developmental issues as well as the political and cultural factors that accompany any major change. Most importantly, the model can provide a means to move the University towards its goal of being an exemplary provider of modern education based on research, innovative teaching and flexible delivery.

7. References

Abstract
Design is a series of choices that interact with each other and that reflect the theoretical underpinnings of a discipline. Techniques used to facilitate learner involvement with text fall within the domain of legibility. The following recommendations for basic typography are based on a number of studies both from print and electronic environments.

INTRODUCTION
Designers of computer screens for web-based applications make choices in manipulating several attributes which are common to both print and electronic media, among them, text, typography, layout, and graphics. Because screens are the direct means of communicating with the learner, design choices determine the success or failure of the web site. The wealth of research on printed texts gives us indications about making some of these choices. That extensive research base has been supplemented by studies of the legibility and readability of information presented electronically and by research into the cognitive processes involved in reading and learning. In addition, we can take into account information on user preferences that allows us to evaluate the probable appeal of our screens to our intended audiences.

INSTRUCTIONAL TEXT
The text and graphic elements of a web site combine to convey a specific message that will be translated into the reader’s knowledge base. The goal of the designer is to arrange screen design elements (Tab. 1) in appropriate combinations that create visible and recognizable structures to facilitate perception, reading, and understanding. The developer’s designs form the basis for an active interaction between page and reader.

LEGIBILITY

Techniques used to facilitate learner involvement with text fall within the domain of legibility. Legibility is the influence of the total format of the display on the ability of the learner to understand the text. Legibility is not just visible text, but also includes the factors of recognizability and readability. The designer must work, to some extent, with these three qualities to facilitate retention of information by encouraging deeper learner involvement.

Visibility refers to the perceptual detectability and discriminability of the printed character. Visibility includes characteristics related to the clarity of the image, crispness of type, and contrast between foreground and background. A visible display presents symbols clearly and accurately. Visibility variables interact with the eyesight of the reader, lighting, contrast, and size and shape of type. Letters that are too small may not be perceived for what they are. Visibility is a prerequisite for recognizability, for without adequate visibility the learner fails to recognize the meaning of individual symbols on the web page.

Recognizability refers to the ability of a page to convey the meaning of letters, words, and objects. Recognizability interacts with both text elements and reader characteristics — the background or prior knowledge of the reader. For example, a first grader may be able to recognize each of the letters on this page, but would have difficulty recognizing the meanings of all of the word symbols on this page, even though they are quite visible. Format variables that effect recognizability include type style, word spacing, leading (amount of space between lines), and kerning (amount of space between letters).

Finally, the third characteristic of a legible web page refers to how readable or understandable the message is. The reader must be able to comprehend the intent of the author and designer. Many of the factors that affect readability are within the domain of the author: syntax, vocabulary, sentence construction, and so on. However, the designer can facilitate readability by creating a micro and macro organizational structure appropriate to the message.

RECOMMENDATIONS FOR BASIC TYPOGRAPHY AND SPATIAL FACTORS

The following recommendations for basic typography are based on a number of studies both from print and electronic environments. Additional information can be found in style manuals including the Yale C/AIM Web Style Guide (http://info.med.yale.edu/caim/manual/).

1. Use only a few simple, familiar, and portable type styles.
   Although most browsers limit the type styles that you can use, graphics and PDF files expand these opportunities. Some type styles are intended only for display, or use as titles and headings. They often set a tone for the text that follows. For example, Avant Garde, is a modern type face useful for display purposes in screens that need to project a feeling of modernism and recency. Other fonts are more appropriate for masses of text and extended reading, including Helvetica, Times New Roman, and Bookman.

   When determining your type style options, choose, at the most, two type styles. One font family may be chosen and used for both headings and text. Or, choose one family for headings and another for the text for visual interest. But, if you find yourself using three or more styles, analyze the reasons carefully. Too many type styles destroy unity and create busy, distracting screens.

2. Use type sizes appropriate for the audience and the amount of reading to be done. Be consistent in their use.
   Type size is a matter of courtesy to the reader of the material. Frequently, a designer chooses on a type size on the basis of trying to fit as much material as possible on the screen. Remember that the reader is going to be between 18–inches and 24–inches from the screen. Any text presented on the screen must be large enough to be read by the average reader from the furthest distance. Usually a 12–point size is probably most appropriate for text, though 14 may be appropriate for younger audiences or people reading from more than two feet from the screen. Keep in mind that point sizes are not consistent and that some 12-point type sizes are larger than
others (Tab. 2). The size also depends, to some extent, on how much reading is expected. The more reading that is necessary, the larger the type should be to prevent tired eyes. Consistency, as usual, is important here. Readers pick up cues from the size of the text used. Large sizes indicate headings. Smaller sizes indicate blocks of information. If the size changes from one screen to another, the reader may become confused as to the importance or the information or the meaning of the size change. Decide on the sizes used for each heading level and for text and maintain those sizes throughout the program.

3. **Use both lower and upper case for text and extended reading.** While all UPPERCASE words may be appropriate for cueing an important word or phrase or heading, lowercase is easier to read words. Upper case letters provide fewer cues as to their uniqueness, interfering with recognizability. Now that most computers give you the options of italics and bold for emphasis, all upper case should be used sparingly. [Special Note on Italics: Depending on the font being used or the size of the type, italicized text can be difficult to read on a screen. Test it out before deciding on its use.]

4. **Keep line lengths around 45 to 60 characters.** Readers prefer short lines, lines of about eight to ten words or 45 to 60 characters long. Although there is some flexibility in this recommendation, Grabinger (1984, 1987, 1993) found, in studies looking at viewer preferences, that readers prefer shorter rather than longer lines of text, especially when single-spaced. When lines are too long it becomes difficult to follow the lines of text completely across the screen. Another reason for keeping lines reasonably short is that it seems that lines around eight to ten words permit more line breaks based on syntax and idea units. This is particularly unique with browsers because the text often fills the width of the screen. Using line breaks, narrower frame, or tables are strategies for keeping line lengths to a reasonable length.

5. **Generally, use single-spacing between lines of text.** The amount of space between lines of text, leading (rhymes with *heading*), is closely related with how long the lines are. Space between the lines helps the reader maintain vertical position in the text. Readers prefer shorter lines that are single spaced. This may be because it produces shorter blocks of text that appear to be manageable chunks of information. However, as lines get longer (more than 60 characters or 10 words), double spacing may be needed. The longer the line, the harder it is to maintain position on that line, therefore more leading is needed.

6. **Left justification is adequate in most circumstances. Use full justification only when proportional spacing is available.** Which is easiest to read? Left justified text. Fully justified text is also common, but is slightly harder to read because of the artificiality of creating line breaks based on the end of a margin rather than the syntax. Fully justified text relies on hyphenation and breaks phrases and words. In text that uses a nonproportional font, an effort to fully justify often creates rivers of white space running down the screen or page. This sometimes occurs with proportional fonts as well. Generally, people use the fully justified style because of an inherent
sense of neatness, thinking the page looks better if both right and left margins are equal. Although it may look neater, it is more difficult for the viewer to follow and read, so choose left justification as often as possible.

**MACRO ORGANIZATIONAL GUIDELINES**

*Organization* refers to screens that appear to have a coherent arrangement of all the major elements. Organized screens have both macro and micro characteristics. In the macro area, organized screens are divided into functional areas: text, graphics, title/status bar, and control panels. In the micro area, organized screens structured in a way that reflects the content of the subject matter. Structured screens use directive cues for emphasis, headings a organizers, and graphic devices to separate the information into chunks and to indicate important material.

7. **Begin your page development by considering macro level organization.**

Generally, the most useful way to operationalize this construct is to arrange the screen into functional areas. Designers should decide on where status and progress information navigation buttons, content displays, control buttons, and illustrations will be located, and use graphic devices such as shading, lines, and boxes to separate one area from another. This design technique works best when consistency is also practiced. The functional areas should appear in the same locations, and the devices used to define them should be the same throughout a program and its parts.

The designer-defined areas of the screen represent the tasks the screen expects users to perform. Heines (1984) described the standard screen components as orientation information, directions, student responses, error messages, and student options. In hypermedia and multimedia applications, we can add areas for information presentation and illustrations. Not every screen needs a place for each of those tasks, it depends on the program.

8. **Create separate areas to indicate important status and orientation information: location, page, topic, subtopic, objective, and so on.**

Because computer programs show only one page at a time, users must be continually informed as to what they are seeing and where they are within the program. With books and magazines, a user can quickly thumb back and forth through the pages. The sense of feel, (e.g., mass, width, pages held between thumb and finger) of a book often indicates where readers are in the book. Unfortunately, it is simply not possible to transfer physical feelings in a computer program. A status area saying “page X of Y pages” is a helpful strategy.

9. **Keep navigation controls in a separate area. Throughout the program, consistently use the same area of the screen for the controls.**

On the web, left/right buttons are usually not necessary because they are part of the browser, however “home” and section buttons should be used liberally to help users get to their desired destination in two clicks or less. Options and control buttons should be located in the same functional area throughout the program. Use shading, boxes, and color to “unify” the buttons.

10. **Use the bulk of the screen to present content. Separate this area from others.**

The content portion of the page is still the most important part of the screen. It should be noticeably separate from control buttons or other indexes. Use tables, frames, lines, boxes, color, and so on to create this area.

11. **Use frames with caution.**

Frames create added development flexibility. People look at web pages on different sizes of monitors. Frames that specify specific pixel widths may not work on all monitors. Instead, specify the size of a frame by using the “percent of whole frame” option. Frames also create problems with links. Links that do not specify a specific frame target often end up in a new window covering the original window. However, with careful development, frames can create a clean and unified appearance.
MICRO LEVEL ORGANIZATIONAL GUIDELINES

Following this macro-level organization, designers should then consider how the screen can reflect the structure of the content to enhance readability. Generally, users prefer screens that use headings, directive cues, and spaced paragraphs to indicate the hierarchy of the content and to break the content into chunks of information.

12. Limit pages to discrete ideas or logical units.
Use the natural separation of screens to separate ideas into meaningful units. Large ideas may need to be separated into several pages, but make them discrete and separate units. There is no need to crowd pages with several ideas.

13. Use headings as organizers.
Headings of at least three levels are useful organizing points for users. Main headings providing orientation can be placed in the area of the screen that serves that task. Sub-headings referring directly to the information presentation should be placed within the text. Phrasing headings, such as questions, can direct users’ attention and facilitate learning.

14. Put paragraphs into bite-sized bits of information by single spacing within the paragraph and using increased space rather than indents to separate paragraphs.
This gives readers manageable chunks of information because the information appears to be in bite-sized pieces. Unlike fiction, readers need built in pauses between each piece of information so they have a chance to reflect on what they have just read before continuing to the next unit of information.

15. Use indents to indicate hierarchically related subject material.
Subsume related material under their super organizing concepts. Traditional outline formats or lists with numbers, letters, and bullets should be listed under the super organizing concepts. In a hierarchical format, this suggests that one level of subheadings are an elaboration of the prior super heading.

16. Group closely related items within a box or a common background color or shading. Use the same graphic devices, as well as white space, to separate unrelated or contrasting ideas.
Graphic devices provide a visually interesting way to link common ideas or to separate unrelated ideas. If shading is used, make sure it does not reduce the visibility of the text it surrounds.

17. Use directive cues (i.e., bold, italic, underlining, inverse) to emphasize important terms or ideas.
Used sparingly, directive cues like color, size, bold, italic, shape, direction, brightness, underlining, uppercase, and inverse can facilitate learning by calling attention to (i.e., making more perceptible) important words or phrases. This technique should probably be limited to one to three items per screen. Flashing, which is another technique used to draw users’ attention, should probably never be used. It can be extremely distracting to users.

18. Set up comparison/contrast situations in a side-by-side columnar arrangement.
Columnar arrangements are particularly useful for both comparisons and contrasts because it keeps in view all the items being compared.

VISUAL INTEREST GUIDELINES
Finally, designers should consider the visual interest of the screen. Viewers dislike screens that are plain or full of text without any headings, directive cues, lines, shading, buttons, titles, or illustrations (Grabinger, 1984; Grabinger, 1987; Grabinger & Amedeo, 1988; Grabinger, 1993). It seems that a variety of well-organized text elements enrich the environment and make it more interesting to explore. Excessive complexity results when too many elements or too much information is crammed on the screen.

19. **Use accepted, general, aesthetic publication guidelines. Strive for balance, harmony, and simplicity.** Balance, harmony, and simplicity are general constructs often given to designers as the basic elements of design. All three constructs can probably be summed up in the word “moderation.” Screens that display balance, harmony, and simplicity are not jammed with information, have elements distributed throughout the screen, and maintain a consistency in styles and locations from one screen to another. The following guidelines help operationalize these ideas.

20. **To help create a sense of balance, maintain consistent internal margins and distribute the bulk of the white (empty) space around the exterior margins of the screen.**

   The notion of balance is a complicated concept with both the weight of objects and the use of space used to create that sense of balance. Heavily weighted objects use think, dark lines or dark colors and shading. Lightly weighted objects use thin lines and light or no shading. **White space** is that space that contains no information, it is empty space on the screen (and could be another color depending on your background color selection). The first step in creating balance is to group the text elements together on the screen and to distribute the white space around the exterior margins. Maintain consistent internal margins among the elements on the screen.

21. **To create a sense of harmony, be consistent and strive for simplicity.**

   Many times “consistency” has been mentioned in this paper. This refers to overall design, directive cues, type faces and sizes, button shapes, icons and so on. Designers often begin with a simple concept, but wind up adding “just one more button” or “one more field” to add that extra option or bit of information. Finally, by the time they are finished, the screen is cluttered with too many buttons, too much text, and too many design elements. Try for the “minimalist” look.

**CONCLUSION**

Good interface design requires close attention to student behavior and attitudes as well as system capabilities. The screen is the central point of the interaction between student and program, so much of interface design focuses on the screen. While a good looking screen requires both artistic talent and a good sense of organization, almost anyone can design attractive, functional screens by applying some common sense. A good place to start is with a design that looks useful to you. Alter it to meet the needs of your program.

While the concepts of organization and visual interest may seem to be common sense, common sense is not always followed by designers. In addition, knowledge of these concepts does not mean that designers will apply them in ways that create aesthetically pleasing and well-organized screens. However the studies by Grabinger and his colleagues suggest that these constructs are important to prospective viewers and may help gain attention and build confidence in using instructional material (Keller & Burkman, 1993).

Abstract: With the increasing power of today's information- and communication technology new application areas have been opened in education and training. At the same time shrinking production and innovation cycles require ongoing lifelong learning and training. With the increasing availability of the WWW, its usage for course distribution and delivery becomes more and more important. To meet the demand for flexible structures in learning and training to adapt to changing situation, the major goals are to increase overall efficiency in teaching and training and to improve learning efficiency. This includes support for self-driven learning, reduction of time and place restrictions as well as availability to wide audience.

Within the European projects DEDICATED and IDEALS, the Interactive Graphics Systems Group (GRIS) of the Darmstadt University of Technology developed concepts and technologies to achieve these goals. These concepts and their realisation within the IDEALS project will be discussed in this paper.

Concepts

Strict Modularization

For a learning system, capable to handle the requirements of the future, modularity of courseware is a crucial design issue. Looking at today's CBT-systems or the WWW, which to an increasing amount is used for education and training purposes, it becomes evident that these learning systems are conceptually based on fixed, monolithic courses.

Almost all of these traditional learning systems allow courses, that they can be split up into different parts, which can be stored separately (modules). Course flow information, layout and interaction description as well as the basic multimedia elements are combined into monolithic blocks of data, see [Fig. 2], whose size depends more on technical issues as disk size than on content-related issues. This and the strong interrelation among the blocks prevents the exchange and reuse of single course components.

Applying the idea of modularization to the area of courseware will change the notion of course. Instead of fixed arrangements of modules there will be a pool of independent modules, from which optimal modules will be selected and combined to a course on demand.

For modular courseware, each module must be complete and self-contained. Modules can make use of other modules, but they are not allowed to contain modules. Instead they only refer to other modules. So, parts of a course can be reused without the need to remove unnecessary parts of a former course. The real advantages of modularization shows, if module references can be specified in a content-driven way rather than solemnly based on identifiers. An author specifies a course, just as with traditional systems, by defining and arranging a set of modules. However, modules can be specified entirely on a goal-oriented level and the decision which module to actually use is done individually whenever the course is run. Thus, modularization allows courses to automatically adapt to a student, so that a student will always get an optimal course.

Automatic, goal-oriented selection and updating of modules can only succeed, if all modules are technically exchangeable. Therefore, referring module must not rely on individual features or assumptions on the internals.
of the used module and vice versa. Instead there must be an abstract interface for modules, which all modules must comply to (black box concept).
Up to now it has been shown, that consequent modularization enables exchange, re- and multiple use of courseware and is therefore the basis for efficient production and usage of digital courseware. The second major aspect, which has to be considered in conjunction with modularity, is a subdivision into three courseware layers, which reflect the different layers of abstraction in the production of courseware.
- On the content layer, it is to be decided, which topics are part of the course and how to arrange them. Therefore the author will subdivide each topic into separate learning goals and organise them appropriately. This requires expertise on the topic, which is to be imparted, as well as didactical qualities.
- On the learning layer, a single learning goal specified on the contents layer is broken down into concrete learning steps. This includes layout and interaction definition. Here expertise is needed in the area of layout and design as well as in pedagogics.
- On the material layer the creation of the elementary course material takes place. Here it is asked for (technical) know-how and skills to create the elementary learning content.
Each of these different courseware layers corresponds to specific view on the courseware and to a different set of tasks for the author. For a complete course all three levels must be specified. Although this can be done by a single author, in real-life course production it will be more typical that several authors with different expertise co-operate. In this case, having besides a horizontal modularization, where a course is split in several parts, also a vertical modularization, which reflects the different courseware layers, will be enormously beneficial, since so each author can focus on the level most appropriate to him.

Self-description and Dynamic Referencing

In order to realise a modular and flexible structured courseware on all levels mentioned above, courseware should make use of courseware modules through links or references. The following section describes a concept for referencing modules through a characteristic attribute description.
Besides the internal representation of the module contents, each module has a self-description for characterisation. Such a self-description is a certain set of attributes, representing different properties of a module. It contains the usual set of technical or administrative attributes like name, creation date, type, author, etc., but moreover a self-description contains attributes, describing criteria characterising the contents or didactical/pedagogical issues, either.
In a way, the structure of a self-description can be interpreted as a (restricted) knowledge or information model. The self-description is a substantial part of each module. Hence, a module on the one hand encapsulates its knowledge in an internal format (the content format), on the other hand the self-description is a characteristic, describing the content in a certain format, so that the module can provide information about itself. The use of the self-description, besides the self-characterisation feature, is the possibility to enable searching for modules, which match specific characteristics, comparable to the classical way of indexing. Concerning the use of self-descriptions for searching, it is essential to avoid different interpretations of self-descriptions. Therefore it is important to restrict and control the set of attributes and valid attribute entries, e.g. by the means of standardised dictionaries.
Having a self-description available for the modules, the referencing of specific modules can be done using either their unique names, or by giving a set of attributes, which a modules self-description has to match. This second possibility can be extended to a more general mechanism, the Virtual Reference. Basically, a Virtual Reference does not address a specific module, but a set of ‘similar’ modules. It is an abstract description of constraints a desired module should match and is resolved during runtime. The possibility of dynamic resolving of reference enables new forms of adaptability of courseware, e.g. using constrains, that take into account the actual learning state, certain preferences, learning strategies, etc.
The issue of adaptability is another important aspect for efficient learning and training. In general, adaptation of courseware requires information about the current learning status of the student. By monitoring the actions of a learner, the modules presented to him and the results of tests information about the a student during his learning session can be gathered in a user profile. The information collected in such a user profile can be used further on to get knowledge about the current learning status of the student, which can be utilised to control the further course flow by influencing the selection of new or additional courseware or within the process of resolving a
Virtual Reference. Again, the information about the modules gained using their self-descriptions can be used here.

Realisation in IDEALS

The ideas presented in the previous sections are the basis for the EU projects DEDICATED [DEDICATED 95] and IDEALS [Borgmeier 96]. Similar ideas and concepts, can be found in COBRA [Beyer 96], OLA [Oracle 96], ARISTO [Llamas 96] and ARIADNE [Forte 96]. The following section will describe the realisation of IDEALS’ Modular Training System (MTS).

As already mentioned, the modular courseware concept and a dynamic referencing mechanism are main features of the IDEALS MTS. IDEALS MTS does not only support courses based on dynamic referencing, but fixed arrangements of courseware too, since this type of course is especially well suited for delivering identical courses to homogenous groups of students. In this case, modular courseware will lead to an reduction of overall effort in course production, due to reuse and multiple use of modules. In contrast, dynamic courses are especially well suited for self-driven learning (learning on demand). However, authors of such dynamic courseware have to specify the course flow without knowing the details of, how the referenced modules carry out their tasks. The paradigm of course changes from a fixed arrangement of courseware into a well-structured set of reusable courseware modules.

Even though it seems quite easy and obvious to realise, our experience shows, that the creation of such modular courses requires a significant change in the way of structuring information and knowledge.

WWW Based System Architecture

Different than DEDICATED, which was based on proprietary client-server technology, MTS uses a client-server architecture based on the open standards HTTP and HTML for transmission and presentation of courseware. Besides being able to benefit from the ongoing development in the area of WWW and telecommunication, using a standard HTML browser on the client side makes MTS courses directly accessible to the entire Internet community. Moreover, this approach ensures that future extensions of HTTP and HTML can directly be used in IDEALS MTS. Therefore the IDEALS software has been implemented as a extension of a WWW Server, see [Fig. 1]. While a standard browser is used on the client side, the server side consists of three components, a standard WWW Server, a Database Server and the MTS Server itself, which communicates and co-ordinates these servers. The WWW Server only delivers the courseware to the student, while the Database Server provides the courseware modules. The MTS Server controls the course flow and the access to the courseware.

MTS Modules

IDEALS MTS supports the three different courseware layer introduced above by providing three different module types. Each module type corresponds to one courseware layer and supports its specific view and style of working. So, in IDEALS, every author can work in a natural and therefore intuitive way on the abstraction level most appropriate. The use of specific authoring tools further increases the efficiency. [Fig. 2] shows the different
layers and their corresponding module types, which are described in more detail in the following section, in comparison to the usual structure of monolithic courseware.

**Figure 2: Horizontal modularization versus modular approach**

*Material Objects* (MO) are the atomic, multimedia building blocks for courses. Basically they are the carriers of the learning content. This includes all standard multimedia formats (as GIF and TIFF for bitmaps and WAV and AU for audio, etc.). But MOs can also be complex program fragments or entire applications, e.g. simulators and microworlds implemented either as Java-applets or as JavaScript fragments, depending on their complexity. The other type of MOs consists of the interaction elements provided by the system for the realisation of an user interface. In the area of MOs, it is IDEALS policy not to invent own formats but use those available for the WWW.

Almost all browser provide build-in support for the formats GIF, JPEG, WAV, AU, JavaScript and Java. Other formats as e.g. video or VRML require helper applications or plugins. Using a plugin allows to seamlessly integrate the presentation with the other elements in the browser window, while a helper-application will always use a separate window to present the data. Common disadvantage to both solution is, the browser must be configured appropriately and a plugin or helper application must be available. An additional problem is, that in this area the development is still ongoing and therefore all the quasi-standards are more or less moving targets. Support for vector drawings and formulas would be most beneficial.

Besides those more technological issues there is also a more conceptual one.

IDEALS MTS requires MOs to be self-contained. Because of this HTML or plain text and JavaScript fragments, which realise learning content must be encapsulated into separate MOs. MOs must also be complete. Therefore if several HTML fragments, e.g. a picture and some accompanying textual explanation, belong to the same learning content they must be encapsulated into the same MO (Compound MO). Such Compound MOs can be realised as HTML fragments. Therefore, IDEALS MTS supports special MOs, which can contain plain or HTML formatted text, JavaScript blocks or any arbitrary HTML fragment.

A *Function Unit* (FU) defines for a specific subject the arrangement (layout) and the overall behaviour (interaction among each other and with the student) of the used MOs, which realises the desired learning step (function in the overall learning process). Such steps are presentation, exploration and test.

The FUs are specified and stored as HTML-1. HTML-1 is an IDEALS specific extension of HTML. To realise the IDEALS specific kind of references a special tag is used which allows referencing of material registered in the database. This specific tag must be used instead of the HREF attribute. Since the student's browser is capable of plain HTML only, the MTS server contains a converter component which replaces the specific tag with appropriate HTML code.

According to the concept, the code to co-ordinate the interaction between different MOs must be part of the FU description. However, with plain HTML one can only create passive documents with, i.e. no interaction between the elements. Therefore JavaScript, which is an extension to HTML introduced by Netscape, allowing to add dynamic functionality to HTML, is used. MTS system functionality, e.g. to update the user profile or call for the next FU, can be accessed from the system using JavaScript.

A *Course Node* (CN) arranges the sequence of FUs based on a didactical concept or a certain learning strategy for the sub-domain. Within a CN an author is not restricted to certain teaching/learning paradigms, but is free
to choose an appropriate one. Since HTML provides only very limited means to structure documents and cannot capitalize contents from structure, MTS uses an own Course Description Language named CDL for the specification of course structure. To create CDL, an author uses the integrated authoring tool. This tool represents a CN as a kind of flow diagram and enables the author to visually create and edit CNs. This is an important issue, since typical authors of CNs are experts concerning the topic but do normally not have programming skills. For this kind of authors such an intuitive user-interface is an essential issue.

Beside the graphical authoring tool, the extended search engine supports authors in retrieving courseware by specifying semantic constraints. Here, the additional characterisation of courseware is a great advantage over the WWW as the material can easily be found by its characterisation. [Fig. 3] shows a screen shot of an authoring session.

![MTS Authoring Environment](image)

**Figure 3: MTS Authoring Environment**

**Course Navigation**

The modularity of courseware has impact on the realisation of the user interface for course navigation. Since an author does not know the situation, in which his module will be used, he is unable to create an appropriate user interface for course navigation. In order to preserve the modular courseware structure, exchangeability and reusability, the user interface for course navigation is provided as a system component. This has the following advantages:

- Since all MTS courses use this system component, there is a unique look and feel, so that a student will become familiar with the system quickly.
- Since MTS provides a system component for course navigation, an author does not need to implement the user-interface for the standard MTS course navigation by himself, and can concentrate on the internals of his FU, which reduces the production effort.
- In MTS FUs never communicate directly with other FUs. Communication with the parent CN is always done via the interface provided by the system. The existence of such an standardised interface is an crucial issue, since this guarantees the exchangeability of courseware.

**Details of MTS' Self-Description and Virtual References**

The basis for the concept of dynamic referencing is the self-description. In IDEALS the self-description contains four content related attributes, *context, aspect, keyword* and *subject*. These four attributes are structured in a hierarchical way. The most general term for describing the content is the attribute context, identifying a specific topic like computer graphics, software engineering, etc. The attributes subject and keyword depend on attribute

BEST COPY AVAILABLE
context. I.e., for every value of attribute context there is a distinct set of valid entries for the attributes subject and keyword. This hierarchy is necessary to distinguish between different meanings concerning the general topic, in which it is used. As a specific term for subject or keyword may appear more than once, it usually has different meanings dependent on the context, it is used for. E.g. the term ‘projection’ is interpreted differently, whether it is used in the context of ‘algebra’ or of ‘computer graphics’. Besides this hierarchical order, the attribute aspect has the same hierarchical level as context. This attribute describes a specific view on the courseware, e.g. ‘introduction of’ or ‘motivation for’, etc.

It can be foreseen at this point, that the set of classification attributes must be extended to a more global classification scheme in order to match a wider range of knowledge as well as didactical and pedagogical parameters. To ensure exchangeability within IDEALS, the catalogues for the different attributes have been standardised between the IDEALS partners, so that the self-description match a common interpretation and meaning, which is needed for sufficient dynamic referencing.

Within the IDEALS’ implementation of the MTS, courseware modules can refer to other modules using the referencing mechanism of MTS. As mentioned above, the concept of dynamic referencing is used in form of Virtual References, which address specific modules using an abstract description instead based on the self-descriptions. The Virtual References enable an author to specify either technical constraints as well as - and more important - constraints based on the attribute sets of the self-descriptions. To enable extensive flexibility, an author can assign weights to each attribute of a Virtual Reference and also to each single attribute value. These weights determine to which degree an attribute is taken into consideration in the process of resolving a Virtual Reference. The author is not limited to give only one single value per attribute, but can combine more complex constraints making use of several valid values from the scope of the attribute using the logical operators ‘NOT’, ‘AND’ and ‘OR’. In this way, the author can define complementary or alternative constraints or can weaken or strengthen single constraints respectively.

The process of resolving Virtual References (the so-called Mapping) is of great importance. The mapping is an iterative feedback process. During the first step of Mapping all modules are determined, that match the maximal set of constraints. If the set of resulting modules is sufficient, it is determined, which of the modules does fit best in order to match the constraints best. Depending on the structure of the Virtual Reference, during mapping a generalisation or deduction with respect to the given weights takes place, until the set of matching modules becomes sufficient. Finally an optimal module will be found and used.

Although the IDEALS MTS collects data about a students learning sessions, his learning results and therefore about this knowledge status at a certain stage, this information currently is not used during the mapping process for resolving Virtual References. Instead, the information can be used directly within the level of CNs. At this level, an author can specify constraints regarding a students knowledge and learning results and explicitly control the flow of presented learning information.

Demonstration of MTS in the University Pilot

In 1996 the main activities, in IDEALS, have been the design and implementation of the MTS. Besides development of the software this included also the set-up of the technical and organisational infrastructure (so-called Local Training Centre - LTC). After the verification of the system succeeded in first half of 1997, the project has entered demonstration phase. Here the department of Graphical Interactive Systems (Germany) together with the Faculdade de Ciencias e Tecnologia da Universidade de Coimbra (Portugal) and the Raahe Laboratory at the University of Oulu, (Finland) jointly developed courseware on "Fundamentals of Computer Graphics". Each of the three institutions used and is still using the courseware, adapted to its individually needs, in its ongoing teaching activities. During this demonstration the experiences of all users (authors, administrators, and students) are monitored and evaluated. The results of this will provide information on:

• Efficiency of the MTS for course production and delivery.
• Learning success of the students and overall learning efficiency of MTS.
• Acceptance of the system from the side of authors and learners.

A showcase with selected courseware from this pilot can be accessed from the WWW via the URL http://ltc.gris.informatik.th-darmstadt.de.

Abstract:
Curricula at the higher and university education level will become more and more flexible and interactive of nature. Problem-based or project-based education will become keywords in such curricula. In this paper we present the design of a project-based study environment on the web. The basis for this design is the e-study concept, studying by means of the Internet. We describe central design guidelines and present ComMedia as an example of such an environment.

Introduction
Curricula at the higher and university education level will become more and more flexible and interactive of nature. Future education will become embedded into the rapidly forthcoming global information society. Information and communication technologies (ICT) enable the students all over Europe to put individual curricula together based on available international flexible and interactive courses. Teachers will be able to guide students in a flexible and interactive way. In the project FLINT (de Vries, 1997) we focussed on the design of study environments in order to enable students and teachers to work and study in a flexible and interactive way. We coined the concept e-study (de Vries, 1998), this concept stands for studying by means of Internet technologies. In this paper we describe some of the results of the project FLINT. The question we want to answer here is how to design project-based study environments on the web. Firstly, we outline the concept e-study. Secondly, we describe key design guidelines for such environments. Thirdly, we describe ComMedia as an example of a project-based study environment.

The E-study Concept
'E-study' concept stands for studying by means of the Internet. On the Internet, teachers are expected to prepare study tasks. While learners perform these tasks the teachers guide the study processes, after which teachers are expected to evaluate the study processes and results. Software tools are needed for preparing study tasks, performing study tasks, guiding the study process and evaluating study results and processes.
Educational Institutions will be able to disseminate certificated courses. Certificated means that these courses are rated against European educational standards. In addition to these courses, a variety of organisations can offer (online) Study Services. For instance, publishers can provide for instructional multimedia information objects (IMIO's). Such objects are expected to become the electronic counterparts of for instance chapters from study books. Figure 1 illustrates the E-study concept.

We use the concepts Interactive Study Environments, Interactive Study Systems and online Study Services to describe the E-study concept (Vries, 1997, Vries & Vogel, 1997). Basically, we see an Interactive Study System (ISS) as a software system consisting of study task forms (electronic forms that provide learners with information and/or tools necessary in order to attain the study goals), study tools (software tools that are particularly designed to enhance individual or group-based study processes), information resources (the multimedia information content matter), and if needed additional materials (information and/or tools that support study processes but which are not offered in an electronic way). The main goal of an ISS is to enable an interactive study process between a user of the system and other users and/or between the user(s) and educational resources. It is important that an ISS can be very small and simple. An example of a simple ISS is an individual study task, a webpage providing learners with information about a specific task, relevant links to information resources, and enabling e-mail contact with the teacher. However, an ISS can also refer to a complete two-month course involving 100 learners, in which course specifically designed study tools and multimedia information content are applied.

To give the needed support to teachers, there is a need for Interactive Study Environments (ISE's). An ISE is a software system for the preparation, application, and evaluation of ISS's. Such an environment consists of the following basic components: preparation, application, and evaluation tools and Interactive Study System Components. An electronic library and an electronic café can for instance extend it. Preparation tools are for instance information editors, 'learners' prior knowledge analysis tools, and ISS-assembling tools. Application

![Diagram](image-url)
tools are for instance learner guiding tools and schedule tools. Evaluation tools are for instance study process/results evaluation tools and Interactive Study System evaluation tools.

The main goal of an ISE is to improve the effectiveness, efficiency and attractiveness of the (re-) design, use and evaluation of ISS's. An environment in which the tools and methods are linked to the design and use processes should help teachers in the assembly process of ISS. We investigate if such an environment supporting a lifecycle of Interactive Study Systems (ISS) can be developed based on insights from the field of method engineering (Brinkkemper, 1996), more specifically situational method engineering (Harmsen, Brinkkemper, & Oei, 1994). In the E-study concept teachers and learners will be supported by means of a wide range of communication and information services, summarised in the concept online Study Services. For instance, educational publishers as ‘content owners' may act as a Study Service Provider. They provide teachers and learners, who apply study books of the involved Educational Publisher with services linked to the study books. Examples of such linked services are for instance: the so-called Instructional Multimedia Information Object's, examples of study tasks, updated instructional multimedia information content, updated links to relevant websites, new study tools, and shared magazines filled with results of various but related study projects. In the E-study concept ISS's, ISE's and study services are interrelated.

In this paper we look at project-based study environments is a specific type of an ISE. Study projects can be seen as a type of an ISS. We took a task-oriented approach in order to distinct guidelines for this type, because project education stands out for doing project tasks.

Design-Guidelines for a Project-based Study Environment on the Web

In Project-based education the tasks of the instructor and students are different from those in a regular school environment. The instructor is no longer the source of knowledge, but he facilitates and monitors learning. Learners face problems that they have to solve by working together in groups. An online project-based study environment has to facilitate such education. Project-based education can be described in three phases; prepare, guide and evaluate education (Dolné, 1977). The instructor will complete these three phases. In the 'guide phase' of the instructor the students complete three subphases: prepare, perform and evaluate the project.

The design-guidelines we mention here are based on the tasks of the users. We first make a distinction between generic and phase specific guidelines. Generic guidelines are related to all three phases, while phase specific guidelines only refer to one phase.

We distinguish four generic guidelines. These refer to information exchange, communication, performance support, and administration. Both instructor and learners need information from each other. Learners need for instance the content matter that the instructor has prepared and the instructor has to give feedback on the reports that the learners have sent in. The users have to be able to up- and download information, for instance documents, to and from the ISE. An instructor has to give feedback to his learners, he has to motivate them and has to take care that they perform their tasks. A learner has to meet and discuss with groupmembers and asks the instructor questions. The users have to be to communicate with each other in an ISE. The project members are not experienced in carrying out projects and the specific project assignments. They therefore need additional support in carrying out their tasks. The users do need appropriate performance support by means of the ISE. An important task of the instructor is to do his administration. During the whole project he performs activities to keep his administration up to date (e.g. enter learners for the project, make groups, write down marks etc.). The instructor has to be able to perform his administration.

The users have specific tasks in each phase, these are project preparation, project performing, and project evaluation.

In the phase 'Prepare Project-based education' the instructor prepares the project which he will offer in the second phase when the students begin with the project. In this first phase he has to make or collect all the documents the students need for the project and make them all accessible at the Environment on the Web. It is therefore very important that the instructor can upload documents to the Environment. This first task is very time consuming. It is therefore important to start a considerable time before phase two starts. Furthermore he organises the project in this first phase. He makes a schedule with due-dates for the assignments. In this way
he can stay in charge of the project. The instructor has to be able to prepare the necessary project information and make this information accessible for students.

In the second phase, where the instructor guides the study processes of the learners, he has to communicate quite a lot with the learners. In this phase he has to monitor his learners and give them feedback on their performance. Also he has to motivate them to execute their tasks and to discuss and meet with their group-members. Communication is the most important thing in project-based education. The instructor needs some means to communicate. During this phase he also has to do administrative work; enter learners- and group-information. When all is done the instructor marks the products of the learners. In this phase the instructor has to monitor for progress. Process control is an important task of the instructor in the second phase (Van der Veen, 1997). The instructor has to be able to guide the study project processes.

The learners begin with their project in the instructors second phase. The learners complete three phases: prepare, perform and evaluate the project. In the first (sub) phase the learners have to get acquainted with the project. The learner first has to make a group with other learners and then choose a subject. In project-based education a problem is the starting point of a project. Then they gather the information they need for the project (projectmanual, articles, schedule etc.). The students need to download these documents from the Environment. In Project-based education every student has a specific role in the group. And with every role there are some tasks the student has to fulfil. The last, but very important, task of this first phase is to make a workplan, where the group write preconditions and basic assumptions, a specification of the problem, method of approach, planning, division of tasks etc. In the second sub-phase the learners perform the project. They do research at the problem by searching (on the web) for literature on the subject, by interviewing experts and discuss with groupmembers. Communication is very important and takes place between groupmembers, between groups and between instructor and learners. The students need means to communicate with others. The final product is mostly a report about the problem. They have to be able to upload the report the Environment, so others (instructor or other groups) can evaluate it in the last phase. In the third sub-phase the learners have to evaluate. The learners evaluate their own product (self-evaluation) on content, structure, style used, and they reflect on their own process (what went wrong, why and how would they do it the next time). Furthermore they have to evaluate the products of other groups (peer-evaluation) and give their comments. The last task for learners is to fill in an evaluationform. The learners give their opinion about the project: what they think of the planning, the content, the assignment, the quality, tasks etc. In a word, students have to be able to prepare, perform and to evaluate the study project.

In the last phase of Project-based education the instructor has to execute his evaluation plan. In this plan he evaluates the planning, the process and the results of the project. Furthermore he analyses the evaluation forms that the learners have to fill in after they have finished the project, in order to further improve the quality of the courses. The instructor has to be able to execute his evaluation plan.

The guidelines mentioned are rather general of nature. Given a specific context of use, they have to be further specified. Grooters (1998) gives a more comprehensive overview of design-guidelines for an ISE for Project-based Education. In the next paragraph we describe ComMedia, a project-based Study environment, in which we meet the stated requirements.

**ComMedia: A Project-based Study Environment on the Web**

As stated, ComMedia is an example of an Interactive Study Environment. We took the metaphor of a company as the point of departure for designing ComMedia. Students are junior and teachers senior members. As a company, ComMedia has the following mission (de Vries, 1998):

- to offer consultation and design services to (non-) profit-companies facing corporate communication-media problems or interested in communication opportunities made possible by information and communication technology developments;
- to offer a usable information and communication platform to students and teachers to set up, look after, pass through, and evaluate study projects.

ComMedia is designed as a virtual learning ‘Knowledge Company’. It is a knowledge company in the meaning of a business and a company, which primary tasks concern knowledge about the design and use of interactive media for corporate communication purposes. The company is a virtual one. It is an imaginary profit company and it exists online only. Last but not least, it is a typical learning company. Its major task is to enable 'junior
consultants’ to become ‘senior consultants’. We identify four major roles: administrator, senior consultants (teachers), junior consultants (students), external consultants (former students) and visitors. Tasks are carried out in (study-) projects. Each project team has a lot of freedom in completing the project, as long as they meet standard preconditions, set by teachers.

ComMedia is designed with a front and a back office. The front office is the reception for visitors. Intended visitors are mainly (non-) profit companies who have an interest in our work, but visitors can also be students who have an interest in the specialisation. Companies have the opportunity to ask for information, to use the 'online knowledge base' called the Cabinet, and to submit assignments, which students can carry out. Possible students have the opportunity to ask for information, and to use the Cabinet.

The back office is accessible for administrators, and senior, junior, and external consultants, so not for visitors. The back office ‘functionality’ for employees is dependent on their roles. The back office consists of four departments, the administration department, the education department, the research department, and the Cabinet. The administration department offers the functionality for managing the company and setting up courses and projects. The user role divides up the access to functionalities. A junior consultant, for instance, has only access to his or her own data. The education department offers the functionality for setting up, looking after, passing through, and evaluating projects. The research department is not active yet. The goal is to develop research facilities for research projects, for instance, computer-supported co-operative work tools for designing flow charts for websites, coaching facilities, etceteras. The Cabinet is the ComMedia repository in the sense of a mine of information. It is an online archive consisting of a wide variety of information genres, for instance, student reports, scientific articles, concept descriptions, methods descriptions, links to interesting information sources on the web (see Figure 3).

Figure 3: The Cabinet in ComMedia
The content concerns the domain knowledge of the specialisation Communication and Media, the design and use of interactive media for Corporate Communication. The Cabinet is being extended and updated continually. For that, we make use of an editorial board. The intention is that all study content materials developed by teachers and students are going to be stored in the Cabinet.

We consider ComMedia as an example of a project-based study environment. It offers teachers the opportunity to prepare, apply and evaluate study projects. Students have the opportunity to pass through these projects. In our courses, we still make use of lectures, practicals, assignments, and etceteras. We consider a study project in ComMedia as a type of an interactive study system. In such a project, students work together in an online project room. There are project information documents available, and they have applicable functionalities at their disposal, like a bulletin board, discussion platforms, and a logbook. They can also make use of an information resource, namely the Cabinet. In general, students can make use of offline information, like lecture materials.

Discussion

We think that our design approach, and as an example of this ComMedia embedded in the specialisation Communication and Media, offers opportunities for lifelong learners to acquire knowledge and/or skills in a flexible way.

ComMedia is going to be used in the second trimester of this year in a course of the study Communication sciences at the University of Twente. In the beginning it will be used in combination with classical lectures. An advantage of that is that the students who work with the environment can give their comments right away. These comments will be used as a formative evaluation, after which improvements will be made. In theory the participants are able to perform all their tasks of project-based education in ComMedia. How it will be in practice is still a question. Because it is not implemented yet, there is no data about the possibilities of the users to perform their tasks. But the expectations for the future are high. No more classical lectures, students and instructors can do their work at home, even if home is at the other side of the world.

The Effects of Two Modes of Interactive Televised Video

Sheryl J. Grove
Department of Education, Southern Utah University, U.S.A.
E-mail: grove@suu.edu

Abstract: The purpose of this study was to compare ITV student satisfaction in performance and its predictors for two settings - one with two sites connected, each seeing the other simultaneously, and one with three to five sites connected, each seeing only one of the other sites at a time. A difference in satisfaction in performance in these two settings was not found but there was a difference found in its predictors.

1. Introduction

With rising educational costs and decreasing resources available to meet them, many students are delaying college until after they have gotten jobs and started having their families. This has contributed to a growing need for alternatives to the traditional mode of classroom instruction. These must be designed to meet the needs of these students who have restricted travel schedules.

Historically, colleges and universities offered correspondence courses to serve such students. These courses, however, offered little personal interaction between student and teacher and no interaction between students. Today, technology can meet the student need for conserving travel time and still offer some of the interaction experienced in the traditional classroom through two-way interactive televised video (ITV). However, using it is very expensive. One way to enhance its cost-effectiveness is to increase student enrollments. This can be done by increasing the number of sites. In doing so, it is imperative that ITV continues to offer learners the satisfaction necessary to perpetuate interest.

Little research has been done to investigate student satisfaction in voice-activated ITV with only one of several connected sites visible at a time. This mode of instruction may minimize potential for interactivity since class size is usually increased and since the teacher does not see all students at all sites at all times. However, preparing teachers for its use may enable them to overcome the barriers of this mode of instruction, producing as much interactivity in this setting as in the simultaneously-viewed point-to-point setting where students and teacher at one site and students at the other site can see each other continuously.

A determination of student satisfaction in voice-activated multipoint distance education can reduce the institutional risk of spending money on a mode of instruction that may not be efficient. Additionally, the determination of predictors of student satisfaction can be helpful to those institutions that have already invested in this mode of instruction since identification of these factors can be utilized to improve ITV programs.

2. Related Literature

3. Research Technique
3.1 Design

A quasi-experimental two-group posttest was used to find differences in satisfaction in performance. It was developed by the researcher. Student ratings were recorded on a continuous scale.

Likert scale questionnaires were used to measure predictors of satisfaction. These included the Demographic Survey and Motivated Strategies for Learning Questionnaire, developed by the National Center for Research to Improve Postsecondary Teaching and Learning (NCRIPTAL); University of Michigan Problem Solving Survey, developed by Berger; Closure/Flexibility Concealed Figures Assessment, developed by Thurstone and Jeffrey; Student Survey of Instruction with instructor Verbal Immediacy and Nonverbal Immediacy Scales developed by Gorham, Richmond and McCroskey; Grand Valley State University Interactive Television Student Survey, developed by Major; and Student Survey of Distance Learning and Distance Survey of Instruction, developed by the researcher. The predictors included:

1) student motivation and learning strategies
2) student field dependence
3) student problem solving types
4) student grade expectancy
5) student intrinsic and extrinsic motivation
6) student ITV orientation and experience
7) student perception of the technology in ITV course
8) student demographic characteristics including gender, program of study, and age
9) student feelings toward students at other sites
10) student feeling part of class
11) student use of the fax, microphones, videotaped class sessions, and their ability to get materials from the library
12) student ability to hear and see the teacher
13) student ability to hear and see other students
14) teacher ability to hear and see students
15) teacher nonverbal and verbal immediacy
16) teacher visits to sites
17) teacher instructional style
18) teacher ITV orientation and experience
19) teacher ITV pay compensation
20) teacher use of zoom
21) teacher use of zoom
22) teacher perception of ITV importance

Other variables assessed were number of sites, numbers of students in the ITV courses, student distance from main campus, and the requirement of the ITV course.

3.2 Treatment and Setting

This study was conducted at Grand Valley State University (GVSU) in Grand Rapids, Michigan. This institution has North Central Accreditation and an enrollment of more than 13,000 students in graduate and undergraduate degree programs.

GVSU has replaced the use of satellite for serving students in surrounding areas with ITV instruction offered in two settings, point-to-point with 2 sites connected and multipoint with 3 to 5 sites connected.

In these settings, the classroom configuration allows each site to act as the host site with other sites acting as remote sites. Two monitors are in the front of each room. The one on the left always indicates what is being transmitted from that room (a graphic, the instructor, or student/s). The one on the right in the point-to-point setting displays what is being received from the other site and in the multipoint setting displays what is being sent from the site activating the broadcast.

3.3 Sample Population

3.2 Treatment and Setting

This study was conducted at Grand Valley State University (GVSU) in Grand Rapids, Michigan. This institution has North Central Accreditation and an enrollment of more than 13,000 students in graduate and undergraduate degree programs.

GVSU has replaced the use of satellite for serving students in surrounding areas with ITV instruction offered in two settings, point-to-point with 2 sites connected and multipoint with 3 to 5 sites connected.

In these settings, the classroom configuration allows each site to act as the host site with other sites acting as remote sites. Two monitors are in the front of each room. The one on the left always indicates what is being transmitted from that room (a graphic, the instructor, or student/s). The one on the right in the point-to-point setting displays what is being received from the other site and in the multipoint setting displays what is being sent from the site activating the broadcast.

3.3 Sample Population
The subjects in this study were volunteer college students enrolled at Grand Valley State University in Grand Rapids, Michigan. There were 237 students who participated in 10 point-to-point courses and 120 students who participated in 4 multipoint courses. These courses represented a wide range of disciplines.

Comparability of the groups was explored. It was found that the groups had no significant differences in year of high school graduation, ethnicity, or grade point but the point-to-point group did have a significantly higher proportion of males.

4. RESULTS AND CONCLUSIONS

4.1 Research Question Results

The research methodology was designed to answer the following questions:

1) Is there a difference in the satisfaction in performance of students participating in point-to-point with two sites connected and multipoint courses with three or more sites connected?
2) Is there a difference in the predictors of satisfaction of students participating in point-to-point and multipoint courses?

Research hypotheses expressed below were tested using regression analyses. The Null Hypotheses 1 was accepted and the Null Hypothesis 2 was rejected. The Alternative Hypothesis 1 was rejected and the Alternative Hypothesis 2 was accepted (Tables 1 and 2).

Null Hypotheses (Ho):
1) There is no significant difference in satisfaction in performance for students participating in point-to-point and multipoint courses.
2) There is no significant difference in the predictors of student satisfaction of performance for students participating in point-to-point and multipoint courses.

Alternative Hypotheses (Ha):
1) There is a significant difference in student satisfaction of performance for students participating in point-to-point and multipoint distance education.
2) There is a significant difference in the predictors of course satisfaction in performance for students participating in point-to-point and multipoint courses.

5. Conclusions

There was no significant difference found in Satisfaction in Performance of students (Table 1). There were differences found, however, in the predictors (Table 2). Only grade expectancy was found to be a common significant predictor in both point-to-point and multipoint groups. With additional analyses, it was found to be a significant predictor at host and remote sites for both groups (Table 3).

Nonverbal communication of teachers, feeling part of the class and having positive feelings toward students at other sites were significant in the point-to-point group but not in the multipoint group (Table 4). With additional analyses, the researcher found that nonverbal communication of teachers was a significant predictor at both host and remote sites while feelings toward students at other sites and feeling part of the class were only significant at the remote site (Table 3).

For multipoint students, taking the class as a college requirement was a predictor of lower satisfaction in performance. This was true, however, only at the host site. Self-efficacy was also a significant predictor and was significant at both host and remote sites (Tables 2 and 3).

5.1 Generalizability of Sample
Since this was a university study, its results may not be generalizable to students younger than adults.

5.2 Important Findings
The researcher conducted an exhaustive review of literature and found no previous studies that compared satisfaction and predictors of satisfaction in performance of students in point-to-point settings to those in multipoint settings. This study explored these to answer important questions related to distance education in the context of increasing alternatives available through ITV technology.

While Scheck and others indicate that large class size has been found to negatively affect student performance, the results of this study indicated that there was no difference in the satisfaction of performance of students in the point-to-point settings and in the multipoint settings. The researcher recommends that educational institutions advance administrative incentive to transmit to more sites from one classroom, thereby, enhancing numbers of students receiving educational services.

Additionally, the results of this study indicated that there was a difference in predictors of course satisfaction in these two groups. The significant predictors, self-efficacy and taking the course as a program requirement, found in the multipoint group are personal characteristics and not related to classroom dynamics. This is not true, however, for the point-to-point group for whom the significant predictors were interpersonal characteristics - nonverbal immediacy of instructor, feelings toward students at other sites, and feeling a part of the class.

These findings indicate that instructors in the point-to-point setting need to be especially cognizant of their nonverbal behavior directed to both host and remote sites. These include teacher’s use of gestures, use of monotone voice, practice of looking at the class, practice of smiling at the class, display of tense body position, practice of moving about the room, habit of looking at the board or notes while talking to the class, practice of smiling at individual students in the class and use of a variety of vocal expressions when talking to the class. Findings also
indicate that instructors in this setting need to be sensitive to student feelings toward others and feeling part of the class. These predictors were consistent with the assertions made by Holmberg, Barker, Catchpole, Kitchen and Kitchen, Nelson, Cprovacara and Peters, and Gorham and McCroskey who emphasize the importance of student interaction and teacher immediacy. Additionally, they challenge the results of research done by Walker and Hackman who suggest that students in these are willing to trade off their socio-emotional needs for contact with the instructors and rapport with classmates for the currency of telecourse information.

The influence of these predictors were “washed out” when multiple sites participated in this mode of instruction and were replaced by self-efficacy and the requirement of the ITV class. In this setting, the sense of isolation at the remote sites may be reduced by the sharing of remote site frustrations at one site with students at the other sites. The old adage “misery loves company” may be manifested here.

College requirement in the multipoint group negatively influenced course satisfaction at the host site but not at the remote site. One reason for this may be that students at the remote site desire to take as many courses as possible using this mode of instruction to experience the benefit of reduced travel. These students may be willing to deal with the challenges of ITV. In fact, Walker and Hackman indicate that amount of information transferred is the primary determinant of learning and satisfaction in telecourses. Students at the host site, however, may be less satisfied with their performance in this context because they are required to face the related difficulties without any benefit to them. The frustrations of ITV may be further enhanced for these students when the ITV course is important in their program and the need to comprehend course concepts and to obtain a good grade is optimal.

Choice may be a very important factor in overall course satisfaction. To provide it for all students, it may be appropriate to: (a) have instructors teach from empty classrooms on campus to students at distant sites desiring the ITV course, and (b) provide the instructor the training needed to enhance nonverbal immediacy of instructor and the interactivity needed for students at the remote sites to feel a part of the class and to have a positive feeling toward students at the host site.

Additionally, it was found that Self-efficacy was a predictor at both host and remote sites in the multipoint setting but was not a predictor in point-to-point settings. The researcher emphasizes that academic performance may be a great concern for students in the multipoint setting since classroom dynamics is very complex. This environment, which has much camera switching, may be overwhelming to some. Those, in this setting, who have a better sense of ability to do well, consequently, are more satisfied with the course. Students who struggle with mastering course content should not be encouraged to learn in this setting without given much support.

5.4 Suggestions for Future Research

To verify the findings of this study and to explore other ITV areas of interest, the researcher suggests the following:

1) Replicate this study using more point-to-point and multipoint classes, instructors, and courses.
2) Investigate reasons that feelings toward students at other sites, feeling part of class, and nonverbal teacher behavior are predictors of student satisfaction in performance in point-to-point ITV distance education and not in multipoint ITV distance education.
3) Investigate reasons that self-efficacy is a predictor of student satisfaction in performance in multipoint ITV distance education and not in point-to-point ITV.
4) Investigate the variables for student motivation and learning strategies, student problem solving types, and intrinsic motivation. These variables had moderately strong relationships to Satisfaction in Performance for the multipoint setting but were not included in the regression model as predictors. The omission of these variables may be due to interaction with Grade Expectancy. Further investigation of these is recommended in future study of ITV.

Abstract: This paper describes the experience at Texas A&M - Corpus Christi in assisting Minority Students to develop software to teach high school mathematics. The first section describes our initial situation: the goals of the projects, students involved, and the domain chosen. The objectives not only consisted in developing useful software but also maximizing the students' learning. The second section describes the development life cycle, which serves as a guide for constructing other educational software prototypes. The third section describes the two prototypes that were developed to learn linear inequalities and difference equations. The fourth and last section describes the goals that were accomplished, it was an example of learning by constructing [Harel & Papert 1990], where students increased their knowledge of mathematics, software design (navigational charts and storyboards), implementation (HyperCard), and pedagogy in a short period of time. It also described how minor modifications in the programs, making them more open-ended, resulted in significant gains.

1. Introduction

The main goal of this project was to supply a group of minority students with a real world research problem as opposed to an artificial or directed experience, thus giving them confidence in their skills and abilities, and enhancing the likelihood of pursuing scientific careers. A second goal was to produce educational software capable of enhancing the teaching of high school mathematics. These objectives are dependent, because the students can only gain skill and confidence in their work by producing educational software of good quality.

The second goal had a sub-goal of producing a prototype that could be presented to teachers and students of the Corpus Christi School District participating in a Summer Camp at Texas A&M University - CC. The development time was a little less than one semester and the group initially consisted of nine undergraduate students from different majors (computer science, math, and biology). Their work time was limited to 10 hours a week, which was sponsored by the alliance for minority participation program of the National Science Foundation. Furthermore, most students had limited experience in computer science and five students left the project due to other commitments. They were replaced by three new students.

2. The Development Process

All undergraduate students were given research material in the domain (mathematics), design and implementation tools (storyboards and HyperCard) and educational software (articles on the web such as those found in the engines of education at http://www.ils.nwu.edu/~e_for_e/). HyperCard was chosen because it is easy to learn, it is licensed by the University, it is a language that doesn't demand a lot of programming time (permitting more time to be spent with the domain problem), it is supported by numerous HyperCard reference books [Goodman 1993, Turner & Land 1994 and there are HyperCard-like development environments that run on other computer platforms (example: SuperCard on Macintosh and MS-Windows, Toolbook on MS-Windows).

After two weeks of researching the material, a bottom-up strategy was adopted. The students were given two prototypes to implement, as opposed to a top-down design strategy, where the student's task would be to design the whole system before any implementation. In the top-down approach, there would be a detailed study of the research material and educational software available prior to design.

Besides meeting external demands, this approach prepared the student in a constructivist way. For a top-down approach to be successful, the students would have to be followers. With the bottom-up approach, the students took control of their projects, thus requiring very little intervention by the professors.

Two projects were chosen: linear programming and interacting growth models based on difference equations. The programmers that developed the difference equations were assigned to test the linear programming and vice-versa. Once the prototypes were finished, they were presented to the Corpus Christi School District teachers who were participating in a summer camp at Texas A&M University. Next, the prototypes were presented to the Corpus Christi School District students. However, our test was quite limited because it was not tested in a real classroom environment. Neither students nor teachers of the Corpus Christi School District had commitments to what the school district students learned during the summer and both were working under university professors, therefore the testing lacked criticism. Furthermore, due to other commitments, the software developers were not present to observe the students using it.
Having developed a prototype, the students had the necessary experience to design the software with a much broader view, being able to adopt a top-down approach. The seven students were divided into four groups to research:

- the educational software existing in the market;
- the design of software to teach mathematics;
- new interface options using HyperCard;
- educational software developing environments.

The natural priority would be to research existing educational software in the market, for the other three tasks were dependent on this one. However, that would have consisted of research in schools and due to the difficulties in obtaining any information during the summer period, the above research tasks were a better option as opposed to everyone researching the educational software on the market.

At the end of the summer, each group presented their results, and all students became more aware of the need to: further research educational software, create an open-ended constructivist software and separate the content from the tool.

3. The Prototypes

Both prototypes attempt to teach mathematics through real world situations, as opposed to abstract formulas that are meaningless to students. With one of them, the problem was to use linear programming to solve the real world problem of trying to optimally feed a cat named Fedora. With the other one, learners were to master difference equations through predator-prey models, where foxes were the predators and rabbits were the prey.

A characteristic of both programs is direct manipulation: as users input data, they see the corresponding algebraic formula and graph immediately. Another characteristic of both applications is that the students' answers are stored in an external text file that permits instructors to critique students' activities. However, both prototypes lacked flexibility, because the examples were hard-coded into the programs. Therefore a second version of both prototypes were constructed to be used in a classroom environment and compared against the first version. In the second version, the software was designed to be a cognitive tool, as opposed to substituting the instructor's lesson. The first version attempted to diagnose the student, giving them precise feedback, while the second version left this part up to the instructor and concentrated in supplying more options to use the software.

Figure 1 shows the problem of feeding Fedora. In the example, cats need fifteen units of proteins, five units of carbohydrates and ten units of fat. One bag of CFS contains three units of protein, twelve of carbohydrates and one of fat. One bag of Extra contains one unit of protein, one unit of carbohydrate and two of fat. Students set up the linear equations A, B, and C on the top right of the screen by entering this information properly. When they click the buttons A, B, and C, the respective lines are drawn on the graph. The objective function shows that one unit of Extra occupies one cubic foot, while one unit of CFS occupies 1.5 cubic feet. In the second version of the prototype, a linear calculator was constructed. Figure 2 shows how the Fedora problem was inserted by the instructors as an example of the Linear Calculator. Fedora was no longer an intrinsic part of the program.

Figure 3, 4 and 5 show illustrate the predator-prey program (second version of prototype). As with linear programming, students constructed a prototype with the example (rabbits and foxes), built into the software. In the second version of the prototype, this characteristic was removed. Students fill in the blanks for initial population, birth rates and death rates of both predators and prey (Figure 3). When they click the create equations button, the change in predator population (delta predator/delta-t) and change in prey population (delta prey/delta-t) equations are generated respectively. They then inform the number of time intervals (run-time=50 in the example) and click the create table button. Finally, they click a button to see one of the graphs: predator population versus prey population, predator population versus time or prey population versus time. The graph shown is predator population versus prey population. In a real world application, the students will not be given a formula, but raw data. In Figure 4 illustrates another characteristic that was added to the prototype. The students try to discover a formula (right side of the screen), based on raw data that is typed in or read from an input file (left side of screen).

4. Evaluation

When the first version of the prototypes were presented to teachers and students of the Corpus Christi School District, there was great enthusiasm. However, the enthusiasm soon ended when the examples were mastered.

When the second version of the prototypes were presented, the initial enthusiasm wasn't as much as with the first versions. Initially, students and instructors wanted the software to perform the calculations for them. However, when they learned that the software was just a tool, and they were going to do the thinking, they began to appreciate more the programs. Although, no formal evaluation took place, instructors were much more satisfied at the end with the results of the second version, because it didn't limit the students creativity. Students even used the programs to create examples that were not thought of by designers and the instructors, such as the one illustrated in Figure 5, where Republicans are the predators and Democrats are the prey.

The project's main goal has been accomplished. Even though students specialized more in the domain within which they had greater background and skills, in a short period of time all students improved in some way their knowledge of: mathematics, software design (navigational charts and storyboards), implementation (HyperCard), and pedagogy. Perhaps more important than the specific knowledge acquired, were the general skills that were developed: team work,
organizational planning and research. Confirming other experiences [Harel & Papert 1990], this was an example of learning by constructing, which is more effective than if the students had sat in a classroom and took notes on how to develop educational software or participated in the project by only implementing the design done by the professors. Students learned the importance of developing open-ended (constructivist) software in a hands-on experience.

Abstract: The term mechANIma tries to establish a connection between "mechanics" and "animation." MechANIma is not simply a computer program or a collection of materials for the mechanics course, but stands for a philosophy of new methods for the teaching and a better understanding of mechanics. With the help of the research group of Prof. Eberhard Keil-Slawik, Paderborn, we try to develop new methods and didactic concepts of teaching mechanics in many different courses taught at the University of Paderborn. The evaluation of new teaching environments and didactic arrangements for the daily use of new media in lectures, tutorials, and student assignments is a particularly important part of our research. Animation systems developed by ourselves offer many advantages for the integration in our didactic concepts: All of our animation systems visualize the effects and parameters of the covering lectures and tutorials. Hence, by modifying these parameters in animation systems, students get a much better idea of the underlying physical and mathematical aspects. Modern electronic learning environments offer possibilities to focus on a student-centered approach for learning. Therefore, the mechANIma knowledge-base and information system develops new forms of teaching and learning methods.

Philosophy

To obtain better results in learning, it is necessary to develop and to establish new media for education in university as well as in schools. It is widely known that individual learning is a rather complex process which cannot lead to good results without considering all forms of human learning. Human learning is a form of social activity. Human learning must be defined as a process of remembering, recollection, and reminiscence. Physical artifacts like pens, paper, books, and also the new electronic media function as an "external memory" [Keil90]. Therefore, students take facts from lectures, courses, or tutorials, and combine them to arrive at a new understanding of the presented material. Consequently, individual learning can be considered to be a self-organizing process.

The problem of conventional learning, as with the help of blackboards, flip charts, and overhead slides, is the nonintegrated use of these media. A student who attends a lecture with many other students, e.g., twice a week, is not able to transfer the presented materials to tutorials, or even to access literature referenced in courses at home. Hence, no continuous access to necessary educational material is guaranteed. A student who does his / her homework must get the same materials as in group working in the university or at the lectures. In the classic form of learning, this continuity was realized in a primitive form by use of pen and paper. Students prepare lessons by reading and browsing through books and papers and make annotations on copies or their own summaries. In tutorials and lectures they have to write down what is written on the blackboard and compare their notes with reference books and papers. In the time of collaborative learning, it becomes more and more difficult for the students to actively participate in discussion groups and to write down necessary facts for the upcoming examination at the same time. Additional successful and effective forms of learning need student-centered structures of teaching. Student-centered forms of learning are defined as presenting different views on the subject to allow students to develop a personal and individual understanding. This may be achieved by the use of electronic media called multimedia and hypermedia with the help of new educational didactic concepts and infrastructure requirements.

Modern electronic learning environments offer possibilities to enhance a student-centered approach for learning. In this concept, the student himself is responsible for his personal learning progress. Socially embedded learning processes are the necessary condition for effectiveness of teaching. To achieve better success in the understanding of the presented material and in order to let students develop their own insights in the topics, it is necessary to offer a wide range of high-quality information. The student has to extract the core informa-
tion from a multitude of imported facts. In conventional forms of learning the students get 
the information step by step (portions of the presented subjects) and are required to take an 
examination later. The students do not feel responsible for the selection of the information. 
Modern forms of learning require the willingness to accept responsibility for the selection 
and for the filtering of fundamental knowledge. The process of extracting the real essence 
may be defined as the real achievement of learning. The goal of the mechANIma project is to 
reduce the break-down in the use of electronic media and to create an interactive learning 
environment that can be actively worked upon by the students.

Such an integrated approach cannot be accomplished by a single research group that creates a 
high tech island within the department of the university. The term “Alltagspraxis” (every-
day-life practice) [BrRKS95] has been used to indicate the goal of setting up a learning sug-
gestive infrastructure that can be used under the typical constraints of the day-to-day teaching 
constraints imposed at a university.

**mechANIma, hypermedia and mechanics**

The term mechANIma tries to establish a connection between “mechanics” and “animation.” 
However, mechANIma is not only a computer program or a collection of different materials 
for a mechanics course, but rather a philosophy of new methods for the training and under-
standing of mechanics. With the help of the research group of Prof. Reinhard Keil-Slawik, 
Paderborn, we try to develop new methods and didactic concepts of teaching mechanics in 
many different courses to students at the university of Paderborn. Especially the evaluation 
of new teaching environments and didactic arrangements for the daily use of new media in 
lectures, tutorials and student assignments is an important part of our research work.

**mechANIma**<sup>teach</sup> - workflow...

One goal of the mechANIma<sup>teach</sup> project is the achievement of a continuous flow of informa-
tion between the students and the lectures. Electronic mail and the concept of workgroup 
computing are widely spread in our modern society. Large companies use intranet solu-
tions and groupware products to achieve a faster and less complicating flow of information. 
At non-computer science institutions of our university the concepts are not always consist-
tently implemented. Therefore we try to put a new “communication layer” and structure on 
top of our traditional organizations and forms of communication with our students. Students 
can communicate by electronic mail among each other and, of course, send emails to the 
staff. A few years ago we developed the idea of a direct access for students to all teaching 
material available at our institute, the Laboratory for Technical Mechanics (LTM).
When the World Wide Web entered the internet, we tried to develop hypertext with the rudimentary Microsoft help system which was not very useful for our texts that contained many mathematical formulas and other complex graphics. Later we discovered the hypermedia system HyperG, now Hyperwave, developed by Herman Maurer [AKM95], which allows a more structured design of web publishing and active working with the materials.

**Hyperwave, history**

In the last years Hyperwave developed from a specialist's system to a widely used modern Web information server, which may be accessed by common internet WWW clients, such as the Microsoft Internet Explorer, Mosaic, Netscape etc. Hyperwave implements a fully object oriented hypermedia database which allows to integrate all known digital media like, hypertext, movies, sounds and animation. Especially the Hyperwave feature for the protection of documents with special access rights, Unix-like group and user structures are necessary pre conditions to organize a course based on electronic media. The possibility of the limited access to documents is particularly necessary for documents which underlie copyright con-straints and may only be read by the registered participants of the course. Consequently, access rights and a user/ group structure are absolutely essential for the use of WWW information server teaching environments. Hyperwave offers an easy way to use user interfaces including a set of special tools which allow in a very simple interactive way to insert hypertexts and all forms of hypermedia documents into the server. Additionally the Hyperwave information server offers special forms of structuring the material with the help of “collections” and “clusters,” a concept equivalent to classical file systems. Besides the features mentioned above, Hyperwave allows for a full text search over the whole database which involves rather complex search terms, e.g., regular expressions, make a work with a large number of hypermedia documents possible.

Hyperwave guarantees that students have continuous access to the latest release of electronic documents. Mistakes which are found in lectures or tutorials can easily be corrected and published on the information server. Printed versions require much longer turn-around times. It is even possible for students to put their homework on the server and discuss it in later tutorials. This concept called learning-supporting “infrastructure” was introduced by [BreKe95] for collaborative learning with the help of integrated teaching and learning environment and satisfies many requirements to achieve more flexible forms of combining individual and social learning processes.

However, in the field of the technical mechanics additional requirements arise besides these concepts. Students have to deal with complex mathematical and physical problems. Therefore, special animation, simulation and visualization software was designed within the mechANIma project in order to visualize the complex mathematical and physical relations of technical mechanics and to overcome the classical way of how to present mechanics, namely with the help of a blackboard and chalk.

**Animation, Simulation, Visualization**

The requirement to visualize complex mechanical effects was the initial spark for the mechANIma project. A few year before the term “multimedia” was created we had tried to develop small simulation software, e.g., to visualize caustic ([Man64], [FeHe96], [Rad70]) effects, which are difficult to show in real experiments. One important aspect of our concept of mechANIma is to use the most popular programming environments like Microsoft “Visual Basic” or Borland “Delphi” which can be handled by “normal” students without special knowledge in computer science. Therefore we are still testing a great range of visual development environments and computer languages. However, the best results were achieved by using the Visual Basic development kits. Our experiences show, that “normal” students of mechanics need only need 4-5 weeks to adjust and to produce nice results with a good for cost-to-effort ratio. High end programming environments such as the family of Microsoft Windows C development solutions offer much greater opportunities, but require a much longer time for non-experts produce results. Especially for students who simply want to visualize an effect which is needed for further research the motivation to use easy and visual...
programming environments is much better. At the actual stage of the mechANIma project we evaluate newer programming environments of the JAVA language in order to find alternatives for the Visual Basic language, which runs only on PC platforms. The screenshot below shows first results.

Animation systems developed by ourselves offer a number of important advantages for the integration in our didactic concepts. The most important aspect is that all our animation systems visualize exactly the effects and parameters addressed in the lectures and tutorials. Hence, by modifying these parameters in animation systems, students get a much better idea of the underlying physical and mathematical effects.

The visualization of a "compressive edge load on a half plane" which is shown in Figure 2, allows to manipulate all necessary mathematical and optical parameters in a very intuitive and interactive way. It is even possible to use the whole system on a touchscreen terminal without connection to a keyboard (all numerical input fields are accessible through a small calculator-like input control). In our laboratory one of these touchscreen terminals is available to the public 24 hours a day. Besides the animation systems students can access the whole mechANIma collection of electronic teaching materials like manuscripts, homework exercises, exams, etc. Also the latest news about lectures or additional events are accessible through these information systems which are connected to the university-intranet. The installation of such terminals was a very important milestone to accomplish a continuous access to media as mentioned in the first section.
Computer Algebra systems
Another important component of mechANIma is the integration of computer algebra worksheets into the Hyperwave information system. Rather complex mathematical derivations are much easier to understand if it is possible to automatically plot functions and equations, modify parameters, or simply by changing a number. A few example screenshots of the mathematical aspects of the "compressive edge load on a half plane" visualization are added in Appendix A.

Course materials containing computer algebra worksheets offer a great flexibility in the possibility of direct interaction. Therefore the concepts of characterizing individual learning as a self-organizing process is achieved by enhancing the possibilities for the student interacting with the hypermedia system.

Virtual Laboratory
As an additional way to illustrate complex mathematical derivations it is planned to prepare virtual views of the experiments. Appendix C shows one of the examples of using Apple Quicktime Virtual Reality to give students an idea of the real experiment. Our experiences show that students can understand the caustic effect much better, if it is shown in a conspicuous manner. The Quicktime VR format allows in a relative simple way to create three-dimensional panoramic views by taking pictures of the real surrounding and the experiments.

As a conclusion, mechANIma is still under construction and will never enter a stage of being complete. The field of technical mechanics is much too complex to say that a hypermedia system and information systems holds all information and visualizations for the whole sector of mechanics. Additional animation and simulation systems are still necessary. New technologies will lead to exciting opportunities for the future. And: social embedding of hypermedia into learning processes will always be a great challenge.

Appendix A: The caustic method
Today the method of "shadow patterns" which also is known as "shadow spot method" or "method of caustics" represents a powerful optical method to measure stress intensity factors in static and dynamic problems of experimental fracture mechanics. The method of shadow patterns was introduced in 1964 by Manogg [Man 64] who performed a shadow optical analysis for a stationary crack under mode-I-loading. Later the method was further developed and its field of application was extended by Theocaris and by Kalthoff and their co-
workers. The physical principle underlying the method of shadow patterns is illustrated in the following illustration.

![Image](image-url)

**Figure 3: Schematic diagram of the caustic effect**

A specimen with a crack is loaded by a tensile stress and illuminated with light generated by a point light source. In this case a specimen of a transparent material is considered. The stress intensification in the region surrounding the crack tip leads to a reduction of both the thickness of the specimen and the refractive index of the material. As a consequence, in the transmission case, the light passing through the specimen is deflected outwards. Therefore, on an image plane at any distance $z_0$ behind the specimen a dark shadow spot is formed. The spot is bounded by a bright light concentration, the caustic. Because the magnitude of the light deflections is correlated with the magnitude of the stress intensification at the crack tip, the shadow pattern contains information about the stress-strain conditions in the vicinity of the crack tip and, in particular, about the stress intensity factor.

![Image](image-url)

**Compressive edge load on a half plane**

The caustic curve is defined by the following mapping equations:

$$w_{1,2} = mr + z_0 d_{eff} \left[ V(\sigma_1 + \sigma_2) \pm \lambda V(\sigma_1 - \sigma_2) \right]$$

The complete family of the deflected light rays form the shadow space behind the object plane. Its surface is an envelope to the light rays and is called the caustic surface. The following equations form the basis for the simulation of the caustic effect (e.g., for the simulation systems shown in Figure 2):

$$x'_{a,l} = mr \cos \phi + \frac{2(P^2 + Q^2)^{\frac{1}{2}}}{\pi} z_0 c(1 \pm \lambda) d_{eff} r^{-2} \cos(2\phi + \alpha)$$

$$y'_{a,l} = mr \sin \phi + \frac{2(P^2 + Q^2)^{\frac{1}{2}}}{\pi} z_0 c(1 \pm \lambda) d_{eff} r^{-2} \sin(2\phi + \alpha)$$

$-\frac{\pi}{2} \leq \phi \leq \frac{\pi}{2}$

Navigating The Virtual Building Site: Quicktime VR In Civil Engineering

Ian Hart
Centre for Media Resources
The University of Hong Kong
Hong Kong, China
Email: ianhart@hku.hk

Abstract: Quicktime VR (virtual reality) is a cross-platform media format made possible through Apple’s Quicktime 3.0 software. This paper examines some its applications in Civil and Structural Engineering education, both for exploration (“The Virtual Site Visit”) and as a means of ordering visual information (a “virtual menu”). The author speculates on the possibility of further educational applications with the addition of Quicktime Layer formats.

CIVCAL

Civil and Structural Engineering is literally one of the biggest businesses in Hong Kong and, hectare for hectare, there are probably more skyscrapers, bridges, reclamation, tunnels and airports under construction in this tiny region than anywhere in the world. For those of us who live in Hong Kong it sometimes seems as though the whole city is a building site.

Yet for engineering students it is difficult to gain practical experience of practical site work and most students will have spent only a short, often frustrating time on a civil construction site before they graduate. There are two main reasons for this:
1. The construction process is slow, so in a one day site visit or even a one month work experience it is difficult to perceive any progress; and
2. Building sites are by nature chaotic with many and varied jobs taking place at the same time — it is often difficult to comprehend what is going on.

It is not surprising then, that for many young graduates the first practical experience of working on site can come as an unpleasant shock.

CIVCAL (CIVil engineering Computer Aided Learning) is an attempt to address these problems by providing a series of “virtual site visits” to significant civil engineering projects in Hong Kong. CIVCAL is based at the University of Hong Kong, but straddles four Engineering Faculties at the City University, Polytechnic University and the Hong Kong University of Science and Technology. It has been funded under the Teaching Development Grants program of the Universities Grants Committee. It commenced in September 1997 and is funded for two years.

When it is complete, CIVCAL will be an easily-accessible data base of photographic, graphic, organizational, financial and structural information on significant current construction sites in Hong Kong such as:
- Chek Lap Kok airport
- Tsing Ma suspension bridge
- Strategic sewage disposal scheme
- Aberdeen landslide, 1996
- HKU Biological Sciences Building construction
- Kam Tin water management system - Rubber dams (see Figure 1), etc.

Each project is the responsibility of a team of engineers and research assistants from one of the participating universities and the coordination, structure and funding of the overall project is overseen by a steering committee.
The material is being developed in the first instance as a WWW site, using HTML as the presentation and hyperlinking technology. Although in the future we anticipate that the project may be reorganized into a series of CD-ROMs to enable faster access and searching, particularly of video, animation, VR material, simulations and mathematical models.

- Click a TAB to select a project
- Click on the PICTURE to visit the project
- Click on a THEME to visit the projects which include it.
- Click the SITE OFFICE to return to this menu.

Figure 1: Menu screen showing projects (tabs) and themes (menu L)

The initial structure of CIVCAL divides the material in two ways: by Project and by Theme. In Figure 1 Projects are selected using the Tabs at the top of the page and Themes using the marginal menu. So the Aberdeen Landslip project is primarily Geotechnical; the Rubber Dam project is primarily Hydrology; and the Airport will include all the themes.

This paper looks at two aspects of this large project: the use of QTVR as a means of exploring space; and also as a means of structuring the material in space and in time.

Menus

The standard means of finding your way around a multimedia data base is by menu and index. Both are useful: alphabetical indexing is a widely understood means of tracking down information, provided you know what it is called (and provided you use an alphabet...); a hierarchical menu is a convenient means of moving from the general to the specific, providing the information is logically structured, but index trees are a labour-intensive way of searching and difficult to browse. Image banks (including video stock-shot libraries) are traditionally classified and searched according to content: location, topic, date, people, etc. Once again an alphabetical or hierarchical classification which depends upon an imposed structured that needs to be learned by the user.

This is not problematic if the Engineering curriculum is a top-down process of instruction, but in a constructivist environment students are encouraged to explore and to find things out for themselves. Building sites are littered with strange equipment and people on them are engaged in arcane processes which seem to have little to do with the job in hand. On a real building site the students could ask questions, refer to plans, or come back next week when the Clerk of Works can talk to them. But in a virtual visit, the only research tool available is the navigation device.
"The Virtual Site Visit" employs two less conventional forms of navigation: VR menus, enabling navigation through space; and 3D menus, which facilitate navigation in time.

**Virtual menus**

VR menus take advantage of Apple Quicktime VR technology to enable exploration and discovery. QTVR comes in two forms: panoramic movies and object movies, both of which are useful discovery tools. They rely on Apple's Quicktime Media Layer software, which in its Version 3.0 incarnation runs equally well on both Mac OS and Windows (3.5, 95 and NT) under both Netscape and Internet Explorer. Unlike 3D software such as VRML, which must be generated from a CAD program, QTVR is a two-dimensional medium generated photographically. The viewer remains in a static position able only to rotate his viewpoint around the inside of a cylinder or to manipulate a small object, although he can move from "node" to "node" using hyperlinks. But it is simple to produce, requires few resources and the files are comparatively small.

**Panoramic movies**

QTVR panoramas are 360° navigable images which run on any computer which has Quicktime installed. The viewer uses the mouse to pan around and up and down the inside of a cylindrical panorama, zooming in and out using control keys. Individual panoramas (or "nodes") may be linked together into a QTVR "scene" which allow the viewer to travel through a space, exploring as s/he goes. Additionally, panoramas may contain "hot spots" which are hyperlinks to other types of information (text, images, movies, etc.) as well as to URLs when used within a WWW page. With the Quicktime 3.0 "fast start" extensions installed, the viewer can began examining the panorama almost as soon as it begins loading.

QTVR panoramas are produced by taking a 360° series of overlapping still images from a tripod. If they were to be assembled manually they would form a sequence as in Figure 3. QTVR software such as Apple’s QTVRAS or Roundabout Logic’s Nodester applies a warp to the image (dependent upon the lens employed) and “stitches” them together (Figure 4). The detail available depends upon the quality of the original image: photographic negatives scanned at 1,200 dpi produce high quality panoramas in which the viewer can zoom in on small details, but may take several megabytes to store; panoramas produced using video or digital cameras make small files, but lack detail. One useful technology for WWW distribution is QTVR’s dual-resolution capability where the end-user can choose between a fast download and image detail. Codecs such as Cinepak, Movie JPEG and Sorenson enable satisfactory compression to 20% or lower. At present, a 320 x 240 QTVR averages 240K and it is expected that future advances in image compression technology will be able to produce even smaller files. Java is also being employed as a replay format by some WWW producers.

**Figure 2: Apple’s QTVR Authoring Studio**

**Figure 3: 360° series of still pictures (courtesy Apple Computer)**
QTVR as a navigation device

In "The Virtual Site Visit" the QTVR panoramas function as navigation devices, or entry points into the data. For example, on the vast Chek Lap Kok Airport site there are literally hundreds of separate but interlocking contracts simultaneously underway: land reclamation, runway construction, airport terminal, roads and railways, communication infrastructure, housing, water and sewage, etc. How to distinguish between them?

The example below illustrates a more modest project, a QTVR coverage of a building site on the University grounds. Figure 5 illustrates:

- A site map with four QTVR locations or nodes. Clicking on any of them will take you to the appropriate panorama.
- From within each panorama the viewer can use the navigation tools to zoom in and our and to move between nodes.
- Clicking on "hot spots" brings up information about particular equipment or processes.
Object movies

QTVR object movies are a little like panoramas in reverse. Rather than turn himself around in virtual space, the viewer uses the mouse to rotate a 3D object in any direction and control keys to zoom in and out. It is an excellent way of presenting small, expensive or obscure components.

Object movies are produced using a camera rig which enables a controlled series of rotations. The resulting images are assembled into a matrix which the software then presents in an order according to mouse movement.

In “The Virtual Site Visit” hot spots lead the viewer to QTVR objects which can be manipulated and inspected. Unfortunately the practical maximum size of objects is 8-10 ins tall and on building sites the most relevant objects are rather larger than this.

3D menus

A factor important in construction, but difficult to manage in navigation, is time. Most of the processes in civil engineering are as much dependent upon sequence and timing as they are upon equipment and technology. The sequence of events involved in reclaiming land from the sea and the time needed for dredging, settlement, etc. are as important as the materials used in the fill. Other factors such a building regulations, safety, comparative cost factors etc. add dimensions to a process which make it difficult to represent conventionally.

One solution is to use three-dimensional menus. Figure 7 illustrates a 3D site map with spatial links (horizontal) and time links (vertical). [Note: This sequence was not completed at the time of submitting the paper, but will be demonstrated in the conference presentation.] Another possibility is to employ animated “sprites”, a feature of Quicktime 3.0 which enables multiple layers (video, audio, text, animation). In this case the time factor could be built into the QTVR panorama itself with an additional “time” cursor enabling navigation to various time periods of the construction (See Figure 8). This possibility is currently under investigation.
Conclusion

Quicktime VR, combined with the flexibility of the Quicktime 3.0 layers is proving to be an invaluable tool for educational multimedia. It can serve as both a medium for exploration of an environment and a tool for navigating through it. This presentation has illustrated its application to Civil Engineering, but at the University of Hong Kong it is currently being applied to a much wider range of disciplines, among them Architecture, Medicine, Art History, and Ecology.

This written paper has been an attempt to explain the essence of QTVR, but it is a dynamic and visual medium which requires a multimedia format in order to appreciate it fully. Interested readers are referred to the following URLs as a starting point for exploration:

Using the Internet to Provide Communication Benefits to a Low Tech Community

Pamela B. Hassebroek
College of Computing, Georgia Institute of Technology, U.S.A.
E-mail: pamh@cc.gatech.edu

Abstract: This paper presents a web site which can foster community building and technology skill building in a technologically inexperienced community. A plan is presented for a project, using this web site, that can overcome the Internet access obstacles of cost of computer equipment and lack of computer training. Two pilot locations have been identified for testing the hypothesis of this research. The user groups and technology equipment in these locations are described.

1. Introduction

This paper describes a plan for bringing the Internet into inner-city communities in America in a way that can address the special needs that exist there. This plan shows how, through the use of the Internet, new communication can foster community building and skills development which could help to break the cycle of poverty that is so prevalent among urban families. The plan includes building a customized web site through a participatory project with the particular group who uses it. The prototype web site, called "Town Square," functions as a communications hub and as a technology learning center. The process requires providing the initial expertise for knowledge transfer and technology support to users who will ultimately be their own information architects and teachers using the equipment.

The central idea of the project is that instances of this prototype will be developed as a collaborative effort with a resident group in a particular location. Through the process of confronting the technology closely, by making choices for personal material and hyperlinks to other sites of interest, the user group is learning about the Internet. They are also learning the techniques that can be used to contribute to the material available in this public forum. A school community, a neighborhood or other group, collectively creates the site that will be personally useful to all of its members. Therefore, the project is not only useful for acquiring technology skills and for creating a useful communication tool but also for building community within the user group.

2. Background

People talk about the positive value of the Internet to society. There is now much evidence that it has power to bring people together, and to help them communicate like no technology which has come before it. There is empowerment that comes from sharing in Internet communities and from the support and knowledge that can be obtained through collaborating with others [Rheingold 1993]. Through telecommunications systems, which include electronic mail, newsgroups, on-line chat rooms, and web publishing, there is much to be gained for undereducated people.

That there are people in America who have no opportunity [Kozol 1991] to utilize the resources available on the Internet is an issue which is being addressed through the initiatives of President Clinton and others. And indeed, all over America wires are being dropped and computers installed in public libraries, public schools and other public spaces. Concurrent with the populating of the Internet, and its increasing accessibility, is the development of technologies which will allow the merging of the Internet with television. Set-top boxes, as they are presently called, such as the one that WebTV Network provides, are a vision of the near future where entertainment, education, and research capabilities coexist and are delivered via television.
The value of the set-top box Internet technology to the low income user is that the web interface can be personally utilized without great cost and without the learning curve required for a fully functional personal computer. This technology is a valuable addition to the work described in this paper.

Everyone who uses a personal computer knows of the considerable knowledge, expense and time required to become a user. There are many people in America who are living at the poverty level, who have limited formal education, and who have family responsibilities. In order to provide this valuable Internet access to everyone, provision must be made to insure that the needs of the underserved community are met.

The Town Square project doesn't remove the time constraint, but its design process adds other benefits that make the time spent even more worthwhile. Work on the prototype design for Town Square began in 1996 in the School of Literature, Communication and Culture at Georgia Tech in Atlanta. The prototype was designed with a particular community as its focus, as information about this group was readily available from many sources and has been widely publicized. That community is the New Community at East Lake (formerly East Lake Meadows), a Federally subsidized housing project in Atlanta. There are images and information within the prototype site which reflect this focus.

3. Pilot Sites

There are presently two sites in the Atlanta area in which the thesis of this research is being demonstrated, one is a public elementary school and the other is a Federally subsidized housing project. The process that is being followed for both sites is the development of a site design group with the Town Square prototype as its focus.

3.1 Benteen Elementary School

Benteen Elementary School, which serves students in grades K-5, is a school with great potential for a very high tech learning environment. Desktop computing and network equipment is either in place or will be in the next year or two throughout the school. In addition, with the help of Sprint and the Harris Media Group, 25 WebTV units were purchased in the '96-'97 school year and unlimited access to the Internet provided through individual accounts attached to each of these units. The idea is that a student can check out a WebTV unit from a "library" and use it at home in the evenings. The school also has Internet access for several of their desktop units and the expectation is that Internet access will be available school-wide possibly as early as the Fall of '98. However, as yet there is no formal curriculum with which to structure or direct the learning of the students with respect to this new technology.

Benteen is a multicultural, urban school, a part of the Atlanta Public School system, which is receiving support from various civic volunteer groups, but with little participation from the families of its students. That the families are 45% African-American, 45% Spanish speaking, 8% Vietnamese and 2% Caucasian, creates some difficulties in developing connections between school and home. There are other factors to be sure, such as the lack of time and a lack of understanding as to how parents should be involved with a school, due to the parents' own childhood experiences and diverse cultural backgrounds. Technology may be able to help bridge this gap.

Since early January 1998, two groups have been meeting weekly in order to participate in a Town Square project at Benteen — a faculty group and a student group. It is envisioned that families will become a part of the participatory project in the near future by attending training classes on Saturday mornings at the school.

The Town Square @ Benteen project faculty group consists of seven faculty members along with the Benteen Technology Coordinator. Lessons are planned for the faculty several weeks in advance, with a formal syllabus and weekly agendas for meetings which are held on one afternoon each week. They are also given assignments for work between sessions. The faculty is encouraged to work together and help each other to accomplish the assignments.

The other group at Benteen is a student group — the "Computer Club," which meets as a part of an after-school program directed by Hands On Atlanta (HOA) AmeriCorps. HOA is an Atlanta organization committed to creating a vehicle for change, driven by volunteers. The AmeriCorps program is a national service initiative which provides education funds in exchange for community service work. There are 10
students in the club who meet together daily for 6 week periods. In the present group, there are 6 boys and 4 girls. At the end of the 6 weeks, the opportunity to participate in the Computer Club will be offered to a new group of 10 students who will meet for the next 6 weeks.

The focus of these early lessons is, in the case of the faculty, learning about the Internet and HTML coding, and for the students, computer literacy, including keyboarding and word processing, along with building skills to develop web pages. Each session lasts about an hour. The goals for the Town Square @ Benteen are as follows:

- To provide education for faculty and students and their families that will enable them to develop web documents suitable for viewing through their library of WebTV units.

- To provide a repository for information about Benteen Elementary School, its community, and its larger environment within the city of Atlanta and the state of Georgia.

- To provide new methods of communication between the school, and the students, and their families.

- To provide a tutorial for computer technology/Internet education.

3.2 DeKalb County Public Housing

Implementation of the Town Square @ Decatur, positioned in a public housing community center in Decatur, Georgia, is in the planning/startup stage. There are three housing projects served by this center, with 230 families in residence, nearly all African-American. As a part of its ongoing plan to improve services offered to residents, the Housing Authority has requested some $60,000. in Public Housing funding this year to purchase equipment and software for their Learning Center and to contract with four certified teachers and two part-time teaching assistants to staff the center. In addition to these funds, IBM and Goodwill Industries, a key service agency in many U.S. communities, have donated approximately $10,000. in computer equipment and classroom furniture.

There are many other support services in place for the Housing Authority tenants which complement the plan for the Town Square project. The goals for this project are much the same as those for the Benteen project. However, this project will offer the opportunity to structure the Town Square effort in a way different from that at Benteen due to the learning center location and its different mode of operation. In this case, the Learning Center will function as the hub for training sessions in a lab setting and the WebTV units will be in the homes of area residents. It is expected that the outcomes of community building and learning will be facilitated in the same way. This experience will give people skills to go to the marketplace and compete for more than minimum wage jobs. Skills in the computer-related technologies offer job potential in almost any industry in America. Can one be useful in a business office today without being able to function well with technology?

4. The Town Square Project

4.1 Product Definition

Purpose Statement: To provide, for users in urban schools and low tech neighborhoods, a development strategy and design prototype which can enable a participatory web site design project. A visible product would be a useful, interactive digital repository for personalized communications links and computer technology tutorials on the World Wide Web.

The Town Square Project was designed to help bridge a gap — between those who need access to income building resources but have few, and the Internet which has the potential for support, both emotionally and economically. The project has three major components: the development of prototype
software, the use of the software as a base for collaborative further development with a target audience, and the analysis of the effort in terms of the proposed outcomes of community building and technology education.

Town Square's area of application is small communities. The intended tasks that the system will initially support are personal publishing, and linking to various WWW sites of interest. With the required Internet access for Town Square, the users will also be able to use e-mail and newsgroups. Ultimately, the site could include a link to a video-conference system within a community's daycare center.

Town Square is a prototype that provides the information components and design scheme for a full-fledged operating site. It can be used to give an initial understanding of the purpose and a plan for design to the participating group. The principal activity of the Town Square project is a participatory design project. Participatory design is on-site design. It involves the user not only as an experimental subject in the sense of evaluating the requirements, responses, desires, and needs of him/her, but also as a member of the design team. Users are active collaborators in the design process, rather than passive participants whose involvement is entirely governed by the designer. This collaboration is envisioned to take place in brainstorming sessions and workshops at a convenient central location for the group.

The Town Square prototype has been designed to the development specifications published by WebTV Network, so that the product is usable by employing either a personal computer with a web browser or by the WebTV and a television. There is also a keyboard available with the WebTV unit for an extra charge, which is essential for gaining skills which will transfer to computer use. In addition to the benefits provided by the style and connection design of the WebTV system, an advantage for home use of the system is that the initial investment is relatively low and the assumption is that most users will already own TVs.

4.2 Design

There are many specific issues with respect to culture, language, and image to consider in the design of this web site. It is a communications medium, with all the considerations for any computer-mediated communication system — literacy level, sharing space, individual presentation style, emotional interactions, and equipment limitations. The development process should also include ideas from users about this site's place with respect to local schools, other local institutions, or other sites outside the local community.

Town Square is organized as a home page leading to four main modules in order to provide for logical and effective maintenance of the documents by the user community. [see Fig. 1] The modules are accessed by links from the home page to: the neighborhood network, community activity information and links, Atlanta resources, and often-needed resources available from the State of Georgia. Links from within these modules can be to hypermedia resources or other information delivery systems. Within a module the user can choose to navigate back to the home document or to any of the other modules.

![Figure 1: Structure of the Town Square prototype](image)

The interface is designed to simulate the look and feel of a grid based conventional print resource. The students are expected to be somewhat new to the medium of web interaction, and therefore would easily assimilate interaction with the new tool if it is familiar in format. After using it for a time, the interface may
logically begin to appear as a control device. The pages are all "color-coded," so that a user can see by the color of the page which module s/he is visiting. The design of the overall product includes an opening screen which is also the central navigation screen or "home page." [see Fig. 2]

The home page will allow new users to understand the purpose and scope of the product. With the headline graphic the user is positioned in the environment. Even though in this case the interface is designed for East Lake, the product can be easily used with a new user community by changing only the neighborhood or group name on the home page. The navigational buttons indicate their affordance quality through rollover text and images. The four photographs are familiar and identifiable as to their physical location in the user's environment, and thus aid the organization of the site. They are also easily customized to a new site by exchanging the four graphics. At the bottom of the page is a navigation bar to link to "quick reference" sites, such as a medical reference, the child care video camera, or the tutorial module.

![Figure 2: Town Square @ East Lake home page](image)

The design of the four main module interfaces is consistent with the look of the home page and has the same navigational design. Each module has a different color to identify the different text content located there. For example, the "Neighborhood" page banner is colored orange to connect with the orange colored photograph and pop-up title flag on the home page.

The main goal for the module pages is that the information be very useful and presented in a simple, highly graphical format. The content of the modules is from various sources. There are other organizations [Center for Applied Special Technology 1996] that are also in the business of assisting with specialized technology education activity on the Internet. Therefore, the practices within the scope of this research is augmented by keeping track of the activities of other researchers. Information provided by the web sites of others is presented as hypertext links with a brief description of the information to be found there. In some cases important content from these outside links will be re-designed and organized on the Town Square linking page so that the user can more easily understand what information is to be found at the outside source and how to access it.

In the tutorial module, the current material is presented as an interactive video. It has been developed using Macromedia Director and compressed for the Web into a Shockwave movie. This material is planned for use both at home and in a classroom setting. When it is used in a class, an instructor will be available to help, if necessary, with the execution of the tutorial documents, as a well-designed resource can be enhanced by a human coach to aid its presentation. The instructor may wish to display this module on an enlarged presentation screen at the front of the class as a visual aid. New tutorial modules can be added as useful material is identified for reinforcement or home study.
5. Development Plans

In order to continue to improve the interface and the process of Town Square implementation, we will continue to examine the issues involved with designing for a multicultural environment, and the design of educational materials for the Web and the WebTV. We will encourage more Atlanta schools to participate in the project, so that the interface will become a useful tool to the school community at large and therefore have input and feedback from a wider user group. This wider usage could provide support for families who must relocate from one school to another, and therefore would enable the family to see a familiar space in otherwise new surroundings. A further development plan is to provide a more complete template for web site design by putting the prototype site documents into a total package which would enable easier site implementation, expansion and management. As more features become available for WebTV units, it is planned that the Town Square will incorporate these into the prototype design.

Organizations are invited to use the Town Square prototype documents freely and thus expand the familiar environment to the benefit of other communities. The designer will customize the graphics to reflect the new community free of charge. The documents may be downloaded from the Town Square website: (http://www.lcc.gatech.edu/gallery/townsquare/).

6. Conclusion

Low tech communities can become participants in the world of computer technology and the Internet by creating a web site which is a personalized communications center. The education that can result involves a community building from within, as users share the information with each other and as educational institutions collaborate with them. It can foster skill building, and be life changing. The technology skills that are likely to result are those of computer literacy, telecommunications, word processing, e-mail, web browsing, on-line researching, and web authoring.

This paper offers a model process and a prototype design for use by a community to build and empower itself with the help of computer technology. Even with the speed of the computer, this is not a quick fix [Gates 1996]. There are many years of sustained effort required for this project to be successful. It must be more than providing money (as in welfare), or equipment, or network access. There must be a provision of knowledge. To ensure that people not only have access to computer technology, but are given the best opportunities to use it for personal and collective benefit, human technology educators must be provided. The Town Square project is in its infancy, but offers a replicatable software design and process that holds the possibility to make a difference in low tech areas in America.

Lifecyle Support for Hypermedia Based Learning

Ralf Hauber, Theodorich Kopetzky, Max Mühlhäuser
Department of Telecooperation, Johannes Kepler University Linz, A-4040 Linz, Austria
e-mail: (ralfltheo@max)@tk.uni-linz.ac.at

Abstract: Despite considerable advancements in instructional theory, most hypermedia-based learning systems found on the Web today are little more than slide shows. To foster more advanced learning systems on the Web, we propose a WWW-compliant approach for capturing instructional knowledge, emphasizing reusability: i) WebStyles for the representation of knowledge (e.g. instructional theories or authoring guidelines) and ii) Ontologies - expressed again as WebStyles - for capturing the phases of learning system lifecycles as well as various instructional models and strategies. WebStyles can be thought of as a typing concept for specifying "families" of WWW documents. Ontologies form the basis for WebStyle reuse and sharing. For the ease of understanding, most concepts will be introduced by way of examples.

1. Introduction

For years now, a sharp contrast persists between two camps of hypermedia-based learning systems (HBLS). Fairly advanced HBLS can be found in the "academic" world. On the other hand, there is an ever disillusioning state of the art of the large number of HBLS found on the Web: even behind the fancy curtains of 3D-VRML welcome screens offered by many so-called "virtual universities", little more than HTML-enabled slides can be found, sometime augmented by animations.

We consider the following to be the four key reasons for this discrepancy: 1. After several waves of enthusiasm and frustration about computer-aided learning, many practitioners do not want to "buy" any further promise. After the age of presentation-type CAI systems induced by behaviorism, the age of intelligent CAI induced by cognitivism, and other exaggerated hopes induced by prophets of one-fits-all theories, authors in the field believe that structuring and assessing the domain as good as possible (using hypermedia) is all they can do - no instructional strategy (disguised as "exploratory learning") is better than a bad, hindering one. 2. By and large, the experts camp has not yet succeeded in putting their expert knowledge into concrete, like for instance typography experts have (cf. desktop publishing tools). 3. The expert pertaining to the HBLS domain is fairly complex and, in particular, distributed over several phases of the authoring process. A single "word processor" kind of tool cannot hold this knowledge; rather, a domain author would have to have several means at hand, accommodating several phases of a HBLS lifecycle. 4. Wherever there has been an attempt to solve the problems described under points 2 and 3, the results were bound to rather proprietary systems and mostly to a particular instructional theory. Neither has there been a full integration with the Web as the underlying technology, nor has there been an easy way to extend such systems towards further theories, models, and methods.

The above analysis does not mean that there were no advancements. Many steps forward have been made, and the time seems to be ripe for cutting the nod. As to instructional theory, the one-fits-all attitude is close to be overcome. For instance, pragmatic constructivism [Good, Wandersee et al. 93] is even based on the observation that each individual has a distinct learning process; nevertheless - or better: just because of this - this theory brings forth concepts and rules that are widely applicable and useful. Even very ambitious approaches like Csikszentmihalyi's flow theory [Csikszentmihalyi 91] are accompanied by very handsome, broadly applicable design rules. Recent discussions between edutainment protagonists - focussing on success factors for instruction like fun, challenge, and engagement like [Quinn 96] - and defenders of "serious" learning systems - focussing on success factors like relevance, cf. [Kent 97] - were marked by the search for the respective pros and cons and not by the search for a single solution or "winner". In summary, instructional theory has to offer useful concepts, but there is a broad variety of "bits and pieces". Thus, openness for all these pieces is a central requirement for advanced HBLS development support. This openness must be generalized from instructional strategies to all facets and phases of HBLS development, such as instructional analysis, domain analysis, user modeling, etc.

Since this article focuses on hypermedia-based learning systems, the residual state of the art discussion will be restricted to hypermedia. Independent from the focus on learning, authoring support for hypermedia has long been recognized as a requirement. However, the WWW is by far the most wide-spread hypermedia system, but by far not the most advanced system. This observation holds for hypermedia authoring/design support: many advancements have been made in integrating design support, typing concepts, and database schema approaches.
with hypertext. For further details of these advancements the reader may refer to [DeVise] or [Grønbæk et al. 94] for DeVise, a hypermedia system of university of Aarhus, to [Furuta, Stotts 89] and [Scotts, Furuta 89] for an overview over Trellis, to [Richartz 96] for PreScripts, and to [Schwabe, Rossi 95] for an overview and [Schwabe, Rossi, Barbosa 96] for more details of the object-oriented hypermedia design method (OOHDM). In summary, there have been considerable achievements in the attempt to provide design support for hypertext; the more promising ones (like Trellis and PreScripts) are based on type concepts of entire hypertext documents i.e. "graphs" of nodes and links (HTML pages and URLs in WWW terms). However, most such developments relate to hypertext systems other than WWW. Even worse, the considerable achievements made are contrasted by a rather moderate state of commercially available authoring tools for WWW. These tools provide templates almost solely on the level of individual HTML pages (nodes in proper hypertext terminology), and focus on features comparable to those of source code management tools for programmers. It is rather in the context of WWW query systems such as WebSQL [Mendelzon, Milo 97] that more advanced typing concepts for entire hypertext documents (sets of HTML pages) have been developed. Despite the varying focus, these examples show that design support for entire hypertext documents is feasible and desirable. We will retain this observation as another requirement for HBLS support systems.

2. The GUTS Approach

Summarizing the analysis from above, we state the following requirements for HBLS authoring support systems:
1. Lifecycle coverage, since HBLS development is a complex, multi-phase process.
2. Openness with respect to a broad variety of instructional theories and strategies, analysis and design methods, lifecycle models, domain analysis and user models, and other constituents and results of the HBLS development process.
3. Incorporation of type concepts for hypermedia as a promising approach to capturing expert knowledge for hypermedia authoring.
4. WWW conformance as a tribute to its role as a de-facto standard and its global deployment.

The GUTS approach (generic unified typing system) leverages off multi-year research at our hypermedia learning group. It is based on two principle approaches which realize the above-mentioned four requirements:
- Requirements 3 and 4 are met by the WebStyle approach to hypertext typing concepts in the WWW context. It is implemented in Java and features full HTML conformance. Openness in the above sense is the key prerequisite for meeting requirement 1. It is achieved by introducing ontologies for all parts that have to be open. E.g., if the system should be open with respect to instructional theories, there has to be an ontology-WebStyle which explicitly specifies a vocabulary (conceptualization) for expressing specific instructional theories.
- The reader may not yet grasp how the introduction of an ontology might lead to support for a certain lifecycle phase or an instructional concept, nor how WebStyle typing actually works. To this end, the authors decided to introduce details of their concept by way of example, rather than by describing abstract architectures or models.

3. WebStyles and Ontologies

The key to understanding GUTS is its way of representing knowledge. In the teaching context, knowledge means i) content of courses, ii) context, i.e. the entities involved in the teaching-learning situation (e.g. learners), and iii) meta-information, i.e. information about i and ii (e.g. a particular structuring of content). All three kinds of knowledge are represented as WebStyles. This is why GUTS is generic and unified. Below we first explain how knowledge is structured and represented in GUTS. Then we briefly introduce WebStyles and examine the GUTS lifecycle based on a toy example course about the astronomer Johannes Kepler.

Knowledge Representation: WebStyles, Semantic Networks, Graph Grammars. The principal mechanisms for knowledge representation and inference in GUTS are rooted in the fields semantic networks and graph grammars (see for example [Sowa 91] and [Rozenberg 97], respectively): The basic underlying data structure is the Graph. Our extended notion of Graphs, called WebStyles, comprise a grammar for expressing both static
(syntactic, structural) and dynamic (semantic, navigational) aspects. The table above gives just one example for each of these aspects, relating to both hypertext structure and content.

Structuring the Knowledge Space: Ontologies, Types. Knowledge representation involves classifying the 'things' to be represented, e.g. «Mars» is a «planet», «next» is an «order relation», «is a» is a «genus-species relation». Ideally the classes (concepts, types) are explicitly written down and put in relation with each other. This is called a theory, conceptualization, or an ontology. (More technically one would call it a type system. Ontology as a part of philosophy is the study of being, or, the basic categories of existence. With the indefinite article, the term "an ontology" is often used as a synonym for a taxonomy that classifies the categories or concept types in a knowledge base. [Sowa 91])

There are ontologies for 'everything'. For instance, in instructional design, if one wants to use Gagné's events of instruction [Gagne et al. 92], he could define an ontology containing «gain attention», «indicate goal», «recall prior knowledge», «present material», «provide learning guidance», etc. Or, to be able to talk in terms of Reigeluth's elaboration theory [Reigeluth 87], one needs «fact», «concept», «principle», and «procedure».

In these examples we did not consider any relations and formalization of semantics. If one tries to work out these aspects, it soon will be evident that something crucial is missing: How can such an ontology be defined? In which language? The answer in our context is: using a particular, built-in ontology. The GUTS representation ontology is rich enough to capture the computational content of new, user defined ontologies.

Ontology-WebStyles (WebStyles representing ontologies) are more than plain vocabulary for objects and relations since rules and procedures as offered add meaning (semantics) to the vocabulary. Hence an ontology-WebStyle specifies values and operations on these values; i.e. it is a type. This is why GUTS is a typing system.

4. WebStyles and Lifecycle by Example

4.1 Introduction

WebStyles are based on work about "genericity and dynamics in hypertexts" [Richartz 96]. They consist of three parts: generic nets, procedures, and rules. Generic nets are in essence graph grammars (cf. [Rozenberg 97]) represented as graphs. An overview of the symbols used with WebStyles is shown in [Fig. 1].

![Figure 1: WebStyle symbols](image)

Transformations: Two kinds of transformations have to be discussed in more detail for WebStyle nets: the instantiation of "sequence nodes" and "fan links". Intuitively spoken, i) a sequence node expands into a "chain" of nodes and links of arbitrary length; ii) a fan link expands into a "bunch" of links originating from the same node but leading to different nodes.

![Figure 2: WebStyle transformations](image)

In [Fig. 2 a)] some transformations have been applied to a sequence node. In [Fig. 2 b)] a possible transformation of a fan link is shown. In [Fig. 2 c)] a net consisting of three types of nodes (required, sequence, optional) and two types of links (fan, required) is presented. By applying the transformations introduced in [Fig. 2 a)] and [Fig. 2 b)] to this net and mapping some generic nodes to instantiated nodes, the net shown in [Fig. 2 d)] can be constructed. As to the semantics of generic nets, note that all instances derived from the sequence node might lead to the same "opt" node - details like these can be controlled, e.g., via reserved attributes.
To find out which nodes and links are affected by a transformation, the so-called chain-algorithm is used. This algorithm defines which nodes and links belong to a chain and, in a first step, marks them. In a second step all the marked objects are instantiated and connected to the original net.

Attributes and Advanced Concepts: Each WebStyle object has attributes like a name, a lower bound and an upper bound. The bounds for example are used by the transformations and define how many nodes or links can be instantiated. Besides default procedures (like isTraversable which tells if an object may be traversed) user defined procedures and rules may be attached to nodes and links. These procedures and rules may influence the construction of and the navigation in such a net. Two more types of objects are supported: alternatives and meta-nodes. Using alternatives, the author of a WebStyle can choose from different possibilities during construction; meta-nodes help to model hierarchies. For a more detailed description see [Richartz 96].

4.2 The GUTS Lifecycle

We will now examine the GUTS lifecycle, developing a toy course about the astronomer Johannes Kepler. (We concentrate on the process and not on the underlying WebStyle.) Usually lifecycles start with a requirement analysis and end with evaluation and modification. We omit these phases in this presentation: requirement analysis is skipped because it is less formal (e.g. for the Kepler course: “A small example course that demonstrates some of GUTS properties, possibly with some relation to the university of Linz.”), and evaluation and modification are left out for the sake of space.

It is important to mention that the different phases are potentially carried out by different people: domain experts, instructional designers, didactic experts, teachers, learners, media experts, and programmers. Substantial progress can be achieved if course authors can (re-)use expert knowledge, i.e. didactic knowledge that was written down by didactic experts, or pedagogical patterns identified by instructional designers, or content processed by domain experts.

Instructional Analysis — The Learning Situation’s "what?". We start with instructional analysis in order to familiarize the reader with the goals. The context used is an astronomical introduction to our solar system. [Fig. 3] shows artifacts of the instructional analysis in a well-known hierarchical style (expanded and collapsed entries are shown, indentation expresses substructure). The ontology for the goal structure is quite simple, we have just one object, goal, and one genus-species relation, subgoal. [Fig. 4] shows a WebStyle notation for this example.

Domain Analysis — Collecting Content. This phase deals with the task of providing content and content meta-information (information about the content) for a specific domain model. Such a model should be objective, in contrast to the outcome of other lifecycle phases (e.g. goals of a course) to maximize possibilities for reuse. For a actual learning material, knowledge from several domains can be used. Each domain has its own ontology. E.g. learning material on our solar system may use the domains astronomy, space aviation, physics, geography, history, etc. In [Fig. 5] we show a fragment of the corresponding domain analysis.

Learner Modeling — Individualizing Courses. As mentioned in the introduction, the pragmatic constructivist approach to instructional theory recognizes that each individual has a distinct learning process. The “failure” of ICAI showed that it is virtually unfeasible to automatically individualize learning material in order to match each learner’s cognitive model. On the other hand there is the need of adapting courses to match the information needs of the learner. The learner model captures parameters that may be used to individualize courses, and the author may provide explicit information about how to make use of them. To cope with the rising authoring effort, GUTS provides means for reusing didactic knowledge represented as WebStyles. A simple example for such a parameter is the «learning...
Instructional Design — The Learning Situation’s "how?" (conceptually). The structure (WebStyle) created during the instructional analysis must be augmented with operational goals, instructional strategies, pedagogical patterns, and presentation strategies. The augmenting process can be guided by strategies formulated as WebStyles (see [Fig. 6]). Depending on meta-information, some automatic generation is possible.

Instructional Authoring — Linking to Content (how realize the "how?"). The structure (WebStyle) from the instructional design must be linked to content, and instructional transactions and presentation details are specified. As in the design phase, WebStyles may guide the task. [Fig. 7] shows an example. The entries for which content exists are augmented with a link to that content, e.g. the entry ‘picture of Kepler’ can be linked to URL http://www.idv.uni-linz.ac.at/kepler/kepler_bild.gif.

User Annotations. All users (learners, teachers, instructional designers, etc.) can add annotations to the learning material which they are browsing through. They can share the annotations with others or set up rules that modify the material depending on annotations. As an example we could imagine a rule expressing that all things which Bob has annotated as being «important» are emphasized (displayed in red color, or played louder if it is an audio stream; in this example, the appearance changes but not the structure).

Temporal Order of the Lifecycle Phases. Domain analysis and learner modeling can proceed in parallel with the other phases. The remaining phases are more or less sequential: requirements, instructional analysis, instructional design, instructional authoring, user annotations, evaluation, and modification. Transformations can be applied in and between all phases, and iterations and validation phases may be added "everywhere".

5. WebStyles Implementation

A first prototype was implemented using JavaScript 1.1. It was capable of dealing with nodes and links, it even implemented the chain-algorithm on a very basic level. The most serious drawback of the prototype was the lack of a proper user interface, so a lot of activities had to be done by hand. Java was chosen as language for the second prototype. The Java prototype features graphical editing of WebStyle nets (this includes manipulation of the graph structure and the objects) and implements the complete chain-algorithm. The prototype is loosely based on the Dexter hypertext reference model [Halasz, Schwartz 94] and is divided into two main parts: the user interface, residing in the class WebStyleEditor, and the WebStyle engine. The engine manages the hypermedia
objects and defines a well formed interface, which is only listed partially in the UML diagram. The Prolog
interpreter in the diagram is used to evaluate the Prolog rules.

Prototype. In order to demonstrate the prototype, a small part of the domain as introduced above is modeled
with the editor. In [Fig. 8 a)] one can see a generic net which models the main characteristics of a biography; it
consists of an overview node Biography, a node for the birth and an optional node for the death of a person. In
addition, a biography contains some major sections (modeled as a sequence node) which can for instance be
mapped to major periods in the life of a person. Each section may have n dates. Furthermore a person may write
publications which have n dates of their own.

[Fig. 8 b)] shows the net after some transformations: some nodes and one fan link have been instantiated.

Figure 8: Screenshots of the prototype, a) the starting net; b) after some transformations

Abstract: The style of computer based educational systems has been changed from individual learning to group learning, cooperative learning, collaborative learning and so on. In the viewpoint of architecture of the computer based educational systems, network typed educational systems have been developed using network and multimedia technologies. We are currently developing an educational system called LEA: Learning Environment with Agent which has the features of both synchronous and asynchronous group learning environments. This paper describes the design and features of LEA.

1. Introduction

Recently, the learning style which computer based educational systems deal with has been changed from individual learning to group learning, cooperative learning, collaborative learning and so on. In the viewpoint of architecture of the computer based educational systems, network typed educational systems have been developed using network and multimedia technologies. Watanabe et al., whose work is called the Global Classroom Project [Watanabe et al. 1995], introduced Internet applications into classes at junior high schools in Japan. Nakabayashi et al. developed an educational system using WWW (World Wide Web) [Nakabayashi et al. 1995, Soga et al. 1995]. Ayala and Yano developed a CSCL system called GRACILE which supports communications by software agents[Ayala & Yano 1994].

The purpose of these works is to develop computer based educational systems which offer group learning environments. Since discussion among students is the most substantial part in all group learning processes, it is very important for the educational systems to have functions for supporting communication. These functions are classified into two categories: one offers the means of communication and the other supports smooth discussion. CU-SeeMe is an example of the former. The discussion supporting system called iDCLE developed by Inaba et al. [Inaba & Okamoto 1995] is one of the latter examples.

In general, communications are classified as synchronous and or asynchronous. The former type is realized by using synchronous communication tools, and the latter type is realized using asynchronous communication tools such as electric mail, electric bulletin boards, and so on. The aim of most existing communication tools is to support only the synchronous type. Group learning environment are classified in the same way as communications. Students can learn more effectively in a synchronous group learning environment than in an asynchronous group learning environment, because they can exchange their opinions, ideas, and so on through real time, interactive communications. However, synchronous group learning environments have a serious problem with schedule management. While students in an asynchronous group learning environment do not need to manage their schedules. So this is a point where asynchronous group learning is superior to synchronous group learning. Students may learn in both types of group learning environment according to their needs. Therefore educational systems for group learning environments should support both synchronous and asynchronous types.

Group learning progresses through discussions among the students. So the quality of discussions among students significantly influences the effectiveness of group learning. Since the discussions are more effective if each student can grasp their understanding level, we propose a
new student model called Public Student Model (PSM) which makes students aware of it. A student model of ITS (Intelligent Tutoring System) does not make students aware of their understanding level. With respect to this, PSM is different from student models of ITS that do not provide this information to students.

We are currently developing an educational system called LEA: Learning Environment with Agent which has the features of both synchronous and asynchronous group learning environments. This paper describes the design and features of LEA.

2. Group Learning Environment

This section describes the features of group learning environment. From the viewpoint of a student who is participating in learning environment, some other students exist in the group learning system and do not in the individual learning system. A student has educational interactions with other students in order to promote learning. Therefore, communication among students is important in a group learning environment.

2.1 Differences between individual learning and group learning

In a group learning environment, students can use the knowledge of other students as a human educational resource that does not exist in an individual learning environment. Therefore, to get the knowledge of other students, discussions among students are essential, and through the discussions, they can learn the subjects at hand more effectively.

Group learning environment progresses via interactions among students. Other students could act as a human educational resource according to their understanding level. In this point, they are different from the traditional resources such as textbooks, dictionaries, and so on. In order to get the understanding level of other students and to behave educationally, a student must present their own opinions and points that s/he does not understand. Therefore, the discussion among students are very important in a group learning environment. The quality of communications among students influences the quality of group learning, because the main difference between an individual learning and a group learning environment is the existence of other students. This feature is the basis of the advantages of the group learning environment.

2.2 The classification of group learning according to the style of communications

In a group learning environment, communications are important. As described above, communications are classified into two types: synchronous type such as a video conference system, a chat application, and so on, and asynchronous type such as electric mail, electric bulletin boards, and so on. Group learning environments are classified according to the type of communications used as synchronous group learning environments, or asynchronous group learning environments, because the discussion among students is most significant feature in a group learning environment. Table 1 shows the features of each group learning environment.(GLE means Group Learning Environment in the table).

<table>
<thead>
<tr>
<th></th>
<th>Synchronous GLE</th>
<th>Asynchronous GLE</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Learning style</strong></td>
<td>tends to <strong>Collaborative Learning</strong></td>
<td>tends to <strong>Individual Learning</strong></td>
</tr>
<tr>
<td><strong>Schedule management</strong></td>
<td>necessary</td>
<td>not necessary</td>
</tr>
<tr>
<td><strong>Response time</strong></td>
<td>short</td>
<td>long</td>
</tr>
<tr>
<td><strong>Quality of communication</strong></td>
<td>good</td>
<td>bad</td>
</tr>
</tbody>
</table>

Synchronous group learning environments tend to have the style of collaborative learning in which members of the group collaborate with each other solve problems by means of real-time,
interactive communication. On the other hand, in asynchronous group learning environment, a quick response from each student cannot be obtained. Therefore a student learns asynchronously with others, when they need others' helps. It is also difficult for students to communicate well in asynchronous group learning environment, because few cases hold common contexts of students' utterance each other, response time is long and so on. However, students do not need to manage their schedules in an asynchronous group learning environment. On the other hand, students in synchronous group learning environment must manage their schedules, and this management becomes more difficult as the group size grows.

3. Public Student Model

In general, the more deeply each student can grasp the understanding level of other students in the same learning group, the more efficient the group learning becomes. Focusing on this point, we propose a new student model called PSM: Public Student Model which allows students to grasp their understanding level.

3.1 Grasping other student

A student can learn effectively in a group learning environment, if s/he can have many opportunities to interact with other students. In this case, other students behave as a human educational resource for the student. However, this human resource is not the same as the traditional representative resource such as textbooks, dictionaries, and so on, because the former resource can behave educationally by grasping their own understanding level and that of other students. In other words, other students are a flexible and adaptive resource. We especially believe that it is important to grasp the understanding level of other students in order to behave as good human resource in group learning environment. Recently, many CSCL systems have been proposed and developed, but there are few CSCL systems that emphasize on this point.

Focusing on the point described above, we propose to open each student model that represents the understanding level of a student in a group learning environment to other students. General student models in ITS and so on can only be referred to by the educational system to identify and infer the understanding level of student[5]. Our approach provides students rich information necessary to grasp the understanding level of other students. PSM has the database which stores the information, and all students in a group learning environment can access this database.

3.2 Information about student in PSM

PSM consists of the following modules that store the student information and are accessed from other students in a group learning environment: (1) an understanding model, (2) a learning history, and (3) a question database. The understanding model presents the understanding level of student. Other students can access this model freely so that they can easily grasp what understanding level the student has already achieved. In addition, a student can also access their own understanding model. This suggests a possibility for the student to use it for her/his reflection and then amend his/her own knowledge by her/himself, although our current system does not help students with this task.

The learning history holds the sequence of the student's actions. Tracing the learning history, other students and also the system can identify the cause of errors and misunderstandings by the student.

The question database is also open to other students. A student can put her/his questions in their own question database. Other students can access this database and put answers into it. In this way, the question database can be used as a temporary memory for asynchronous question and answer.
4. LEA: Learning Environment with Agent

As described in Section 2, learning environments are classified as either synchronous or asynchronous. We conjecture that learning environments should have the features of both types in order to compensate the defects of each type. Group learning environments that have both synchronous and asynchronous properties allow students to be absent temporarily from the system. To allow the absent student to learn from the results that were obtained during her/his absence, we introduce an agent that plays the role of absent students. In section 3, we proposed the PSM in order to aid in effective group learning. To satisfy the requirement, we are developing the new learning environment called LEA: Learning Environment with Agent. In the following, we outline LEA and describe its goals.

4.1 System configuration

Figure 1 shows the configuration of LEA system. LEA offers a virtual space and an agent for each student. Every student manipulates their agent to learn in the virtual space. Next, we describe the functions of main modules in the LEA system in the followings.

![Diagram of LEA system configuration]

**Figure 1: System configuration of LEA**

4.1.1 Virtual Space

In the virtual space (LEA group learning environment), every student learns her/him subject(s). There are domain modules in the virtual space. The domain module provides educational tools for specific domain. For example, the domain module for mathematics offers virtual ruler, compass and so on.
4.1.2 Agent

Each agent may be in either marionette or normal mode. In marionette mode, a student can completely manipulates the agent to learn in the virtual space. On the other hand, in normal mode, the agent simulates educational activities an absent student without her/his manipulations. An agent can report the performances taken during the normal mode to the client student, when the student uses LEA again.

4.1.3 Agent Control Module

This module controls the activity of an agent and decides an agent behavior based on commands which the student set in advance. Then, the agent executes educational action of the absent student in the normal mode.

4.2 Learning in virtual space

LEA system contains a shared virtual space and students' agents. Each student has one own agent. Students behave as virtual people in the virtual space. The students gather potential members, make a learning group, and learn their common subject(s) in a classroom of the virtual space. The virtual space provides classrooms for each domain. Each classroom is separated into small rooms based on fields, groups and so on. In this way, the virtual space is structured as a hierarchy of fields, groups and so on. This structure makes it easy for students to look for members and groups interested, because LEA is not a domain dependent system and group learning about some domain is feasible in the virtual space offered by LEA. In addition, LEA has a function to show the members of each group and the theme to be discussed. Figure 2 shows an example LEA virtual space.

![Figure 2: LEA virtual space](image)

4.3 Learning through agent

An agent has two modes: marionette and normal mode. Students can use these modes according to their needs. In the marionette mode, manipulating an agent, students gather potential members, form a learning group, and learn subject(s). In this mode, they learn synchronously. On the other hand, in the normal mode, an agent supports students who cannot participate synchronously. In this mode, an agent asks questions and participates in the group learning which is selected by the absent student. The agent reports the contents of the learning sessions perform during the normal mode to the client student, when they return to the LEA. In this mode, students learn asynchronously.
In the LEA, students behave as virtual people and the system does not show the personal information of students. Hiding the information makes students evaluate other students properly through their actions in the virtual space only. We adopt PSM model as a student model for group learning. So, students can use the knowledge of other students by accessing the other students’ PSM as an educational resource. Students who participate asynchronously can learn more deeply, since their knowledge is reflected to the group learning.

5. Conclusions

This paper described LEA that supports both of synchronous and asynchronous group learning. In LEA, students can learn in the virtual space. LEA makes possible to bridge between synchronous and asynchronous group learning, since students can learn synchronously and asynchronously by using agent in two modes. We have proposed PSM which is a student model for group learning, and adopted it in LEA. Students can discuss effectively, since PSM makes their level of understanding available to other students. However, we have some problems with PSM and LEA that remain to be solved are described.

PSM inherits the same problems which traditional student model has, such as how dose the system generate excellent model, how does problems to solve the model. Besides, there are problems with to get the necessary information to make PSM from discussions among students and how to model students, how to represent the understanding model so that other students can grasp the understanding level of a student. Developing LEA has two big issues. The first problem is how to realize behavior of an agent in the normal mode. It is desirable to have the behavior of an agent in the normal mode be the same as behavior in the marionette mode. Although, it is hard to make such an agent completely by employing state-of-art AI technologies, we are currently considering the alternative method using current technology. The other problem considers LEA group learning environments where students participate synchronously or asynchronously, simultaneously. In such situations, the existence of students who participate asynchronously in Synchronous Group Learning may confuse other students who participate synchronously. We will consider this problem through experiments with a prototype of LEA. In this way, as our future works, we will solve those problems of PSM and LEA, and consider the learning style bridging synchronous and asynchronous group learning.

Abstract: The convergence of technologies that allow the representation of ideas in many different media formats (data, text, graphic, sound and video) and the growth of constructivist approaches to learning has created new challenges for learning software development. The applications increasingly incorporate more production-focused learning strategies. Typically instructional designers have accessed models that were devised within a behavioural approach to the learning task. Many of the popular instructional design models do not reflect this change in philosophical orientation and suggest anything more than a process. This paper describes how an award-winning interactive learning product, developed within a constructivist paradigm incorporating problem solving challenges for learners (including both task/deductive and data/inductive driven scenarios), is used in classrooms.

Introduction

The convergence of technologies and the growth of constructivist approaches to learning have created new challenges for learning software development. Typically instructional designers have accessed models that were devised within a behavioural approach to the learning task. Many of the popular instructional design models do not reflect this change in philosophical orientation and do not suggest anything more than a process. Recent proposals [Jonassen and Tessmer, 1996-7] seek to refocus attention on learning outcomes and suggest new tactical guidelines for developing technology supported constructivist learning environments. This paper describes how an award-winning interactive learning product incorporated cognitive tools and problem-solving challenges for learners, including both task/deductive and data/inductive driven scenarios, has been used in a classroom. It presents the results of a study to investigate the use of several cognitive tools which were devised to support learners when they were faced with complex scenarios (ill-structured problems), which might have multiple “correct” solutions [Jonassen, 1997].

Constructivist learning environments with embedded cognitive tools make assumptions about the actions of learners. [Hannafin and Land, 1997] have identified the lack of understanding of the problem solving and data exploration processes that learners undertake in such environments; and the motivation that learners might have to complete tasks. Hannafin has proposed that learners need to constantly apply a theory-action model as they investigate issues and view data, that is, they will develop a theory about the solution to a problem or about data access, and take action to test that theory. We sought to investigate the theory-action model through setting a structured and ill-structured problem solving [Jonassen, 1997] and log the construction of ideas by collaborative pairs of students.

Exploring the Nardoo: A Constructivist Learning Environment

The approach used to develop Exploring the Nardoo has been supported by close links between classroom teacher practice, innovative software tools, and learning strategies, which allow students to construct their solutions to the challenges posed. Exploring the Nardoo is a software package that provides a dense information landscape of resources based on general issues in ecology. The resources provided consist of a number of different media formats (data, text, graphic, audio and video). Additionally, a number of tools are provided to assist learners in the collection and manipulation of those resources such as: simulators;
measurement tools; a media viewer; a Personal Digital Assistant (PDA) for resource collection and note-taking; and, a Text Tablet for manipulation and editing of information collected [Harper et al, 1995]. The purpose of the package is to engage students in long-term studies using the skills of problem solving, measuring, collating, elaborating and communicating. The package was designed for high school use, for students aged from 14 to 18 years, and is based on current Australian state and national curriculum documents for Biology and Geography.

The information landscape design of Exploring the Nardoo uses spatial and geographic metaphors: a Water Research Centre and a navigable fictitious river environment. On entry to the environment, users are challenged by three researchers in the Centre to help them solve problems and carry out investigations on the river. The challenge posed by the researchers encourages active learning and supports students to construct their ideas in teams from measurements taken, resources reviewed, maps interpreted and data analyzed. By providing a metaphor easily linked to the real world, students are encouraged to apply scientific concepts and techniques in new and relevant situations throughout the problem-solving process within this ecology-based application. In so doing, the learner is likely to become more interested in developing questions, ideas and hypotheses about the learning experiences encountered. A broad range of investigations are presented to the user and include issues such as fish dying from pollution, weeds infesting the river, and communities discussing farming practice.

Students need to extract ideas and information from what can often be a complex and bewildering array of resources. Software applications (tools) to help with this task should be readily accessible for both extraction of information and for representation of ideas and information. Recent research on learning endorses the use of such mechanisms to facilitate and support learning [Lajoie and Greer, 1995]; especially in conjunction with existing and new interactive multimedia titles. The study sought to investigate how school students use complex cognitive tools to solve task/deductive and data/inductive problem scenarios.

Phase I: Two Classroom Experiences of a problem-based package

In order to gain awareness of the types of cognitive tools that might assist students, the researchers needed to develop an understanding of the way students use the range of tools currently available in Exploring the Nardoo. The first two phases of the study were intended to investigate student use of the package in two different modes. Both studies took place in Science classrooms at Smith's Hill High School in Wollongong, New South Wales. The first study was intended to observe students using the tools and to examine their solutions to a number of different problems in a classroom setting that offered a constructivist learning environment. The second phase of the study involved students being oriented to the tasks in two different ways; setting the problem in a structured framework and setting a task that was ill-structured.

In phase I, the researchers had access to two classes (n=47) of year 11 Biology students. Prior to the first class in which Exploring the Nardoo was introduced, members of the research team met with the teachers to discuss the roles of the teachers and researchers in the classroom and develop a strategy for using Exploring the Nardoo for the subject. It was decided that students would work in pairs (where possible) and be asked to complete one of the investigations in the package. Additionally, teachers were asked to take the role of mentors, helping students with any difficulties with the package and essentially limiting instruction to classroom management. Phase I was implemented in the classroom over a two week period and consisted of a total of eight hours exposure. At least one member of the research team was present at each lesson to provide technical assistance and observe the implementation process. Data collection consisted of observations of students using the package, a group log book that was to be completed at the end of each session, electronic versions of the PDA and writing tablet for each group after each session, final student reports and teacher interviews. Students were also asked to draw up a knowledge map of the package after their second lesson and their final lesson to gain insights into the students understanding of the package structure.

Observations of Student use of the Package

Student groups were asked to fill out a log book on a lesson-by-lesson basis to record what they did during that lesson and what they would do the next time. The log books were not well used, with most students preferring to record their ideas for the next session in their electronic note book, and abandoning the use of the log books after the first few sessions.
Initially, many of the student groups went directly to areas of the river and began to explore by clicking on the highlighted sections. A few groups explored the Water Research Centre in depth. Students often used the search engine/computer database as method of collecting information. In the first lessons, student groups played the sound and video files. Many student groups experimented with editing the text font, size and colour in their Text Tablet and PDA. Some groups minimized the PDA and moved it around the screen so as much of the river system or Water Research System could be viewed as possible. As the groups progressed the groups became more involved in completing the investigation, they made more use of the linked media, examining the text as well as the visual and audio components and focused on resources that would help with their solutions in an organized way.

**Analysis of knowledge maps**

Knowledge maps were analyzed qualitatively with attention to such attributes as the format (use of text, pictures or, concept map structure); concepts about Exploring the Nardoo (i.e., identification of: information resources; tools; environmental issues; river segments/time zones); learning process; and, “reviews” of the package. Not all students completed a pre- and post-instruction knowledge map. Many of the students noted the resources, tools, time zones/river segments and issues in their knowledge maps. There were not clear differences between the first and second maps in terms of these concepts.

In summary;

- Often times, the environmental issue aspect of the package was identified on the map by a specific problem (e.g., fish kill, pollution, water management) rather than the content.
- The concepts about the tools in Exploring the Nardoo were also specific to particular tools or action of using the tools (e.g., measuring, note taking). Tools most often mentioned were measurement tools and the PDA. One student mentioned the computer when describing "appropriate search engines are available so as to obtain this information".
- A number of information resources were mentioned by many of the students including the files in the cabinet, audio and video files, pictures and descriptions of plants and wildlife, and newspaper articles.
- Many students noted the concept of the river segments and time zones in the landscape of Nardoo.
- Only two students specifically mentioned the researchers in the Water Research Centre.

For some students, it was apparent that they were aware of the learning process embedding in the package and the learning process involved in using Nardoo. For the most part this is apparent in the second knowledge map (i.e., after students have been though the process of the investigation). However, a few students noted this in their first map.

Some students commented on the use of the information in the Nardoo to "make conclusions" or "formulate your own ideas on what you think of the changes" or "help understanding of the issues". Furthermore, a few students noted that the package is a "learning aid" and that it "makes you think instead of thinking for you". One student went so far as to note the concepts of open and structured learning when she described that students can “simply explore the Nardoo and take notes or you can choose an investigation”. Some students mentioned the concept of the virtual experience with such descriptions as: "hands on experience"; "simulated excursion"; "exploring an imaginary place but learning about real issues"; "develop research skills without going out and physically measuring" and, “designed to give high school/tertiary students a 'feel' of what responsibilities and duties an Environmental Scientist/Biologist is responsible for/incurs during their day-to-day work".

**Teacher Interviews**

After the conclusion of the implementation of the learning activity in the classroom, members of the research team interviewed the two teachers individually. After reflecting on the process of the learning activity and reviewing the student group reports, one teacher believed that the students collected all the relevant resources but felt that, when it came down to putting it together and making all that abundance of information something more concise, the students had difficulty. She explained that even though she reminded her class “don't just copy slabs of information and regurgitate it in your report, make sure you read it, understand it, relate it to a question”, based on the student reports presented, she felt that she could have reinforced this concept of analyzing the information more. She commented that she was impressed with the speed at which students engaged in the activity and the range of ways they used the package, and suggested that, the next time she used the Nardoo for a learning activity, she would provide more direction or assistance on how to handle the information collected.
The other teacher also believed that the students picked up on how to use the package quickly and made good use of most of the resources. However, he believed that the students could have made better use of the measuring tools. He noted that the students tended to just copy measurements into their notes and rarely analyzed the measurements.

Phase II: Concept Mapping and Problem Structures

The outcome of phase I led us to understand that, while students have no difficulty navigating through Nardoo and collecting information, they do have some difficulty in synthesizing the information and arguing for a solution. The research team decided to provide students with a concept-mapping tool, Inspiration, as a cognitive tool for argument development. The focus of this phase of the research was to understand differences in how students use Exploring the Nardoo when given either a structured or ill-structured problem task. This phase was implemented in the classroom for a two week period, amounting to eight to nine hours of exposure for each student. At least one member of the research team was present at each lesson to provide technical assistance and observe the implementation process.

The students in phase II came from an Environmental Studies elective class (n=22) for year nine and ten students. It was decided that students would work in groups of two. Half the class was given a structured problem (Blue-Green Algae) and half the class was given an ill-structured problem (Water Plants and Weeds). To facilitate this, a special version of Exploring the Nardoo was pressed with the investigations button disabled. An instruction sheet for each of the structured and ill-structured problems was developed. Both instruction sheets explained that students were to: analyze the problem and write a report that clearly identified the problem and argued for potential solutions to the problem in the region. They were also asked to produce a concept map of their solution.

Concept Map Analysis

The concept maps were reviewed both qualitatively and quantitatively. Measures of the concept maps were calculated [Ferry et al., 1997] and scores ranged from 39 to 143, with the structured problem students averaging 96, and the ill-structured problem students averaging 55. It was noted that:

- Groups with the structured task tended to categorize the concepts into causes, impacts and solutions.
- Some groups with the ill-structured task had difficulty defining the problem; two of the five groups with the ill-structured task identified a number of problems (e.g., weeds, chemical pollution, logging,) in the area of the river system.
- Groups with the structured task were more likely to include specific solutions to their problem than those groups with the ill-structured task. Of the six groups with the structured task, five included specific solutions, while only two of the five groups with the ill-structured task included specific solutions to the problem on their concept map.
- Male students tended to use single or few words for concepts while female students were slightly more descriptive and detailed in their concepts.
- Two groups with the ill-structured task seemed to have pasted chunks of text from their report into the concept map.
- Females in both the structured and ill-structured task groups tended to create traditional, tree-structure concept maps. Males in both the structured and ill-structured task groups did not use a tree structure but tended to compartmentalize concepts in a more loose structure.

There is evidence of gender issues that will need to be investigated in further studies.

Student Work

Student groups were asked to save their work in a unique file after each lesson. These were analyzed to understand which resources were collected and how those resources were utilized to support the students' final argument. Students with the structured task tended to focus on the radio, television and newspaper information resources while students with the ill-structured task were more likely to collect all the resources on their problem including information about plant and animal life which related to the area of the river being investigated but did not relate to the problem to be solved. Students with the structured task tended to manipulate the information collected at a very early stage in the learning activity (within the first three lessons) while the complete raw information resources appear in the files of the students with the ill-structured task until the last lessons of the learning activity. The final report was marked by an experienced teacher, who
evaluated them in terms of quality of argument, overall quality of their answer, use of inferences and use of concrete supporting details. The marker found that overall, students who attempted the structured task produced higher quality work in terms of related resources and solutions to the problem.

Student Interviews

Each pair of students was interviewed about their use of Exploring the Nardoo. In response to the question: "Did you find it difficult to solve the problem?" none of the groups, who had the structured task, found it difficult to solve the problem. Most mentioned that all the information made it easy to solve the problem. One group with the ill-structured task in their concept map identified a number of issues rather than one specific problem, and mentioned that there were “lots of small problems but not one problem to solve”.

When asked the question 'How did you go about solving the problem?' most students mentioned that they first went to the river to explore but collected most of their information from the Water Research Centre. Groups with the structured task (blue-green algae) mentioned returning to the river to take measurements. Two of the groups with the ill-structured task, who had difficulty both identifying the problem, and generating a solution, noted that they used the concept map in an attempt to solve the problem.

All groups worked out how to use the package though exploration and trial and error (i.e., clicking on things to see what happened). No groups used the help files/videos to get to know the package, although some groups mentioned that a little instruction on how to use the package (e.g., measurement tools) would have been helpful. This information was available in the help menu as a walkthrough movie for all groups.

When asked ‘When did you use the concept map?,’ most of the groups explained how they first collected information from the package, then developed their concept map, and finally wrote their report. Two groups, both with the structured task, noted that they developed their concept map and report at the same time. Generally, students felt the concept-mapping tool helped them to develop their report. Only one group (with the structured problem) mentioned that they wrote the report before developing the concept map.

Discussion

From the data collected, it is apparent that learners have no difficulty using Exploring the Nardoo in general and, more specifically, accessing the information in the package. The navigation was well understood and students' knowledge maps of the structure of the package supported their apparent understanding of the information structure. However, when provided with a structured or ill-structured problem-solving task, students tended to spend time discovering how to use the package and then focused on the task provided. Structured-problem solvers tended to approach their task in an organized fashion, they focused on the resources that supported a solution and constructed concept maps that were clear representations of their solutions. The ill-structured problem solvers tended to spend more time accessing resources that did not directly support problem solution, but did, in the main, identify a problem and possible solution. Their concept maps were not as rich as those developed by the structured problem solvers.

The results obtained from the use of this product in schools have shown that students need to be supported when dealing with complex and many-optioned situations. The learners’ skills required to work effectively within these environments have been shown to require an understanding of idea construction tools, such as concept mapping and their abilities to re-focus and extend their information is critical in success. Several of these learning environments have been constructed to allow the representation of ideas with not only text and pictures but also dynamic models of relationships between variables, and information displays in multiple media forms. The results also indicate this process can support hypothesis generation, but it may require some more constrained problems before being effectively employed.

In terms of the [Jonassen, 1997] model for the design of ill-structured problem tasks, the students had no difficulties with the early steps in the process. They were able to articulate the problem space and the contextual constraints, and they also identified in greater detail than the structured problem solvers, the opinions and perspectives on the problem. However, as they tried to generate possible solutions and assess their viability they failed to focus their solutions on precise aspects of the problem. It appeared that they did not want to “let go” of the information they had collected. Additional support tools to assist their process to aggregate information and create meaning aggregations would appear to have been useful. Creating groupings and testing the options for
best solution “fit” were not really attempted. Most groups simply found the first one that worked. Tools which could suggest options and let students test each option before it was discarded would also be useful.

These further tool development directions would help students to identify patterns, links and similarities in complex information environments. It appears that to support the implementation of elements of constructivist learning frameworks such solution finding tools might prove invaluable [see also Savery and Duffy, 1996]. These tools might also tap into the socio-dialogical approaches to problem solving and support the call by constructivist to facilitate alternative ways of generating understandings rather than the traditional focus upon the printed text.

While interactive multimedia packages that support student-driven exploration and investigation have captured many multimedia designer’s imaginations, they have not yet realized the extent of support for the generation of meaning that is required when the task is ill-structured. *Exploring the Nardoo* is an example of a product, which, while providing some cognitive tools to support student investigation and consolidation, works well for the tasks, which are structured, but as the complexity of information and lack of structure increases, some students are unable to identify with what key elements they are dealing. It would seem that cognitive tools which scaffold effective problem-solving will need to be more dynamic, and assist with some procedural what-if sequences.

Abstract: Media selection is a key step in the educational design process. We present two types of approaches to media selection: rational-choice approaches and social-influence approaches. We argue that designers should combine these two types of approaches in a combined bottom-up/top-down media-selection process. Furthermore, as examples of the two types of approaches, we describe two conceptual frameworks: task/media fit and core/complementary media, respectively. These may help designers in finding a balance between an 'objectively' optimum choice and factors in the implementation context.

1. Introduction

A new machine, a new course... Marian is a training developer in the company that introduces this new machine, and she takes on her task in a thorough way: after analyzing the problem and the task, she uses a well-known model for media selection to decide on the instructional medium. A computer simulation is developed, with a series of built-in assignments, which allows operators to develop insight into the production process and the ways in which they may control this process by using the features of this new machine. Operators may use such a computer simulation independently, in the work place, at those moments that suit them best.

The computer simulation, once ready, yields many positive responses from Marian's colleagues. However, it is never really implemented. Operators do not have any experience with computer simulations, and their managers prefer to send them on a half-day course, from which they return with a file of course materials and a manual.

What went wrong in this example? Something in the introduction process? Or was the media-selection decision not feasible? Media selection: a second example.

Jack develops and gives management and communication training. Role play is a common ingredient: it is effective and cheap to implement. For a new course about managing immigrant employees, Jack develops a number of role plays. Course members take turns to play the roles of, for example, a young Moroccan shop-girl and her manager.

Already the first time that the course is given, the decision on role play as the educational medium does not appear to be such a good one. Course members have difficulties identifying themselves with the role of the foreign shop-girl, and doubt whether they are able to apply the theory from the course materials in their work settings.

Media selection, often it is a decision taken implicitly. “Management wants more computer-assisted instruction”, and thus the training design includes CAI. Or it is force of habit that determines the media selection, as in Jack's case. A quite different approach is the systematic, conscious and explicit media selection process. All those media selection models in the literature are there to be used, aren’t they? Marian, in the first example above, utilizes such a model. However, the products of both Marian and Jack fail.
In both cases media selection is a critical success factor. In this paper we focus our attention to media selection as one step in the process of educational design. In doing so, we acknowledge that the concept ‘media’ is hard to define: sometimes hardware aspects are critical in the selection, sometimes aspects of the organization of information and communication – the software. We will not go into this distinction, as this seems not to be a concern of instructional designers in practice.

In this paper we introduce two types of approaches to media selection, of which Marian’s and Jack’s way of working are examples. Marian’s approach is what we call a ‘rational-choice approach’, while Jack’s is an example of a ‘social-influence approach’ to media selection. The examples above show that neither of the two approaches is superior – the ‘truth’ will be somewhere in the middle. Where exactly? That is something that instructional designers will best be able to determine themselves, per specific situation for which they have to select media. This presentation does not contain any prescriptions – just because prescriptions do not apply to all cases of media selection: every concrete training situation is different. We are convinced, however, that insight into the foundation of the arguments that designers use (maybe unconsciously) in selecting media will help them find the optimum middle more effectively.

We thus aim to contribute to the toolbox of frameworks, methods and techniques that educational designers use in their daily practice. Besides an introduction to the two types of approaches, we present two specific conceptual frameworks which we have experienced to function well in practice. The framework of ‘task/media fit’ is an example of a rational-choice approach, while the ‘core/complementary media’ framework fits within the social-influence approach. In addition, we will argue that educational designers should always combine a rational-choice approach with a social-influence approach, making the media-selection process a combined bottom-up/top-down design process.

### 2. Rational-Choice and Social-Influence Approaches to Media Selection

Media selection is an important step in the design process for education and training. We distinguish two types of approaches to making decisions on media to use: rational-choice and social-influence approaches [Fulk et al. 90]. For reasons of clarity of our argumentation we will draw the differences between these two approaches more into extremes than is common practice.

Marian’s media-selection decision is made according to a task analysis and a model for media selection, and as such is an example of a rational-choice approach. Characteristic to rational-choice approaches is [Fulk et al. 90]:

- every medium has fixed, inherent characteristics
- every task can be defined in terms of objective characteristics
- media selection is an independent, rational task
- media selection is motivated by a strive for efficiency

Media selection according to a rational-choice approach is often a matter of finding a best ‘fit’ between characteristics of the task and characteristics of the medium. In practice, this means:

- media selection takes place for specific educational tasks
- media selection is a bottom-up design process that starts from considering the educational tasks

Rational-choice approaches are often worked out in the form of prescriptive media-selection models. [Reiser & Gagné 82], [Romiszowski 88] and [Sorenson 91] collected a large number of such models. Many of these are in the format of a flow-chart, a matrix, or a worksheet. This makes them look very practical, but the large collection of models indicates that this is not the same as being applicable in a large variety of situations.

Jack’s ‘unconsciously made’ media-selection decision is an example of a social-influence approach of media selection. Characteristic to this type of approach is [Fulk et al. 90]:

- characteristics of media and of ‘good media selections’ are determined in and through a social context, and thus are variable
- social influencing of media characteristics may take place...
through overt statements of various people (e.g., colleagues) about media characteristics, task characteristics and media selections – statements which decision makers consider in their own evaluations of media characteristics

- if decision makers subsequently express these opinions to their colleagues in the context of specific decision-making situations, thereby making them even more salient
- through vicarious learning, through observations of success or failure of others’ media selections
- media selection is not an independent task; however, selections can be rationalized retrospectively for the specific situation to which they applied – thus media selection is a subjectively rational task
- media selection may be motivated by a strive for efficiency, but this does not need to be so.

Media selection according to social-influence approaches is again about finding a ‘fit’ between characteristics of the task and of the medium. However, unlike rational-choice approaches, various interpretations of these characteristics and of the final decision are considered, all of which are constructed in a social context. This makes media selection a subjective process. In practice this implies that:

- media selection takes place for a larger whole of educational tasks
- media selection is a top-down design process which starts from current ideas about ‘good’ media selections for the educational setting

In general, social-influence approaches to media selection are not worked out in the form of handy, ready-to-use models. Recognition of social-influence processes, though, may help to rationalize, understand, appreciate, and accept or improve ‘practice’.

We have introduced two types of approaches to media selection: rational-choice and social-influence approaches. Next we will discuss two specific conceptual frameworks that each are an example of one of these two approaches, and that offer a limited but useful perspective in the practice of media selection:

- task/media fit (a rational-choice approach)
- core/complementary media (a social-influence approach).

### 3. A Rational-Choice Approach to Media Selection: Task/Media Fit

The ‘rational-choice approach’ for media selection discussed below is based on the idea that characteristics of the educational task and characteristics of media used to accomplish this task should be aligned in order to achieve the best ‘task/media fit’. The task/media-fit framework is based on ‘media richness theory’, which has been developed within management theory and communication science (see for example [Daft & Lengel 84], [Daft et al. 87]), and was adapted for educational settings by [Heeren 96].

With regard to the educational task, its complexity as a communication task is considered (the form of communication is determined by the educational method). ‘Complexity’ refers to the extent in which it is necessary to reduce potential differences in interpretations of the task content. Knowledge transfer of a series of concepts is an example of a moderately complex communication task between knowledge source (teacher, book) and learner. Transfer of motor skills is already more complex, which also deals with the communication between knowledge source and learner, but probably much more fine-tuning is required for a satisfactory transfer. Examples of rather complex tasks are negotiation among learners, or collaborative decision making – tasks in which differences in interpretation of case elements existing among participants need to be solved.

*Media* are considered with regard to the ‘richness’ they offer. Various dimensions of richness are distinguished, which also differ in importance depending on the specific situation. Examples of medium richness include: an audiovisual medium is ‘richer’ than a medium that offers audio only, which is again richer than a text medium. Also, a medium that supports direct interaction, such as an interactive computer simulation, is considered richer than a medium that offers feedback only after some time, such as a written test.

In order to derive a good fit, task/media combinations should be chosen within a ‘band of good fit’, indicated in [Fig. 1]: complex tasks require a rich medium, for simple tasks a ‘lean’ medium is a better choice. An example: for a negotiation task a face-to-face role-playing game (rich medium) is a good choice; for knowledge transfer which requires reflection activities in the learner, relatively lean media such as written materials are a good choice.

In practice, often the ‘richest possible’ medium is selected. Rich media are most often also more costly. If the richness of the medium is not necessary to achieve the learning goal, too much money is spent (efficiency loss).
The costs which determine efficiency are measured not only in terms of money, but also in terms of time or effort. For example, adding moving images to a simple presentation is not only more expensive, but also diverts a learner's attention. In case of a too lean medium, however, effectiveness loss may occur. Selecting electronic mail as the only medium for team work on solving a problem, for example, is asking for trouble—the medium is not interactive enough to support this process well, and will lead to loss of quality and effectiveness.

**Figure 1:** Task/media fit according to media richness theory.

Admittedly, the danger of effectiveness loss should not be overestimated. People have the capacity to easily adapt to a somewhat too lean medium by exerting more effort (a precondition is that they possess the skills to compensate for the lack of richness of the medium). It is interesting to relate this to a motivational and instructional-design aspect: if learners are challenged to utilize their skills, they will be more motivated to fulfill the task and to exert more effort on their task performance, which in turn may lead to deeper processing and, as a result, to better learning [Salomon 84]. Of course, the extra effort should be ‘well spent’: for example, effort exerted on overcoming the shortcomings of a badly designed user interface does not contribute to learning [Heeren 96]. Furthermore, [Heeren 96] showed that various media may be effective and efficient in a certain situation, or fall within a ‘band of good fit’; see [Fig. 1]. Therefore, for achieving optimum learning effect, the leaner of these media should be chosen.

According to the task/media-fit framework in [Fig. 1], for each of the communication tasks within the series of educational tasks of a course a well-fitting medium should be selected. This means that media selection should take place when the instructional design is worked out in detail, often at the same time as the educational method for each task is chosen. Media selection thus is an activity in a bottom-up instructional-design process. The final media mix for a complete course then is the sum of a series of media selections for different educational tasks.

In summary, media selection according to the rational-choice task/media-fit approach is balancing between effectiveness loss and efficiency loss, by choosing a medium that is rich enough but not too lean to fit the complexity of the task. Media selection according to this framework, taking place separately for each educational task within a course, may be characterized as a bottom-up design process.

4. A Social-Influence Approach to Media Selection: Core/Complementary Media

The second conceptual framework which we present in this paper, core/complementary media [Verwijs 98], is an example of a social-influence approach to media selection. Central starting point for the core/complementary media framework is that, in practice, the main medium for a course is often decided in advance, before the instructional-design process starts. Possible reasons for this are, for example, that a certain medium has been used for years already in the particular course or in similar courses; that the instructor is used to the medium; or that the medium selection has been ‘imposed’ by others (management, a client). The major part of the course will then be carried out through this medium: it is the core medium (the ‘major’ medium) in a media mix.

Limitations of the core medium are then dissolved by utilizing one or more complementary media. Using only one medium is often insufficient to attain all course goals; it is more efficient to add a specific medium that is
more appropriate for carrying out particular tasks or reaching certain goals. The educational tasks or goals for which the core medium is not particularly appropriate are then performed or achieved through complementary media.

For example: in recent years computer-assisted instruction has often been used in education and training. In general, these computer programs are very suitable for knowledge transfer, but are not very effective in the teaching of social or motor skills. Different media will need to be used which complement the CAI.

A second example is derived from distance education. Written materials have been the core medium in distance education for many years. With developments in information and communication technology (CAI, WWW, e-mail, computer- and video-conferencing as complementary media), certain course goals can be achieved better without requiring students to travel to face-to-face meetings.

The approach of combining core media and complementary media is not only applicable to hardware (such as selections between television, computer, book), but may also be used for software decisions. For example, if a decision has been made to use CD-I for a certain course (hardware), still decisions on how to design the CD-I (software) have to be made. In this regard a core medium, such as image stills with text, can be taken as a starting point, and the shortcomings of this medium can be complemented by using, for example, moving images and communication media for consulting a remote teacher. Now that multimedia is being used more and more, we expect that decisions on core and complementary media will be made more often on the software level.

Thus, in the core/complementary-media framework, a media mix consist of a core medium and one or more complementary media. The decision on the core medium is not made in a rational way, but is determined by influences of the decision makers in interaction with their social environment. Especially in the case of new technologies, decision makers appear to be sensible for influences from their social environment [Webster & Trevino 95].

The selection of (core) media is made on the course level, in an early stage of course development. In this regard, media selection is a step in a top-down instructional-design process; the selected core medium determines to a large extent the design of the course.

In summary: According to the social-influence approach, media selection is determined in the decision maker’s social environment, and decisions are based on their preference and experience. Media-selection decisions are made on the course level and often in advance; media selection may thus be characterized as a design decision in a top-down educational-design process. The medium selected in this way is the core medium in a media mix. Besides the core medium one or more additional media are used to compensate for the limitations of the core media in certain educational tasks; these are the complementary media in the media mix.

5. Complementarity of the Approaches

We have distinguished rational-choice approaches and social-influence approaches, and have discussed an example of both approaches: task/media fit and core/complementary media, respectively. These two conceptual frameworks should be considered as guidelines which instructional designers may use in deciding on media. In particular, we argue that designers should view rational-choice and social-influence approaches as complementary, and should combine frameworks such as task/media fit and core/complementary media. In doing so, their media selection process becomes a creative, heuristic process, in which they combine bottom-up and top-down ways of working. By combining rational-choice and social-influence approaches disadvantages of one type of approach can be dissolved by applying the other type of approach. The approaches thus complement one another [Webster & Trevino 95].

By applying a rational-choice approach such as task/media fit, optimally effective and efficient media selections can be made for each educational task. However, this may easily result in a large, diverse, fragmentary, and hard-to-implement media mix for the whole course. Also, rational-choice approaches do not take into account the media and facilities which are already in use or available in the educational setting; this applies even more to the media-selection models we mentioned earlier. For implementation this is a disadvantage, both from a social-organizational and from a cost perspective. These disadvantages may be taken care of by applying rational-choice approaches in a flexible way. By applying a social-influence approach, such as core/complementary media, at the same time, a core medium for the whole course and other available media may direct the process of media selection per task.
Vice versa, the application of only a social-influence approach, also if this occurs in a conscious way, has an important disadvantage. The educational designer is not easily inclined to look beyond the collection of familiar media or the new media which the client likes to see used. This may easily result in sub-optimal media selections. This disadvantage may be relieved by considering the best medium for each separate educational task, followed by a cost/effectiveness estimation of the replacement of the medium that would otherwise, from a social viewpoint, be preferred. Furthermore a rational-choice approach to media selection may provide convincing arguments to experiment with media which have the potential to yield better learning results, or to prevent decision makers from wasting money on fancy but inappropriate media.

In practice media selections often seem to be made impulsive or badly-reasoned, which some may judge as ‘wrong’. We doubt if the latter can be justified: in such cases the designer may be acting on a basis of educational knowledge and experience combined with knowledge of the actual and aimed-at situation [Verwijs 98]. [Webster & Trevino 95] found that for new media the social-influence factor is more important than for traditional media, because the application and way of using of traditional media are well accepted and clear. A client may view a certain type of medium as an important element of the aimed-at situation; a medium in a particular educational situation which is selected based on trends or hypes that a client wishes to join (“We must have multimedia!”), may be viewed as a decision that can be rationalized in retrospect. Rational-choice and social-influence approaches thus cannot be viewed separately from one another in practice. Their application though may be made more effective. Instructional designers who have to decide on what media to use should be conscious of the advantages and disadvantages of both rational-choice and social-influence approaches, and act upon this. This implies combining bottom-up and top-down design processes, in which the optimum middle will be different for each educational situation.

6. Summary

In summary, we have presented the following guidelines for media selection:

1. Consider for each particular educational-design situation what is an ‘objectively’ optimum choice for each particular task (rational-choice approach), and combine this with the best choice within the social context (social-influence approach)
2. Consider task/media fit as a rational-choice framework, and core/complementary media as a social-influence framework for thinking about media selection
3. Approach media selection as a creative and heuristic, combined bottom-up/top-down design process, in which the guidelines above may serve as resources

An Interactive Intelligent Language Tutor Over The Internet

E-mail: heift@sfu.ca

Abstract: This paper describes an Intelligent Language Tutoring System (ILTS) for German. The German Tutor is the grammar component of a comprehensive multi-media course, specifically adapted for distance education over the World Wide Web. The Intelligent Tutor parses student's answers to introductory language exercises. The system analyzes the linguistic source of an error and reports its description to the student. Through this analysis it infers an approximation of the learner's competence and adapts the instructional strategy accordingly. The main advantage of the system is its ability to individualize instruction and to provide insight to the student as an inherent feature of learning exercises.

1. Introduction

The project describes an Intelligent Language Tutoring System (ILTS) for Distance Education over the World Wide Web. The predominant characteristic of Distance Education is the separation of student and instructor in space, and consequently, time. One-way communication media, such as radio, television, film and video came to dominate the field of distance learning because of their ability to deal at least partially with this difficulty. While broadcasting technologies using a single-source/multiple-receiver model, greatly enhanced print-based instructional media, feedback within the model was awkward or non-existent. It is, however, commonly accepted that the most effective education, particularly in second-language learning, requires two-way communication. For this reason, Computer Mediated Communication (CMC) has become to play an ever more important role in both traditional and distance education.

The German Tutor, an Intelligent Language Tutoring System is conceived of as the grammar practice module. An Intelligent Language Tutor over the World Wide Web combines the flexibility and intelligence of an ILTS with world-wide availability of WWW applications [Brusilovsky et. al 1996]. Predominantly, existing second language learning applications use simple grammar practice and their feedback mechanism is more restricted than their off-line counterparts.

The goal of the German Tutor is to provide meaningful grammar practice for foreign language learners through computer-mediated communication. Meaningful grammar practice requires intelligence on part of the computer program. Without intelligence the system is merely a method of presenting information, one not especially preferable to a static medium like print. In order to go beyond multiple choice questions, relatively uninformative answer keys, and gross mainstreaming of students characteristic of workbooks, the German Tutor emulates two significant aspects of a student teacher interaction: it provides error-contingent feedback and allows for individualization of the learning process.

Generally, Intelligent Tutoring Systems consist of 3 components: the domain knowledge, the student model, and the teaching module [Wenger 1987].

The domain knowledge in Intelligent Language Tutoring Systems is modeled by Natural Language parsers. The strength of Natural Language Processing is that the student tasks can go beyond multiple-choice questions and/or fill-in-the-blanks while still allowing for a sophisticated error analysis. Simple drills are based on string...
matching algorithms, that is the student response is compared letter by letter against an answer key. With meaningful grammar practice, however, one obviously cannot enter arbitrarily many sentences into memory for purposes of comparison. Natural Language Processing allows for more than a mere indication that an error has occurred: it can give a description of the error, and go to an even deeper linguistics analysis in order to isolate the source of the error. Thus a Natural Language parser provides the analytical complexity in an Intelligent Language Tutoring System.

Students all learn at their own pace and the student model provides the “key to individualized knowledge-based instruction” [McCalla & Greer 1992]. The student model keeps track of the learner history and provides learner model updates. It is used by the system to inform the teaching module and allows the system to adapt to individual student needs and alter the instructional process accordingly.

2. Grammatical Formalism

The German Tutor parses students’ answers to introductory German exercises. Typically Intelligent Language Tutoring Systems augment grammars that parse grammatical input in one of three ways. They may augment rules such that if a particular rule does not succeed, specific error routines (meta-rules) force application of the rule by systematically relaxing its constraints, or they may augment the grammar with rules which are capable of parsing ill-formed input (buggy rules) and which apply if the grammatical rules fail (see [Liou 1991], [Weischedel 1983]). With feature grammar formalisms, they may also alter the unification algorithm itself such that in the event of conflicting feature values the parse does not fail, but instead applies a different set of procedures [Hagen 1994]. In particular, parsers designed for language instruction typically contain components which search for errors in the event that the grammatical rules are not successful.

Unlike other systems, the German Tutor does not seek errors, but instead records whether or not grammatical constraints are met. The system returns structures which provide possible feedback and student model updates of different level of specificity. The computational analysis reflects the underlying pedagogy of the system. The goal is to analyze students’ language input rather than the more modest requirement to recognize ill-formed construction.

The German Tutor is written in ALE (The Attributed Logic Engine), an extension of Prolog. ALE is an integrated phrase structure parsing and definite clause programming system in which the terms are typed feature structures. Typed feature structures combine type inheritance and appropriateness specifications for features and their values [Carpenter & Penn 1994].

The grammatical formalism used is derived from Head Phrase Structure Grammar [Pollard & Sag 1994], a unification-based grammar theory. It is one of a family which share several properties. Linguistic information is presented as feature/value matrices. Theories in this family are to varying degrees radically lexicalist, that is a considerable amount of grammatical information is located in the lexicon rather than in the grammar rules.

3. Program Architecture

The pedagogical goal behind the German Tutor is to provide error-contingent feedback and allow for individualization of the learning process. For example, if a student chooses a wrong article in German the error might be either incorrect gender, number, or case. In such an instance the program must be capable of distinguishing between the three error types since “... for almost all cognitive learning, instruction is enhanced by evaluative feedback” [Venetzky & Osin 1991, p. 9]. In addition, inexperienced students might require detailed instruction while experienced students benefit from higher level reminders and explanations. To achieve this, the German Tutor, consists of four components: the Domain Knowledge, the Analysis Hierarchy, the Student Model, and the Filtering Module, given in Figure 1.
3.1. The Domain Knowledge

The goal of the parser and the grammar is the generation of phrase descriptors. A phrase descriptor is implemented as a frame structure that models a grammatical phenomenon. Each member of the frame consists of a name followed by a value. For example, number agreement of subject-verb in German is modeled by the frame [number,_] where the underscore represents a value for each number. Consider examples (1) and (2):

(1) *Die Familie gehen nach Paris.

(2) Die Familie geht nach Paris.

*The family is going to Paris.*

The phrase descriptor for (1) is [number,error], while that for the phrase in (2) is [number,none]. A system presented with (1) will instruct the learner on the nature of number agreement while the successful number
application in (2) will be recorded in the student model.

In addition to the grammatical features defined in HPSG the grammar uses a type descriptor representing the description of the phrase that the parser builds up. This type is set-valued and is initially underspecified in each lexical entry. Thus descriptor not only tracks whether the input is ill-formed but also records whether the sentence is grammatical. During parsing, the values of the features of descriptor are specified. For example, one of the members of descriptor, vp_num in Figure 2, tracks the number agreement of subject-verb in a main-clause. Its value is inherited from the sg feature specified in the verb geht.

\[
\begin{align*}
\text{cat} & \left[ \text{head v} \right] \\
\text{content} & \left[ \text{index} \left[ \text{num} \left[ \text{sg 1} \right] \right] \right] \\
\text{descriptor} & \left[ \text{main\_clause} \left[ \text{vp\_num 1} \right] \right]
\end{align*}
\]

Figure 2: Descriptor vp_num of the verb geht

3.2. The Analysis Hierarchy

The second component of the system is an Analysis Hierarchy. The purpose of the Analysis Hierarchy is to take phrase descriptors as input and generate possible responses that the instruction system can use when interacting with the learner. A response is a pair that contains a message the system will use to inform the learner if a phrase descriptor indicates there has been an error and a student model update. The student model update is a name of an error category in the student model with an increment or decrement.

The Analysis Hierarchy generates sets of responses of increasing abstraction. As an example consider the ungrammatical phrase in (3). An experienced student should be informed that Ball is a masculine noun, that the preposition mit is a dative preposition and that the determiner der is incorrect. A student who has mastered case assignment (as indicated by the student model) may be informed only that the case of the prepositional phrase is incorrect.

(3) *mit der Ball.
    mit dem Ball.
    with the ball.

The Analysis Hierarchy is implemented in DATR [Evans & Gazdar 1990], a language designed for representing multiple inheritance. The language is well suited to constructing responses from phrase descriptors. The Sussex version of DATR is implemented in Prolog and consequently the interface between the parser and the Analysis Hierarchy is a natural one.

3.3. The Student Model and the Filtering Module

The two remaining modules of the German Tutor are the student model and the Filtering Module. The student model keeps track of the learner history and provides learner model updates. On the basis of the learner model, it decides on the specificity of the feedback messages. There are three different kinds of learner levels considered in the system: the novice, the intermediate learner, and the expert. The student model passes feedback messages to the Filtering Module suited to the level of the learner.
The Filtering Module has two tasks: it filters all parses and feedback messages. Due to language ambiguity parsers generally produce more than one interpretation. The first task of the Filtering Module is to decide on the desired parse. The second task is to determine the order of the feedback messages showed to the learner. The Filtering Module displays one error at a time and once the student makes the required correction, the whole evaluation process starts from the beginning.

4. Conclusion

The system described is the grammar component of a Distance Education course for German on the Internet. The German Tutor creates error-contingent feedback and learner model updates of different levels of specificity thus allowing for individualization of the learning process. The German Tutor contains grammatical constructions of an introductory course for German although at this point the lexicon is limited and needs to be expanded to fully encompass students' input in such course.

The suitability of the computational analysis used in the German Tutor is two-fold: first, the grammar is sufficiently general that it does not distinguish between grammatical and ungrammatical input for the phenomena it is designed to handle. This generality has the advantage of reducing the number of rules required by the grammar. Second, the decoupling of the parsing system from analysis of whether or not the input is grammatical has the practical advantage that development of each can proceed independently.

Abstract: In this paper we introduce a new application called multimedia annotation, which is currently developed in the EU-funded ACTS project DIANE. We describe a system for instant multimedia authoring with special features for supporting the creation and annotation of multimedia documents in a distributed working environment e.g. distance education. It gives both teachers and learners the capabilities for multimedia authoring, which makes learning to a collaborative effort with the important feedback from the learners to improve the quality of the teaching material.

1. Introduction

The decreasing cost of computers with multimedia capabilities and the increasing availability of high-speed networks like ISDN or ATM emerge new possibilities for distance learning and teaching concerning the use of multimedia [Abowd et al. 96, Muehlhaeser 95, Luther 94, Edwards et al. 92]. Several approaches how multimedia can be used to support teaching at universities and schools were proposed (virtual university, authoring on the fly, use of whiteboard applications as a replacement of chalkboards) [Ottman et al. 95, Bacher et al. 96, Bacher et al. 97, Will 96, Will 97], but they are often not general enough to be applied to other distributed working environments without problems or changes.

The possibilities of multimedia allows to adapt the content of a teaching course to the preferences of learners, but in a distributed learning scenario this flexibility is not taken into account due to the missing contact between teachers and learners: a teacher in a classroom scenario can vary the content or the structure of his course or lessons according to his experience with the learners and can fine-tune or adapt the course to the specific needs and interests of the students. In a teleteaching scenario this possibility of positive feedback is very limited, although it would enhance the quality of learning considerably.

Most teleteaching courses on the Web are HTML-based documents [Langenbach et al. 97, Kutschera 96]. The only possible feedback of the learners is email to the teachers or WWW-based forms to allow suggestions or questions. Both methods have the drawback that they are completely text-based and referring to the course or its content is difficult.

Teletraining and distance education typically require a lot more preparation time than traditional classroom teaching. Incorporating the feedback of students and the adaptation of the course are features, which would result in an enormous increase of time for course preparation.

The annotation system [Fischer 96, Benz et al. 97a, Benz et al. 97b, Benz et al. 97c] described in this paper is being developed in the project DIANE.¹

¹ The project DIANE is being funded by the European Commission under the ACTS Contract AC082
Actually, a system based on annotations offers a solution to the problem above: the course material can be annotated by the students with all the media available, each part of a document can be referred to or changed by adding questions, suggestions, thoughts or comments. This feedback of the learners results in annotated documents, which can be taken as the basis for a refined course. This interaction between teachers and learners is an essential point for improving the quality of the teletraining material. The learners are not left to study by themselves, but get tutors assistance and are able to collaborate with other participants of the course via DIANE.

The teacher plays more the role of a coach or moderator (as in moderated newsgroups) for providing the basis for a discussion, while the final course material with all the contributions from the students itself is developed during the lessons and is more or less a by-product of the learning process. This approach has turned out to be very successful especially in collaborative working environments as it can be seen from the increasing number of newsgroups and mailing-lists, which support the annotation feature in a text-based form. The extension of authoring to a variety of media as offered by DIANE results in flexibility in the selection of the appropriate media and a shorter document creation time both for instructors and students.

2. The Annotation Engine

The engine shown in Fig. 1 can be seen as a series of players, each one capable to present a multimedia document. The synchronised output of the players is sent to the various devices in the system: audio, mouse display, windows system, etc. The annotation process, however, implies the creation of a new document Di+1 based on the presentation above plus additional live media (such as audio, application output, video, etc.). The new document is stored in the document database.

![Figure 1: The annotation engine](image)

The set of documents D1, D2, Di feeding the players in Fig. 1 are not selected arbitrarily; they represent a thread linked by special links, the annotation links. Assuming in this example that Di is an annotation of document D2, the semantics of the link Di->D2 is to combine the presentation schedules of both documents.
according to time and spatial reference points (created while recording Di). Therefore, when the user selects Di for presentation, the engine loads Di, D2 (and recursively D1 since D2 is an annotation of D1), resolves the references and creates one, combined presentation schedule.

3. System Usage

The annotation system was designed to be general and support almost any distributed working environment. Other multimedia authoring systems have the drawbacks of being either too application specific, too complex to use, or have no support for distributed environments.

These limitations are not present in DIANE:

- application output recording (screen grabbing) in a continuous or frame-by-frame mode creates a media which is integrated into documents in form of an animation or slide show. Therefore, any external, available tools can be used for authoring.
- the user interface to DIANE follows the VCR paradigm, being easy and intuitive to use.
- the client-server architecture with a central server for document storage and management and clients for authoring and annotation is appropriate for distance learning.

Annotations in DIANE are comments, suggestions, thoughts, questions or markers realised with text, images, slide show, video, audio, mouse movements). Actually, DIANE can handle and retrieve multimedia streams from various sources like camera, microphone, applications screens or files without the help of third-party tools. This makes it particular easy for a user to integrate any media object into his documents.

A DIANE document with slide show media (collection of frames from the screen output of an application), audio, pointer, text and image can be seen in the following figure. The VCR-type buttons on the top of the window allow the replay, pausing and recording of annotations.

![DIANE Document Viewer](image)

**Figure 2: DIANE Document Viewer**
Annotating a document like the one in Fig. 2 is done by pressing the (red) annotate button. The presentation is paused and a new document with the original and new media is created. The added objects become visible when the replay time of the annotated document is equal or greater than the annotation time.

4. Use of DIANE in distance learning scenarios

DIANE is also well suited for various learning scenarios and can be customised to any working environment when necessary. In order to answer the needs of data security in corporate environments like companies, hospitals or research centres, authentication and encryption of the communication over the network has been combined with a role-based access control applied to each document. Thus, viewing of whole threads of annotations can be restricted to certain closed-user groups.

The first step in distance education is always the preparation of the course material. The system is content neutral and provides:

- hyperlinks for linking DIANE documents
- media recorders for the integration of text, graphics, video, audio, application output, mouse pointer movements, markers on arbitrary positions in the document
- integration of HTML documents in a DIANE document

In addition to the annotation link semantics mentioned in section 2, a hyperlink with a similar behaviour to that of a HTML link is provided: if the link icon is pressed during a certain (visibility) period, the presentation is interrupted and the new target document starts playing; otherwise the presentation is continued. This feature allows it to combine documents in a common context without displaying them simultaneously (e.g. examples, references).

The integration of HTML documents makes it possible for the multimedia author to use the elaborate text formatting techniques of Hypertext or to include already existing WWW documents without changes. Additionally to these generic functions, the instructor can also grab any portion of the computer screen displaying for example the output of an application or third-party tool and integrate it into a document. This feature is of particular interest, when instructors, as experts for a subject, intend to teach the use of special applications not available to the learners. Therefore, application output recording removes most restrictions on the subject of a teaching course, provided that the material is available in digital form (data or computer application).

On the other hand, the general document model used in DIANE can pose some problems to authors of educational material. An annotation document has always a time dimension extending static documents (text, HTML). This feature requires the authors of multimedia documents to think spatial and temporal dimensions (an displayed object, i.e. a window can not only be placed somewhere in the document, but appears at a specific time during the replay).

Nevertheless, the annotation feature reduces the gap between traditional and multimedia document composition by letting both tutors and students insert intuitively media during the replay of annotated document solely through the use of VCR well-known controls. Instructors do not have to build up a perfect teaching course from the beginning, they can do it gradually (e.g. it would be sufficient to create a minimal multimedia course containing no more than essential keywords like in transparencies with a soundtrack containing explanations of the teacher). This flexibility reduces the production time of multimedia documents considerably without reducing the quality of the course.

The second step in the teleteaching scenario with DIANE is the information exchange between teacher and learners based on the course material created in the first phase, and as mentioned above, this step is also an update and online-refinement of the course according to the special needs of the learners. DIANE offers the same capabilities for multimedia authoring to all users regardless of their roles. The same recorders necessary for integrating multimedia objects in the document, can also be used for annotations. The annotation feature of DIANE favours the asynchronous usage and is therefore appropriate for on-demand learning, learner support,
courses and lectures without losing the collaborative element. In addition, synchronous sessions which make use of videoconferencing and application sharing applications can also be annotated for later processing. The annotations of one learner can be made visible to the instructor, but also to other learners. Therefore, the information flow occurs not only between teacher and learners, but also between learners themselves, which is as important as the first one.

5. Conclusion

The DIANE user combines the roles of provider and consumer of multimedia information (or teacher and learner in a teleteaching scenario). Therefore, both sides can play an active role in the learning process, which is closer to traditional classroom teaching with its synergetic potential. Through annotations, we have not only a way of producing educational content, but also building teaching scenarios and incorporating the collaborative component of conventional classroom education. DIANE is being currently tested at VCPC with respect to the preparation of courseware for parallel programming tools and methods and to its ability to use this courseware in collaborative teaching sessions with students. Collaborative work scenarios are tested between two researchers teams in Vienna and Graz using broadband ATM network.

A EuropeMMM catalogue is designed specially for teachers and trainers who need to save time and effort in putting together courses which include multi-media elements. Authors and educators can select multi-media material from such catalogue and produce their own custom material for teaching or other purposes. Through the use of EuropeMMM and W3, RBL becomes widely accessible to students while at the same time reducing the costs of production through shared intellectual capital.
In this paper we describe how EuropeMMM (http://wbt.iicm.edu/EuropeMMM) allows authors and educators to select multi-media materials from a central, transnational W3 site to produce their own custom material for teaching or other purposes. We also provide details on how multi-media content can be contributed to the central repository.

1. Introduction

The issues of teaching, productivity, and instructional technology can be considered from a number of differing perspectives. The need for increased productivity in tertiary teaching is driven by an internet-based, international level of competition and constrained institutional budgets. It would appear that more instruction must be delivered to more students in more physical locations within existing budgets or there will be significant restructuring within academia.
Marketplace forces have come to the ivory tower. Fortunately technology may have a role to play in the solution. The Dearing Report [Dearing, 1997a] has noted a need to shift from teaching methods with high variable costs to those with lower variable costs. It also noted that investment in new technology has led to higher costs but without immediate improvements in efficiency. Teaching methods were considered across three major categories: lectures, small groups and resource based learning (RBL) The argument that institutions must increase enrolment without encountering a high marginal cost for each additional student is supported by the analysis of costs associated with the development of resource based learning. RBL, as defined by Dearing, is a combination of lecture notes, courseware, CDs, and customised spreadsheets - not the powerful multi-media products currently available. Yet the financial impact of RBL is such that adding interactivity and communications technologies to a course of study, with its attendant increased development costs, can be realistically amortised over a larger student enrolment. The net result
is "a better cost curve that is capable of withstanding expansion". [Dearing, 1997b] The optimism for an RBL solution to the cost / service squeeze may be overly optimistic given a stated maximum 200:1 ratio for development time to a student's time-on-task (contact time). Industry experience would place Dearing's development ratio in the lower quartile based upon our current capabilities for highly interactive, multimedia products. [Golas, 1994] Thus, development costs could be much greater; in fact, by a factor of three. Fortunately, the Dearing Report embraces the notion that RBL can be developed using internal and external resources and a mixture of these sources. Change agents in education and industry well understand the impact of the NIH syndrome. For personal and practical reasons instructors insist on adding their own content - placing their personal *imprimatur* on the deliverable.

Fortunately, instructional technologies can make a positive contribution to RBL by allowing the instructor to mix and match materials developed by themselves or departmental colleagues with resources developed elsewhere.

It has been argued that information technologies (IT) have not resulted in the expected increase in productivity. [Landauer, 1995] [Hitt and Brynjolfsson, 1996] In several studies, thousands of US companies have reportedly not received the expected benefits from their IT investment. Yet in less than ten percent of the cases was the problem traced to technical reasons. The principal reasons were found to be human and organisational [Griffith and Northcraft, 1996]. In education, instructional technologies often fail because of a lack of subject matter expertise, peer review, student (end-user) involvement, and multi-faceted usability testing. [Mauldin, 1996].

2. EuropeMMM

A EuropeMMM catalogue is designed especially for teachers and trainers who need to save time and effort in putting together courses which include multi-media elements. Authors and educators can select multi-media material from such catalogues and produce their own custom material for teaching or other purposes. Through the use of EuropeMMM and W3, RBL becomes widely accessible to students while at the same time reducing the costs of production through shared intellectual capital.

Reuse of MM materials means to be able to use a piece of such material in different contexts. Generally, the term “different contexts” can be seen as different parts of a single application or different systems. In this paper, we discuss only the later part of the definition – reuse in different applications.

The main motivation for reuse is cost. Producing quality multi-media material is expensive and time-consuming; thus, using the same material for several applications is important, since the new applications will require less time for their development and will cost much less than developing their content totally from scratch.

Finally, reuse may be implemented with two techniques, *by-reference* or *by-value*. By-reference means that an item is referenced from two or more different contexts. By-value means that at least two copies of the same item exist in different contexts [Garzotto, Mainetti and Paolini 1995] [Garzotto, Paolini and Schwabe 1993].

Since the project deals with generating new applications we consider the By-value reuse as the most likely method.

A system to support Net-based reuse of multi-media materials requires at least three components:

- a mechanism that allows individuals to access, search and browse the catalogue of existing multi-media materials to locate items of interest;
- a simple yet powerful reuse engine which allows users without any additional know-how, to reuse multi-media components;
- an interface which allows different authors contribute to the catalogue.

In this paper we describe these three components as they have been implemented in the project. It should be especially noted that the current interface, as it is presented in the paper, has received many critical notes from users and currently is a subject of re-consideration.
2.1 Browsing the Catalogue

The catalogue is built as a hierarchy of so-called indexes of reusable MM Materials. The following toolbars are used for navigating:

- Description: This is a collection of Animations, Still images and textual fragments which are supposed to be reused for preparing Introductory courses on the Internet.

Introduction to the Internet

- 01. Internet connects computers
- 02. Internet is a network of computers
- 03. Internet is as a collection of resources

Pragmatically, the internet is as a collection of resources that can be reached from those networks.

Animations: □ □ □
Still Images: □ □ □
Texts (HTML): □

Note, the search engine on the left side toolbar which provide a convenient possibility to access a MM material of interest.

2.2 Reusing MM materials from the Catalogue

The catalogue serves so-called registered EuropeMMM authors. Each registered EuropeMMM author receives a particular User ID and Password from the catalogue administration.

The EuropeMMM authors are supposed to create their own online courses by means of reusing the material available from the catalogue. Each course created with the system, gets a unique name which is an course ID. Thus, an author having ID "Course_1" is working on the course named "Course_1". Of course, one and the same person may ask for different IDs to work on different courses. Each course is a sequence of so-called pages. Pages have names (i.e. titles) and are sorted in the ascending order of their names to automatically generate links for the forward and backward traversing of the course. Thus, for example, if there are three pages named "page_10", "page_20" and "page_30", each will be presented in the same order to users.
Pages can be created from scratch and uploaded into the server, or pages can be created by means of reusing MM materials from the supplementary catalogue. The process of reusing multi-media material is a fairly simple one: whenever a user accesses reusable materials that are suitable for a particular course, he/she might press a button "reuse", and a special form containing 5 fields appears:

- **Personal Locker/Personal Course** - appears automatically and corresponds to the current user's ID;
- **Title for the New Page** - a very important attribute, since it defines an order of pages within the course. (In a simple case, authors can use the following naming schema: Page_xx where xx is a number defining a relative position of the page.)
- **URL** - this field can be used by advanced users to provide direct access to some pages;
- **HTML Text / Plain Text** - actually this an author's main contribution. It is the "content" or explanations for students. It is also possible to mix existing MM material (from another source) with the author's own HTML material. The author's contribution (in HTML) may have been prepared by means of some other system, editor, or application.
- **Layout type** - defines how the applet will be mixed with your explanation. Currently there exist four predefined templates, but this number is easily extendable.

Once these steps have been completed the author is only one mouse click from the creation of a new, good looking HTML page.
Once, Jack visited a computer-supported talk and was fairly impressed.

True EuropeMMM Story

Please note that the reusing mechanism mentioned above can be applied recursively to add more MM or HTML elements to such documents.

2.3 Contributing to the Catalogue

Contributing to the catalogue can be seen as a threefold task:

- the author physically uploads a multi-media element into the server and provides some guidance for visualisation the file and embedding it into HTML documents;
- the author places the file on a particular position within the hierarchy of catalogue indexes;
- the author provides necessary key words to simplify locating of the material by means of the search engine.

Contribute to the EuropeMMM Catalogue

EuropeMMM utilises a simple approach to these three tasks. Thus, the system supports a list of so-called registered formats. There is no need for authors to define any additional rules for visualisation and/or reuse of files belonging to such registered formats. Obviously, such standard MM elements as still images, sound, movies, etc. are automatically recognised and uploaded using special predefined rules.
Moreover, the system automatically assigns a necessary plug-in, determines the geometrical configuration and sets up other additional parameters for such external MM applications as Shockwave, Authorware, Flash, MM Toolbook, HM-Card and many others. Thus, in the case when an author is intending to contribute with a file in such standard formats, only a name of particular file residing on a local drive needs to be specified (see the uploading form above) and the system determines all other parameters automatically from the known extension. There exists also a rather sophisticated form for defining a new MM format (which is not discussed here).

The system uses the current user's position within the catalogue as a default place to insert information on a new contribution. If the author is not satisfied with the current position, it can be modified using the combobox on the top of the form.

After successful uploading of the new file into the catalogue, a special form is offered to define a description of the material including list of keywords.

3. Conclusion

EuropeMMM is an environment to assist instructors and institutions in improving instructional design and instructional delivery through the cooperative development and exchange of instructional content. Using vehicles like EuropeMMM, instructors can move beyond the book and the lecture to better engage their students, and to generate in them a genuine enthusiasm for learning and self-discovery.

As it was mentioned above, while a general idea of creating a catalogue of reusable MM materials has been enthusiastically accepted by test users, the concrete user-interface solutions were a target for substantial critical comment.

It should be noted that system's functionality is based on CGI scripts and HTML forms which do not support such advanced GUI as click and select, drag and drop, etc. Hence, it was agreed to develop a new version of the user's interface using Java programming language and, hence, supporting all the advanced features mentioned above. We hope to report on the new version of the system at the next ED-Media conference.

Abstract

This paper reports on a collaborative CD-ROM project between an Intermediate Spanish class and Alándaluz, an ecological group in Ecuador. The main goals of this international class project were to integrate language, culture and literature around the theme of the environment and to establish a partnership with Alándaluz. A preliminary assessment of this 10-week class project suggests that electronic media development is a feasible curricular strategy to help the foreign language profession embrace cross-cultural communication and collaboration with communities at home and abroad.

1. INTRODUCTION

Foreign language professionals at the secondary and post-secondary levels lack a uniform vision regarding the role of modern technology in language teaching and learning. Between highly-publicized initiatives such as the development of the foreign language proficiency guidelines at the post-secondary level and the National Standards for Foreign Language Learning (NFLS) at the secondary level, educators have yet to agree on how to assist language students acquire the skills needed for the next millenium: linguistic, social and technological competence with an environmental conscience. This paper describes a cross-cultural CD-ROM project which illustrates how language educators can integrate modern technology along the NFLS, aim at enhancing their learners' overall proficiency and, at the same time, allow students to take part in an international, ecological collaboration.

2. LANGUAGE LEARNING: COLLABORATION THROUGH TECHNOLOGY

Following the publication of the National Standards for Foreign Language Education in late 1996 by a consortium of professional organizations under the leadership of the American Council on the Teaching of Foreign Languages (ACTFL), teachers have begun to emphasize language learning and teaching along five main standards: communication, cultures, connections, comparisons, and communities. These interconnected standards, also known as the five C's of foreign language education, clearly redefine goals and content of the foreign language classroom. Students are expected to:

- communicate in languages other than English,
- gain knowledge and understanding of other cultures,
- connect with other disciplines and acquire information,
- develop insights into the nature of language and culture,
- participate in multilingual communities at home and around the world. [National Standards 1996]

In order to help foreign language practitioners implement the standards, the ACTFL project team included in the publication a total of 34 learning scenarios from pilot sites across the country. Each describes the projects and the standards that were targeted. Surprisingly, many of the project descriptions fall short on collaboration and technology, the very two core characteristics that seem to connect all five standards.
2.1. COLLABORATION

Methodological, curricular, as well as professional needs have been the driving forces behind many collaborations. The NFLS as well as Collaborations, the title of the 1997 Northeast Conference report, are prime examples of such collaborative efforts. Two articles in Collaborations illustrate how teachers can target the national standards at the high school level through video materials [Schwartz & Kavanaugh 1997] and e-mail communication [Haas & Reardon 1997]. Both collaborations involved high school and university teachers and resulted in media and technology-enhanced projects on Guatemalan immigration and Chilean folk art. These two articles emphasize the cultures standard of the NFLS and show how video and e-mail can help integrate various curricular experiences such as reflection, critical thinking, and learning strategies. A recent example on how educators at the college level might employ e-mail to enhance student-student collaboration can be found in [Fischer 1996]. Using the metaphors of “tourist” and “explorer,” the author urges teachers to help students move away from superficial learning, the “tourist” mode, toward the “explorer” approach in which students engage in purposeful learning. All three examples suggest that collaboration has a social dimension. Moreover, it appears that collaboration, whether aimed at improving language proficiency or (cross-) cultural competence through working relationships among teacher and/or students rests on social interaction. According to [Skillen 1993], the construction of knowledge through collaboration is deeply rooted in the work of Vygotsky’s who claimed that social experience precedes all higher level cognitive processes.

2.2. LANGUAGE LEARNING TECHNOLOGIES

What is the role of modern technology in teaching and learning foreign languages? What should it be in light of the national standards and the fundamental importance of collaboration? These were the two main questions that guided the design and implementation of the CD-ROM project with Alándaluz.

Regarding the first question, several of the publications on technology and language education over the last four years suggests that researchers and teachers have started to explore new ways of using technology. The contributing authors to Bush’s volume on technology-enhanced language learning [Bush 1997] voice optimism regarding the effectiveness of multimedia, the benefits of technology to enhance receptive and productive skill learning and in using technology to improve teacher education. In [Boswood 1997], the authors provide the reader with practical suggestions on how to use technology for word processing, desktop publishing, e-mail and MOOs, working with the web and other applications. The article by [DeWert & Heining-Boynton 1997] describes how technology literacy has become crucial in improving teacher preparation programs. [Finnemann 1996] and [Warshauer 1995] describe the potential of the Internet and the Web and illustrate how teachers and students can benefit from working with these technologies.

As to the second question, modern technologies should enhance the teaching and learning foreign languages according to the national standards. For example, [Garrett 1997] encourages teachers to use technology-based materials to enhance interactive language learning. Her recommendation clearly aims at the communication standard. [Moeller 1997] argues in favor of collaborative learning and exploring with technology as opposed to using technology merely for instructional purposes. The author advocates having students and faculty work together to determine the best use of technology in the language curriculum. A similar collaborative approach is favored by [Lange and Wieczorek 1997]. They invite teachers to (1) connect each project with a cultural aspect; (2) promote communication among the collaborators which uses purposeful, authentic language; (3) incorporate technology to allow students to see the real, global aspect of communication; (4) help their learners make connections to other disciplines, and (5) incorporate elements of action research with its key elements of reflection and action. As the next chapter will show, these suggestions were not only helpful in facilitating learning around the national standards, but also helped design around the project several elements of active collaboration.
3. THE VISTAS ECOLOGICAS CD-ROM PROJECT

3.1. DESCRIPTION

This CD-ROM project was conducted during the Winter Quarter of 1998. Over a period of 10 weeks, second-year Spanish students at Santa Clara University (SCU) worked together with Alándaluz, an ecological center on the coast of Ecuador. For the partner in Ecuador, the development of the CD-ROM was one of the motivating factors; however, the group also wanted to promote its ecological philosophy regarding self-managed and self-sustainable local community development among students in the United States. As described in the previous chapter, the main goal for the Spanish class was to target the national standards; however, since learning about Ecuador in second-year classes and textbooks is often reduced to abstract summaries and brief chapter notes, a secondary goal was to show the country's rich cultural patterns and traditions around the theme of the environment. For this purpose, the various ecological groups which form Alándaluz (a hotel and restaurant, a construction company, a biological farm, and a travel agency) turned out to be very beneficial. In support of the overall course goals and to frame student learning and project development, the following objectives were developed:

- obtaining information from Ecuador in Spanish using e-mail
- providing feedback to written communication in Spanish and to report responses orally to class
- group discussions of articles from abroad on the environment
- designing Web pages and pressing the beta CD-ROM
- establishing a cross-cultural collaboration.

Based on the motivation and particular needs of both partners as well as the availability of unique resources/skills on either end—subject-matter expertise and print/video information about ecology (Alandaluz) and technological resources and development/instructional time (SCU)—the goal was to make the Vistas Ecológicas project a mutually beneficial collaboration between North and South America.

3.2 IMPLEMENTATION

The Vistas Ecológicas project was implemented in three stages: pre-production, production, and post-production. The actual development work was primarily carried out in the university’s multimedia lab, whereas the discussion of product rationale, content, and dissemination was integrated into the regular classroom. During the quarter, classes (of 65 minutes each) met twice a week in the regular classroom and once a week in the media lab. Since students were required to spend two lab hours per week on the project, they placed themselves into one of these five project (thematic) teams: Centro Alándaluz (lodging), Pacarina (travel), Amingay (consulting services), Lotización (housing development), and Cantalapiedra (biological farming). In order to provide ongoing support for the various teams, a resource expert as well as a student aid accompanied the CD-ROM development during all three stages. In light of the short development time, several arrangements had been made in conjunction with the university’s instructional resource expert. First, it was decided to develop the CD-ROM as a Web-based application to facilitate ongoing feedback from Ecuador as well as for the convenient and efficient pressing of the disc itself. Second, a shared directory was set up on each of the lab computers to give all student team easy access to the resource materials. Third, an account on the web server was established for each project team to store all the data and files (image, text, video) in the lab. Finally, Front Page 98 was chosen as an authoring tools because of its easy of use.

Pre-production began with setting up the five development teams each of which consisted of three students. After they had discussed in class the rationale for such collaborative products, each team began to examine the available resources from Alándaluz and to introduce themselves via e-mail to their collaborators. The students described their role in the project and included several questions about each of the center’s different activities. By the end of pre-production, they all had received responses from Alándaluz and were eager to start the actual development process.

The production stage began the second day of the third week. In class, students had just finished reading web articles on the floodings in Ecuador and the draughts in Colombia caused by El Niño, when the first delay occurred. As it turned out, this weather phenomenon led to dramatic emergency measures in Ecuador and severely impacted the communication between SCU and Alándaluz. For two weeks, the e-mail contact between
the two collaborators was interrupted. In the meantime, however, the student aid was able to design with each project team a template to give each project a uniform appearance. During this “outage,” students digitized segments from a promotional Alándaluz video and scanned postcards that had arrived from Ecuador at the beginning of the quarter. Fortunately, by week six, students once again received e-mail from Alándaluz via Quito. While they were pleased to receive more content information and a few design suggestions, the news about the structural damage El Niño had inflicted on the hotel, the farm, and the beach was terrible. The last two weeks of the production phase, student were asked to incorporate an “interactive comprehension” element into their project pages. Students were reminded that their collaborator did not want an electronic travel brochure but an interactive medium that was promotional as well as educational. With this in mind, and with more content to work with, all five teams developed such a comprehension feature. Not surprisingly, the most popular feedback format was called “examencito.”

Week nine marked the beginning of the post-production stage. All teams were asked to correct their pages for content and linguistic accuracy and to remove all hyperlinks from their projects. With the help of the student aid, this worked rather well. The last week of classes, members of each team reflected in class upon the value of such cross-cultural collaborations, the problems they encountered and how this project may have helped them gain a better understanding of environmental challenges from a Latin American perspective. Before pressing the final version of the CD-ROM, all project pages were proofed one more time and a preliminary copy was pressed. The following week, students then pressed their own personal copy of the final beta version of the CD-ROM.

3.4 RESULTS AND DISCUSSION

To what extent did the Vistas Ecológicas class project meet some of its ambitious goals: targeting the NFLS, facilitating local and international collaborations, and incorporating modern technology? In order to answer this question from several perspectives, this section includes observations from two students who were invited to comment in writing on their overall experience with this project-driven Spanish class.

Regarding the NFLS, students were able to address the communication standard. Using e-mail to request information in Spanish from the partners in Ecuador and making reports in Spanish to their classmates helped the students to practice written as well as spoken Spanish. However, both students indicated that they would have preferred a complete immersion experience even to the point of exclusively using Spanish in the multimedia lab. One of them wrote: “I feel it is crucial to use the time of technological integration to the learn the language more fully.” In targeting the cultures standard, students read information about the ecological efforts of Alándaluz and other groups in Ecuador. They also discussed newspaper articles on this topic in class. It appears that learners increased their cultural knowledge about Alándaluz as well as Ecuador. Did students gain cultural understanding? Judging by one of the student comments who wrote that “I was challenged to discover that technology could be used to promote the conservation of the environment, contrary to the many fears that the technological world will overrun the natural world,” it seems that this student’s reflection did allow him to understand part of the environmental philosophy of Alándaluz. As to the connections standard, students clearly recognized the link between the Spanish component and the environment. One of students found the project interesting because “we were working directly with people who were thousands of miles away... I learned a great deal about Ecuador and the challenges they [Alándaluz] are experiencing due to environmental dangers.” Moreover, this experience allowed learners to compare environmental efforts underway in Ecuador to the several ecological controversies in their home states. This comparisons standard helped learners develop insights in the nature of language and culture. For example, following the bad news from Ecuador, students were asked to discuss how newspapers in Ecuador described the reactions of the people in the affected area to these three forms of precipitation: lluviza (drizzle), aguacero (downpour), and tormenta (thunderstorm). Finally, this project reflected the communities standard. At SCU, students created a multilingual community and communicated with the various Alándaluz communities in Ecuador. As one student described it, working directly with Alándaluz allowed her to receive “the most up-to-date information as possible” and to gain “real-life experience.”

Did the project facilitate both a local and international collaboration? What began as a working relationship between SCU and Alándaluz, soon showed signs of a partnership. A few of the students realized that the process of collaboration was more important than the final product. However, as one of the student comments illustrates, the majority of them was more interested in the product: “Some of the development
groups did not receive information until very late in the development process. This hindered their ability to effectively create a product according to their wishes.” Of course, the hope was that students would demonstrate an awareness of the cultures and communities standards and the importance of collaboration for building cross-cultural competence. At the local level, students proved to be more versatile collaborators. Most students interacted well with each other in their respective teams, with the exception of one group as this student comment highlights: “...when working with a group, one always runs the risk of having a group that does not work well together. However, this is one of the difficulties the group must overcome if they wish to be successful.” Indeed, that group finished their work as well.

Finally, with respect to integrating modern technologies into the Spanish class, the project seems to have achieved this goal. A preliminary appraisal suggests that technology did not override the course objectives of the class. At the same time, the overall course theme—ecology—was integrated in such a way into the regular classes that it provided constant thematic links to the development work in the multimedia lab. For example, students could easily see how the discussion of the role of nature in a specific short story related to some of the environmental issues they described in their own development groups. Of course, it took learners several weeks to recognize some of the advantages of incorporating technology into the Spanish class. Selected student comments indicate that they were initially skeptical and apprehensive as to how both components would fit together. Looking back, one student wrote: “Upon entering a Spanish class that included the use of technology, I was skeptical of how the class would function. I had never used any recent technologies in any high school Spanish class... I feel that the whole class learned the basics of how to use technology in an integrative learning process.” Toward the end of the course, Initial uneasiness about using technology had turned into proud ownership of having created a CD-ROM. This became evident a few days prior to pressing the trial CD, when one student brought a friend to the lab to show off her group’s work.

4. SUMMARY

The Vistas Ecológicas project has shown how teachers can modify intermediate-level Spanish classes in order to target the national foreign language standards. Through technology-enhanced learning projects, students can become involved participant learners and acquire, at the same time, the technological skills needed to become developers and teachers of their own.

The collaboration between SCU and Alándaluz has also illustrated the potential of international partnerships. Rather than simply leaving a partner empty-handed or merely learning about each other, such projects can pave the way for learning with each other.

Finally, technology-supported collaborations can empower the partners at either end and allow them not only to think globally and to act locally, but also to help them join forces on behalf of a common good, the environment.

Abstract: The paper presents findings demonstrating benefits of cooperation between a commercial multimedia production company and an United States elementary school district that resulted in a unique curriculum integration project. The results of the study indicate a positive impact of the curriculum-tailored, interactive multimedia simulation on both the teacher's perceptions and teaching methods and the Grade Two students' motivation, understanding, and thinking skills. Conclusions based on the results should assist curriculum designers, teachers, and multimedia producers achieve better integration of educational software in school curriculum.

During the last decade we have witnessed a significant rise in the number of computers in schools and in the amount of sophisticated instructional software in the commercial education market. However, the integration of educational technology in school curricula still lags behind earlier expectations. Several reports and researchers [Drazdowski 1997]; [Maddux, Johnson & Willis 1997]; [Szabo & Schwarz 1997] have tried to explain this gap, usually in terms of a failure by colleges of education to expose students to educational technology and to train them adequately in this area, budget limitations, the teachers' fear and reluctance to incorporate computer technology in their classrooms, and infrastructure organizational difficulties. These explanations ignore the relationship between software producers and educational consumers (schools, teachers, and students). An alternative explanation - and solution - for the limited success of educational technology in schools involves, not just the factors highlighted above, but the mismatch between available software and teacher requirements. Because teachers have increasingly to integrate commercial multimedia products into the existing curriculum, the products can inadequately fulfill the teacher's specific learning objectives. An obvious solution to eliminating the mismatch is a collaborative partnership between software producers and teachers. Some educational multimedia software companies acknowledge the possible mismatches and employ ex-teachers or consult practicing teachers. However satisfactory this practice may be in the resultant stand-alone educational CD-ROM, it still ignores the need for significant systemic and curricula rethinking and restructuring between the stakeholders and within their organizations: the software company, school boards or government education departments, individual schools, and teachers.

Such creative restructuring occurred between an educational multimedia producer and an American school district, its schools, and teachers. In 1993 the Plano Independent School District (PISD), Texas, decided to shift the teaching methodology and segregated discipline-based curriculum of its elementary school system into a thematically integrated, computer-based curriculum [Jacobs 1989]. Edunetics, a multimedia production company, was contracted to help redesign the curriculum, inservice teachers in the area of computer technology, and develop educational computer software that would serve as the backbone of the new integrated curriculum. The participating K-5 teachers were released part-time to work cooperatively with the pedagogical
and content experts in Edunetics. Together they identified 36 topics based on six themes stipulated in Texas-wide elementary curricula and structured around different core Organizing Ideas. In essence, the production process was designed so that the PISD teachers expressed their curricular needs. The multimedia company was responsible for translating those needs into a computer product. The collaboration represents a unique enterprise where an educational software company and teachers equitably shared decisions to produce digital and non-digital educational products that focus appropriately on curricula needs. Through such cooperation, the teachers were empowered through having a major stake in the conceptualization, content, and user-learner interface design of each CD-ROM.

Our project was not concerned with ascertaining whether learning with particular software produced better test scores than learning without the software. Rather, the research examined the incorporation of educational multimedia as part of a newly-designed integrated curriculum in the "messy" environment of a classroom over a period of time. The researchers were interested in how the use of the software impacted the classroom teaching-learning community. The paper focuses on particular aspects of the wider research, distinguishing between findings which contribute to (a) a clearer understanding of the learning process in an authentic context, (b) the teacher's role and the classroom computer culture, and (c) the production knowledge of the producer.

Methodology

The qualitative interpretive research was designed to assess aspects of the educational implementation of the PISD curriculum integration project. Dependability and confirmability of the data were enhanced through triangulation of varied data collection instruments; site engagement for the six week duration of the integrated curriculum unit; and researcher observations authenticated by video and audio taped data.

The research was conducted in a Grade Two class in one of the PISD participating elementary schools in Plano during the Spring quarter. The teacher had trialed the Beta version of “Message in a fossil” (MIF) in her Grade Two classroom two years before, and used the final product in the year previous to, our research. The class was chosen because it was the most ethnically and socio-economically diverse compared with those of the other volunteering teachers; even so, it was still significantly middle America. From the 20, seven year old students, the teacher was asked to select three, same-sex groups of two children based on ability. The study used these pairs for in-depth study. The outcome of the teacher’s selection was one pair of two high achieving female students; one of two low achieving male students; and the third comprised two male students, one high achiever and one low achiever. Based on research [Inkpen 1997]; [Inkenpen, Booth, Gribble & Klawe 1995], it was thought that for the scope of this investigation, mixed gender groups would provide one too many variables.

The software, MIF, is a simulation [Rieber 1996] in which the student is a paleontologist who excavates in virtual grid dig-sites, discovers plant and animal fossils, predicts what they might be, identifies them by comparing them with those in the fossil collection, and, based on the uncovered fossils, reconstructs the prehistoric world by constructing a museum diorama. In this interactive environment, the student emulates a scientist and practices science skills. "Message in a fossil" was incorporated into a six week integrated curriculum unit with "Evidence" as the Organizing Idea. The major theme of the unit was gathering, interpreting, and communicating evidence to solve mysteries and problems, particularly those that inform our understanding of the past. For approximately 45 minutes each day, the class worked in stations where each small group activity integrated the Organizing Idea and theme across curriculum areas. One of these daily rotating stations was learning with MIF. The teacher also included MIF into the time allocated for reading. This meant that each student used the software each day for 20 minutes during reading, with some using it twice a day during their station activity time. In addition, when they finished other work children could choose to work with MIF, if a computer were free. The classroom had seven computers and a printer that were networked to a fileserver through which the children accessed the software.
Global data were obtained from pre and post, written and interview questionnaires with the students and teacher. The student written questionnaires were administered by the teacher who read out each question at a suitable answering pace for the children. The researchers felt that it was appropriate for Grade Two children to have test items that utilized hands-on activities which were administered via pre and post audiotaped interviews. Pre and post audiotaped, flexible open-ended structured interviews were conducted with the teacher. Data were also obtained from the teacher's anecdotal and assessment sample records. Indepth data were obtained by narrowing the research focus to the small sample of six students. Each student in the three paired groups was administered a pre and post open-ended structured interview. Additionally, each pair was video and audio taped and observed whilst working together on the computer: twice in the first week and once a week for the following five weeks. Based on the recorded observation notes, retrospective recall interviews were conducted by a researcher with both students at the end of each video and audio taped MIF session in order to prompt recollections of their thinking, reasoning, strategies, and feelings during the activity.

RESEARCH FINDINGS AND ANALYSIS

Student Learning Outcomes and Processes

Some of the findings are grouped into the following subthemes: acquisition of scientific concepts and processes; independent decision-making and conflict resolution strategies; and motivation and enthusiasm.

The first subtheme grouping is the students' acquisition of scientific concepts and processes. From the pre and post questionnaire test items, there was a 28% improvement in students' scientific conceptualization and processes. From the data it is clear that all the children could correctly identify a fossil from rocks at the end of working with MIF and the other Organizing Idea integrated curriculum activities. However, only 56% could verbalize how a fossil was formed. Although there was a video about the formation of fossils in the software, less than half the class appeared to have visited that site other than during the whole class tour.

Comparison of the pre and post tests revealed a significant improvement in the students understanding of the complex concept of decay and longevity. They were required to identify which of six items (an apple, wooden door, shark tooth, bread, a sea shell, a book), presented as labeled pictures, they could still dig and find if the items had been buried a long time ago. Of the six items, two were correct. Out of a possible 36 correct answers (2 questions by 18 children), 35 correct answers and 1 incorrect answer were recorded in the post test. This was a substantial improvement on the pre test results with 26 correct answers and 37 incorrect answers recorded.

There was improvement in the students' ability to sort items into logical categories. Logical categories included such things as "mammals" and "have fur" whilst illogical groupings were given labels like "all part of nature" and "the remaining animals". Out of 18 students, nine provided significantly more logical groups out of their total number of groups in the post test compared to what they had in the pre test. Seven students had the same number of logical categories in the pre and post interviews whilst two gave fewer logical groups in the post test. We also analyzed the students' answers in terms of the scientific groupings used in MIF. In the post test, all students used the criteria utilized in the software, with six using more software criteria in the post test compared with the pre test; three students used fewer categories in the post test. It would seem that MIF and the other activities helped most students internalize what constitutes logical and scientific criteria and how to appropriately categorize that criteria.

The simulation, MIF, required the students to construct dioramas with fossils found in various habitats. To ascertain their ability to conceptualize which fossils belonged in the same habitat, the students were presented with four labeled pictures of fossils and asked to identify the fossil that did not belong in the same habitat as the other three. There was an improvement of 17% from pre to post test.

The results of the children working with the same partners with MIF for the six weeks are worth comment. On the days when the research was not being conducted, the students either, with few exceptions, chose the same
partner or worked individually (Student interviews). There was an improvement in results from pre to post tests. In comparison with the classroom results some items revealed a significant difference. For example, as mentioned above, explaining how fossils were formed was answered poorly by the class; this makes the post test results for the pairs significant: 80% of the five students (one did not do the post test) answered correctly in comparison with 45% of the rest of the class. It is possible that the interactions between relatively permanent partners when working with MIF may have helped their understanding.

An analysis of an individual writing activity on dinosaurs and fossils that was set by the teacher at the end of the six weeks reveals internalization of content. The target was three facts - which they all achieved - and as much as they could write in five minutes. As the teacher pointed out, the topic was of "very high interest to them" so the quantity was no real surprise. Their answers did not reflect the traditional focus on listing the names of dinosaurs and the facts. They wrote more generally, even the lower achieving students. They talked about evidence and problem solving as well as correctly using paleontologist, diorama, and interdependence (a "buzz word for them"). Their writing included such things as: using a digging grid; measuring and labeling fossils; fossils were evidence that dinosaurs existed; "if you want to find out about them you can look at fossil remains"; the fact that "dinosaurs lived a long time ago and that some lived in the ocean and some on the land". A few students included the idea that dinosaurs and people did not live at the same time. Their writing overall contained high level information and embodied concepts presented in MIF and the other integrated activities.

Working with partners with MIF promoted student independent decision-making and conflict resolution strategies - the second subtheme. The teacher gave an example of the former: "Knowing where to go next, when to proceed to the next level of difficulty, and what to do if they couldn't finish their diorama at a single sitting, they totally took care of that themselves. And I've never had a group like that before. Usually, I spend the first few weeks hovering, giving directions." The students also resolved potential conflict issues about who to work with and how to work together equitably. For instance, sharing control of the digging and building the diorama were quickly decided and occasionally renegotiated amicably between the female and the high/low achieving male partners. However, in the second week the low achieving male partners took their shirts off and threw a few punches. As commonly reported in the literature (Inkpen, et.al., 1995), one of them explained that "we were trying to fight over control"; each took credit for solving their dilemma by being the one to establish taking turns on the mouse after each fossil find.

The third student learning outcomes and processes subtheme is motivation and enthusiasm. What the preceding discussion does not provide is any sense of the atmosphere or what occurred in the classroom learning community during the six weeks. The students' unanimous perceptions were that "you learned a lot" working with MIF, which was "cool", "lots of fun", "interesting", and "never boring". Data from the interviews, observations, videos, and teacher records confirm a consistently high level of enthusiasm, on-task behavior, friendly competition, supportive cooperation, use of appropriate language, and transference. There are three major interrelated reasons for these ingredients in the classroom learning climate and outcomes.

(i) Working with partners on MIF was the reason the teacher singled out as probably the most significant. All students mostly worked with partners and, depending on how they felt or the availability of their partner, they would choose to work with another person or, occasionally, alone. The six teacher-selected students were also allowed to choose other partners or work alone during non-research times. Irrespective of the set-up, there was discussion, requests for help, and unsolicited advise, between partners and neighbors as well as up and down the computer row.

In comparison with previous years, working with partners "made an incredible difference." Previously, it took the six weeks for any student in the participating schools to complete a certificate and it was "really frustrating for them ... I have never had anyone do expert level before." This year in the research class, there were certificates and dioramas at the end of the first week; by the end of the unit, a whole classroom wall was covered and all students had got to the expert level of difficulty. This permitted "better internalization of the vocabulary. They were not just listening by themselves; they were communicating" their understandings. Having partners "kept them focused" and provided "security so they could take risks" in their decision-making.
Working with partners also seemed to have an effect on the classroom learning culture: "They all wanted to get the dioramas and they wanted to get the certificates. But when someone put up a certificate everybody would hover around them: 'What did you get? 'What did you put in it?' 'Where did you find it?' You know, they really were interested in a very positive way, a very supportive way." (Teacher post interview). There was not so much a competition as a collaboration.

(ii) MIF itself promoted motivation and enthusiasm. The user interface design is unproblematic with meaningful navigational icons, and is enticing. The learner interface [Reeves 1993] contains various pedagogic elements that may have been influential in the children's learning outcomes. The software provides the necessary intrinsic motivational ingredients for an effective simulation: challenge, curiosity, fantasy, and control (Malone 1981); [Rieber 1996]. The children were "actually in control; they had so much ownership of it" and "felt like they were scientists doing it ... it was very real life for them" (Teacher post interviews). The challenge for self-improvement triggered further reading in order to do better in MIF. A number of students researched dinosaurs and fossil-related topics at home in order to "learn more about how to put the bones together" or "know what some of the things were when I got onto MIF."

(iii) The final contributing reason to student motivation and enthusiasm was the integrated curriculum. The teacher believed that MIF would produce meaningful learning outcomes if used as a stand-alone but its real value was enhanced through appropriate curriculum integration of software and other classroom activities. Indeed, one of the girls in the research pair explained that one reason she enjoyed MIF was "because it fits in with our integrated [sic]." The teacher further elaborated: "Even though Communication was the Overarching Concept and Evidence was our Organizing Idea, it was almost like 'Message in a fossil' was the organizing idea. It was the heart of everything." The teacher believed that this allowed them to make bigger connections within and between the activities.

The Teacher and the Classroom Computer Culture

This study identifies the teacher as a key component in the successful incorporation of computers and multimedia into the classroom. Her three year involvement in the PISD project had strengthened the teacher's enthusiasm for incorporating computer technology in the classroom: "I think it's the most wonderful thing that has happened ... and having the software that supports our curriculum has been fantastic, because it really makes a difference, particularly in what they [the children] like." Obviously, the number of computers was a bonus that supported the computer culture.

The research influenced the teacher's usual practices with respect to individual versus partnered work with the computer. Previously, all the PISD teachers using MIF decided that there would be a one to one ratio of child to computer: "We have wanted everyone to have, this American thing, you know, their own dig site; they had to own it." Because of our research request, the teacher changed strategies and organized for the remaining children to choose their own partners or work alone. During the post interview the teacher argued that partners allowed her to put into practice her pedagogic philosophy to maintain a facilitator role with an emphasis on student responsibility for their own problem solving. Instead of directing, data revealed that the teacher asked questions in response to the students' questions. Even when the paired low-achieving students resorted to throwing punches, the teacher suggested they solve their conflict in non-physical ways and (seemingly) confidently walked away. At the end of the six weeks, the teacher was adamantly committed to using partners when working with MIF and other similar computer software because "I can see nothing but benefits."

Contributions to the Production Knowledge of the Producer

The findings have practical and economic implications for multimedia producers. "Message in a fossil" is a pedagogically effective simulation, and could be viewed as an exemplar. Importantly, if the questions that were answered poorly on the post test are of curriculum significance, for example, how a fossil is formed, then
they need to be woven into the simulation more substantially. Teacher support materials could contain possible strategies for student to computer ratio usage.

Another issue for multimedia producers concerns a post questionnaire item that required students to link a picture of the computer interface icon with its topic label (e.g., Museum). Half the students incorrectly matched some of the icons. These incorrectly identified topics (including fossil formation) were extraneous to competing the diorama or achieving the three certificate levels. Only seven students said they visited these topics. This implies something about the willingness of students, at least Grade Two students, to diverge from the mainstream of the simulation activity. In such cases, the educational multimedia producer has options: if the content is considered important, then it needs to be a mandatory part of the simulation rather than nice-to-have extension activities; decide to exclude these non-simulation sections thereby cutting production costs; or produce a multipurpose CD-ROM, like MIF, that combines a simulation with an extension database for multi-age level usage.

**Conclusion and Challenges**

The research suggests that producer-teacher cooperation in the planning and development of interactive multimedia products has a number of positive outcomes that could help redress the reluctance by schools and teachers to incorporate more extensively educational software into the class curriculum. First, the software that was produced proved well-tailored to curricular, teaching, and learner needs. Second, classroom implementation of the software in the way in which it was intended, i.e., within an integrated curriculum, produced positive outcomes in terms of students' content knowledge and process skills and the teacher's teaching strategies. Third, the interactive multimedia simulation and the use of computer partners promoted a classroom computer culture and learning climate that was enthusiastic, motivated, and cooperative. Of course, there are limitations in generalizing this study. To augment the findings, further research is planned in various classroom contexts; for instance with differing cultures and grades, teachers with little to advanced computer expertise, and using the software as a stand-alone activity compared with its incorporation in an integrated curriculum.

Abstract: The paper explores the runability cause-effect patterns of teachers’ mental models when involved in one-on-one teaching-learning episodes using electronic resources in the context of authentic school assignments. The findings describe where variations existed in the mental models with respect to the perceptions of themselves as teacher and learner with electronic databases, their students, lesson planning, teaching strategies, and goals.

Introduction

Economic, political, and educational progress depends on strong electronic information literacy skills for global access and effective use of information. Productive teaching of computer-based electronic resources requires teachers to have appropriate mental models or schemas of the characteristics and protocols of these resources and strategies to teach effective access, research, and retrieval skills to meet individual students' needs. One method for constructing an appropriate teacher profile paradigm is to explore those mental models in situ. This involves studying changes to the schemas during and after teaching episodes. It also requires a further step that is usually not taken in mental model computer database studies. The paper demonstrates that formulating a relevant teaching paradigm involves examining the impact of changes in one mental model on another mental model or, indeed, other mental models. It reports the study of the cause-effect interconnectivity of various mental models utilized by ten American and Australian teachers when involved in one-on-one teaching-learning episodes using electronic resources in the context of researching information for authentic school assignments.

Mental models

A mental model is defined as a schema or internal domain-specific representation of an object or event that may be incomplete. Mental models can be conceptualized as tools that allow individuals to understand problem situations and predict outcomes as a consequence of their actions [Johnson-Laird 1983]; [Bliss & Ogborn 1989]; [Renk, Branch & Chang 1993]. In a teaching/learning situation where new information is added to the student’s and teacher’s knowledge, mental models will consequently be in a state of change. They are continuously processing their current schematas as a "runable" event by attaching new information to them and deleting context-irrelevant information from their mental models. This concept of "runability", or the changing state of mental models, is a core defining characteristic of a mental model; in some sense,
runability is a processing mechanism itself, a process rather than a product [Jih & Reeves 1992]; [Randell 1993]; [Rogers & Rutherford 1992].

The notion of users' mental models is an accepted concept in the human-computer interaction literature although it is often given different terms such as conceptual models, cognitive models, and component models [Staggers & Norcio 1993]. Even so, the research literature dealing with mental models and usage of electronic databases tends to have a narrow focus. First, it mainly concentrates on the learner or user rather than the teacher or librarian, for example, [Stine & Wildemuth 1992] and [White 1994]. Second, it often attempts to establish whether there was a transition in the user’s mental model conceptualization from naive to expert, and proceeds to explain why this did or did not occur [Carmel, Crawford, & Chen 1992]; [Doomen & Leuven 1997]; [Jacobson & Jacobson 1993]; [Moray 1986]. Third, the literature significantly focuses on mental models as product rather than process [Randell 1993]. Indeed, although the literature does not deny, it devotes little attention to the multiplicity of mental models simultaneously held by the participants and thereby ignores how these various mental models interact to impact on runability. Thus this paper does not concentrate on the teachers' beginnings or arrival (i.e., comparison of their initial and final mental models) but examines the teachers’ dynamic mental model adaptations to a complex changing environment [cf. Carley & Palmquist 1992] and [Randell, 1993].

Research Goals

The researchers investigated runability, that is, if and how the teachers' mental models changed during the teaching-learning episodes in order to build a profile of appropriate mental model elements. Those selected for discussion are mental models of: (a) the electronic data base, (b) the role of the teacher, (b) their lesson goals, and (c) their teaching strategies.

Methodology

The following methodologies were chosen to achieve the research goals:
(a) individualized interviews using structured, open-ended questionnaires at the beginning of each individual’s participation. These open-ended questions were grounded in the data from a pilot interview and the work of researchers who had previously investigated mental models.
(b) video-taped teaching-learning episodes. In order to obtain a realistic situation, the teachers were asked to structure the teaching episode so as to replicate their normal practice. Thus, the teaching/learning sessions lasted for however long the teachers maintained the instructional interaction.
(c) individual process-tracing stimulated recall interviews based on the videotaped episode. The methodology adhered to the strict protocol developed in Australia for text and interactive multimedia qualitative studies [Marland, Patching & Putt 1992]; [Putt, Henderson & Patching 1996]. Each teaching episode videotape was replayed to the teachers to stimulate their recall of their thinking during the episode.
(d) two individual post interviews containing a set of open-ended questions. One was conducted immediately after each stimulated recall interview while the final, smaller post-interview was administered to each teacher at the conclusion of all previous data collection sessions.
(e) analysis of the data with the aid of the qualitative software package, [QSR NUD*IST 1997]. First, the teachers' mental models were identified. Second, the extended network of concepts within each of these overarching mental models [Carley & Palmquist 1992] were identified from the data and entered into NUD*IST within the identified coding category nodes. Third, the researchers pulled data from any of the nodes in any combination desired.

Sample
The researchers employed a purposeful sample in the United States of one elementary, one middle school, and four secondary media specialists, each with two student participants. These media specialists, selected by the differences in experience and teaching background, were located in Georgia. The study was replicated in Queensland, Australia, with media specialists chosen by their availability and level as closely replicating the United States media specialists as possible. (In Australia media specialists are designated teacher librarians but the term, "media specialists", will apply to both sets of teachers.) The students were chosen by the classroom teachers at the request of the media specialists and had an authentic assignment that required the use of an electronic database resource. By having the media specialists each teach two students, the researchers could identify any adjustments in the teachers' mental models in response to each student's needs and the teachers' reflections on the first teaching/learning episode.

Findings and Discussion

From triangulation of the data it was possible to construct a "before", "during", and "after" profile of the media specialists' mental models as teachers of electronic databases. This paper is concerned with examining some of these mental models in the "during", runability stage of the profile of the teachers. Hence, the before and after profiles are summaries of the findings that, nevertheless, help provide a contextual overview.

The "Before" Profile

The before profile contained the following sorts of mental models. All media specialists held perceptions that their mental model of the database was satisfactory. Their mental models of the role of teachers contained samples of teacher-as-expert, teacher-as-director-of-events, teacher-as-colearner, and teacher-as-facilitator. Their teaching strategy mental models advocated a hands-on approach with the student in control of the keyboard and mouse. Their mental models of what constituted appropriate planning resulted in the following sorts of preparation: only a couple had one or more practice sessions on the database; none developed pencil-paper lesson plans; most reactivated their schema to massage certain teaching strategies into some sort of mental procedural list; and some relied on their years of experience to allow them to utilize effectively their mental model "on the fly". There was variation in the teachers' mental models of their lesson goals: some saw student procedural understanding as the outcome; a few aimed for a conceptual framework in which were located the procedural steps of access, research, and retrieval; many saw having a tangible outcome - a print-out of a list of references or information - as the appropriate goal. The summary details an incomplete list of the teachers' mental models. It nevertheless provides a conceptualization of the number of mental models that teachers utilize for any teaching-learning episode and the range that occurred within the research sample.

Runability: An Examination of the In-Situ Profile

An examination of the "during" teacher profile stage highlights what impact the cause-effect changes in some mental models had on the runability of other mental models.

Not surprisingly, all the teachers perceived they had an adequate mental model of the electronic database they chose to teach to meet the students' assignment needs. The teaching-learning episodes exposed discrepancies with these perceptions. Analysis revealed there was a range from a superficial working knowledge to robust conceptualisation of their database mental models. Significantly, the same range existed within several individual teachers' mental models of the database, thus exposing a fluctuating understanding of the complexities of the databases. Such inconsistencies in their mental models of the database had repercussions for the teachers' mental models of (a) the role of the teacher and (b) the teaching strategies utilized during the lesson. The following helps clarify this example of mental model runability.
Two media specialists experienced near-replica "technical nightmares", that is, breakdowns in their mental model conceptualization of the database protocols when attempting to establish dial-up access through the Internet to the university and public libraries, respectively. One media specialist's mental model of herself as a teacher of electronic databases was that of co-learner with the student. Putting her mental model into practice, she openly discussed her bewildered lack of success and ensured that the student was co-solver of the teacher's predicament. During the stimulated-recall interview, the teacher stressed that she consciously thought that her teaching strategy demonstrated her mental model of the teacher as co-learner and that it would help the student create a new, or reinforce her existing, mental model of the legitimacy of the teacher as a continuing learner. In contrast, another media specialist's ambiguous mental model permitted her to admit errors while still maintaining the role of director-of-events, thereby overlooking the possibility of inviting her student's involvement in finding solutions. She reported that her overriding consideration during technological "moments of panic and discomfort, because of unfamiliarity with the database," involved a mental model of the role of teacher as expert: "I was concerned a little bit about my own image ... I didn't want to come across as if I didn't know what I was doing." Her mental model involved her normal immediate preference for "abandoning ship" and asking the student to come back later. Time-out would allow her to develop a more consistently robust mental model of the database that, in turn, would reestablish her mental model of herself as teacher-as-expert of electronic databases in both in her own and, ipso facto, the students' eyes.

Most media specialists' mental models of the lesson goal were for the students to acquire procedural understanding, that is, be able to repeat the procedures for access to the database and location of appropriate content. This mental model dovetailed smoothly with the added goal of obtaining the best immediate resources for their students' assignments. Too few of the media specialists helped their students form a mental model or image of the resource itself in its broader dimensions. According to researchers [Borgman 1984] and [Brown, Collins & Duguid 1989], students need to be exposed to the use of a domain's conceptual tools in authentic activity for robust mental model acquisition. Teaching with the goal of obtaining a successful product, such as a list of appropriate resources, has been a traditional approach for resource location and access. The goal has concentrated on imparting a set of procedures for the student to follow. Thus, its transferability to teaching with electronic resources, as demonstrated by some of the media specialists, is problematic. When confronted with electronic resources users do not have the opportunity to see everything that the database contains as they can with print resources. They are confronted with one computer screen with one page of information. A mental model of the information and all the various linkages to the information is necessary before students can create their own mental models of the procedures they need to follow to retrieve information successfully.

All the media specialists held mental models of how to teach database access, research, and retrieval that reflected an important tenet in Piaget's and Bruner's learning theories, that of direct experience. Students were to have hands-on experience with the computers. Some teachers shared this mental model with their students thereby making the rationale visible in terms of student learning outcomes: "... you will remember more if you do it yourself instead of my just telling you how to do it." Most initially had a mental model of sitting beside the student who had control of the keyboard; some did not succeed because their mental model in operation was affected by their mental model of the student's ability: "The temptation to touch the keyboard was too much given the student's hesitancy and I sort of jumped in." Others encompassed a show-and-tell-then-copy-me strategy whereby the students took control during the latter half of the lesson in order to demonstrate their ability to replicate the teacher's procedures. Although all allowed hands-on, many teachers used directive statements or questions; only a few adopted a questioning technique that involved procedures, predictions, and consequences of the database's navigational and/or hypermedia features.

An examination of the interconnectivity of two of the teachers' mental models with respect to their lesson goals, teaching strategies, and role of the teacher helps clarify these points. One media specialist concentrated on the student's acquisition of procedural skills while the other saw conceptual as well as procedural understanding as the important learning outcome. Both used questioning strategies. A simple tally of the number and types of questions from the transcriptions of the taped video lessons reveals significant differences. The former teacher asked 79 questions of which 30 (38%) required a yes/no answer and a further 34 (43%) were also of the closure type needing the correct answer. The latter teacher asked 54 questions of
which 11 (20%) required yes/no answers with a further seven (13%) being closed-answer questions. For the former teacher that left a mere 15 (19%) questions that demanded higher level thinking from the student; for the latter, a substantial 36 (67%). Both sought answers requiring deduction, prediction, and interpretation; however, the teacher whose goal was for the learner to be able to conceptualize the relevance of the hypermedia and navigational features of the database also required the student to compare, explain, synthesize, and extrapolate. Neither media specialist experienced conflict among their teaching strategies and lesson goal mental models and their mental models of the role of the teacher. It was no surprise that the data revealed the former teacher's mental model held the teacher-as-director-of-events whilst the latter depicted the teacher-as-facilitator.

Conclusion

The profile of the teachers' mental models at the conclusion of the study revealed that some media specialists made dramatic changes to some of their mental models, for the better, in their perception; others made modifications to counteract weaknesses; and some maintained the status quo. This last group retained a mental model that essentially held that there was one way to teach electronic database skills regardless of the student's age, learning style, level of computer/database expertise, student outcome needs, and, significantly, the database itself. Data suggests that they did not recognize the inappropriateness of these mental models, particularly when teaching the lessons. Data also revealed that the "status quo" group and a few of the other media specialists had no perception that their mental models as carried out in practice did not reflect their "before" mental model. Interestingly, some media specialists did perceive this, and acknowledged this verbally in their first post-stimulated recall interview. However, the mental models evidenced during their second teaching-learning episode did not reflect their earlier statements and belief that they had now, indeed, incorporated the changes to their mental models. Our study suggests that mental models are ingrained during initial experience with print resources and the procedures used to teach access of information in print resources. Transition to electronic resources requires of acceptance of changes in mental models to incorporate consistent robust conceptualization of the hypermedia features of electronic databases.

The Highschool Project Mobile Classroom in Baden-Wuerttemberg

Hans-Wolfgang Henn
Staatliches Seminar für Schulpaedagogik (Gymnasien), Karlsruhe, Germany
e-mail: Wolfgang.Henn@lehrer1.rz.uni-karlsruhe.de

Abstract: In the German federal state of Baden-Wuerttemberg, extensive tests on the use of computer algebra systems are going on since 1993. With the beginning of the school year 1996/97, we have started a pilot project that is at present unique in Germany. All students of five 11th grade classes (age 16 - 17) from different towns in Baden-Württemberg have been equipped with a modern notebook and will work with MAPLE for three years until their final exam. One of our major goals is to bring more applications and modelling into every day teaching experience.

1 Introduction

The Federal Republic of Germany consists of 16 federal states which are all independent in matters of education and culture. I will talk about my native state Baden-Wuerttemberg, where I am responsible for the training of future high school teachers. Deficiencies of our teaching that have already been known before TIMMS make it necessary to reflect on the ways of contents, methods, and didactics of teaching in its present form [see Blum 1995]. After TIMMS brought mathematics teaching into public view we hope and believe, however, to be able to change something over the next years [see Henn et al. 1998b].

2 Computer Algebra Systems (CAS) in the Classroom in Baden-Wuerttemberg

We regard the sensible use of computers as a new didactic and methodical dimension. Especially computer algebra systems alleviate the numerical and algebraic „burden“ and thus make it possible to concentrate on modelling activities [see Henn 1998a]. In Baden-Wuerttemberg, extensive tests on the use of computer algebra systems are going on since 1993 [Henn 1996]. We will examine the influence of such systems on school mathematics and their educational goals and the ensuing consequences for a mathematics education fit for the 21st century. We will investigate questions such as the following: What exactly are the real potentialities for the use of CAS to support mathematics teaching? Which conditions favor its use? Where do obstacles lie, are they located in the hardware or the software, at the cognitive level, in the didactic practice, or in the daily use? Luckily, we have in principle a free hand as far as the ministry is concerned. The excuse „I would like to do it but the guidelines don’t allow it“ isn’t valid any more. First, we started to offer courses for Mathematics with CAS at the higher secondary level in more than 40 schools. We work with the software DERIVE and MAPLE. Normally, the students work in the schools' computer labs.

3 Framework of the Pilot Project

With the beginning of the school year 1996/97 we have started our most ambitious pilot project Mobile Classroom which is up to now unique in Germany. In order to optimize assessment of the long term consequences of CAS, all students of four 11th grade classes (age 16 - 17) in different towns in Baden-Wuerttemberg have been equipped with a modern notebook, a fifth school has joined this school year. In Year 11 students can choose between advanced-level and fundamental-level courses, then work with their notebook until their final examination, where they will receive special examination problems. The CAS MAPLE is used. „Normal“ teachers
teach these students. It is exciting to watch this teaching and to discuss with all who are involved! The teaching project receives high public attention - a fact that is also appreciated by the respective members of the local state parliament. Often newspapers and local TV stations report on such project classes. The project received no recommendations regarding contents from the ministry (apart from allowing students to transfer into a „normal“ Year 11 class). Project teachers reported regularly and in detail on planning, teaching, results, and experiences with their classes.

We mathematicians of the Karlsruhe seminary provide pedagogical advice for the project, especially with regard to educational concepts, proposals for teaching, exchange of experiences, design of syllabi, joint meetings with project teachers in Karlsruhe or other meeting locations, and informative classroom observations. The Internet is used as an electronic filing system for all reports, material, exchange of information, and e-mail contacts. Participating students and teachers are interviewed and a detailed annual report is provided for our ministry.

4 First Experiences From the Instruction Experiments

In general, students are much more motivated, there is a lively working atmosphere that differs pleasantly from the usual bored, receptive behaviour in Year 11. Mathematics teaching, however, becomes more challenging. Demands on teachers are high. Getting to know the CAS used and subject-related teaching preparation are very time consuming. The teacher rôle is completely different, away from being the central mediator of mathematical content towards the planning of courses and worksheets and giving advice to classroom workgroups. A high measure of flexibility is asked for.

During the first year the chronology of teaching in all four classes was motivated by the regular grade 11 curriculum, apart from the topic binomial distribution and tests which had to be omitted because of lack of time. For quite some time the handling of the CAS dominated teaching. The desired open approach were realized more and more towards the end of the school year. Typical problems then included, for example, the reinforcement of traditional teaching content by the transition to two-dimensional functions, the investigation of curvature as important curve characteristic, and the development of problem-solving competence using real life problems. These insights into methods of mathematical modeling are neglected in traditional teaching and therefore pose special difficulties for students.

Obviously, the new tool was to be used as often as possible, which also conformed with students’ exspectations. Thus, teaching contents such as equations of straight lines, simple manipulations of expressions or the schematic curve discussion was treated in too much detail with the CAS - topics where paper-and-pencil methods make much more sense. In some cases MAPLE syntax was learned as a purpose for itself, in few cases students got lost fooling around in computer programming aspects.

The CAS proved to provide a special advantage for mathematical concept formation through its features for visualization, animation, and the automation of calculation processes. Problems resulted from the high technical and syntactical demands which left little time for phases of explanation. All colleagues clearly agreed on this point. In future this will have to be remedied by changes in the selection and weighing of teaching contents. Also, one must carefully pay attention to a correct mathematical language, students tend to talk in MAPLE commands.

The chosen schoolbook was rarely used. Teaching methods were characterized by the use of worksheets, an instructional mode which furthers independent work. However, a danger lies in too thoroughly „pre-thought“ teacher solutions that can be followed by students without much thought. („Didactics of the return key“). On the other side a variety of different solution proposals result within classes which can be very valuable from a didactical point of view. Yet often time was lacking for discussion and teacher prepared solution sheets took over the role of learning control. This is contraproductive and leads to a pure consumation of solutions.

As a rule, tests were written in two parts, one part with, the other without computer. Assessment was further influenced by class participation, project papers and coursework. Problems for the final examination in Baden-Wuerttemberg are posed centrally. As some of these problems turn out to be trivial when using a CAS we plan the following: Participating colleagues pose two complete problems (consisting of various small problems from all covered topics). One of the problems is given to all students of this teacher. Thus topics can be tested that have not been covered by all classes. An additional problem is worked out by us and given to all students.
An anonymous student questioning at the end of the school year showed that all students would again decide to take part in the CAS project. They experienced the computational facilities of the CAS as a relief and the visualization possibilities to be a great help for understanding. Emphasis on independent and cooperative learning modes were seen as very positive. However, no one wanted to do completely without traditional teacher-centred instruction.

5 Computer Algebra Systems - Challenge and Chance

I want to summarize: The CAS computer should be used as a methodical supplement to classical media such as blackboard, exercise book, etc, but it should not substitute them to a major part. As a rule the design of a problem solution has to be done using paper and pencil. The MAPLE slogan „the end of the pencil“ is nonsense! This is also emphasized by students’ comments such as: „One cannot think behind a computer monitor“. The aim is certainly not to perfect computer science aspects. A main point is the didactical reduction to central concepts of the subject, not the accumulation of new contents even if it may be easily accessible from the CAS perspective. Thus, compared to the first course, time can be won, time that is urgently needed to strengthen the explanation aspect. Traditional mathematics teaching is accused - and not without good reason - to put too much emphasis on syntactical skills. It would be a catastrophe if this situation was to be strengthened by an uncritical computer use. The aim cannot be to automatize classical curve discussion methods by computer use even if these methods are part of each Abitur examination, but to help understand criteria and concepts and to apply them in appropriate situations. The new tool CAS enables us to do this, because it allows open-ended problems that lead to individual new solution strategies and motivates creativity. This conscious problem solving process usually requires a mathematical modeling, i.e. a translation of the situation under discussion into mathematical language [see Henn 1997].

6 A Look in the Classroom
6.1 The CAS helps to solve problems ....

The following problem is typical for a relatively open-ended problem formulation that is still stated in a way to enable all student to work on it according to their individual abilities:

<table>
<thead>
<tr>
<th>Discover and prove!</th>
</tr>
</thead>
<tbody>
<tr>
<td>a. f is a polynomial function of third degree with zeros -1, 2, and 5. Draw the tangent to the graph of f for m = 3.5. What do you notice?</td>
</tr>
<tr>
<td>b. Does your conjecture also hold true for a polynomial function of third degree with three other zeros?</td>
</tr>
<tr>
<td>c. Can a corresponding conjecture be transferred if a polynomial function of third degree has only two zeros?</td>
</tr>
<tr>
<td>d. Can a corresponding conjecture be transferred if a polynomial function of third degree has only one zero?</td>
</tr>
<tr>
<td>e. Are there any generalizations to other functions?</td>
</tr>
</tbody>
</table>

Without much effort students formulate a first MAPLE worksheet. Only little MAPLE syntax is needed. MAPLE draws the graph of f and the tangent. Numerical values have been chosen in such a way that the desired theorem stating that for three zeros n₁, n₂, and n₃ the tangent for m = (n₂ + n₃)/2 passes through the third intercept point with the axis (n₁,0), becomes obvious. An abstractly thinking student is going to choose the approach

\[ f(x) = a (x - n₁)(x - n₂)(x - n₃) \]

immediately and to check with MAPLE that the equation t(x) = 0 has solution n₁. She has then already answered question b. and c. by writing down the double zero twice. A more visually minded student will investigate further examples, which is easily done by variating his own worksheet. Question d. can be seen as trivial or in a more difficult direction, our theorem can, for example, be generalized by substituting the three zeros by three arguments with the same function value a. Finally, the last question e. is completely open-ended, for example the question can be reversed to searching functions f with three zeros n₁, n₂, and n₃ with a tangent to m = (n₂ + n₃)/2 with zero n₁.
6.2 ... but the CAS can also be contraproductive!

The harmonic series provides a nice example of how a problem can be solved by suitably thinking after the computer has failed. Addition of the first \( n \) summands of the series by computer shows on one hand that computation time increases dramatically with growing \( n \), whereas the series seems to converge somewhen. This result should not be withheld from your students. By appropriate addition of the next \( 2^m \) summands respectively it is shown by hand that each time more than 0.5 is added to the series sum, making it clear that the harmonic series diverges. The power of MAPLE can create false ideas among students if the system is use meaninglessly:

For small values of \( n \) MAPLE calculates at once the exact value of \( \sum_{i=1}^{n} \frac{1}{i} \). Unfortunately, MAPLE provides a good approximation for any \( n \) almost immediately, because much mathematical knowledge has been worked into the system. MAPLE recognizes series such as the harmonic series and knows that its value can be expressed by means of the digamma function. When the sum is calculated for a variable upper limit \( n \) the MAPLE command

\[
> s := \text{sum}(1/i, i=1..n); \\
s := \Psi(n)+\gamma.
\]

is at once answered correctly by

Then, if one asks MAPLE

\[
> \text{limit}(s, n = \infty);
\]

the right answer

\[
\infty
\]

is given. But, who wins anything if students are confronted with this misunderstood „general abstract nonsense“ without any comment?

6.3 The CAS Supports Concept Formation

Rates of change are an adequate approach to calculus. This idea opens the way to many applications. The rate of change is often known (directly or by modelling) and the function can be reconstructed from this. The right understanding of the basic principle leads to all differentiation and integration rules and clarifies the ideas which are behind curvature and arc length. Just the same as we leave the calculation of sine values to the pocket calculator, we leave the practical calculation to CAS. In principle, it carries out algorithms which are understood and done by hand for the simplest examples. The following example indicates a graphical approach to the derivative as local rate of change and to the integral as its reconstruction. Starting point is a current test report about a new cartaken from a motor journal. In the table of data and measured values, among other things there are the times of acceleration from 0 to \( v \) for different velocities \( v \) [see Tab. 1].

**Table 1: Table of Data and Measured Values**

You can immediately make qualitative statements like „the car accelerates quicker at the beginning than later“. The precisation of this sentence in the sense of a quantitative statement is a typical problem of science!

To improve the first results, we should have more information about the connection between time $t$ and velocity $v$. We can obtain this information indirectly by drawing a curve through the measured points. The type $v(t) = t^2$ is the most adequate of the function types known from lower secondary level. A corresponding function has first of all to be adapted, using the measured values and the maximum velocity of [Tab.1]. MAPLE takes on the calculation and the graphical representation [see Fig. 1]. With it, we are able to compare the acceleration values in a more meaningful way advising MAPLE to calculate for a fixed $\Delta t$ the average rates of change

$$a(t) = \frac{v(t + \Delta t) - v(t)}{\Delta t}$$

and to represent them graphically. This is done in [Fig. 2] for $\Delta t = 1$ sec.

![Figure 1: Velocity-Time-Diagram](image1)

![Figure 2: Acceleration-Time-Diagram](image2)

Now, the acceleration behavior of the car can be seen much more clearly. For a more precise analysis, MAPLE has to calculate the average accelerations for a fixed value of $t$ and for the time interval from $t$ to $t + \Delta t$. Doing this for $\Delta t = 1$ sec, 0.1 sec, 0.01 sec, and so on, the stabilization of the values becomes clear quickly! The way from the average to the local rates of change with the graphical background of the transition from the secant to the tangent is done informally.

A second question is added to our data of velocities. How far has the Porsche driven by accelerating from 0 to 250 km/h? The basic idea is to reconstruct a function through its rates of change. Here, we get a first estimate, assuming a constant velocity between two points of measurement. That means 0 km/h as lower, 50 km/h as
upper estimation respectively between 0 and 2.1 sec, and so on. Usually, the students propose the starting point with a velocity linearly growing in every time interval, too. The three estimations give first estimations for the total distance. The third leads later to the trapezoid rule. The method can be improved immediately by reducing the time interval $\Delta t$ and making use of our function $v$:

The total time $t = 17.4$ sec has been divided in $n$ equal intervals of length $\Delta t = \frac{17.4}{n}$ sec. Then, MAPLE calculates improved lower and upper estimates for the total distance. Again, some experiments show that the values stabilize with growing $n$ and show the way to the definite integral! Eventually, we are able to check two further statements of the motor journal: Among the data of acceleration, two times are given in [Tab. 1] for driving a distance of 400 m and of 1 km, beginning at zero velocity and with maximal acceleration. We can control these times with respect to our curve of velocity. We substitute $n = \left\lfloor \frac{t}{\Delta t} \right\rfloor$ (\lfloor \ldots \rfloor means the floor function) in the sums for the time interval $\Delta t = 0.1$ sec and obtain two values to estimate the distance $s(t)$ from 0 to $t$, accelerating with a stationary start that we can compare with the measured values of [Tab. 1].

Such an approach to the basic concepts of calculus avoids that derivatives are internalized only as tangents and integrals only as areas!

7 Conclusion

In the meantime, the use of computers belongs to the cultural skills. You cannot imagine the professional working day of the 21st century without multimedia applications. You must learn to use the new technologies responsibly. Education cannot shut itself off from it. „Education is the only raw material, out of which successes may grow in the future for German export“, said Prof. Schlafke of the Institute of German Economy. The TIMSS study shows that we have to take counter-measures in Germany to do justice to this claim again. It is one reason that the question about goals of the mathematics education has been drawn into the centre of attention. The crisis of mathematics education has become obvious clear through the advent of computers. „The computer forces us to think about questions which we would have had to address a long time ago did we not have computers“, Prof. Schupp pointed out. The development of mathematical concepts is only possible with many examples and counterexamples experienced at first-hand, then by classifying and organizing. Student’s autonomy in thinking and acting, visualizations and dynamic figures support this process. In the States, those ideas are combined in the „Rule of Three“:

Every topic should be presented geometrically, numerically and algebraically.

Lessons, which are classical and focused on calculations, loose their importance and with that freedom arises for a reorientation of mathematics lessons. The second basic principle of the American curriculum reform calls this the „Way of Archimedes“:

Formal definitions and procedures evolve from the investigation of practical problems.

The computer opens up quite new dimensions for these new approaches to mathematics. Let us take the chance!

Abstract
This paper describes a qualitative study into students’ use of higher-order thinking as they use an interactive multimedia program based on a situated learning framework. The analysis of types of talk used by students as they worked with the program clearly shows that the majority of their thinking was higher order, as defined by [Resnick 1987] and other theorists. Social, procedural and lower-order talk was less evident but present in their talk in reduced proportions. These findings suggest that a multimedia program based on a situated learning approach can provide a learning environment capable of supporting and maintaining substantial levels of higher-order thinking.

Introduction
Many educators and researchers discuss the importance of engaging students in activities which require more than the simple application of rules and procedures. [Collins, Brown and Newman 1989] contend that few educational resources (including interactive multimedia) are devoted to higher-order problem solving activities, and few activities require students to use cognitive and metacognitive strategies and processes. [Collins, et al. 1989] suggest that higher order learning—‘cognitive and metacognitive strategies and processes’—can ‘best be taught’ through methods that employ a situated learning approach (p. 455).

While higher-order thinking might most simply be described as ‘all intellectual tasks that call for more than information retrieval’ [Baker 1990], [Lewis and Smith 1993] give a more comprehensive definition: ‘Higher-order thinking occurs when a person takes new information and information stored in memory and interrelates and/or rearranges and extends this information to achieve a purpose or find possible answers in perplexing situations’ (p. 136). Many studies have produced methods and procedures to classify and define higher-order learning. However, as [Newmann 1990] points out, each approach has its own persuasive rationale. He contends that it is not productive to try to choose the best, but more sensible ‘to search for a common conception that embraces diverse emphases but which attracts professional consensus’ (p. 42).

Situated Learning
To date, there appears to have been scant research into whether higher order thinking is enhanced and promoted by learning environments based on a situated learning framework. The majority of studies that have been conducted to investigate students’ use of higher order thinking as they use multimedia packages report little evidence of in mainstream student activity (e.g., [Frampton 1994]. While the proponents of situated learning continue to claim that higher order learning is a consequence of learning within a situated learning environment, very little research has been done to evaluate the impact of situated learning elements on students’ thinking, particularly with regard to the use of interactive multimedia programs.

This paper describes a study which investigated students’ thinking as they used an interactive multimedia program based on the situated learning approach. The learning environment incorporated nine characteristics
of a situated learning model, namely: an authentic context; complex authentic activities; multiple perspectives; expert performances; coaching and scaffolding; opportunities for collaboration, reflection and articulation; and authentic assessment [Herrington & Oliver 1995]; [Herrington, Sparrow, Herrington, & Oliver 1997]. The learning environment was designed for preservice teachers of mathematics. The multimedia program focused on the issue of assessment and presented a number of resources for preservice teachers to investigate from a variety of perspectives, such as short video clips of assessment strategies being used in classrooms, and interviews with teachers and students on the strategies; and a variety of text documents, such as a description of each strategy and mathematics experts' views. As they used the program, the preservice teachers were given a complex and sustained authentic task to investigate in the form of two letters: one from a parent complaining to the school about the number of tests her child is required to take, and the other a memo to the new teachers at the school (the preservice teachers) asking them to prepare a new assessment plan for mathematics in the school. It was hypothesised that the situated learning model, used in the design of the program, would lead to substantial levels of higher-order thinking in its implementation. Four groups of two students were videotaped using the resource over two semester weeks, and their discussion was transcribed for analysis with qualitative analysis software.

Framework for analysis

Several frameworks have been developed for analysis of student cognition within learning environments, which served as a useful starting point for the current study (e.g., [Marland, Patching, & Putt 1992]; [Alexander & Frampton 1994]; [Nastasi & Clements 1992]. These frameworks use the basis of student talk as a means of identifying cognition and thinking with the nature of the talk being used as an indicator of the form of cognition and thinking undertaken by the student. The work of [Henri 1992] was most useful in providing a model for analysis of the data in the study. Henri developed her framework for analysis of student talk in a computer-mediated conferencing environment. Student exchanges during lessons were monitored and analysed using content analysis. Clearly, the categorisation of spoken messages within learning environments is a practised format for analysis of student talk.

In order to classify students' talk as they used the interactive multimedia program on assessment, a table of indicators was prepared based on the characterisation of [Resnick 1987] of higher-order thinking. To simplify the classification for the purpose of the research, several of Resnick's characterisations were combined to enable more distinct categories to be drawn. It was also necessary to draw up similar criteria for the classification of talk which could not be considered higher order—Social, Procedural and Lower order—rather than have a simple category of Non-higher order thinking. All student talk was classified according to the scheme which is represented diagrammatically below [Fig. 1]:

![Flow chart of classification scheme of student talk](Image)

Figure 1: Flow chart of classification scheme of student talk

The unit of analysis
In order to assign student talk to a category, it was necessary to define the 'grain size' of the unit of speech to be classified. The method used was to count each instance of a type of talk as it occurred [Henri 1992] which enabled the detection of types of talk which may have been neglected by other methods, such as the counting of passages of dialogue, turns at talk, or individual words. Each category of talk, together with a definition, a short summary and example of type is given in [Tab. 1].

<td>Off-task</td>
<td>Any statement not related to the subject matter</td>
<td>G: We got caught in a traffic jam ... We didn’t see it happen but we saw a van, the side of it was all smashed in.</td>
</tr>
<tr>
<td></td>
<td>On-task</td>
<td>Any social statements which relate in some way to the task</td>
<td>C: Hey I know this guy ... He was my teacher. What a spin. I wonder what he is doing.</td>
</tr>
<tr>
<td>Procedural</td>
<td>Equipment</td>
<td>Any exchange of information related to the equipment</td>
<td>R: No you won’t have a volume on this ... It’d be on the Apple menu. You have to go into systems folder then control panel.</td>
</tr>
<tr>
<td></td>
<td>Software</td>
<td>Any exchange of information related to the software</td>
<td>C: That didn’t work.</td>
</tr>
<tr>
<td></td>
<td>Task</td>
<td>Any exchange of information related to the task</td>
<td>G: Are we actually supposed to prepare this as a report to staff?</td>
</tr>
<tr>
<td></td>
<td>Lower order</td>
<td>Any student talk which is routine, requiring little thought, or the mechanical application of well known rules</td>
<td>C: You are missing an r in strategies.</td>
</tr>
<tr>
<td></td>
<td>Higher order</td>
<td>Any student talk which involved deciding on an approach to adopt, suggesting a course of action, or any expression of dilemma or uncertainty</td>
<td>L: So really we want to look at all of them don’t we?</td>
</tr>
<tr>
<td></td>
<td>Path of action</td>
<td>Any talk which involved decisions about which elements of the program to access, what to save in the notebook and negotiations on how to proceed</td>
<td>R: We should go right through the whole lot again. We need to make more notes on it.</td>
</tr>
<tr>
<td></td>
<td>Judgement</td>
<td>Any statement or question which referred to students’ attempts to interpret and defend their understanding of the issues presented in the assessment program</td>
<td>G: If you’re going to do anecdotal records ... D: You wouldn’t carry them around. You’d make notes and put them in later.</td>
</tr>
<tr>
<td></td>
<td>Multiple perspectives</td>
<td>A statement or question was classified in this category if it suggested an alternative approach or challenged a conclusion, or previously made point, by providing an alternative perspective</td>
<td>R: OK investigations, factual ... Ah, factual, factual recall, rote learning.</td>
</tr>
<tr>
<td></td>
<td>Imposing meaning</td>
<td>Talk was classified into this category if it referred to a possible solution to a problem or suggested alternative solution, if it expressed a decision about what to believe, or the creation of a new idea, or if it drew cautious conclusions</td>
<td>G: Obviously we can introduce all of the strategies but not to start with. I think in the lower primary you probably can’t expect them to do a mathematical investigation, so if they start out with oral work in the lower school and work towards doing the written ones in the upper school.</td>
</tr>
<tr>
<td></td>
<td>Metacognition</td>
<td>Any comments which showed that students were aware of their own thinking and performance, and comments related to the use of this awareness to improve performance</td>
<td>G: What was that? I didn’t get any of that. E: I don’t know what to do. Where is that piece of paper I had before? [The activity].</td>
</tr>
</tbody>
</table>

Discussion

The analysis of the transcripts showed that higher-order thinking was a substantial component in all the students’ talk. In each of the four groups observed, the proportion of higher-order thinking to the other major categories observed was quite consistent and was measured at around 70% of the total talk.
[Fig. 2] shows the proportion of categories for Group 1. The two students in this group used a substantial proportion of higher-order thinking in their talk as they used the multimedia program. Lower order comments, together with social talk, were kept to a minimum and procedural matters occupied only a moderate amount of their time. Like Group 1, the students in Group 2 used a substantial proportion of higher-order talk (70%), a moderate amount of procedural and minimal lower order talk. Of all the groups, this group had the most social talk, largely centred around discussion of their mutual friends, computers and work from other units of study. The students in Group 3 were least typical in their pattern of talk. There was a complete absence of social talk which appeared to be the result of the fact that they did not know each other prior to commencing work on the program. The amount of higher-order talk was 71%. A relatively high amount of procedural talk was observed in Group 3 and this was largely related to recurring computer equipment problems which were not satisfactorily rectified until the second week of the study. Like the other groups, however, they had a high proportion of higher-order talk, and minimal use of lower order talk. Group 4 were similar to the other groups in their use of a substantial amount of higher-order talk (68%). The remaining categories of talk were also comparable with other groups.

**Proportions of higher-order thinking**

The high level of higher-order thinking amongst all the groups meant that there was a substantial number of units of meaning in students' talk which could be classified according to the classification scheme (Table 1). While the amount of talk was quite consistent between the groups, there were many differences in the extent and levels of the various forms of higher-order thinking evident in the talk. The proportion of each of these types to the whole of higher-order talk for Group 1 is shown in [Fig. 3].

![Figure 3: Proportion of categories of higher-order thinking: Group 1](image)

The students in Group 1 used a substantial amount of all types of higher-order talk identified in the classification scheme. As with most of the groups, Uncertainty, Path of action and Judgement comprised the major part of their talk, with the other classifications making up the remainder. Clearly, these students were relatively comfortable working together, with the total of Uncertainty and Path of action totalling less than half their talk. The moderate proportion of Multiple perspectives appeared to indicate that these students were not excessively argumentative or critical, but were not afraid to challenge each other or the program when they saw the need. These students were also capable of spending a good proportion of their time Imposing meaning on their learning and coming to conclusions about the task and the recommendations to include in their reports. As with all the groups, these students' expression of metacognitive awareness was minimal, and it is possible that this is a type of thinking which does not manifest in the spoken word as well as the other categories of talk.
Figure 4: Proportion of categories of higher-order thinking: Group 2
The interesting aspect of the analysis talk in Group 2 [Fig. 4] is the relatively low proportion of Uncertainty and Path of action compared to Judgement and Multiple perspectives. This division indicates that these students were forthright and confident in working out their path through the interactive multimedia program, and that they appeared to very comfortable working together. The high proportion of Multiple perspectives indicates that they adopted a very critical approach to the information they were obtaining from the program and from each other. The high proportion of Imposing meaning also seems to indicate that they were then readily able to consolidate the information into a meaningful form.

![Figure 5: Proportion of categories of higher-order thinking: Group 3](image)

While it is difficult to nominate an optimum spread of talk to categories within higher-order thinking, clearly Group 3 had difficulties which become apparent with closer scrutiny of their types of talk. The high percentage of time spent in both Path of action and Uncertainty reflects the tentative nature of their collaboration [Fig 5]. Almost three quarters of the total talk fell into one or other of these categories. As they were unaccustomed to working together, the students appeared to spend a relatively large proportion of their time consulting with each other about the nature of their collaboration—how they were to proceed, how to interact, and the responsibility each was to take in the process. Another interesting finding in the proportion of talk for this group was the almost complete absence of Multiple perspectives talk between the two students. Their collaboration was characterised by a reluctance to challenge each other’s ideas or to challenge the perspectives that were presented in the multimedia program.

The students in Group 4 [Fig 6] used relatively little talk which was classified as Uncertainty and Path of action indicating that they needed minimal talk to establish a working relationship and a proposed plan of action. Like others, they demonstrated a high proportion of Multiple perspectives as they used the program. However, a large proportion of this talk was an argumentative style of interaction they used as they worked together, rather than a thoughtful disagreement with ideas presented in the program. This is possibly evident in the fact that there was a minimal proportion of talk which was classified in the category of Imposing meaning. These students, unlike Group 2, did not use the multiple perspectives they offered each other to inform the meaning of the task.

![Figure 6: Proportion of categories of higher-order thinking: Group 4](image)

**Discussion**

It is interesting to note the wide disparity between types of higher-order thinking used by the students as they used the multimedia program. The findings show that all the students used a substantial proportion of higher-order thinking in the situated learning environment, where other studies (e.g. [Frampton 1994]; [Oliver &
McLoughlin 1996] have shown little. The possibility exists that the classification scheme developed to analyse students' talk was not a precise enough instrument to truly reflect the cognition of students as they used the program. For example, comments such as 'What do you want to do now?' may be closer to a cliché or automatic response than a thoughtful reflection of the best course of action. However, even with a reclassification of Uncertainty and Path of action as Lower order thinking, Higher-order thinking remains a high proportion of the type of talk used by all the groups. An explanation for the amount of this type of talk is that the constructivist nature of the learning environment provided greater opportunities for students' higher-order thinking.

Another interesting finding was the non-sequential nature of the types of thinking used by the students, confirming the contentions of [Resnick 1987] and [Newmann 1990] that higher-order thinking is relative and non-hierarchical, and counter to behavioural theorists such as [Bloom 1956] and to some extent, [Gagné 1985], where progression to each level of the hierarchy is dependent upon mastery of the previous level. If one accepted a hierarchical approach to classification of thinking, it might be expected that students would begin with a little social talk to establish their working relationship; then procedural talk as they worked out the computer equipment, the software and the task; they might then be expected to move to lower order talk before using higher-order talk later in the session. Interestingly, there was no sequence or pattern to their use of talk. From the beginning, the students moved freely and without notice to any type of talk.

The analysis of types of talk used by students as they worked with the interactive multimedia program clearly shows that the majority of their thinking was higher order, as defined by [Resnick 1987] and other theorists. Social, procedural and lower-order talk was less evident but present in their talk in reduced proportions. These findings confirmed our expectations that a multimedia program based on a situated learning approach could provide a learning environment capable of supporting and maintaining substantial levels of higher-order thinking. Our findings contrast with many previous studies exploring students' cognition and thinking in multimedia use. The findings suggest that the instructional design embraced in the situated learning program and its implementation in this study successfully integrated a number of elements and components often missing in applications and uses of multimedia in contemporary learning settings.

Abstract: In this paper, as the first step to realize support facilities for learning from surfing, we propose a filtering method to support surfing. In surfing, a user is often provided too many choices to reflect the collected information. In such situation, learning from surfing is inefficient. We propose a filtering method where shifting interests in the surfing are modeled and the choices are ordered following the interests. The user can easily find the choices which are nearer to his/her interests. Because the load to find adequate information is reduced, the user may afford to learn from the collected information.

Introduction

Browsing is one of the most popular ways to gather information in database with hypertext structure, for example, digital libraries or WWW [Kaplan 1993; McKnight 1993]. Although the purpose of the browsing isn't learning, a user can get much knowledge from the collected information [Salder 1993]. Because this learning is a secondary effect of the browsing and isn’t organized, it is difficult to control from the educational viewpoint. However, the amount of the knowledge acquired from browsing cannot be neglected. We believe the way to support learning from browsing is an important issue in learning systems.

Usually, the browsing is carried out under a clear task [Balabanovic 1995; Carmel 1992]. In such browsing, to complete the task should take precedence to learn. To support learning from the collected information may interrupt to complete the task. Therefore, the browsing with a clear task isn’t an adequate target of the support.

Every browsing, however, doesn’t always have a clear task. People often browse WWW or encyclopedia in CD-ROM format without clear tasks. Such browsing is often called "surfing." Because the purpose of surfing is usually to surf, educational interruption may be allowed. Our research objective is to support learning from surfing.

Although user's interests often shift depending on the collected information, it's not haphazard one( so, we often call surfing "context-sensitive browsing"). In this paper, as the first step to realize the support facilities for learning from surfing, we propose a filtering method to support surfing which named Context-Sensitive Filtering, CSF for short. In surfing, a user is often provided too many choices to reflect the collected information. In such situation, learning from surfing is inefficient. In the filtering method, the shifting interests in the surfing are modeled and the choices are ordered following the interests. The user can easily find the choices which are nearer to his/her interests. Because the load to find adequate information is reduced, the user may afford to learn from the collected information.

In this paper, we propose a model of the shift of user's interests. Then, we describe a method to filter information based on the model of the interests. We have implemented the filtering method for encyclopedia in CD-ROM format and confirmed that it is useful for free browsing [Hirashima 1998]. CSF on WWW is also discussed.

Context-Sensitive Filtering

Outline of Context-Sensitive Filtering

Figure 1 shows an example of browsing history. Here, an ellipse is a node: letters included in the ellipse are indexes
an index, nodes including the index are shown in the selection window as candidate nodes.

**Selection Window:** In the selection window, titles of the candidate nodes are shown and a user can select one as the next browse node. Our research objective is to order candidate nodes by relevance to the user's interests inferred from the browsing history. In the list of the candidate nodes, more relevant nodes for the user's interests are placed upward in the list, so the user can select them easily. When the user clicks a title in the list, the node content is shown in the text window.

Figure 2 is the snapshot where a user had read the explanation of "Client Server System" shown in the Text Window. He/she had then checked the "Useful Node Check" box. In the Index Window, a list of indexes of the "Client Server System" node has been shown. By clicking "personal computer", which is an index shown in the Index Window, the content of the Selection Window is renewed. The Selection Window contains 91 candidate nodes which have "personal computer" as an index, but only 20 can be displayed at any one time. After selecting a node in the Selection Window, the content of the node will be shown in the Text Window.

We have confirmed that CSF is useful for free browsing in CD-ROM encyclopedia [Hirashima 1998].

**Context-Sensitive Filtering on WWW**

Nodes in CD-ROM encyclopedia follow basic guidelines to design hypertext. Therefore, one node has one topic and the contents is concise to be able to read through it briefly. Modeling of user's interests of CSF depends on the characteristics of the node. On WWW, however, nodes, that is, pages often don't follow the guidelines, for example, one page has several topics, or the volume of the content is too much. Therefore, modification of WWW pages is necessary to use CSF effectively.

The purpose of modification of WWW pages is to give the two characteristics to the pages: (1) one page has one topic, (2) one page has adequate volume to read through it briefly. To realize the modification, partitioning methods of WWW pages are described in this section. First, partitioning following HTML specifications is described. Then, partitioning by heuristics is reported. Here, although CSF uses the divided pages to models user's interests and to order search results, a browser provides a user with the whole page. So, the part of the divided page is shown first, but the user can see other parts in the whole page in the same way as usual browser.

Because WWW pages written by HTML, every page has the structure defined by HTML specifications. By using the specifications, the content of the page can be divides into several document blocks. The Headings in the BODY elements represents hierarchical structure of HTML document. The TITLE element in the HEAD elements represents the title of the document. Following HTML specifications, Headings and the TITLE element compose a tree structure. Each Heading divides a document into several smaller document blocks. Then, the lowest Heading makes the leaf document block. This leaf document block is a divided page which is dealt with a page in CSF. The divided page is characterized not only by the content of the divided page, but also by the upper structure in the tree structure. Therefore, indexes of the divided page consists of indexes which come from the content of the page and come from the upper structure of the page.

However, WWW pages are often written not following HTML specifications. For example, font specifications sometimes used as headings. In such case, the largest font part is regarded as H1 level, and so on, is an useful heuristics. The leaf document block generated by Headings, often include too much content to read through it briefly. In such case, paragraph tags can be used to divide the document block again. In order to realize CSF for WWW pages, such heuristics to divide HTML documents are important.

By using the above modification, divided pages are listed in Selection Window. As the explanation of a page in Selection Window, a summary of the hierarchical structure of the page are shown. The summary consists of the first one line of TITLE element, H1 element and so on. When a user selected a divided page, the whole page is provided to Page Window and the part beginning with the divided page are shown.

**Related Work of CSF**

Research on adaptive interactive systems is a very active field, especially in the domain of adaptive hypermedia
systems [Brusilovsky 1996; McKnight 1993]. The adaptive hypermedia system builds a model for the individual user and applies it for adaptation to that user. CSF, which can currently deal with only text, is a method to realize the adaptive hypermedia system. The technique of adaptation in CSF is adaptive ordering [Brusilovsky 1996], which orders the links to the next page according to the user model. This technique is used for several adaptive hypermedia (or hypertext) systems [Armstrong 1995; Kaplan 1993; Mathe 1996], where each page has many non-contextual links. The hypertext for which CSF is implemented has the same feature. Therefore, adaptive ordering is an adequate technique for realizing adaptation, but it isn't the main characteristic of our research.

The user model is the main characteristic of our research. Several systems build a user model, referring to his/her browsing history to adapt the hypermedia links. HYPERCASE [Micarelli 1996] estimates user's current goal using case-based reasoning and Hynecosum [Vassileva 1996] identifies user's level of experience. Since their modeling methods use the structure of hypermedia, only well-structured hypermedia is a target area. Our target area, however, is Information Retrieval Hypermedia (IRH) [Brusilovsky 1996]. In IRH, since the size of hyperspace is usually very large and users have various purposes, it cannot be structured beforehand. Encyclopedia or WWW is an example of IRH.

There are several user modeling methods which are independent of the structure of hypermedia. The main component of the user model in HYPERFLEX [Kaplan 1993] is a matrix of relevance, which stores relevance values between each pair of documents and from each goal to each document. If the user selects the current search goal from the list of existing goals, HYPERFLEX orders links from the current node according to their relevance to the selected goal. WebWatcher [Armstrong 1995] logs user's successful and unsuccessful searches as training data, and selects an appropriate hyperlink, by using machine learning methods and user's information goal, which is identified by him/herself. Adaptive HyperMan [Mathe 1996] uses relevance network, which records the relevance of references based on user feedback for specific queries and user profiles. The relevancy of information is calculated by using the relevance network. The above approaches are powerful and independent of hypermedia structure, but they should be provided several user features, for example, direct interactions of his/her information goal.

Although such interactions have the effect of making user models more precise, the load of the user significantly increases. Our target browsing, that is, surfing or context-sensitive browsing, has no clear task or purpose, in other words, browsing itself is the task or purpose. In such browsing, the choice of any links in hypermedia isn't a critical decision. If anything, the interactions which disturb user's browsing should be avoided. From this point of view, Letizia [Lieberman 1995] uses the past behavior of the user to anticipate a rough approximation of the user's interests. This is the closest work to us. Lieberman also insisted that "indicators of interest probably ought to have a factor of decaying over time" and "some action may have been highly dependent upon the local context, and should be forgotten unless they are reinforced by more recent action." However, in [Lieberman 1995], a concrete method to deal with the shift of user's interests in the browsing isn't described. Besides this, [Lieberman 1997] insisted that Letizia serves the user by noticing serendipitous connections. This means that Letizia also deals with long-term interests. In contrast, CSF is a method which concentrates on dealing with the shift of user's interests in the browsing. Through experiment by real users' browsing, we confirmed this concrete method was promising.

Several researches of student modeling concentrated on the shift of knowledge [Huang 1992; Kono 1994]. Because the student's knowledge shifts as the results of his/her learning, the purpose of modeling is similar to our modeling. However, since educational interactions, which are generated based on the student models, are really critical for the students, the student models are usually required to be precise. To satisfy the requirement, they are usually built based on many interactions with the student and analyses of domain structure. Therefore, the purpose of modeling is similar but the techniques are quite different from CSF.

When a user surfs WWW, he/she often uses search engines (for examples, "Web Crawler" [Pinkerton 1993] and "Alta Vista") in addition to the links designed by authors. The research of search engines, therefore, is also close to our work. They have the ability to order retrieved pages according to relevance to a user's specification. Search engines require users to state their specification clearly. In our filtering method, when a user selects an index, the user's interests are inferred by using the browsing context. The user's specification is complemented based on them.
Concluding Remarks

As a first step to realize "Learning from Surfing," we have introduced Context-Sensitive Filtering. In surfing, user's interests gradually shift depending on the browsing context. The main characteristic of CSF is the model of user's shifting interests. Our filtering method can order candidate nodes according to the model. We have implemented a browser with this filtering method as an encyclopedia in CD-ROM format. The effectiveness of this method was confirmed through an experiment where real users browse nodes freely, following their interests. We also discuss CSF on WWW. Evaluation of educational standpoint is our future work.

Abstract: The authors have introduced intranet-based training to their university-level courses in electrical engineering, enhancing standard methods of teaching through interactivity and nonlinear reading. Hypertext Markup Language (HTML) is used for platform independence. Two different approaches were studied. One of them is the advancement of lecture notes thereby using the potentialities of HTML documents and modern browsers. The other one has led to a HTML-based hypermedia-tutorial where interactive problem solving is made possible by means of online simulations and other methods. Both approaches foster active learning methods. Evaluation shows that students like the idea of using internet-based multimedia education for adding new value to classical forms of education, as opposed to replacing them.

Introduction

Conventional forms of university education, particularly when delivered to large audiences, traditionally suffer from a lack of interactivity - the subject matter is being presented by the lecturer, the students consume it passively. Additional exercises in small groups only partially fix the problem, as the individual student may still not be motivated to deal with the subject directly.

One possible reason might be the discrepancy between the students' "learning rhythm" and the time table presented by the lecturer.

We are, therefore, offering additional and new forms of education that enable students to create their own time tables and to follow their own needs and interest.

HTML Based Lecture Notes

In classical university education, lecture notes have proven successful in helping students to find their own rhythm and to gain deeper inside into the subject they are studying. Furthermore, lecture notes could serve as reference books.

However, mere transfer of lecture notes into a document file would not add any functionality to the text, nor would it encourage students to become more active. On the contrary, a simple text is more difficult to read from a computer display than from a book, for most people.

It is just one of the disadvantages of classical documents that there is nearly a must to read them "linearly", that means following a prescribed schedule at least for a certain section. Following own mental leaps turns out to be difficult. Once the reader has left the intended reading sequence several times in a row, it will be hard for him to return to the point from which he started to follow his own thoughts.

We have, therefore, not only translated lecture notes on topics of microwave engineering into HTML documents, but also enriched them by navigational tools. These documents are accessible via intranet and readable using a browser which is able to handle frames.
In a three-frame browser window [Fig. 1], one frame (Contents-Frame) holds the structure of the document at any time, and allows easy access to arbitrary parts of the text. A second navigational frame provides access to the document's index, providing reference book functionality (Index-Frame). The actual lecture notes are shown in a third frame (Text-Frame) that may be enlarged to cover nearly the whole terminal screen. This is shown schematically in the following figure.

![Frame structure of the browser window that gives access to the HTML based lecture notes.](image)

**Figure 1:** Frame structure of the browser window that gives access to the HTML based lecture notes.

A mouse-click onto one of the section titles in the Contents-Frame changes the content of the Text-Frame that now shows the starting part of the selected section. It is thus always possible to find the section of interest.

The widths of the Contents-Frame and the Text-Frame can be changed in order to gain a better overview.

Explanatory links are available as well from terms being used in the text as within graphics through clickable image maps. Thus, a mouse-click leads directly to an explanation of the term or of an illustration of a figure. Further links allow to find the way back to the starting point.

One particular feature of these lecture notes is that they use intensively mathematical deductions. Since these are on a high level of abstraction, it seems to be necessary to liven up the script by numerous figures and animated graphs. The latter ones are embedded into the HTML-document as animated GIF-graphics.

At the time being, the user of the HTML based lecture notes is not yet able to influence these animated graphics. This will be changed in the near future. It is planned to use forms that are evaluated for parameters. These are the input of a server driven program that in turn produces a new graphic.

Our HTML lecture notes are not interpreted as a substitute for printed material: we would like to use them as an additional offer to students.

**The Hypermedia Tutorial**

We observe that students often lack an intuitive understanding of the subject at hand. In the example studied next, an introductory course on analog circuit design for second-year students, it was evident that students often memorized the formulae presented during the lectures, but had no concept of how to apply the presented methods to problems not explicitly solved in either lecture or exercise.

Beginning in 1996, we introduced a novel computer-based training method which we like to call "hypermedia tutorial", accessible on the university intranet. It does not replace the traditional methods of education, namely lecture and problem-solving exercises, but provides an additional opportunity for the student to individually test his or her knowledge and gain an improved understanding of the subject matter. In the development of the hypermedia tutorial, we were led by the following fundamental requirements:

1. The program's user interface should not present an obstacle to the student. It should be usable on different platforms.
2. The program should provide a high degree of interactivity, both in testing comprehension and in using simulations to improve the student's intuitive understanding. The testing part should not be exclusively multiple-choice based.
3. For cost reasons, it should be implemented using public domain tools, where ever possible.

In our solution to these requirements, we chose HTML documents to provide the platform independence. Interactivity is realized using a scripting language and CGI scripts developed by our group. It parses user input in
HTML forms, performs server-side evaluations and simulations, and generates dynamic HTML pages (including graphics) returned to the user.

The program has several distinct parts, distinguished by different background colors to facilitate navigation. There is a service section, presenting the accompanying lecture's structure (with hyperlinks to problems and simulations), up-to-date information, and a repository of material distributed during the lecture.

A quiz section tests the student's comprehension of the presented material through small problems where answers are given either in multiple-choice form or, more often, through numeric input entered into forms. The answers are evaluated based on rules, set in a file not visible to the student, and results are returned to the student, including a short description of the proper solution when errors have occurred.

The simulation section uses both server- and client-side simulations of electronic devices and circuits, always with graphics output, to visualize important relationships and concepts. The student may alter parameters and re-run simulations at will. Simulations close to reality, e.g., using SPICE, are contrasted with idealized expressions developed during the lecture to demonstrate ranges of validity and possible pit-falls.

A FAQ (frequently-asked questions) section provides additional in-depth explanations in areas where questions frequently occur, or where errors are often observed during written exams. The FAQ pages are hyperlinked to evaluation documents in the quiz section, but may also be viewed directly. Figure 2 shows the overall structure of the program.

Figure 2: Structure of the program underlying the hypermedia tutorial.

The program is implemented on a Pentium-class PC with 32 Megabytes of RAM. Only standard text and graphics editors where used in the creation of the HTML pages.

Evaluation of responses to questions in the quiz section is achieved through a CGI script written entirely in C. When a user submits an answer, the appropriate script file is read, the rules contained therein are extracted, and the user input is evaluated. Numeric answers do not have to be exact - the rules file defines a window for the proper answer. The set of rules also allows to group wrong answers, and provides different feedback depending on the likely error the student committed, where possible. The evaluation feedback, with explanations of the proper solutions where necessary, are then formatted into a dynamic HTML document and sent back to the student. Clear graphical symbols for correct and wrong responses provide rapid feedback.

After the hypermedia tutorial had been completed, its success was evaluated using questionnaires handed out to all attendees of the "Introduction to Analog Circuit Design" lecture series. Participation in the evaluation was voluntary and anonymous. Of a total population of 80 students, 37 returned the evaluation forms. If we take the returned results as representative of the overall student population, we find that 50% participated in the hypermedia tutorial on a regular basis.

On the evaluation forms, students were confronted with several statements - positive and negative - whose applicability they had to grade using a scale of 0 (strongly disagree) to 5 (strongly agree). The main results of the evaluation are shown in Figures 3 to 5.

With an average rating of 3.9, most students followed the intended use of the hypermedia tutorial, namely to augment, not replace, the conventional lectures and problem-solving exercises [Fig. 3]. Participants found that
the on-line simulations visualized the lectures' subject matter (average rating 3.8) and improved overall comprehension (3.8).

![Figure 3: How the tutorial was accepted by students](image)

Those who participated in the hypermedia tutorial were also asked to rate the importance of several possible future on-line educational offerings, along with those already implemented. Here are the results sorted according to the rank and showing the average score in brackets:

1. Frequently Asked Questions Pool (4.7)
2. Problems with evaluation of response (Quiz) (4.1)
3. Additional Course Material
4. On-line simulations (3.8)
5. Tutoring by electronic mail (2.5)
6. Conventional online lecture scripts (2.4)

![Figure 4: Acceptance of different offerings within the tutorial](image)

The less favorable rating for tutoring by email confirms our impressions gathered in the course of this program - the possibility to pose questions and receive answers by email had been offered and seen no usage at all.
While we readily concede that the results of this particular poll have been biased by what was actually offered, we conclude that students like the idea of using internet-based multimedia education for adding new value to classical forms of education, as opposed to replacing them.

Non-participants were asked to rate questions relating to their reasons for staying away. The results show that they are not opposed to computer-based methods per se, but were not willing to take the additional time necessary to work with the tutorial (results sorted according to the rank and showing the average score in brackets):

1. Not enough time due to other classes (3.0)
2. Lectures and problem-solving exercises sufficient (2.2)
3. Treatment of subject in this form not efficient (1.5)
4. Computer-based training just an irrelevant fad (1.1)
5. User interface to complicated (0.6)

Figure 5: Opinion of students who did not participate the tutorial

Further Developments

The success particularly of the hypermedia tutorial encourages us to further develop our on-line offerings. Based on the gained experiences, we plan to include simulation tools into the lecture notes on microwave engineering as well. Furthermore, it is thought of including lecture notes to the hypermedia tutorial, thus merging both types of intranet-based education offerings. Similar plans exist for further courses, e.g. mathematics. A course on Fourier series is being worked out at the moment.

Conclusion

Two intranet-based teaching methods, the "hypermedia tutorial", and lecture notes with additional functionality have been successfully implemented at the University of Ulm. Built around HTML documents and CGI scripts, they achieve a high degree of interactivity with the user.

In the hypermedia tutorial, problems with server-based evaluation of responses test comprehension, while server- and client-side simulations are used to visualize concepts and improve intuitive understanding.

At the end of the first term it was offered, the hypermedia tutorial has been evaluated through questionnaires. The results show a strong positive attitude of students towards this innovative educational method, as well as the students' personal impression that it improved their comprehension of the subject matter.

While the method has been developed for a course in electronic circuit design and is being adapted to problems in microwave engineering in the near future, we believe that it holds promise for other subjects as well.
At the time being, similar experiences are collected by our colleagues from the departments of biophysics, anatomy and applied physiology at the university of Ulm [see Gruler et al. 1998]. Since much more students are in their courses, a larger statistical ensemble is available there for evaluation. We are looking forward to their results.

Abstract

This paper reports on a comparative assessment of a multimedia learning environment based on a guided discovery approach (CORE) with two control conditions (lecture and electronic book). The three learning experiences were embedded in a B.Sc. Diagnostic Radiography curriculum. As part of the normal teaching and learning, three groups of students from year II of the B.Sc. course used one of the learning methods. The syllabi across the three learning conditions were closely matched. Quantitative and qualitative measures were taken of effectiveness and usability. All the groups demonstrated a significant baseline to post learning session knowledge increase. The CORE approach was identified by the students as the most effective method of learning. The students identified a range of factors which contributed to the CORE condition being effective. These factors included: learning in context with real examples that integrate diverse subject areas, engagement in the learning process, and learning from mistakes.

Introduction

Computer assisted learning (CAL), at home and in educational institutions, is continuing to gain popularity. Various reasons account for this including the increased range and availability of software products, competitive prices, falling cost of hardware and increased hardware capability and the need to consider work based education and training. With many educational institutions considering the use of CAL within their curricula it becomes essential that these approaches to learning are evaluated for educational efficacy.

For many years, various forms of CAL have been used in health professional education and training. In the early years the emphasis was placed on enhancing diagnosis by simulated approaches. For example, De Dombal [1969] described a prototype for aiding surgical diagnosis, Brody [1973] proposed a simulated patient for dental student patient history taking and Rosenblat [1984] argued the value of simulations, suggesting that clinical simulations can be used to replicate the actual medical cases. Whilst CAL appears to have had a long history in some elements of medical education and training, Tessler [1989] commented

"of all the medical specialities, diagnostic radiology is the most dependant upon computer technology and computer based educational applications in radiology have been noticeably lacking" (p 1169)

Similarly this appears to be the case for radiographer (diagnostic radiography) education and training and until recent years publications about CAL approaches have been either descriptive or speculative in nature.
Nuclear medicine involves the application of radioactive substances for the diagnosis and treatment of disease in humans. Within the UK elements of nuclear medicine are studied within diagnostic radiography degrees. Diagnostic radiography is a field allied to medicine. It involves the application and integration of several subject areas in order to produce a competent practitioner skilled in the art and science of diagnostic imaging. Clinical practitioners must integrate successfully the diverse subject areas in order that competence can be developed. Traditional approaches to teaching and learning often involve classroom contact, together with supporting personal study. During these sessions theoretical material is presented and assimilated from the fundamental subject areas. Clinical observation and subsequent practice then ensues. For effective learning, the complex knowledge and skills have to be reduced to a manageable form which can then be delivered in a logical sequence within a curriculum. Efficient and successful integration of subjects and the linking of theory to practice may prove difficult with traditional approaches.

Subject integration and linking with [virtual] practice may however be achieved through computer mediated virtual environments. The particular constructivist approach selected here is the CORE method. This is a radical constructivist approach which provides a set of design principles for the acquisition of competence in relatively complex domains [Boyle, 1997]. The CORE approach emphasises the need for a structured curriculum. This feature seemed particularly important for this learning domain. Content is organised into functional units which each culminate in the learner displaying a new level of competence in the domain [Boyle 1994]. The pedagogical emphasis is on learning from examples in context. This approach encourages the learner to infer and develop their own understanding of the domain. This understanding is progressively refined as the learners attempt to answer questions and solve problems. Each learning block then culminates in the learners giving a full expression of the competence they have acquired.

The CORE approach was first applied to learning to program [Boyle and Drazowski 1989, Boyle and Margetts 1992]. The competence was expressed in this domain by the students writing a full program incorporating the language constructs they had just mastered. Multimedia technology supported the creation of virtual environments which permit this approach to be applied to a wide range of domains. It was decided to develop the main prototype using this approach, and to assess its effectiveness against two control conditions: a multimedia lecture and a hypertext based electronic book.

The objectives of this study were:

- To develop a computer based multimedia learning environment for skeletal scintigraphy (an aspect of nuclear medicine) based on a constructivist guided discovery approach.
- To evaluate the guided discovery approach against two control conditions.
- To identify which guided discovery design principles enhance learning.

Method

Three learning methods were developed: guided discovery (CORE) computer assisted learning environment (experiment condition); computer based learning environment based on a book metaphor with hypertext (control condition 1); typical multimedia lecture (control condition 2). The syllabus for each was closely matched. Both computer versions contained extensive use of video with narration, medical images, pictures and text. The typical multimedia lecture used slides and overhead projection acetates.

Prior to the comparative evaluation a range of measures were taken to establish learning method quality. For the computer based versions these included various estimates of software usability (eg Software Usability Measurement Inventory (SUMI), Porteous [1993]), robustness, accuracy and content completeness. For the multimedia lecture the lecturer’s ability was assessed objectively (using a standard instrument) on two occasions: one during the experimental lecture and one under non experimental conditions. Comparative data was established from other university lecturers.
For comparative evaluation the three learning methods were embedded in the curriculum of a
diagnostic radiography degree. Three groups of second year diagnostic radiography degree students
experienced one of the three learning methods, various measures were taken to assess group
similarity. Twenty five students participated in this part of the evaluation. Three quantitative
measures were taken to assess student knowledge. A multiple choice questionnaire (test) assessed
baseline knowledge. Post learning knowledge was assessed by the test, essay and case study. Since pre
tests may improve learning by communicating what should be learnt from the material the baseline
test was administered under examination conditions three weeks before students used the learning
experiences. The test was administered again immediately after the learning experiences. The essay
was completed under examination conditions within 48 hours of students using the learning
experiences. The case study was completed during the five days following exposure to the learning
experiences. Marking schemes were developed and applied for all three measures and two assessors
marked each script blind.

Qualitative measures were taken after the 25 degree students and an additional 20 volunteers had
experienced the CORE software. Observations, interviews and a focus group discussion were
conducted. Additionally the 25 students completed a questionnaire after they had experienced all three
methods of learning. This questionnaire established their opinion about each of the three learning
methods.

Results

SUMI estimates indicate both computer based learning methods were consistent with or higher that
state of the art software usability. Observations and user comments support this finding. The software
was robust and the curriculum was acceptable both in range and accuracy. Lecturer assessment
suggested he performed similarly under experiment and non experiment conditions. In addition the
lecturer performed similarly to the comparative data established from other university lecturers. These
findings indicate the three learning methods are of an acceptable quality and suitable for comparative
evaluation.

All quantitative knowledge assessment measures were marked using the marking schemes. Minor
variations between markers were only noted in the essay. For the minor discourses an arithmetic mean
was taken between the two marks. Marks were concordant between markers for the case study and
tests.

The test data demonstrated a significant baseline to post learning experience increase in knowledge
(p<0.001, paired t test), see table 1. The case study data demonstrated no significant difference
between the groups (table 2). Overriding course management problems precluded the lecture group
from completing the case study. The essay data (table 3) demonstrated a statistical difference between
the CORE and lecture groups (p=0.0001, unpaired t test) and between the CORE and electronic book
groups (p=0.002, unpaired t test). Time to complete the learning experiences is indicated in table 4.

Discussion

The various measures taken to assess student group similarity indicated: academic abilities were similar; age ranges and means were similar; gender bias was in favour of females. Unfortunately, the three groups had dissimilar knowledge of the domain (established through the baseline test).

The lecture group had the highest baseline test knowledge, being significantly higher than the electronic book group (p<0.01). Other confounding factors between groups were however comparable. Academic ability, based on year I and year II results was not significantly different. Computer ability [Eachus 1996] analysis indicated, between groups, there was no significant difference. Analysis of group composition suggests that, apart from baseline knowledge, the groups are similar for a range of confounding variables and that differences in learning between the three groups may be attributed to the learning methods themselves.

All three groups demonstrated a significant knowledge increase from the baseline condition (p<0.001, paired t test). The CORE group had the highest average post learning score (76%) with the lecture group achieving the lowest (59%). No significant difference exists between the groups, though the difference between CORE and lecture groups was almost significant at the 5% level (p=0.07, unpaired t test). Average knowledge gain is the same for both CAL conditions (48%), with the lecture group demonstrating the lowest increase (24%). This difference is significant (p=0.005, unpaired t test). As illustrated by knowledge gain, the electronic book and CORE groups both perform better than the lecture group. This may suggest that CAL is more effective than lectures for short term knowledge retention.

On the case study the electronic book and CORE groups perform similarly, with no significant difference between them. For qualitative comparative analysis, during completion of the case study, students were allowed to use any learning resource at their disposal. This may suggest that allowing access to other learning resources can affect the outcome and lessen the difference between the conditions. The essay data clearly indicates the CORE group perform significantly better than the other two groups. This may suggest that this type of assessment, learning using a CORE approach, may assist with internalisation and retention of information, whereas the lecture and electronic book may not promote this as effectively.
A similar comparative study [Boyle 1994], outlines a large scale analysis of a CAL prototype for computer programming. The prototype, based on the CORE approach, involved four groups of students studying four different programming courses. The CORE prototype was assessed objectively by comparing the performance of the volunteer students with previous student cohorts. The previous courses had been delivered by a “traditional” lecture programme. Year I results were used as the performance indicator with which groups and cohorts were compared. Students using the CORE prototype demonstrated a decrease in failure rates for two of the courses: in one the failure rate decreased by 47%, the other by 38%. The Applied Computing course demonstrated a minor improvement in pass rates, the final group however (Higher National Certificate course) failed to show any improvement, though an explanation was offered relating to the lack of planning for the implementation of the CORE method. A mixed response was therefore noted, but generally this was in favour of the CORE approach.

Boyle indicated the methods of assessment were those traditionally used on the courses - a combination of course work and examinations. Boyle’s study suggests that CAL for computing may enhance learning and the approach produces similar, and in some cases superior, outcomes when compared to the traditional lecture programme. The data in the current investigation has similarities in this respect. For example, certain elements of the post learning test and case study data indicate similar outcomes. The essay and elements of the test data indicate the CORE condition elicits an improvement in learning.

Qualitative analysis students and volunteers indicated the CORE environment was the preferred method for learning. Factors which enhance learning are varied and establish the value of certain CORE design principles. The CORE approach encouraged volunteers to follow the structure imposed by the designer, whereas the electronic book did not. Many features within the CORE focused learning. For example, assessment improved motivation to learn, allowed for rapid assessment of learning effectiveness and enabled identification of misunderstandings. Immediacy of assessment feedback was considered important in rapid and effective learning, a volunteer indicated

"the immediacy of the computer feedback is very important ... when a human teacher assesses me it can take weeks for the feedback and by then I have forgotten what responses I had initially given".

Mistakes were also seen as opportunities from which to learn, particularly since corrective feedback was offered on incorrect response. One volunteer indicated

"I tend to learn from my mistakes".

The CORE environment was considered engaging, enabling learners to switch off from distractions and even enjoy the learning experience. One volunteer indicated

"the CORE held my attention for two hours .... amazing!!"

Another user was amazed that

"CORE with headphones sucked me in ..... I just got cut off from distractions"

The use of real examples which integrated the fundamental and discrete subject areas was important for two reasons. First learners recognised that the examples (particularly the video clips) conveyed important information which they had to identify: they were not to be viewed passively. Second, learners recognised the value of learning from real examples because they assisted in assimilation of the discrete subject areas in context. One volunteer indicated

"the use of real clinical video and pictures is better than text alone ... I think you scrutinise it more and it therefore makes you think harder"
Even though the CORE approach was considered the best method for learning several limitations were noted. Human tutor support was still considered essential, particularly for improving motivation and allowing learners to ask their own questions. Additionally, at times, the lack of ‘full multimedia’ appeared to detract from learning. Finally the increased time to complete the CORE, compared to the other methods, was considered as a limitation. However if the learning was effective, as suggested by this study, it is clear the additional time invested was time well spent.

Conclusions

The CORE environment was found to be more effective than the two control conditions. Factors which contributed to the effectiveness were varied and included the value of subject integration, assessment and learning in context. Limitations included lack of human tutor support and increased time to learn within the CORE environment.

HyperMeasure: A Hypermedia Casebook for Teachers

Jeffrey K. Horvath
Andersen Consulting Education
jeffrey.k.horvath@ac.com

Abstract: Recently, there has been much optimism about the promise of hypermedia in case-based teacher education programs. For years, the predominant medium by which cases have been communicated has been text. Many teacher educators have become dissatisfied with the difficulty of representing the complexity in an ill-structured domain such as teaching with purely textual case descriptions. In response, many teacher educators have turned to video presentation of cases. Video, it has been argued, can come closer to representing the complexity of a case in an ill-structured domain such as teaching. Video by itself, however, usually lacks organizational structure and can be difficult to work with and understand for a novice. Hypermedia, with its ability to incorporate multiple forms of media, including text and video, has been proposed as an ideal medium with which to communicate cases in teacher education. As with any powerful tool, however, hypermedia technologies must be used in a thoughtful, well-principled manner in order to take full advantage of its capabilities. This paper describes the design of a case-based hypermedia system, HyperMeasure, designed to help teachers further their understanding of how children think and learn about measure.

The work presented in this paper was completed as partial fulfillment of the degree of Doctor of Philosophy in the Educational Psychology department at the University of Wisconsin-Madison.

In recent years, teacher educators have become dissatisfied with the traditional 'theory and methods' form of teacher education [e.g., Lampert & Ball, 1990]. In response to this dissatisfaction, many educators and researchers have proposed new case-based methods of teacher education [c.f., Case Methodology, 1990; Case Methods, 1991; Merseth, 1996]. There is growing concern, however, about the most effective way to present cases to teachers [Vye, Burns, Delclos & Bransford, 1987]. Researchers have become dissatisfied with textual and strictly video presentation of cases and have suggested hypermedia as a powerful medium in which to present cases for teacher education [Lampert, Heaton & Ball, 1994; Merseth & Lacy, 1993]. Despite all of the optimism about case methodologies and the promise of hypermedia, however, there has been little empirical study of the effectiveness of hypermedia case-based teacher education materials.

Case-based Methods for Teacher Education

Traditional teacher education reduces the complexity of the learning process in order to focus on its regularities. New teachers are expected to "apply" knowledge of these regularities to the classroom contexts in which they later find themselves [Lampert, Heaton & Ball, 1994]. New teachers often are thrown into the classroom with nothing but a bag full of general theories and very little practical knowledge about how to handle the everyday specific complexities that they will encounter. Not surprisingly, this mismatch between teacher preparation and practice has led to under-prepared teachers.

There has been much optimism recently about the promise of case-based reasoning [Riesbeck & Schank, 1989] and, by extension, a case-based pedagogy for educating teachers [c.f., Case Methodology, 1990; Case Methods, 1991; Merseth, 1996]. Although there has been little empirical work demonstrating the benefits of a case-based pedagogy over traditional knowledge delivery pedagogies for teacher education, researchers have proposed a number of advantages for case-based methods in teacher education for several reasons. First, as demonstrated in other fields [Carter & Unklesbay, 1989; McNair, 1954; Williams, 1992],
Case-based instruction develops skills of critical analysis and problem solving which are critical in ill-structured domains like teaching. Second, cases have the power to represent complex situations in a realistic, understandable fashion. Third, cases can provide teachers with key examples of student thinking [c.f., Fennema, Carpenter, Franke & Carey, 1993]. Finally, cases allow students to actively engage in their own learning.

**Hypermedia Presentation of Cases**

Hypermedia has a number of features that make it a potentially useful learning medium for presenting cases of teaching and learning (Koehler & Lehrer, in press). First, different chunks of information can be directly associated in multiple ways. Cognitive flexibility theory posits that in order to learn and understand complex material, learners must approach the domain from multiple perspectives (Spiro, Coulson, Feltovich, & Anderson, 1986). Second, hypermedia allows for the presentation of cases in chunks that are large enough to capture the real world complexity of teaching, but small enough to be comprehensible by novices. Third, a case-centered hypermedia system allows for multiple viewpoints of the same subject and the active construction of one's own knowledge (Bransford, Sherwood, Vye & Reiser, 1986). Since hypermedia systems are designed as a non-linear, web-like structure of linked ideas, there is no predefined path that a learner must necessarily traverse when navigating through that web. As such, each learner must decide their own trajectory through the web and, hence, decide their own trajectory for potential learning. Learning in a hypermedia system is a learner-centered, constructive process.

In summary, hypermedia seems to be a better medium for case-based teaching methods than either the text-only or video-only methods that have been tried in the past. Text-based systems have difficulty capturing all of the complexity of cases, whereas video-only systems can have difficulty providing a coherent organizational framework for viewers. Hypermedia, by combining multiple media formats, can provide the best of both worlds—rich video with textual annotations and organizational structures.

**Teaching Measurement for Understanding**

Today, children typically enter school having experienced a great many ideas about space—how to describe it, how to depict it, how to navigate through it, and, most relevant here, how to measure it [Lehrer, Jenkins & Osana, 1997]. In their pre-school years, children frequently hear measurement terms such as "inch" and "foot" and often see conventional tools of measurement such as rulers, yardsticks, and tape measures. Moreover, they are often familiar with the procedures for measuring length. For example, they often know that in order to "measure" something, you "put a ruler next to it and read off the number." This knowledge is typically enough to allow them to measure some objects successfully. The teaching of measurement in the primary grades is usually characterized by giving students rulers, having them measure a few items around the classroom, and asking them to record their results on a worksheet. The introduction to area measure is typically just as sterile. Learning how to measure area usually boils down to counting squares or memorizing a formula.

As Nitabach and Lehrer [1996] point out, this method of teaching 'measurement' falls woefully short in helping children develop an understanding of space. Procedural competence is not the same as understanding. If we are to expect teachers to be able to teach measurement for understanding [not just procedural competence], we must help them identify the fundamental building blocks of an understanding of measurement [Horvath & MIMS Collaborative, 1997]. The purpose of HyperMeasure is to help teachers understand how children think and learn about measure. For a more complete description of the measurement principles which informed the content of HyperMeasure, see Horvath (1998).

**Designing HyperMeasure**

The design of HyperMeasure was informed by a set of cognitive principles of hypermedia design [Koehler & Lehrer, in press]. Learning with hypermedia is sensitive to a number of factors including the
structure of the domain and the design of the interface. Koehler & Lehrer’s [in press] design principles take what has been learned from cognitive science and human-computer interaction over the past few decades to describe five principles for designing high-quality hypermedia systems. In the following sections, I will briefly describe each of the five principles and then explain how each is realized in HyperMeasure. For a more complete treatment of these design principles, see Koehler and Lehrer [in press].

Use Non-Linearity To “Criss-Cross” The Landscape

For complex domains, provide multiple entry points to the information. According to cognitive flexibility theory, learners are much more likely to learn and understand material from complex domains if they can revisit the same ideas from multiple perspectives [Spiro, Coulson, Feltovich, & Anderson, 1986]. HyperMeasure is designed along four thematic strands - Big Ideas, Cases, Tools & Notations, and Connections [Figure 1a]. These four themes provide four different entry points to the information contained in the system.

Provide Learners with Examples

It is important to provide learners with examples of that which is to be learned when the properties to be learned cannot be explicitly stated, or when such properties are highly related and “criss-crossed” in the manner described above. Moreover, examples can play a crucial role in case-based learning [Williams, 1992] and in helping learners construct relationships [Ward & Sweller, 1990].

HyperMeasure is replete with examples, primarily video examples, of students’ thinking and classroom activities. These videos exemplify all of the information [e.g., principles of measurement, the role of tools, etc.] discussed in the system. Additionally, the cases in the Case theme are all extended examples of children’s thinking and learning about measure. A case can be thought of as a deep, extended example. As such, the underlying pedagogical principle at work in HyperMeasure is to teach via examples.

Make the Structure of the Domain Visible

Domain experts typically have more principled and more numerous connections between individual pieces of knowledge than their novice counterparts for any given domain [Chi, Glaser, & Rees, 1982]. To help novices move towards a better understanding of a domain, the representational landscape should explicitly model the conceptual landscape of the domain. To make these connections and associations explicit, and thus more accessible to a novice, hypermedia documents should clearly signal the presence and nature of associations (e.g., typed links). Hypermedia systems should also include navigational tools that explicitly show associational structure to readers (e.g., graphical browsers).

HyperMeasure includes many tools which help make the structure of the domain visible to the user [Koehler & Lehrer, in press]. Many of these tools serve the dual purpose of navigation as well. This will be discussed further in the next section. HyperMeasure includes five tools that help the user understand the
Make Navigation Easy

Navigating in hypermedia systems is different from navigating in traditional learning mediums such as texts because readers of hypermedia are required to select the learning sequence. This sequencing process, called “navigation,” is demanding of working memory [Recker, 1994]. When the resource demands of navigation and learning jointly exceed working memory capacity, users can become confused and “lost in hyperspace.” To mitigate this problem, hypermedia systems should make navigation as easy as possible.

Many of the structural tools discussed in the previous section serve the dual purpose of navigation [Koehler & Lehrer, in press]. For example, the hierarchical outline [Figure 1b] can be used to navigate through HyperMeasure by selecting items from the outline.

Layer Related Information

In many hypermedia systems, clicking on a link replaces the current screen with new information. The transitory nature of information (i.e., one screenfull of information can be replaced by another) can be problematic to a user when that information is implicitly related. For example, text and video examples should be layered on top of the information that they are exemplifying because examples only make sense in relation to the principles conveyed in the main text. That is, to claim that something is an “example” is to claim that it is an “example of something.” For readers to make the connection between an example and a larger principle requires access to both. By “layering” information, there is less “cognitive cost” for accessing information.

HyperMeasure is replete with annotations, most which are video [Figure 1c]. HyperMeasure, as it is currently designed, contains approximately 2.5 hours of video clips, broken down into approximately 100 different clips. Nearly every card in the system uses these annotations to exemplify the information discussed on the card. All annotations are implemented via pop up windows [Koehler & Lehrer, in press]. When a user selects a video annotation typed link, a popup window appears with a brief textual description of the content of the video. The user can then watch the short video clip. All the while, the original anchoring text from the card is still present on the screen so that the user does not have to remember the information and, thus, their working memory should be less taxed.

Integrate Design and Evaluation

It is imperative that the design of a hypermedia application be tightly integrated with assessment and evaluation of that system. It may seem obvious that the designer of a hypermedia learning tool should test the tool to determine if it successfully helps the user learn the content information. However, all too often, designers base their design decisions on what they think will work but never actually take the time to check to make sure that it does. The design of HyperMeasure has been strongly based on the results of formal and informal feedback from users and other design experts during each stage of development.

During the early phases of the development of HyperMeasure, several researchers and elementary classroom teachers provided detailed feedback about the overall design of the system. The type of feedback that they provided typically dealt with the overall design of the system (e.g., card layout, naming conventions, etc.). All of the feedback was incorporated into the early design of HyperMeasure. While these early reviews of HyperMeasure were important, they did not provide a true indicator of how well users could actually learn about measurement. Consequently, as part of the design process, an empirical study was conducted to investigate what type of learning occurred when HyperMeasure was used by pre-service teachers (i.e., the population that HyperMeasure was intended for) for a prolonged period of time. The learner-based results of that empirical study [Horvath, 1998] will be used to further refine HyperMeasure.
In summary, HyperMeasure was designed based on a set of cognitively-based design principles. Each of these principles was based on the findings of research in cognitive science and human-computer interaction. However, as in all designs, the application of these principles for the design of HyperMeasure involved successive approximation, not simple algorithm.

Conclusion

There has been much optimism in recent years about the promise of a case-based pedagogy for improving teacher education. Cases are powerful instructional tools which have proven to be very useful in other professional fields. Many researchers feel that hypermedia technology has many advantages that make it a valuable method for communicating cases. Unless these capabilities are combined with a firm understanding of cognitive science and how the two interact, these advantages will never by fully realized however. HyperMeasure is a case-based hypermedia training system designed to help grade-school teachers learn about how children think and learn about measure. It was designed with a set of well-thought out, cognitively-based design principles so as to maximize its usefulness and power as an instructional tool. For a discussion of an empirical study of the success of HyperMeasure in helping pre-service teachers improve their knowledge of teaching measurement to children, see Horvath [1998].

Abstract: This paper describes our experience at the University of Ottawa, Canada's largest bilingual University, in creating materials to support the teaching of Zoology courses in both French and English. Over the past four years the project, Digital Zoology/Zoologie Numérique, has evolved from a series of digital slides to an electronic atlas that is now used by students for: preparation prior to their labs, support during the labs, and review after the formal lab sessions have been completed. DigiZoo, as the students have named it, consists of approximately 30 modules providing students annotated diagrams and photographs of the same specimens that they use during the lab. It also includes brief descriptions of the major classes and phyla including a hyperlinked glossary for key zoological terminology and additional information on the evolution of the various taxa using interactive cladograms. DigiZoo does not replace traditional instruction but is, instead, provided as an optional resource that is available for student's use. Data on its use indicate that the students spend a significant amount of time using it and do so without requiring any form of academic coercion.

Introduction

As Steve Gilbert (1996) points out in his article “Making the Most of a Slow Revolution” we are, in many cases, still waiting for a demonstration of the effective use of the new technologies in teaching in Higher Education. Although there are a number of reasons for this, one common thread that is emerging from successful applications of information technologies to teaching is the importance of addressing pedagogic, or curricular objectives for using technology, rather than using it for the sake of the technology. As Diane Laurillard (1993) wrote:

“We should return to a consideration of what the student needs. Then we bring the two (student and media) together to see if they fit. The (pedagogic) needs as defined will challenge the media, and clarify the extent to which they fail to deliver what pedagogy requires...In reality, this never happens. Funds are given for the development of materials using a particular medium, and the search is on for the learning objective that best fits it.”

New approaches based on technology must be grounded in the fundamental program of the department and have the support of the faculty members involved if they are to succeed. The link to the student’s own needs is also just as important. In our own project, Digital Zoology/Zoologie Numérique we were concerned about whether we needed to force the students to use the application with some kind of a participation mark or, instead, let them vote with their keyboards on the effectiveness of the material being created by making it optional. We report in this paper on the reasons for creating Digital Zoology/Zoologie Numérique and the consequences of our decision on how we integrated it into the course.

Pedagogic Objectives

The role of the Zoology course in the core program of Biology at the University of Ottawa was being questioned by the Department. Its cost, relevance, numbers of students and the availability of teaching materials were all open for discussion along with what potential new technologies had to solve, or at least help with, some of the challenges that we were facing. Among these were:
• **Didactic materials in French.** There is a wealth of zoological material available from North American publishers but very little is available in an electronic format. There was little or nothing available in French in the traditional media, and material in an electronic format was non-existent. What was available in French was more suited to High School rather than Post-Secondary level instruction because of the larger size of the secondary school market.

• **Availability of materials in the new media.** For obvious reasons, scanning existing materials was not a viable alternative for creating the materials we required. In addition to drawings, the special photographs of dissections and laboratory preparations that we needed were not available in either traditional or new media.

• **Student preparation and review.** As is traditionally the case, Zoology students are given a series of stylised drawings, some specimens, and a text based manual with instructions on how to dissect and view the salient features of their specimens. With only one chance to dissect the specimen and only the one lab period to work with it, there is no time for the students to practice and correctly identify what they were expected or see. It should not be a surprise that many students did not find these dissections interesting.

• **Cost of specimens and their effective use.** We felt that we should be able to use the new media to enhance student’s understanding of their materials and at the same time link the in-lab experience to subsequent review by the students. We did not want to replace traditional dissection, a fundamental skill in Biology, with virtual dissections.

• **Demonstrators background.** Introductory Zoology courses cover such a wide and broad range of materials that it is unlikely that any graduate teaching assistant has the breadth of knowledge to effectively demonstrate the lab sessions. This is especially true when you realise that the current graduate TA’s are the products of the Zoology courses with many of the same problems that we had already identified.

• **Lexicon of Zoology.** Every discipline has its own unique lexicon which it is appropriate to expose the students to whenever possible.

**Solutions to the Challenges**

**BIODIDAC**

Because French and English versions of the illustrations and photographs that we needed were not available we created them and catalogued them on a web site: BIODIDAC (www.biodidac.uottawa.ca). The artist agreed to give the copyright for the illustrations to BIODIDAC and these are distributed royalty free on the web site for educational and non-profit applications.

**Figure 1. Sample screen showing specimen, diagrams and annotations.**

**Figure 2. Taxon information box showing interactive glossary.**
In addition to the drawings that were required for the course, digital photography was used for the specimens, microscope slides, and dissections that the students would be seeing in the lab. The material in the image bank was also utilised in the lectures using PowerPoint presentations. This created a link between the lecture and lab components of the course. The BIODIDAC image bank now contains close to 3000 images, and five Canadian Universities have contributed images to this on-line pedagogic resource in Biology.

Digital Zoology / Zoology Numérique

A major part of DigiZoo, as our student's call it, are the components designed to support the laboratory sessions with the use of annotated diagrams and photographs of the specimens that the students work with (fig 1). In addition to laboratory support, DigiZoo contains a hyperlinked glossary of zoological terms in both French and English along with information on the biology of the various taxa being studied (fig 2) and their evolution through the use of interactive cladograms (trees) (fig 3). DigiZoo currently consists of 29 modules including more than 40 organisms that are commonly used in traditional Zoology laboratory exercises. It is used in the French and English versions of Animal Form and Function (introductory zoology), and the third year courses Invertebrate Zoology and French and English versions of Vertebrate Zoology.

Figure 4. Interactive cladogram.

Figure 3. Module utilization on each day of the week by students in the Thursday and Friday laboratory sessions.

In this paper we report on the use of DigiZoo by students in the Animal Form and Function course (95 students in the English section and 68 in the French section). Although only twelve modules relate directly to that course, students are not prevented from looking at others in the application. If they choose something that they are not responsible for they are advised of that before that particular module opens. Students have access to DigiZoo on the 60 computers in the Undergraduate Science Computer Room which is open from 8:30 am – 5:30 PM Monday-Friday and during the laboratory sessions where a computer is shared between 7-8 students. The graphically intense nature of the materials does not lend itself to web based delivery, although samples of individual modules, without navigational links between them can be found at http://www.edteched.uottawa.ca/reports/digizoo.

Students in the course are not required to use DigiZoo. For those who do, the application's design allows us to log their activity and movement between the different modules in the program. Students are advised that the program does monitor activity but that the log files are not analyzed until after the final grade of the course has been given. The associated lab sessions were on Thursday and Friday mornings.
Student usage

Evidence of the effective use of the modules for preparation and review of the lab materials can be found from the data log for student’s use of the modules. The number of hits, when a module’s file is opened and closed, indicates that most of the students in Thursday’s lab visit DigiZoo on either the Wednesday before or the Friday following their lab. The majority of students in the Friday lab make the heaviest use of DigiZoo on the Thursday prior to their lab session (fig 4) indicating that DigiZoo is being used to prepare for that current week’s lab. The second part of our objective was to allow the students to review lab material prior to the lab exam. If we look at the number of hits that had a duration greater than 5 minutes (the module was in use for more than 5 minutes) in the week prior to the lab exam, we see the modules being opened from 120 to 150 times each day (fig 5) compared to the lower levels during the remainder of the semester. Clearly the students were using DigiZoo to review for their final exam.

When the data is plotted for either the first or second half of the semester, without the week prior to the exam (first part of the semester is shown in fig 6), we observe an interesting echo with respect to how the modules for any particular lab are used. There was a peak of activity during the week when the lab was offered and a second peak, or echo of usage, the following week (Fig 6). This is explained by the observation that, on average, a student

![Figure 5. Number of hits, modules opened and closed, during the semester for each of the lab sessions.](image1)

![Figure 6. Number of hits, modules opened and closed, for each of the labs during the first half of the semester.](image2)

![Figure 7. Number of time that modules were being used for different lengths of time.](image3)
logged into DigiZoo 5.9 times during the 11 weeks of the labs. Over that period the average student used the application every other week to look at the materials for the next day's lab (initial peak) and review material from the previous week (echo peak from previous week). On average, students used 12 modules, the minimum number that are directly related to the course. We felt that any module that was open for less than two minutes was being used only for navigation or quick reference and we did not include those in the analysis of how long individual modules were used for study (fig 7). Approximately 700 times the students worked in a module for between 2 and 5 minutes; 500 times for between 5 and 10 minutes.

We have not quantified the effect of DigiZoo on the effective use of the lab specimens but one observation that we do have is that student activity in the lab sessions was affected by the presence of the computers in the lab. Where previously students would attempt their dissection and then ask for an explanation of the result from the Graduate Teaching Assistant they were now asking each other for explanations and referring to the materials available on DigiZoo which was available in the lab. This effectively freed the Teaching Assistants to do other things during the lab which allowed us to add small group discussions to the sessions.

Evidence for the effectiveness of DigiZoo in preparing the demonstrators for the labs is only anecdotal. Graduate TA's reported that their ability to access the materials across the network allowed them to better prepare and become familiar with the materials at a time that was more convenient to them than the traditional weekly demonstrator's meeting. They could get their own specimens, take them back to their labs and work on them at a time convenient to them.

Conclusions

Although preliminary in nature, we feel that these results confirm the importance of combining technology and pedagogy to effectively meet the needs of students and the objectives of the curriculum. The student's use, either by its frequency or duration, supports our contention that they feel that DigiZoo is an important and valuable addition to the course. This is further supported in a less quantitative manner by student's comments in the course evaluation itself.

Sir John Daniels (1997) describes the success of the mega-universities as being due, in part, to technology and that "They owe it to the new application of technology rather than to applications of new technology". We feel that this very subtle semantic distinction applies to our own DigiZoo project which does not depend on the most recent advances in the use of multimedia. Instead it relies on the use of digital imagery distributed using networked resources that are common to many University campuses and commercially available multimedia software (Authorware). We also feel that beyond the technical issues that the blend of technological solutions with the pedagogic challenges of course and curriculum revision have allowed the creation of a tool that is completely integrated into the course's lecture and laboratory components.

The success of our attempt at achieving this is supported by the students own voluntary use of DigiZoo, demonstrating that if a multimedia application meets the type of criteria outlined by Laurillard (1993) then we do not need to use any form of academic coercion to demonstrate its validity.

Using an Open Architecture to Build Social Learning System on World Wide Web

Chang-Kai Hsu, Min-Lung Lee, Wen-Han Lin and Jia-Sheng Heh
Department of Information and Computer Engineering
Chung Yuan Christian University, Chung Li, Taiwan, 320, R.O.C.

Abstract: This paper discusses a separate, rearrangeable and open architecture of Social Learning System on World Wide Web. Rearrangeability means that such systems are built by several independent modules, called software components (Soft-ICs), and a suitable recombination of these modules can create a new SL system. From this viewpoint, all SL learning models can be analyzed into several basic learning components stored in different places. This brings the charm of separateness. Openness means that every module communicates through standard protocols, therefore other people are able to develop their own components if necessary.

1. Introduction
Late in the 1980s, the research of SL (Social Learning) system became mature. [Blo84][Chan88][Chan95] An SL system describes learners’ behavior and their relationship in a learning group. The participants of an SL system include users and their learning partners, which could be real human beings or computer-simulated agents.

For SL systems, it is hard to develop a ready-made system, which can fit different new requirements. As WWW (World-Wide Web) becomes a universal networking platform, it is possible to connect Web-based SL systems across the world. [OCL97][OCHH97] However, the flexibility of such systems is still a problem.

If any system’s subsystems can be decided in advance, then it is possible to create such system with specific proposition. This is an idea similar to the layout of a circuit with different kinds of IC (Integrated Circuit).[CDK94][Orf96] Such Soft-IC and soft circuit concept can be applied to set up our SL systems. To facilitate this approach, this paper analyzes SL systems based on Soft-IC concept.

Using these ideas as the core, we develop the rest sections. Section 2 is focused on the model of SL systems, the cooperation among learners [Chan95a] and the basic elements of Web-based SL systems. In section 3, these basic components and their interfacing format, interactive flow and packet formats are analyzed in details. Section 4 uses Petri net to analyze the above basic learning components. Two realistic learning models of SL systems: asynchronous cooperative learning model [TSH97] and composite learning system are implemented on WWW to prove the open architecture of SL systems in section 5. Section 6 is a conclusion.

2. Learning Models of Social Learning Systems
Social Learning systems are often divided into two kinds: Centralized SL systems and Distributed SL systems. The former means that all learners and teachers have access to the same computer; whereas, learners and teachers in the latter systems are located in different places and communicate through network. As Internet emerges, distributed SL systems become more popular today. No matter whether centralized or distributed, social learning systems are usually composed of several independent modules, called components or Soft IC. Each component communicates with other modules through standard protocols and forms an open architecture, as Figure 1 shown.
The interactions of distributed SL systems can be *collaboration* and *competition*. In addition, they both have two kinds of spatial temporal relationship: *synchronous* and *asynchronous*. With these taxonomy, Web-based SL systems can be classified into seven models:

- **Single Learning Model**: In this learning mode, there are many limits when studying. Since a learner does not keep any connection with server, the learning progress could not be recorded. However, he/she can download necessary learning systems to his/her browser.

- **Single Learning On-Line Model**: The user must login a server and after get authentication, he/she can obtain many resources from server. This system can record all the learning process. In this mode, the courseware can always be kept at the latest version and the user can often obtain the latest knowledge and teaching resources.

- **Asynchronous Collaboration Learning Model**: Users also login servers, but need not go with other users at the same time. Users logining at different time may exchange messages through BBS (Bulletin Board System) or mailbox. Any user can post his/her problems to message board or BBS to wait for answers of other. Therefore, users help others asynchronously.

- **Asynchronous Competition Learning Model**: Users must login a server but need not have any connection with others users. However, all learning data, such as users’ learning rate, their scores and learning states, are collected in the server and can be acquired by every user. This forms one kind of competition among users.

- **Synchronous Collaboration Learning Model**: Users login some servers and then their learning states are recorded accordingly. Moreover, since there are communication links among users, such as white board and talk, they can solve problems through questioning or opinion exchange. This makes users learn faster and more efficient.

- **Synchronous Competition Learn-ing Model**: In this model, every user logins one server and connect to other users. These users’ learning states are recorded and broadcasted. Thus, the progress of one user will incur others’ emulousness and competition is formed.

- **Mixed Learning Model**: Each of Models 1 to 6 provides one special character of some ideas. This model combines more than one of above learning models and forms a kind of multiple characters.

After these seven learning models are analyzed, some general concepts embedded in these models can be caught. It is possible to find several *BL (basic learning) modules*, which can be used repeatedly. These basic learning modules include system control panel, learning panel, identification module, recorder, bulletin board system (BBS), learning status display, real-time communication module, SC (synchronous controller) and GC (group controller), whose relationship with the above seven learning models are listed in Table 1.
3. Analysis of Basic Learning Modules

In order to implement SL systems on WWW, we first have to analyze BL modules to understand their basic functionality and communication requirements. With these modules, any kind of SL systems on WWW can be assembled easily. This makes an open architecture of social learning systems.

- **Functions of System Control Panel**
  (1). System flow control (includes scene change control): This component sends open/close-window messages to browser to change homepages (scenes). It also receives messages from browser and parses it to do some relevant process.
  (2). Learning model control: by what users assign.
  (3). User identity Recording: calls identification module to execute user authentication process whenever user logins or other modules inquire.

- **Functions of Learning Panel**
  (1). Textbook browsing: for users’ reading or doing do some exercises.
  (2). Measurement of learning outcomes: It could be an instructional questionnaire, a preview test, a score rating or a general exercise. After processed, its results will be shown on learning status display. This panel is the most important interface between users and system kernel.

- **Functions of Identification Module**
  (1). User authentication: When getting user’s identity from system control panel, this module will check user’s registration data, such as username and password, and then other modules can request user information directly.
  (2). User information management: This includes password change, user account creation/deletion and group creation/deletion. These kinds of information are so important that only administers can get access to them.

- **Functions of Recorder**
  (1). Data recording: processes and records any data sent by other modules.
(2). **Data restoration**: Other modules may ask for recorded data.

- **Functions of BBS (Bulletin Board System)**

  1. **Post/read/reply/delete message**: according to users’ instructions.
  2. **Change board and discussion forum**: ditto.

- **Functions of Learning Status Display**

  1. **Display learning status sent by other modules**: The display styles are also controlled by other modules through some control instructions, such as data type, data value, user’s name, group name, and so on. This module also handles some error exceptions.

- **Functions of Real-time Communication Module**

  1. **Transmit message inputed by user**: Then users can send messages to server in real time.
  2. **Show messages dispatched from server**: If there is any status change on server, this module will display the present situation instantly.

- **Functions of SC (Synchronous Controller)**

  1. **Get control token**: An SC client will send a login message to its SC server, then this server will deliver control token to the first user and announce to other modules or users.
  2. **Transfer token**: When another user asks for token, the SC server will decide the next token-owner.

- **Functions of Group Controller**

  1. **Create/Delete a group**: When a GC client sends a creation/deletion request including users’ number and group identification to GC server, GC server will add/delete relevant information to/from group database.

After analyzing social learning models and the corresponding basic learning modules, we can get some understanding of their relationships. Now, a few examples can be given to get indepth understanding.

First, we take a look at Single Learning Model. In this model, both System control panel and Learning panel are needed. However, Identification module is optional since a user can just read textbook, without logging in any server. On the other hand, Asynchronous Collaboration Learning Model implies that Identification module, Recorder, Bulletin board system and Group controller should be added. But other modules are not necessary.

Up to now, we have introduced basic functions of social learning components. By distributed object principle, every component is an independent object, which can be treated as a piece of software IC. The following will use these Soft-ICs to propose an open architecture of social learning systems on WWW.

### 4. Open Social Learning System

In order to analyze the key status of basic learning components and their relationships, Petri Net is chosen. A Petri Net is a quintuple \( P = \{p_1, p_2, ..., p_n\} \) is a set of finite place, marked by “\( \square \)”. \( T = \{t_1, t_2, ..., t_n\} \) is a set of finite transition, marked by “\( \square \)”. \( A : (P \times T) \cup (T \times P) \) is a group of directed arrows, marked by “\( \square \)”. These arrows represent the status that transmission from \( P \) to \( T \), or \( T \) to \( P \). \( M \) the place which owned token, marked by \( \square \). \( P \cap T = \emptyset \) and \( P \cup T \neq \emptyset \).

Under this basic definition, we can define a set of symbols in our analysis model:

1. \( \square \) represents a computer.
2. \( \square \) is one process in the computer.
3. \( \square \) is the present process.
4. \( \square \) represents an event on trigger.
5. \( \square \) is a user before computer.
6. \( \square \) is the user with some token.
7. \( \square \) is a memory buffer receiving event from another user.

With these definitions, many properties in multi-user multi-processing systems, such as multi-process branching, timeout procedure and multithreading, can be easily indicated, as Figures 2 shown.
Figure 2 System control panel and its procedure

By a distributed multi-server system. If any server crashed or got some trouble, the other servers still work normally. This means multi-server system provides more reliable environment. However, there still exist some potential problems:

Problem of Incomplete Components Loading

Because of the multi-processing architecture, more than one component may load data and do some processes at same time. This makes the whole system more efficient, but also brings some trouble. The system may be stuck in an unstable status, waiting for the coming all needed resources. When on WWW, this problem can be solved by the media tracker method provided by Java.

Problem of Chain-Calling between Components

This is a hidden problem in multi-tasking system. When one component called by another one wants to call a third component, this brings deadlock problem. On WWW, the function setTimeout() offered by JavaScript gives one solution. When a component is called, the system sets a timer. As the timer overflows, the system creates a new process/thread to go on. Thus, the blocking can be untied.

5. Experiment System on WWW

To prove the feasibility of our open architecture of social learning systems, a homepage named Social Learning System on WWW is made. This experimental homepage includes Asynchronous Collaboration Learning Model and Mixed Learning Model, each with courses being Chinese and mathematics.

As mentioned, the Asynchronous Collaboration Learning subsystem uses Learning panel and Bulletin board system in Chinese course, as Figure 3 indicated. As the snapshot shown in Figure 4, students can review lessons and post questions to message board at their free time. With such design, students can share learning experiences with friends from all the world.

Besides asynchronous message board, the Mixed Learning subsystem in Figure 5 possesses TextPhone to exchange opinions, Learning status display to show users' learning status and Synchronous controller to assign corresponding exercise. Moreover, a synchronous computer game embedded with some lessons is added to make students happy to learn, as shown in Figure 6.

6. Conclusion

In this paper, we propose an open architecture of social learning systems on WWW. This architecture possesses a set of independent learning components, a set of open interface protocols and one construction method. One example is actually implemented on WWW to demonstrate the feasibility and flexibility. Such structure can be applied not only to society learning system, but also to other similar systems.

Up to now, we only study the prototype and demonstration of this open architecture. More experts with professional knowledge and domain teaching knowledge should be invited in the future. Furthermore, such architecture should be invested through strict educational evaluation to prove its learning effectiveness.

Designing Instruction for the Web: Incorporating New Conceptions of the Learning Process

Nancy P. Hunt, Ed.D.
Education Centre
Lincoln University
Canterbury, New Zealand
huntnp@lincoln.ac.nz

Abstract: New technologies such as Magnetic Resonance Imaging (MRI) and Positron Emission Tomography (PET) have led to recent discoveries about how the brain works, indeed how we learn. The interactive capabilities of WWW-based instructional strategies can be employed to better match how we teach with how we know students learn. This paper provides a summary of new conceptions of how learning occurs, an overview of instructional strategies which are known to promote learning, and an argument for taking advantage of the interactive capabilities of the WWW to create an optimal setting for learning. It concludes with a description of a staff and media development project which successfully integrates these ideas to enhance undergraduate education.

Learning is the process by which we acquire new information. Memory is the process by which that knowledge is stored and recalled when required.

The typical tertiary education classroom, can better be described as a theatre of transcription than an optimal setting for learning. To walk into most undergraduate classes, one would likely see students frantically taking notes while their professor stands at the front engaging in a 50-minute monologue of factual information, stopping only to scribble a few words or a diagram on the chalkboard. There is often little interaction among the learners or between the teacher and learner.

How congruent is this description with what is known about how students learn? Not very.

The Learning Process

Previous conceptions of learning envisaged filling empty spaces with information, which became "bins" or neatly organised "filing cabinets" of knowledge from which the mind retrieved what it required. Today we know that learning is not a process of filling an empty bin with knowledge for later retrieval. There are no bins of knowledge that we look for when we learn or remember. A memory does not exist in a specific location in the brain. As early as 1949, it was known that long term memory is developed through the establishment of repeated connections, or pathways, among masses of neurones [Hebb, 1949]. It is the activation of the mental pathways, rather than the arrival at a specific destination, which enables us to learn and remember.

The brain works through "an electrochemical process, which distributes both chemicals and electric charges through an incredible network of tubes extending throughout the brain and body. It appears that learning consists of the growth of additional neural connections stimulated by the passage of electrical current along nerve cells (neurones) and enhanced by chemicals (neurotransmitters) discharged into the gaps (synapses) between neighboring cells" [Valiant, 1996]. Mental effort actually changes the physical structure of the brain, as additional neural connections are created, the density of the brain's mass is increased. (Note: To be called "dense" or "think-headed" is a compliment!)
People learn differently and know things differently because they take different pathways on different occasions, dependent on the context, their previous experiences, and their current physical and emotional state. Not all pathways are accessed in the same way. The nature of the learning or memory task will prompt different access routes.

However, as a particular pathway is re-used, additional connections are built which strengthen the linkages. Undoubtedly some of these mental pathways, like tracks in a forest, become so worn that the mind seeks to use these easy routes to arrive at an understanding -- the path of least resistance. Other paths are more difficult, are never discovered, or are overgrown for a variety of reasons. As pathways are lost with non-use, we “forget.” In many cases learning means adjusting existing pathways or removing pathways among memories that become “known” as incorrect.

Assumptions on the Nature of Learning

From the argument that learning occurs through building and traversing neuronal pathways, we can assume that:

- Learning occurs through making connections.

  It is doubtful that any idea is ever truly new; for a new idea would have to be constructed by the mind without any links to anything already known. Even a new word in a different language will be processed by the mind through links to existing words in the vocabulary. Those links may be words with similar meanings or simply similar sounds.

  For example, one person seeing the word “togafiti” for the first time may associate it with the word “graffiti” or a Roman toga. Another person, who recognised the word as Samoan and knew that the “g” is pronounced “ng” would follow entirely different pathways that lead to a connection with something to do with “Tonga.”

- The best predictor of what students learn is what they already know.

  New learning is more easily achieved if there is an existing pathway or framework waiting for it. These existing pathways can facilitate or hinder new learning. Sometimes existing pathways divert new ideas into what the learner wants to believe and thus affirms existing beliefs, even when the incoming idea is contrary. If what is “coming in” happens to be diverted into an existing pathway, the learner may feel more comfortable than if the new information challenges an existing concept. Any biology teacher can tell of students who achieve pass examinations on the principles of biological evolution, but not believe the basic tenets of the theory. The new pathways were not embedded or placed in contradiction with deeper held beliefs.

- Nothing is learned until it is internalised into long term memory, ready for later retrieval along well-worn pathways.

  Learners can create a new pathway easily, but that path will not be available in a month’s time unless it is very strongly connected with a specific context, something already known, or frequently rehearsed. Memory consists of all the bits and pieces of an experience -- the sights, sounds, smells, and emotions. Each fragment is stored in areas of the brain responsible for handling that particular sensation. Sounds are stored in the auditory cortex, sights in the visual cortex, etc. Keeping track of what’s where is a region of the brain called the “hippocampus,” which functions as a sort of memory index. Recalling an event requires re-assembling all those fragments, it is literally a process of re-membering.

- Students learn in different ways.

644
Students have different preferences for the way in which they learn and these preferences vary within individuals, across time and contexts. Each student's mental pathways are idiosyncratic. The specific bits of knowledge and links among them will differ because of life experience and preferred methods of receiving and processing information.

**Instructional Strategies which Promote Learning**

Perkins proposes that there are three dimensions of intelligence: neural, experiential, and reflective. He posits that in-born, neural intelligence can be influenced through nutrition and maturation, though very little can be changed through instruction or practice. Educators do, however, have great opportunity to influence the other two. New neural connections are developed as students experience their environment; and additional connections are created as they reflect on their experiences and seek alternate pathways to understanding. [Perkins, 1997].

Assisting students learn involves creating opportunities which facilitate the building and activation of these mental pathways. This is best done by gaining an understanding of what students already know; followed by designing activities which require them to reflect upon the new information, affirm correct conceptions, and alter any previous misconceptions.

**The Three R's --** Information is not knowledge. Information is not connected; it is "out there" waiting for students to bring it into their knowing. To do that, they need to do more than say it, print it, hear it, read it, sing it, dance it or spell it. Teachers have to encourage connecting information to something already known and that process is best achieved with Reflection. Reflection is thinking about something, examining any linkages or any connections anew; indeed thinking about one's thinking. Reflection is encouraged through asking questions which require analysing similarities and differences, applying the information to new situations, and assimilating, or synthesising, the new information with what was previously known. Lev Vygotsky discovered that the brain learns and remembers more information during socially interactive vs. isolated learning situations; the physical characteristics of the brain change as we engage with others [Caine & Caine, 1997]. Therefore, students may most benefit from presenting these questions as items for discussion in small groups or in the larger classroom setting.

Sometimes this reflective process will reveal misconceptions in previous understandings and prompt the Reconstruction of old pathways. Jean Piaget, a noted Swiss educational psychologist, developed a theory of intellectual development which recognised that increasingly complex levels of thinking and understandings of the world are developed in a number of stages brought on by life experience and maturation. For example, infants understand the world through their senses. If they can see Mommy, they know Mommy exists. However, if Mommy disappears from their sight, then Mommy no longer exists for them. This is why infants will become frightened when Mommy leaves the room. It also explains the fascination with "peek-a-boo" type games, in which the adult disappears and instantly re-appears. It is through these experiences, and natural maturation of the brain, that infants come to understand object permanence -- "Mommy still exists even if I can't see her." Infants reconstruct their mental pathways to accommodate this new understanding.

To prevent the loss of a useful pathway or script, teachers need to encourage Rehearsal through repetition and revisitation. Running the script again and again, along varied routes strengthens the pathway. Storytellers remember stories by telling them. Comedians remember jokes better than others because they tell them. Some teachers remember faces or names better than others because they repeat them or recall them more often. Teachers lose the names of last year's class through non-use, though they remember the complex taxonomies in their own disciplines through frequent recall.

This repetition should come from presenting the information in a variety of ways; for rote rehearsing is not as effective as rehearsing with a variety of stimuli and in a variety of contexts. For example, to assist students understand the concept of "virus," the term could be presented in computing,
biological, and medical contexts. Similarly, increasing the number of senses involved in the learning experience contributes to the amount of information received and retained.

Students enjoy variety and will learn more when the instructional methods change than when they are boringly similar. Some will prefer information to come to them on a screen or in a book or from a friend or from a teacher. Much is known about the benefits of varying the approach to meet the different needs and preferences of students. Researchers have identified eighteen factors (elements of the emotional, sociological, and physical environments) which affect learning styles [Dunn, Dunn, & Price, 1987]. Effective teaching methods recognise and allow for this variety in the learning style preferences of students.

Supporting Learning with Modern Technologies

Interactive multimedia (known as "hypermedia") learning materials offer many pedagogical advantages which address the needs identified above. First, the combination of text, graphics, video, and sound enable the creation of multi-sensory experiences which are more likely to be remembered. Their interactivity precludes the necessity for presenting the information in a linear form. Indeed, Bill Atkinson, the creator of HyperCard, the first widely available hypermedia authoring tool, refers to it as an electronic construction set which creates new possibilities for teaching and learning. Each learner can experience a different presentation based upon the paths they choose.

Learners do not have to sit passively watching a presentation someone else has prepared. They are allowed to interact with the media themselves. They can access the presentation in the order of their choice and they can use many resources to create their own study materials, thus guiding their own learning. Marchionini [cited in Azarmsa, 1991] refers to this as a "fluid environment (which) requires learners to constantly make decisions and evaluate progress, thus forcing students to apply higher order thinking skills" [p. 170].

For example, an author might create a hypermedia resource on Napoleon Bonaparte and, at key points, link passages of text, graphics, video, and sound. These links to additional information would be signalled to the learner by means of a font change or graphic icon. Learners might have the option to see a picture of Napoleon, review a map of Napoleon's campaigns, skip to a passage about his exile on Elba, get biographical data on Josephine, or obtain a definition of an unfamiliar word. In other words, each time the material is read it could be accessed in any sequence and to any degree of detail. Students could explore these links to construct their own pathways regarding Napoleon's decision making skills, his driving personal characteristics, etc.

Teachers and students learn from each other [Angelo, 1993]. Hypermedia offers a tremendous potential for enhancing these teacher-student and learner-learner relationships. Students can develop their own tours through the knowledge base and share their experiences with their teachers and other learners. Further, the creation of multimedia and hypermedia materials fosters cooperative relationships among learners as they work together to share the creativity and responsibility needed to produce such a project.

The rapid advancement of the Internet, particularly the development and prolific expansion of the World Wide Web, enable educators to create multimedia teaching resources and interactive instructional strategies which can be delivered to any student without regard to time, place, or computing platform. Educators must recognise, however, that the medium of delivery is not the most important condition for learning. It is no better to distribute large amounts of static information via the WWW than it is to engage in a 50-minute monologue. Nothing happens until the learner is actively engaged; and at a level beyond passively responding by copying a lecturer's words or pressing an <ENTER> key.

WWW-based instructional strategies vary in terms of the degree of interactivity between the learner and the teacher, the learner and the learners, and the learner and the material. Figure 1 illustrates the range between passive to active instructional strategies.
Educators must adopt teaching strategies which marry the new conceptions of learning with the benefits of WWW interactivity. However, academic staff tend to teach as they have been taught. For teachers to adopt new instructional strategies (technology based or not) involves raising the teachers' awareness of how they and their students learn and supporting their moves to teach differently. It involves an awareness of new methods, developing new skills with the methods and knowing when to apply those methods to optimise student learning [Joyce and Showers, 1998]. The process is further complicated when staff are expected to use technologies, such as WWW, with which they are unfamiliar.

5. The materials require that students work collaboratively to respond to assignments or create new learning resources to be shared with other peers.

4. The materials require that students seek additional information and write their own materials which link to the existing ones.

3. The materials contain questions that students are asked to reflect on or respond to, either off-line or online. Answers are provided through successive screens or through teacher marks or comments.

2. The posted materials have “hot point” links to other related or supportive information.

1. The teacher's written lecture notes, tests, diagrams, questions, exams, etc. are placed on the web without alteration.

Figure 1: Continuum of Interactivity Available via the WWW

Linking New Conceptions of Learning with Teaching via the WWW

Personnel within the Education Centre at Lincoln University (New Zealand) have designed a new staff development project, PROJECT LEARN, which recognises the new conceptions of learning, the interactive potential of the World Wide Web, and the challenge of assisting academic staff adopt these new technologies into their instructional repertoire.

Many tertiary institutions are moving into distance delivery of their educational programmes by adopting Internet-based methods. At Lincoln, we are encouraging academic staff to use these same technologies to first support and enhance our on-campus learning. Beginning by supplementing on-campus instruction gives us more control over the pace and assessment of our innovations and gives us face-to-face connection with students. We believe that combining teaching methodologies which focus on how learners learn with WWW-based delivery methods will give us a model that works equally well for on-campus and off-campus students; for the WWW allows for the best of both worlds: independent pathways through the material and interaction with teacher and peers.

PROJECT LEARN, initiated in June, 1997, is primarily an in-depth media and staff development activity. It is structured to respond to earlier feedback from academic staff (survey data obtained in April, 1997) on what resources they needed to incorporate more technology-based instructional methods in their classrooms: knowledge of how to re-design their subjects and the technical support necessary for developing new curriculum resources. Paramount features of the project are the incorporation of two principles found to be important when supporting teachers: providing different
strategies for different stages in the change process, and offering continued monitoring and support as the new strategies are implemented [Scott, 1996 and Joyce & Showers, 1988].

PROJECT LEARN is currently focused on first-year compulsory subjects taught within the University. In subsequent years, second and third year compulsory subjects will be brought into the project. By concentrating on compulsory subjects, we are able to direct our efforts toward creating materials which will be used by the greatest number of students—thereby increasing the impact of our efforts for change.

Project personnel recognise that developing a deeper understanding of content requires more than passively absorbing a body of facts and regurgitating it in an examination. Students learn best by being engaged with the content, actively processing the new information in new ways [Bonwell & Eison, 1991]. A key premise to PROJECT LEARN is that the instructional resources developed will engage students in exercises which promote an active learning experience, where active learning is defined as “instructional activities involving students in doing things and thinking about what they are doing” [Bonwell & Eison, 1991]. It takes advantage of the WWW’s interactive capabilities to design learning experiences which allow students to interact with (not just read) subject-specific material, interact with related resources which peak their personal interests, and interact with other students and teachers to enrich and embed their learning.

The PROJECT LEARN team is made up of content specialists (the academics teaching the subjects), instructional design specialists, graphic artists, HTML programmers, and some managerial and clerical support. Currently, no attempt is made to fully convert an on-campus course to distance delivery. Rather, the team begins by having an instructional designer meet individually with each academic to gain an overview of his or her instructional goals. These two then identify one element of the subject -- perhaps a teaching strategy, assessment activity, or content module -- which can be better accomplished by taking advantage of WWW capabilities. The instructional designer then discusses the issues with the technical support staff for the creation of the materials. The academic is brought in periodically to review the work in progress.

During the development process the academic’s involvement is two-fold: providing the content and the instructional objectives. When the subject is taught the following semester, the academic is given additional assistance with implementing the Web-based resources. The academic will later be expected to maintain and further enhance the resource.

Features of the project which have thus far indicated success include: the acceptance of the client academic staff (12 of the 15 academics approached eagerly agreed to participate); the creation of a template to facilitate efficient web development; and the diverse, yet complimentary, skills of the project staff involved. February, 1998 saw the first PROJECT LEARN materials being used by approximately 2500 students. An evaluation of the materials—in terms of their content validity, instructional design, and impact on student learning—will be conducted. Those results should be ready for presentation and discussion during the Ed-Media/Ed-Telecom ‘98 conference.

Abstract
This paper reports on the latest development of the "Virtual Apparatus Framework", a contribution to efforts at the University of Melbourne to mainstream the digital transformation of curricula. We discuss the integration of the educational content and pedagogical functions of learning components using an XML compatible script. Our approach facilitates component re-usability and administration and is based on a database model matched with an authoring system that hides the technical details while preserving the contribution of content experts to the courseware development. In particular, this paper is to be the reference point of version 1.1 of the VA framework.

Introduction
The concept of "Virtual Apparatus" (VA), software components written to a specification and providing interactivity on a web page, was discussed and demonstrated at ASCILITE 1996 [Ip and Canale,1996]. We have since brought the implementation forward so that virtual apparatus built using different technologies (such as Java Applet, Active X controls & Macromedia Shockwave movies) can now communicate via scripting on the enclosing web page [Ip et. el.1997]. As we put the framework to real use, we recognize that there may be three different types of virtual apparatus, differentiated by the way instructional content is related to the functions provided:

- Some virtual apparatus are generic and content-free, for example a data logger. A data logger may continuously monitor the performance of a learner and store or pass on information for immediate feedback, assessment or evaluation purposes.
- Some virtual apparatus are content-rich, for example a simulation of a particular scenario. The virtual apparatus itself in this case contains the educational content. It may however, still be usefully operated with other apparatus, such as the data logger.
- Other virtual apparatus may be generic but content-dependent, such as a question shell object [See Fritze and Ip (this volume)]. These virtual apparatus are loaded with instructional content in order to operate.

While the first two types can be implemented as Version 1.0 virtual apparatus, additional support is necessary for the third type [see our online resource for the details of the Version 1.0 specification, located at http://www2.meu.unimelb.edu.au/virtualapparatusframework/]. Version 1.1 is an extension to the virtual apparatus specification1.0 that defines a standard mechanism to support the generic but content-dependent virtual apparatus. Virtual apparatus
developed in accordance to version 1.0 and version 1.1 are inter-operable. The content is expressed in a tagged format and is referred here as VAScript.

Typical use scenarios

Learning Engine object model (with a master object)
The Learning Engines Project [Fritze and McTigue, 1997] outlines particular model of interactive object that can be independently produced and combined into useful learning activities. These objects correspond to visualisations, simulations, dialogue shells and interface extension components. The dialogue shell object takes the more important role, acting as a controlling agent that shapes the dialogue between the learner and other objects. The shell derives its content from a VAScript.

In the illustration below, we show two such components on a page. The bottom component is a particular dialogue shell, the Tutorial Item Set, which embodies a series of questions items specified by its current VAScript. The upper object is an interactive graphing object which can both plot curves and interpret those sketched by the student. The graph object has plotted an initial curve as specified by a <command> tag in the VAScript of the Item Set and relayed by the VAmessenger. The VAmessenger is the agent controlling inter-object communication within the VA Framework [Ip et. el. 1997]. A curve entered by the student has been reported back to the ItemSet which has judged it against the specified criteria and shown a corresponding feedback message. It is possible, if the author deems appropriate, to send a drawing command to the graph using the <command> tag in the ItemSet script to display the correct answer.

![Graph and Tutorial Item Set](image)

NALSSAS model (using peer-to-peer relationship)

Another project being undertaken for NALSAS (National Asian Languages and Studies in Australian Schools Taskforce) to teach Mandarin to teachers, assumes a different content model. All the components of a learning activity on the Web page communicate via the VAmessenger. No component is in a master position. The Flash Card, Sound Player and Pinyin Input software objects have been constructed as version 1.1 virtual apparatus and have their respective scripts. When the page is requested by a student, the server generates these...
three scripts. When the student clicks on a "start" button on the tool bar, a message is sent by the tool bar apparatus to the VAmessenger. Logic written within the VAmessenger generates a command received by the three objects to use the first item in their respective scripts. The Flash Card displays a Chinese character briefly. The Sound Player plays the sound corresponding to the character and the Pinyin input is receives typed input from the student corresponding to the pinyin of the flashed character. After a correct input, the Pinyin Input sends a message to this effect and VAmessenger asks the other components to advance to the next element in their scripts. The synchronization is established by the index attribute in the second layer tags of the respective scripts.

An interesting point about the NALSAS project is that, while the flash card and sound player are shockwave movies, the tool bar and the pinyin input are Java applets. The VA framework provides the mechanism that enables them to inter-operate on the same page.

![Diagram of components](image)

**Flexibility in adding data-logging functions as needed**

A data-logger is an invisible apparatus. When activated by a line in the VAmessenger, a copy of all messages passing through the messenger can be relayed to it. In an online environment, the data-logger can establish a direct database connection to the server(e.g. via JDBC using a data logger written as a Java Applet). In an offline situation, another data-logger (e.g. written as an Active X control) writes the data to local storage. As long as both data-loggers have the same registered methods and properties, changing from online to offline delivery requires a change to just one line of code. In some situations, this can be automatically generated by the server side component.

**Adaptive content delivery using a back-end database server**

The functionality provided by the virtual apparatus on the page can be easily customized by a content author or an instructional designer, for example in the flash card example above, by setting the number of times the Chinese character is to be flashed. Content sent to the virtual apparatus as VAScript by the back-end database can be adapted according to the performance and/or background of the student. This flexibility is made practical by the principle of separating software function from content description.

**Technical Specification of VAScript**
The Virtual Apparatus specification 1.1 concerns three parts:

- format of the educational content (i.e. VAScript).
- the compulsory parser behaviours to handle the VAScript. In different circumstances, a parser may exist within a virtual apparatus or externally as a generic parser apparatus.
- the support on the browser (using browser scripts) for VAScript.

VAScript is based on XML (Extended Markup Language). XML is a document specification offering significant advantages over HTML, particularly with its extensibility and DTD (Document Type Description) metadata descriptions and will soon replace HTML as the major Web document standard. The following is the technical specification of VAScript which relies on an understanding of XML.

VAScript Syntax

A VAScript is a tagged document in the form of an XML document with the following notable features:

- every virtual apparatus supporting specification version 1.1 can have its own set of recognized tags. The definition of the tags, known as the DTD part of the VAScript, is also part of the specification.
- the DTD definition is now a part of the VAinfo and hence the function getVAinfo will return the DTD as well. VAinfo is a mechanism defined in Specification version 1.0 to enable content author to read the methods and properties of a virtual apparatus.
- the DTD defines the legal tags within the VAScript supported by the associated virtual apparatus. The meaning and/or the functions of the tags are specified as comments in accordance with the syntax requirement of XML document.
- In order to enable future compatibility with metadata, all the tags will begin with "VA:". Note the colon "::" is included. Effectively, all VAScript will operate within our own namespace.
- The DTD of the top element of a VAScript is:

```xml
<!ELEMENT VAScriptName (SecondLevelTagName+)>
<!ATTLIST VAScriptName LoadState (auto|preload|incremental) auto>
```

(Note: If LoadState=auto, the VAScript will be loaded using the default behaviour of the virtual apparatus. If LoadState=preload, all the SecondLevelTagName will be loaded and made available at the same time. If LoadState=incremental, each SecondLevelTagName is treated as an element in a set. The virtual apparatus should provide mechanism to handle the SecondLevelTagName one by one.)

See an explanation of the syntax of the DTD grammar at Appendix 1.

- The second level tag must be in the following form:

```xml
<!ELEMENT SecondLevelTagName (OtherElements+)>  
<!ATTLIST SecondLevelTagName Index ID #IMPLIED>
```

(Note: Index is necessary for all second level tags because on a web page, there may have several virtual apparatus interacting in order to provide a rich experience to the learner, these virtual apparatus rely on index to synchronize the content. As such, a server-side component should ensure that all Index on different VAScript on the
same page are mapped correctly. If Index is not supplied, it will be generated internally by the virtual apparatus, however it will not be available for use by the other virtual apparatus.)

- `<EXTERNAL> </EXTERNAL>` is always implicitly defined and is supported by the build-in parser. The `<EXTERNAL>` tag is defined as follows:
  ```xml
  <!ELEMENT External (*)+>
  <!ATTLIST External
  target NAME #IMPLIED
  TargetLoadState (discard|append) append
  ExportIndex (UseSource|UseTarget|Increment|$ID) UseSource>
  ```
  (Note: Any VAScript which are enclosed by the `<EXTERNAL> </EXTERNAL>` tags is called embedded VAScript. Embedded VAScript is not understood by the current parser and should be forwarded to the target virtual apparatus as specified in the target attribute. The embedded VAScript is a full VAScript with its own Top level element.

Upon arrival at the target virtual apparatus, the embedded VAScript will replace the previously loaded VAScript at the target virtual apparatus if the TargetLoadState=discard. It will append to the previously loaded VAScript if the TargetLoadState=append.

The Index in the second level element of the embedded VAScript will take the parent VAScript's current Index if ExportIndex=UseSource. The Index will be that specified in the embedded VAScript if ExportIndex=UseTarget. The index will be the numeric additive sum of the parent VAScript's current Index and the embedded VAScript Index if the ExportIndex=Increment. Finally, the index of the embedded VAScript will be ID if ExportIndex=$ID)

- `<command> </command>` is always implicitly defined and is supported by the build-in parser. The `<command>` tag is defined as follows:
  ```xml
  <!ELEMENT command (*)+>
  <!ATTLIST command
  target NAME #IMPLIED>
  ```
  This is used to send command to the target virtual apparatus.

**Compulsory parameters supported by Version 1.1 virtual apparatus**

Virtual apparatus conforming to virtual apparatus specification 1.1 must also support the VAScriptURL parameter. This parameter provides the URL of the VAScript which maybe loaded during initialization. On successful loading, the virtual apparatus will send the message "VASLoadOK". Then the VAScript will be parsed. On successful parsing, the message "VASParseOK" is sent.

**Compulsory behaviours supported by Version 1.1 virtual apparatus**

Virtual apparatus conforming to virtual apparatus specification 1.1 must implement the following methods:

- `SetVAScript(VAScript, LoadState, IndexState, InitIndex)` where InitIndex is the first index in a set, replacing the index in the incoming
VAScript. InitIndex will be ignored if IndexState=UseTarget. If the LoadState=Append, the treatment of the index will depend on the IndexState.

This method will load the VAScript and parse accordingly. On successful parsing, send message "ExtVASParseOK"

- SetVAScriptURL(VAScriptURL, TargetLoadState, ExportIndex, _CurrentIndex)

This method is similar to the previous method except it will initiate a loading of VAScript using the VAScriptURL. On successful loading, send message "EXTVASLoadOK". Then the VAScript will be parsed. On successful parsing, send message "ExtVASParseOK"

The built-in parser must support the following:

- When the <external> tag is encountered, the content of this tag is passed to VASforward() method in the browser environment.
- When the <command> tag is encountered, the content of this tag is passed to VAScommandSwitch() method in the browser environment.

Browser Script support for Version 1.1

When a page contains one or more virtual apparatus meeting this specification, it must implement:

- VASforward(target, VAScript, TargetLoadState, ExportIndex, CurrentIndex)
  Where target is the name of the virtual apparatus to get the VAScript with the specified TargetLoadState, ExportIndex and currentIndex.
- VAScommandSwitch(target, commandstring)
  Where target is the name of the virtual apparatus to receive the command specified in command string.

Concluding remarks

The VAScript provides a way of applying XML, as a powerful document description language, to educational content in the form of modular software objects. While the Chinese flash card described may fall into the category of practice and drill, more sophisticated uses are also supported by the framework, such as with the Learning Engine components. The time and effort invested in creating the interactive graphing object, for example, can be better justified with its re-use in different subject areas by redesigning the scripts, rather than the object itself. At the same time, the object, as a virtual apparatus, can inter-operate with others through a communication standard offered by the VA framework.

Architecture in the Digital Domain: A Collaborative Design Studio

Barry Jackson,
School of Architecture
New Jersey Institute of Technology
Newark, New Jersey 07102, USA
bxj2634@tesla.njit.edu

Abstract: This paper describes an interdisciplinary design studio that utilizes concepts and methodologies intended to create a comprehensive approach to the organization of building design through the merger of several techniques. These techniques include 1) collaborative learning and design, 2) using multi-tasking workstations, 3) hypertext learning modules and courseware, and 4) interdisciplinary team teaching. The studio merges the preceding teaching paradigms, building on current research and the experience of the faculty. The studio also establishes the premise that architectural design studio and engineering laboratories (structural and mechanical) will need to be organized across departmental boundaries as team oriented activities. The paper discusses the issues of ease of interface (both person to person and person to machine), the continual shift between synthetic and analytic processes in the context of problem solving, methods of representation, design assignments which increase the domain of possible useable forms, and design methods and process.

The Problem

Architects and engineers, who need to interact during their professional career in order to build any kind of complex building, are educated entirely separately. “Over the past century, increased movement toward concentration with an academic discipline has taken charge of the curriculum, as well as serving to compartmentalize the professorate and the institution.” [Landry 94] The vertical separation of disciplines occurs in most universities. This suggests a need for modification of the curriculum, the delivery of course material and teaching methods. Fortunately, this comes at a period of reflection in schools of architecture when, as Mitgang suggests, there are “growing doubts over whether the traditional educational environment is preparing students for a rapidly changing world outside.” While “schools remain wedded to shopworn traditions” there seems to be a growing malaise about the role of design as the centerpiece of architectural education. [Mitgang 97] Recognition of the problem also comes at a time when new teaching methods are emerging.

The major effort in trying to reform elements in the curriculum (particularly in different departments) depends upon what might be termed “changing the culture” of the curriculum. To create these changes architectural design studio and engineering laboratories will need to be organized comprehensively, across departmental boundaries. In the course of these revisions they will also need to be changed from independently organized activities to team oriented activities.

The problem with the vertical separation between disciplines is that students from each discipline learn to solve their part of the problem independently. This separation discourages them from understanding the relationship among the problem components. The students can complete their projects without having the opportunity to gain insight to the trade-offs required for an optimal solution. While courses in each department include information about the other disciplines, each is taught in a manner which tends to diminish the importance of integration. Moreover, the ultimate professional relationship among the disciplines, which in the building industry consists of teams, is downplayed by the students working as individuals in their classroom experience. Research outside of the architectural and engineering professions suggest that “future work situations are likely to use a complex mixture of different information channels, including video conferencing, e-mail, small group work, and on-line searches. The design parameters of (these) information systems (will) rely on an awareness of how the social and technological aspects of human interaction intertwine.” [Kilker & Gay 94] These are the conceptual underpinnings of the development of a new approach.
Designing the Solution

The hypothesis of the faculty is that a concurrent and collaborative design environment will add to the problem-recognition and problem-solving abilities of the engineering and architecture students. In most workplaces in the building industry, problems solving and design require collaboration among members of a group. These activities require that people share information and coordinate their activities in a setting that allows for immediate interaction [Kilker & Gay 94]. Traditionally, in the professions, although the design and production of buildings requires collaboration, the work is done serially, with drawings passing among the professions and each adding their skills and recycling through the process until the project is completed. No methods of optimization are applied because of the way the design process is structured. Optimal solution spaces are closed off by the time each new part of the process is introduced. Therefore, the focus of the studio is around the activities in which the students can engage to help construct a comprehensive knowledge base necessary to design, optimize and build complex structures.

The potential impact of the studio is to improve the education, professional behavior and attitude of students as they prepare for various aspects of the building industry. The students will have the opportunity to see how the separate courses they have taken in architecture, structural engineering, and building performance are integrated. They will see that contemporary construction is not a simple separate, sequential process, but rather a system characterized by integration and a search for optimal solutions. When design is objectively considered as an iterative, multifaceted process, and a series of problem solving sequences, a significant paradigm shift can occur. Thinking this way, we discovered, was imperative because the way engineering and architecture students learn is different.

Ultimately, the intention is to create a completely computer mediated environment, where students will work on their designs and problems, communicate with each other and others more distant, and receive courseware and criticism at the workstation. The innovative aspect of Total Studio is that it is interdisciplinary, and has been designed from the beginning to provide the format for the perpetuation, replication and dissemination of the studio in a continually upgradeable hypertext format. This focus is away from the traditional piecemeal architectural methodology.

Implementing the Solution

The Underlying Pedagogy

The study of building design must be rooted in a general theory of building science in which architectural space and form, structure, and the effects of the bounding envelope for moderating the environment are considered inseparably. Optimization is a complex problems to solve. "In architecture, aesthetics deals with the way buildings look: the skin, form, site, and overall image within the culture to which they belong. In engineering, technology is informed by modern science and is systems and process oriented. Controlling building environments (both actively and passively) can produce more insightful architecture when an understanding of the aesthetics of the building envelope (static) is paired with an appreciation of the technology of the building systems (dynamic)." [Greenwood et al 97] The studio focuses on the development of structural, energy and spatial intuitions and the relationship among them. Study of highly indeterminate structures is crucial for understanding building frame design. For energy analysis and building performance, it is preferable to analyze a skin-dominated building so that relationship of form to energy flow can be considered. The goal of the faculty is to identify projects at the appropriate scale to study these relationships.

Collaboration and the matrix of studio organization

Collaborative design—thus collaborative learning about a project—is a new concept for students in the studio. A very serious introduction is required to get the students working collaboratively. "By collaborative learning is meant a learning process that emphasizes group or cooperative efforts among faculty and students, active participation and interaction on the part of both students and instructors, and new knowledge that emerges from an active dialog among those who are sharing ideas and information." [Turoff 95] While group criticism and group research is a normal activity in the design studio, designing together is not. Turoff, is his years of development of computer-mediated environments at NJIT concludes that "in many learning situations it has
been observed that two people working together at a computer learn more working together than either one separately. It is this ability to share the actual interactive process of “creating the painting” that this approach entails.” [Turoff 95] This suggests, as Feisel points out, that “we need to design an educational process that involves students in one another’s learning and rewards mutual accomplishment.” [Feisel 94]

To facilitate the collaborative idea of teaching and learning, the studio is organized around a matrix of teams and groups. Teams are defined as a number of students assembled to apply techniques and complete a design task. Groups are defined as a number of students organized to develop techniques and learn a particular set of the task. Each student is a member of one team and one group. The sets of teams and groups act as support clusters for each student. In the spring semester of 1997, the four by four matrix of teams and groups worked as theorized. The teams and groups for the first part of the semester were four member each. When the major design project began the teams of four were divided into teams of two. This afforded the opportunity to modify teams to improve interpersonal relationships among the members.

The Learning Groups

In theory, the learning groups should be divided among the three disciplines involved in the project: architectural design, structural design, and mechanical design. Each learning group will be led by an instructor who will develop the educational modules associated with that discipline. The members of each learning group will be responsible for learning the software packages associated with specific segments of the problem and also be encouraged to share their knowledge. To test the learning group concept last spring, project research assignments were made by the learning groups.

The Design Teams

The design teams develop the building design as a whole. During their sessions with the design instructor they work together on the development of the project, each member looking at, and engaging, the design from the perspective of their learning group. Understanding the concept means having access to various forms of representation, selecting ones that are most appropriate for particular uses, and using them accordingly.

The Laboratory

The studio is held in an advanced graphics computer lab with video equipment available for both local viewing, editing and broadcasting. Last year the laboratory had its equipment augmented through funding from the National Science Foundation (NSF) for the project titled Development of Interdisciplinary Courses and Laboratory Facilities [see the Appendix]. The primary computer workstations available are Silicon Graphics (SGI) Indy models. The full complement of equipment is eleven workstations, the fastest of which is an Indigo Impact, with 128 MB of RAM. The UNIX based workstations are extremely flexible and able to multitask flawlessly. Students can be logged into multiple computers anywhere on the network and run several software packages simultaneously. The terminals are linked together through a hardware and software system called Comweb which allows faculty to control of all workstations for the purpose of software instructions, group critiques, and other demonstrations. The computers are networked with adjacent laboratory facilities and the Internet.

The Four Modes of Representation

One important idea in the studio is to dampen the use of the computer as the central tool. The computer needs to be on equal footing with all the tools in the toolbox. This is accomplished directly through the assignments which emphasize the four modes of representing architecture. The notion of multiple representations of information is central to the course and is discussed thoroughly with the students at the beginning of the semester. Narrative descriptions of initial and final concepts are required, as are short written reports on field trips and research issues. Building class site models and chipboard study models in the traditional way—especially as a comparison to the 3D computer models—is emphasized. Students learn to study their work simultaneously via the computer models and via physical models and sketches to augment their visual perception and other cognitive skills. Research suggests that students relate to what they see on the screen better if they can relate it to previous experiences. [Roberts, et al] Final projects are presented on traditional “boards” which allows computer work to be communicated as others (especially clients) perceive it, and gives the students the opportunity
to mix their media, drawing on strengths and skills they may have previously acquired. My own experience as a designer indicates a multimodal design process is most useful. Project are also represented on the Internet.

Preliminary Results

The present manifestation of the studio has been offered in the academic year of 1996 and the spring of 1997. The following items have been implemented: 1) collaborative learning and design, 2) computer mediated environment, and 3) preliminary interdisciplinary work. Deep within this seemingly complex learning environment are elements of the traditional studio. The semester is divided into an analysis phase and the design phase with a few short research assignments interspersed. The two semester sequence is designed to emphasize structural issues in the fall semester and building performance issues in the spring. Development of a preliminary syllabi quickly dispatched the idea that such a holistic approach could be accomplished in one semester.

Collaborative learning

From the faculty point of view dividing the class into teams has two major effects: 1) it increases management time to continually monitor the interpersonal problems which occur as people adjust to working together; 2) it reduces the number of critiques and increases the time available for each critique. In addition, it increases the students’ effective working time because they need to manage each other and spend time in the studio discussing the problem and working together.

The computer-mediated environment

The computer-mediated environment works as follows: Course material created on the word processor is converted to HTML, stored on the server, accessed, displayed and disseminated through Netscape. This provides the student and others continual access to all of the course material as it is posted and modified. The NJIT library catalog is also available through the workstation so that references to books and articles can be located immediately by the student.1

We have found that it is imperative that faculty take a hands on approach to imparting computer skills. Comments from the students indicate they are more confident in the instructors who are hands on and display their skills directly rather than those who are more aloof and directive in their approach. The experience of the last two semesters suggests that teaching small groups of students detailed methods of access to the computer systems diffuse information among the students more rapidly than imparting the information to the whole class in a formal setting. The students learn more quickly in informal settings in which they are able to communicate directly with their peers. Research by Roberts et al also suggest that of the critical variables for productive learning, “the most important is the faculty’s pedagogical style in their direct teaching and the student interest in the subject. The faculty must be sensitive to both the need to empower students exploration by providing them with the skills they need to explore... through direct teaching as well as allowing and encouraging students to do their own exploring.” [Roberts et al]

Problems

The development of TOTAL Studio is an evolving effort. A review of the three semesters of experience have yielded the following findings: 1) students are slow to conceptualize the multitasking potential of their workstations, and therefore under utilize the potential of the UNIX environment, 2) there are only a finite number of teaching hours in a studio and having to spend time teaching software subtracts from the time used for teaching principles of design, and giving individual design criticism, and 3) creating the studio as designed requires outside support as leverage against the internal politics in the various departments.

While working on teams is generally not part of the studio culture, last spring all but one of the teams operated successfully—an improvement from the fall semester. The reason for lack of success in teamwork seems to be based on the conflict in personality, differences in work ethic and habits, the lack of experience in working on teams, and a mismatch in skill levels between team members. In anonymous evaluations, the students commented that “I liked the team thing as an idea. It didn’t work out for me though because I had a hard time with my partners. I do think in the future, team design is a good idea.” Or “Groups of people helped but caused many disagreements which slowed down progress. Although the thought of putting people together was a good
one.” The history of the studio as a collaborative one aids in the development of teamwork because it generally excludes students who are determined to undermine the concept.

The engineering component of the course has not been fully implemented. This has occurred for a variety of reasons. Without funding there is no leverage in the other departments and therefore no way to influence faculty teaching assignments. There has been no publicity in the other departments for the course. What was substituted was lectures on building performance and structural design without getting involved with trying to teach additional computer systems in the classroom. Funding for the project is expected for the Fall semester of 1998 in which the full compliment of activities will be pursued.

Conclusion

The metaphor, changing the culture of the curriculum, may seem slightly pedantic; however, methods of teaching have been passed from generation to generation in the most unquestioning manner. New technologies, as precursors of changing methods, are often resisted. The efforts to change, sometimes abetted by the layers of accrediting organizations, are held back by the ‘viscosity’ in the organization. Creating a change that evolves, rather than changes abruptly, gives the results an opportunity to become integral to the culture and reaffirmed by tradition. Our team of faculty expect criticism from our colleagues, from professional organizations with long standing paradigms and vocabularies holding antithetical views, and even from the students. We are abetted by the support of outside funding, which adds an imprimatur to our efforts. At the core of our activity is the goal of helping to “lead the professional to a future of greater relevance and responsibility.”

[Mitgang 97]

Abstract: This paper provides an overview of five innovative projects involving network learning technologies in the United States: (a) MicroObservatory Project, (b) Teaching Teleapprenticeships, (c) Learning through Collaborative Visualization (CoVis), (d) Knowledge Integration Environment, and (e) GLOBE. Each of these projects has an explicit research orientation that allows for principled ways to consider the successes and failures of the respective projects. After a brief overview of each project, features common to these projects are discussed, followed by a consideration of challenges to be faced as innovative pedagogues and network technologies are used to support educational improvement and reform.

The purpose of this paper is to provide an overview of selected innovative projects that use electronic computer networks in the United States. It should be stated at the outset that such a paper can only be a snapshot of what might be described as one of the largest educational experiments in history. Beginning in the early 1980s, many in the United States became concerned about declining educational achievement (The National Commission on Excellence in Education, 1983). Since that time, numerous initiatives have been implemented to improve the quality of K-12 education in the U.S. A common aspect of many of these initiatives has been the utilization of computational and communication technologies to support systemic and curricular reform [Honey and McMillan 1994; Hunter 1992; President's Panel on Educational Technology 1997]. However, there have also been cautions against assuming that technologies in and of themselves will substantively enhance educational outcomes and effect reforms [Educational Testing Service 1997].

Yet there is no denying the fascination in the U.S. with computer and network technologies, in particular the World Wide Web. Nearly all universities and businesses now are "on the Internet" and have Internet "addresses" (i.e., URLs, universal resource locators). As of 1997, sixty four percent of the schools in the U.S. have a connection to the Internet [Educational Testing Service 1997]. Also, there have been national initiatives, such as the Goals 2000: Educate America Act (signed into law in 1994), that have promoted the applications of technology, including networking, at the pre-college level. Other national programs have aimed to form cooperative partnerships between the U.S. federal government, states, local communities, individual schools and school districts, and private companies to help foster the use of technologies at the K-12 educational levels.

Yet what do we know about the ways educational technologies mediated by electronic networks may be used to achieve substantive educational outcomes? What are the lessons that have been learned? And what are the lessons still be learned? This paper will provide an overview of what is know about these questions based on selected projects involving schools and electronic networks in the U.S. The first portion of the paper provides a survey of exemplary educational networking research projects. The second section of the paper considers these projects more generally in terms of their underlying learning and theoretical frameworks, research issues, and general lessons learned.
EDUCATIONAL ELECTRONIC NETWORKS: SELECTED INNOVATIVE CASES AND PROJECTS

There are quite literally thousands of schools in the United States which are now using network resources in a variety of interesting and creative ways--far too many to be systematically considered. Five projects are discussed in this paper which utilized computational and communication technologies in educationally innovative ways: (a) MicroObservatory Project, (b) Teaching Teleapprenticeships, (c) CoVis, (d) Knowledge Integration Environment, and (e) GLOBE. Also, each of these projects has a research orientation that allows for principled ways to consider the successes and failures--the lessons learned and to be learned--of the respective projects. Given the limitations of space, these projects will be generally discussed in terms of their goals and major findings. For more detailed information, the reader should consult the references and Web sites for these projects.

MicroObservatory Internet Telescope

Astronomy is a popular science among the nations' youth and adults. However, the opportunity for learning astronomy by doing original research with professional grade instruments has been extremely limited for most students. In 1992, the MicroObservatory telescope network became the first generation of remote astronomical scientific instruments available on the Internet [Sadler, Gould, and Brecher in press]. The MicroObservatory is a collection of small, high-quality, and low-maintenance telescopes operated by the Harvard Smithsonian Center for Astrophysics. A Macintosh computer through an Ethernet communications protocol controls each telescope. The MicroObservatory Web site allows the user to control one of these special telescopes from his or her desktop. This makes the experience of high quality astronomical observations available in real classrooms rather than just from relatively inaccessible mountain observatories. The MicroObservatory user can schedule real-time use or program delayed observations and network delivered digital photographs.

The MicroObservatory has been used remotely in ten high school classrooms throughout the US. Experimental use has also been extended to introductory astronomy courses at the college level. Participating teachers use the MicroObservatory to demonstrate daytime observations during class periods, or download images taken by MicroObservatory telescopes. Students often work collaboratively to initiate their own astronomy investigations using the MicroObservatory telescopes over the Internet. For example, students found Comet Hale-Bopp to be an exciting object to observe during the spring of 1997. Students recorded the comet's shape and brightness over time and, some downloaded images from other students to make short movie of the comet. Similar to professional astronomers, students must write proposals to obtain time on the telescope for observations, and work with other users to analyze the images collected. Overall, student use of the MicroObservatory network of telescopes has indicated students can in fact conduct interesting scientific activities in a manner similar to research scientists.

Teaching Teleapprenticeships

The Teaching Teleapprenticeships Project at the University of Illinois has been exploring frameworks for learning that use electronic networks to create apprenticeship-like, asynchronous or synchronous learning environments for teacher education [Levin and Waugh in press]. A variety of frameworks for Teaching Teleapprenticeships (TTa) have been integrated into learning activities in many different preservice and inservice education courses. These frameworks include question answering and asking, collaborations, student publishing, utilization of Web resources, and project generation and coordination. For example, in the "question answering and asking" framework, undergraduate biology students were engaged in extra-credit course assignments as mediators to answer pre-college students' science questions. A suite of telecommunication software (e.g., Eudora, Gopher, Newswatcher, and Netscape) and a laptop computer were provided for each participating preservice education student.
The main features of the TTa approach include: (a) preservice or inservice students receive a "tele-field experience" for participation in a K-12 classroom as a "teaching teleapprentice," (b) students practice answering the kinds of questions they will be faced with when they are teaching K-12, (c) pre-college students interact with a diverse set of advanced learners (i.e., the teaching teleapprentices in the project) in a manner that was found to be scaleable, and (d) undergraduates receive support in their mediator roles from their university instructor and graduate assistants. Network technologies allow novice teachers to start as "legitimate peripheral participants" [Lave and Wenger 1991], and then to gradually take on more central roles in networked-based projects. Students in the TTa Project were able to learn in meaningful and contextualized ways (i.e., school related) supported by multiple mediators (e.g., practicing teachers, fellow students, scientists, education faculty), while serving as valued mediators themselves to pre-college students. Other aspects of the TTa Project have investigated the nature of the mediator roles for learners and teachers as important factors for the successful use of new distributed learning environments and ways to integrate teaching teleapprenticeship frameworks into supportive and sustainable institutional structures.

Learning Through Collaborative Visualization (CoVis)

The Learning through Collaborative Visualization (CoVis) Project at Northwestern University and SRI International was one of the four initial NSF-funded National Networking Testbeds for Education [Pea 1994; Pea, Edelson, and Gomez 1994]. The CoVis Project has investigated how students can acquire scientific understanding mediated by scientific visualization software in collaborative environments, and how to support project-enhanced learning of science in a community that extends beyond the classroom. The central goal of the CoVis Project is to utilize advanced technologies and innovative pedagogical approaches to help make the teaching and learning of science more like the practices of scientists. The CoVis Project provides students with collaboration and communication tools that include: desktop video teleconferencing, shared software environments for remote, real-time collaboration access to the resources of the Internet, a multimedia scientist's notebook, and scientific visualization software.

The initial classroom uses of the CoVis Project started in 1992 with 296 grade 9-12 students in Chicago area. Students in the CoVis Project primarily study atmospheric sciences with some environmental science emphasis. For example, they may use tools such as Weather Visualizer and Climate Visualizer to investigate the progress and changes of major hurricanes through animations based on visible and infrared satellite data. Student activity logs are recorded in the Collaboratory Notebook and may be shared among a group of collaborators. Through a diverse suite of communication technologies, students engage in dialogs with practicing scientists in "teleapprenticing" relationships (Levin et al., 1987; Riel, 1992). The ongoing assessments of the CoVis Project investigate issues such as scaling, culture diversity, equity of access, sustainability, attitudes toward science and technology, and pedagogical improvement related to the use of networking technologies for remote collaboration.

Knowledge Integration Environment (KIE) Project

The World Wide Web is a complex resource that presents significant challenges to teachers to use in educationally powerful ways. In contrast to the focus of the CoVis project on network-mediated, collaborative data visualization, Dr. Marcia Linn and her colleague at University of California at Berkeley have developed a different model to foster Web-mediated learning. In the Knowledge Integration Environment (KIE), middle and high school students not only look for information on the Web, but also analyze evidence and provide scientific explanations about real world phenomena and problems. Research involving KIE has investigated the use of on-line scaffolding and guidance, student search strategies on the Internet, individual and collaborative sense-making of science evidence, on-line discussion tools, and reflection for science learning. KIE research findings suggest that students' performance in searching relevant sites improved through collaborative search activity and using the design library that contained pre-selected sites related to student project areas. Given that information found on the Web is often very complex and ill-organized, an "advanced organizer" approach was developed for KIE to provide key ideas.

665
about the Web content and sources with the intent of helping students become more critical in interpreting evidence and more successful in applying evidence to their projects. Overall, the KIE research to date has demonstrated that providing specific types of scaffolding and support to students as they utilize Web resources for inquiry projects can enhance student learning of scientific knowledge.

The GLOBE Program

The Global Learning and Observation to Benefit the Environment (GLOBE) program is a major Internet-based international science education program that was enunciated by Vice President Al Gore on the Earth Day April 22, 1994 [Means & Coleman in press]. GLOBE aims to enhance student's understanding of earth systems as well as to promote science and mathematics learning and environmental awareness. Through the GLOBE program, K-12 students around the world use the Internet to collect environmental data, perform measurements, exchange data, and interact with scientists and with other students. Students also use software developed by NASA to visualize the data they have collected from ongoing research investigations being conducted by practicing scientists. GLOBE participants come from more than 3,500 schools in 50 countries.

Empirical results of GLOBE activities for the past three years are being collected largely through electronic surveys. On-site observations and interviews at selected sites conducted by SRI, International researchers are also being used to supplement the survey data. Students are asked to reflect on their involvement in GLOBE activities and their attitudes and beliefs about technology, science, and measurement issues. Teachers are surveyed concerning the ways in which GLOBE activities are implemented in their classrooms, the challenges posed by setting up the program, and their strategies for dealing with problems. Participating scientists provide comments on the quality of various types of student-collected data and the ways in which the data support the scientists' investigations. Recent evaluations of this large scale, ongoing project suggest students are quite motivated by the authenticity of their participation in GLOBE research and the use of state-of-the-art technology [Means & Coleman in press]. Significant learning outcomes have also been found related to student performance on taking measurements, sampling principles, and data interpretation. Overall, the GLOBE program is a very interesting and important project in terms of the large implementation scale, the use of innovative learning approaches and activities, and the significant learning outcomes being documented.

LESSONS LEARNED

The previous sections have primarily described the features and learning activities associated with selective exemplary educational network learning projects. In this section, we consider general issues related to the use of educational networks that have emerged from these projects.

The projects described above reflect a wide range of ways that electronic educational networks may be used. The MicroObservatory, CoVis, and GLOBE projects scaffold students to be involved with scientific projects in ways that are qualitatively similar to professional scientists. The KIE project also involves students in projects, but provides ways to support students' critical and thoughtful use of Web-based resources as part of project activities. And the Teaching Teleapprenticeship project focuses on teacher education, and utilizes various network resources to support collaboration and apprenticeship learning mediated by the network.

There are also other general features shared by these projects in a "family resemblance" manner. These include:

- employ a constructivist framework for learning and teaching;
- involving students in authentic activities and tasks;
- involving students in "tele-apprenticeship" collaborations with peers and adult practitioners and experts;
- promoting intrinsic motivation;
• enhancing student generated inquiry questions and interest in independent learning;
• changing the teacher's role from information provider to facilitator and mentor;
• scaffolding higher order student engagement in problem-solving and inquiry activities;
• providing technological support for teachers and students to facilitate productive learning activities;
• developing scientific software to be integrated into curriculum for advanced activities;
• providing asynchronous and synchronous activities in different places and time (removing physical constraints); and
• providing equitable access to network learning technologies.

There are many nuances in terms of how these features are instantiated in the different projects discussed in this paper. For example, the ideas of "teleapprenticeship" are implemented differently in the Teaching Teleapprenticeships Project and the CoVis Project. Overall, these various projects should be regarded as model cases of innovative and generally successful approaches to using the technological affordances of nationally and globally interconnected electronic networks in educational contexts. However, the full value of these projects is not just in detailing their successes, but in learning from the difficulties and problems they encountered, which we consider next.

Lessons to Be Learned

Internet technologies provide ways to interconnect people around the world in ways and on a scale that has never before been possible. Combining these technologies with innovative ways to improve and reform education thus represent significant challenges to teachers, students, schools, school systems, and national educational systems. In this section, we discuss some of these challenges and issues.

Based on the projects discussed in this paper, there are several areas that need further research in applied contexts (i.e., real classrooms) to address. For example, many of the projects were mainly science oriented due to funding priorities for research in the United States. How may these technologies and learning approaches be adapted and used in liberal arts and social science domains? Also, most of these projects were assessed using innovative learning outcome measures or qualitative methodologies. How will it be possible for traditional large-scale quantitative standardized assessment methodologies to measure that types of learning outcomes associated network learning projects? If so, how? If not, what are the implications for large-scale assessment methods? These projects primarily employed open-ended student directed learning activities involving electronic networks (e.g., CoVis, MicroObservatory). How can teachers meet curriculum content requirements and national standards, particularly at the high school level, with primarily student directed learning activities? These projects involved tens to hundreds to thousands of schools, yet there are over 100,000 schools in the U.S. alone. Will it possible to "scale-up" to hundreds of thousands of globally distributed schools? Finally, the successes reported in these projects were associated with a constructivist learning framework and educational epistemology. How can constructivist based network learning approaches be implemented in school situations which may be employ an "instructivist" approach teaching, learning, and assessment?

Given the relatively short period of time these technologies have been available in the schools, it is certainly understandable that there are not "definitive" answers to these and other questions related to how emerging network technologies can be infused into the educational activities of our children. However, it should be stressed that there are many who feel that the research and experiences to date concerning the educational efficacy of network learning environment technologies warrants continued implementation concurrent with continued research investigating questions of learning efficacy and implementation [President's Panel on Educational Technology 1997].
Conclusion: Learning New Lessons

Clearly there is much that has been learned in the research oriented U.S. educational network projects to date. This continues to be a time of rapid development with respect to the cluster of computational and communications technologies that comprise the Internet. Higher connection speed with the Internet II, faster and less expensive computers, new programming paradigms with network-based languages (e.g., Java), desktop video conferencing, Web-based digital video and audio, virtual reality (VRML) simulations--the list is seemingly endless and ever changing. The pace of technological change at this point in history is certainly a challenging issue to be confronted by those who are interested in exploring the emerging possibilities of network learning environments.

One major lesson of these projects, though, is that technology per se is not the most important issue. Of course, each of these projects has had to grapple with the complexities and the frustrations of implementing their respective models of learning mediated by technology. But the main lessons to be learned from these projects relate to the constructivist pedagogical and curriculum innovations they employ, and how the computational and communication technologies may be used to help facilitative those innovations. More research and practical experience is certainly necessary as the task of educational improvement and reform mediated by technology continues. The true challenge is to continue learning new lessons.

Adoption Patterns of Faculty Who Integrate Computer Technology for Teaching and Learning in Higher Education

D. Michele Jacobsen
Educational Psychology, University of Calgary, Calgary, Alberta, Canada
dmjacobs@acs.ucalgary.ca

Abstract: Why is the integration of technology for teaching and learning so appealing to some faculty, and not to others? The present investigation builds and extends upon Rogers' (1995) diffusion of innovations framework and adopter categories in an attempt to accurately reflect and describe faculty innovativeness with technology for teaching and learning. Information collected from faculty across disciplines at two major North American universities is analyzed for the differences between early adopters and mainstream faculty, the rate of adoption of educational technology by faculty, resulting changes to the teaching and learning environment, the incentives and barriers to integrating technology, preferred methods for learning about technology, and methods for evaluating the outcomes of integration.

Introduction

Recent estimates indicate that colleges and universities invest billions of dollars per year for the acquisition of computer technology [Geoghegan, 1994]. Instructional technology [IT] may support and increase the efficiency of the teaching-learning transaction or even modify educational processes, especially with regards to distance education and “anytime, anywhere” access [Daniel, 1997]. Formal evidence linking this investment to higher productivity [Schwalbe, 1996] and changes and improvements in the teaching and learning process is accumulating [Kulik & Kulik, 1980, 1987] [Ehrmann, 1995], and new research approaches and methodologies are being developed to adequately study the unique issues involved in educational technology [Bull, et al, 1994] [Clark, 1989] [Reigeluth, 1989]. In some cases, integrating technology into the teaching-learning transaction has been found to transform the teacher’s role from being the traditional "sage on the stage" to also being a "guide on the side", and student roles also change from being passive receivers of content to being more active participants and partners in the learning process [Alley, 1996] [Repp, 1996] [Roblyer, Edwards, & Havriluk, 1997]. IT is currently being used effectively in higher education for information access and delivery in libraries, research and development, as a communication medium, and for teaching and learning. Increased access to and use of the Internet is making a unique contribution to the teaching and learning process [Shaw, 1994] and will be an important part of future strategies to provide services to increased number of students in very diverse locations [Daniel, 1997].

Despite research and testimony that technology is being used by more faculty, the diffusion of technological innovations for teaching and learning has not been widespread, nor has IT become deeply integrated into the curriculum [Geoghegan, 1994]. Estimates suggest no more than five to ten percent of faculty utilize technology in their teaching as anything more than a "high tech" substitute for blackboard and chalk, overhead projectors, and photocopied handouts [Reeves, 1991]. Although there is a growing number of faculty who are very enthusiastic about adopting technology because of the potential of newer tools for their students, there is still a large number of faculty who seem hesitant or reluctant to adopt technology for their teaching tasks. Explanations for limited adoption may be found in the many barriers that still constrain use by enthusiastic beginners; user friendliness is a seductive term which misrepresents current technological reality. While acknowledging improvements in current design, computers and peripherals are still not well-designed, fault-free, and easy to use. As such, the evaluation of the success of educational technology still seems to depend largely on how well “early adopters” make it work. Given the size of investment in instructional technology in higher education, the increased demand for distance education in the future, and the demonstrated effectiveness with some educational outcomes, it seems reasonable to investigate why the integration of technology for teaching and learning is so appealing to some faculty, and not to others.

Diffusion of Innovations
A conceptual framework for analyzing faculty adoption of technology patterns is provided by Everett Rogers' [1995] theory of the diffusion of innovations, which defines diffusion as "the process by which an innovation is communicated through certain channels over time among the members of a social system". The four main elements are the innovation, communication channels, time, and the social system. [Rogers, 1995] defines an innovation as an idea, practice or object that is perceived as new by the individual, and diffusion as the process by which an innovation makes its way through a social system. For our purposes, the innovation is instructional technology for teaching and learning, and diffusion is the extent to which all faculty have adopted this innovation. Because individuals in a social system do not adopt an innovation at the same time, innovativeness is the degree to which an individual is relatively earlier in adopting new ideas than other members of a system. Based upon empirical investigations and market research, [Rogers, 1995] describes five adopter categories along the continuum of innovativeness [Figure 1] which are ideal types designed to make comparisons possible based on characteristics of the normal distribution and partitioned by the mean and standard deviation.

When an innovation has been adopted by most or all of the members in a social system or adopter category, diffusion has reached the saturation point. [Geoghegan, 1994] suggests that this saturation point has been reached with early adopters of instructional technology, but that "critical mass" alone, the segment of the diffusion curve between 10 to 20 percent adoption or the "heart of the diffusion process" [Rogers, 1995], is not enough to stimulate adoption by the mainstream [i.e., 84% of the population]. Geoghegan [and Wertheimer & Zinga, 1997] contrast early adopters, who are risk takers, more willing to experiment, generally self-sufficient, and interested in the technology itself, with early majority faculty who are more concerned about the teaching and learning problems being addressed than the technology used to address them, view ease of use as critical, and want proven applications with a low risk of failure. Early adopters make an innovation visible to the mainstream, decrease uncertainty about an innovation, are more experienced with technology and have higher use innovativeness [Ram & Jung, 1994], thus capitalizing on technology's many features and options. They seek different uses of technology to solve novel problems and contribute to new and better uses of technology. However, by making adoption look relatively easy, early adopters may disguise the extensive knowledge and skills that mainstream faculty will need in order to adopt. Universities are in a situation where there is widespread adoption of instructional technology by innovators and early adopters, but limited adoption by mainstream faculty. It is apparent from various descriptions of early adopters and the mainstream [Geoghegan, 1994] [see Jacobson & Weller, 1988], that these two groups have different characteristics, motivations, and needs. Therefore, campus-wide integration plans cannot be developed on the assumption that mainstream faculty will naturally use computers as readily and easily as the early adopter. Research into the adoption patterns of various technologies by higher education faculty will give insight into strategies for encouraging more widespread adoption.

**Methodology**

The present investigation surveyed faculty members from across disciplines at two major North American universities. Items gathered information about technology use patterns, computer experience and use of technology.
for teaching, general self-efficacy [Schwarzer & Jerusalem, 1995], changes to teaching and learning, incentives, and barriers, using a web-based survey instrument [http://www.acs.ucalgary.ca/~dmjacobs/phd]. Invitations to participate were distributed using paper-based mail, e-mail, and a campus newspaper. To solicit a representative sample, paper-based versions of the survey were also made available to potential participants. Complete data was obtained from 76 subjects (38.2% female, 61.8% male), 55 of whom completed the web-based survey and 21 the paper-based version. Subjects were on average 45.5 years old, had an average of 12.5 years experience as faculty member, and hold various academic ranks within their institution [i.e., 19.7% assistant professor, 35.5% associate professor, 26.3% professor, 18.4% lecturers and sessionals]. Over 65% of participants hold appointments that are tenured or leading to tenure. The majority of respondents teach 100 or less students per semester, and represent a range of academic disciplines: Agriculture, Continuing Education, Education, Engineering, Environmental Design, Fine Arts, General Studies, Humanities, Kinesiology, Management, Medicine, Nursing, Science, Social Science, and Social Work.

Computer Use in Classrooms and Faculty Expertise

According to the Annual Campus Computing Survey [Green, 1996], adoption of technology for classroom use has risen between 1994 and 1995; e-mail use has almost doubled to 20%, presentation software use is over 25%, and the use of multimedia and CD-ROM-based materials is just under 10%. The present study indicates that the adoption of technology for classroom use is even greater in 1997. Faculty were asked to indicate whether they had ever used any of 44 types of computer software and tools in a course they taught. Word processing is used by 60% of faculty, spreadsheets by 38%, charting & graphing by 36%, databases by 34%, presentation software by 34%, and 18% have used CD-ROM-based materials. A number of faculty use instructional courseware for teaching: tutorials 18%, drill & practice 14%, simulations 17%, and games 6%. E-mail is used by 67% of faculty in their teaching, on-line databases or library catalogues by 46%, newsgroups by 29%, and FTP by 23%. Newer technologies, like the World Wide Web, have been adopted for searching & browsing by 56% of faculty, and by 36% for web page creation and editing. It seems fair to suggest that communication technologies are the proverbial carrot that entices mainstream faculty to adopt technology for teaching and learning [Foa, 1993]. Once faculty are intrigued by e-mail and the Web, they may start asking questions about other technologies [Gilbert, 1995]. Faculty rated their level of expertise [i.e., 0.none, 1.a little, 2.fair, 3.substantial, 4.extensive] with 44 types of computer software. Findings indicate that faculty tend to develop a level of personal expertise with a particular computer technology before attempting to integrate it into their teaching [i.e., these technologies have been personally adopted by late majority].

Changes to Teaching and Learning

[Hadley & Sheingold, 1993] indicated that significant changes can take place as teachers integrate computers into instruction. Faculty were asked to use a five-point scale (1.strongly agree, 2.agree, 3.neutral, 4.disagree, 5.strongly
disagree) to indicate their level of agreement with statements about how the integration of technology may change the teaching and learning environment. Faculty most strongly agreed with the following five statements:

<table>
<thead>
<tr>
<th>Statements - Changes to Post-Secondary Teaching and Learning</th>
<th>Mean</th>
<th>SD</th>
</tr>
</thead>
<tbody>
<tr>
<td>Faculty will spend more time preparing materials and resources for instruction.</td>
<td>1.77</td>
<td>1.00</td>
</tr>
<tr>
<td>Faculty can expect more from students in terms of their pursuing and editing their work.</td>
<td>2.05</td>
<td>0.84</td>
</tr>
<tr>
<td>Faculty will spend more time acting as a guide and facilitator with individual students.</td>
<td>2.44</td>
<td>1.19</td>
</tr>
<tr>
<td>Faculty are better able to tailor students' work to their individual needs.</td>
<td>2.48</td>
<td>0.95</td>
</tr>
<tr>
<td>Faculty can be more comfortable with students working independently.</td>
<td>2.59</td>
<td>1.21</td>
</tr>
</tbody>
</table>

While four of these statements describe benefits to student learning, it is also clear that faculty can expect to invest additional time preparing materials and resources when they integrate technology into teaching and learning. When asked to elaborate on the nature of changes they have observed as a result of using technology in teaching, one person confirmed that “it increases preparation time in the short run [first year or two], but allows for rapid changes/updates in web materials in the long run”. So, the investment of time can yield returns. Technology can also appeal to some students, and not to others: “Some of my graduate students are frustrated when I ask them to try to use new technological tools...those who have an open mind and flexible learning style like using technology enhanced instruction; others do not and resent the demand on their time to change. Some of the more shy and quiet students blossom in terms of their learning when technology is introduced”. The next comment touches on the fundamental changes that technology integration seems to require of teachers and learners: “I still struggle with students who are conditioned to a system of grades and dependency ...who are reluctant to take responsibility for their own learning. However...a small number of students do seem to be catching on to the idea that they are in charge of their learning and willingly take risks”. New tools both provide and require a new approach to teaching and learning.

### Incentives to Integrate Technology

Given the time and effort required to integrate technology into teaching, different reasons tend to motivate and keep faculty engaged with this task. Some incentives are more important for encouraging faculty members to integrate technology in their teaching [Hadley & Sheingold, 1993]. Using a five-point scale (1. strongly agree, a major incentive, 2.agree, 3.neutral, 4.disagree, 5.strongly disagree, not an incentive), faculty indicated the extent of their agreement with twelve incentive statements. The following five reasons emerged as the most important incentives:

<table>
<thead>
<tr>
<th>Incentive Statement</th>
<th>Mean</th>
<th>SD</th>
</tr>
</thead>
<tbody>
<tr>
<td>I get personal gratification from learning new computer knowledge and skills</td>
<td>1.80</td>
<td>0.84</td>
</tr>
<tr>
<td>Computers are a tool that help students with learning tasks, such as writing, analyzing data, or solving problems.</td>
<td>1.82</td>
<td>0.98</td>
</tr>
<tr>
<td>By integrating technology, I am helping students to acquire the basic computer education they will need for future careers.</td>
<td>1.92</td>
<td>1.01</td>
</tr>
<tr>
<td>Technology tools enable students to help each other and cooperate on projects.</td>
<td>2.22</td>
<td>0.97</td>
</tr>
<tr>
<td>Computers enable me to make a subject more interesting.</td>
<td>2.28</td>
<td>0.97</td>
</tr>
</tbody>
</table>

While four of the highest rated incentives have to do with providing enriched learning opportunities for students, the number one incentive for integrating technology is the personal gratification one gets from learning new computer knowledge and skills. When asked to elaborate on the incentives for using technology, one person wrote, “I am convinced that I can provide a better introduction to complex subject matter using interactive, computer-based technology than I can using either the traditional classroom or any paper-based medium”.

### Barriers to Integrating Technology

Many faculty are highly motivated to integrate computers for teaching and learning. Although many have developed impressive expertise in using computers in their classrooms, to a greater or lesser extent, all faculty experience barriers when they attempt to integrate computers in their teaching. Faculty used a five-point scale (1.strongly agree, a major barrier, 2.agree, 3.neutral, 4.disagree, 5.strongly disagree, not a barrier) to rate the
significance of twenty barriers, adapted from [Hadley & Sheingold, 1993], to the use of computers for teaching and learning in the campus environment. The following six statements describe barriers that most faculty agreed were impediments to integrating technology on campus:

<table>
<thead>
<tr>
<th>Statements - Barriers to Integration</th>
<th>Mean</th>
<th>SD</th>
</tr>
</thead>
<tbody>
<tr>
<td>Faculty members lack enough time to develop instruction that uses computers.</td>
<td>1.50</td>
<td>0.82</td>
</tr>
<tr>
<td>There are problems scheduling enough computer time and/or resources for different faculties' classes.</td>
<td>1.78</td>
<td>0.89</td>
</tr>
<tr>
<td>Financial support for computer integration from administration is inadequate.</td>
<td>1.80</td>
<td>0.86</td>
</tr>
<tr>
<td>There are too few computers for the number of students.</td>
<td>1.86</td>
<td>0.94</td>
</tr>
<tr>
<td>There is inadequate financial support for the development of instructional uses of computers.</td>
<td>1.88</td>
<td>0.93</td>
</tr>
<tr>
<td>The reward structure does not recognize faculty for integrating computers for teaching and learning.</td>
<td>2.06</td>
<td>1.26</td>
</tr>
</tbody>
</table>

In response to a request to elaborate upon barriers that may prevent or discourage faculty from using technology in their teaching tasks, 58 faculty submitted responses. The most common explanation for non-adoption was the perceived lack of time to learn how to use technological tools as well as learning new methods for teaching. Several faculty identified "faculty complacency" as a reason for non-adoption, and suggestions were made that many faculty will not adopt unless they are forced to by formal administrative expectations. Some faculty pointed to the importance of research over teaching in annual merit reviews, and the absence of recognition for the use of technology for effective teaching and learning. A faculty comment confirms that "the barriers are not specific to computers but are the general lack of any reward whatsoever for effort put into teaching excellence". Among many faculty, there is the perception that technology is still an unproved instructional intervention: "Due to the fact that there is insufficient data to support the efficacy of computerized teaching, only the risk takers in academics are prepared to spend the time developing courses for this medium". Hence, early adopters integrate despite risk.

Learning About Technology

Individuals tend to have preferred methods for learning more about technology. Faculty were asked three questions for which they were asked to rank the importance of different methods for learning about technology, getting help and support, and accessing information about innovations. In terms of media and methods for acquiring NEW computer application skills and knowledge, faculty ranked the following from most to least important in descending order: [1] hands-on experimenting and trouble shooting, [2] mixture of manuals and hands-on, [3] hardcopy materials, books, etc., [4] on-line manuals, [5] workshops and presentations, and last, [6] structured courses and guidance. A good number of Technology Integration Plans suggest that faculty need more workshops and courses in order to acquire the knowledge and skills they need to adopt technology. However, future plans for professional development should be informed by faculty member's expressed preferences for more hands-on experimentation and trouble shooting.

In terms of HELP or ASSISTANCE with using computers, faculty ranked the following sources of support from most to least important in descending order: [1] colleagues on campus, [2] one-on-one assistance, [3] experienced graduate students, [4] media center support staff, [5] hot-line, or telephone assistance, [6] outside professionals trained in technology use, and last, [7] colleagues at another institution. Faculty prefer to get help from colleagues and graduate students, and want one-on-one assistance, rather than relying on outside professionals or colleagues at another institution. Combined with the preferences expressed in the first part, it appears that the most successful professional development would be to have just-in-time, one-on-one access to colleagues and experienced graduate students when one runs into trouble experimenting and playing around with new technologies. Faculty were asked to rate the importance of various sources of information for keeping abreast of changes and innovations in the area of computers. From most to least important in descending order, are: [1] colleagues on campus, [2] an informal network of friends and family, [3] innovative graduate students, [4] on-line computer newsgroups & websites, [5] conferences, demonstrations and workshops, [6] colleagues at another institution, [7 tie] popular computer magazines, [7 tie] popular newspapers and television, [8] hardware and software stores, vendors, suppliers, and also [9] hardware and software catalogues and brochures. The highest ranked source of information is a colleague, followed closely by friends, family, and innovative graduate students. Faculty prefer to learn about changes and innovation from people they know and to which they have immediate access. Five sources of
information that were ranked “not important” or “neutral” sources of information about changes and innovations in the area of computers, from least important: [1] department chair, [2] university administration, [3] refereed computer journals, [4] publications from major computer vendors, and [5] on-line computer journals. Faculty apparently do not look “up” for information about technology innovations, nor do they rely on vendors or refereed journals.

Discussion

Previous explanations for why the majority of faculty did not adopt technology for teaching and learning focused on blame. Faculty were blamed for being stuck in traditional methods of course delivery, were labeled as resistors and charged with negative attitudes towards technology [Gordon, 1983]. These explanations were based on a poor understanding of the difference between faculty who readily adopt technology for teaching, and those who do not. The challenge for researchers interested in the adoption of technology is not to assign blame nor to attempt to fix faculty attitudes. The challenge instead is to draft technology integration plans and design new educational systems within the logic and meaning of the emerging paradigms that are informed by our growing understanding of the complexity and interconnectedness of faculty social systems, communication channels, and patterns of diffusion. A different support infrastructure is clearly needed for mainstream faculty than that which sufficed for early adopters of technology. A number of system-wide initiatives have been implemented at various higher education institutions which provide models for encouraging wider diffusion of technology for teaching and learning, and bridging the gap between early adopter success and more mainstream adoption.

The present research provides additional support for three trends identified by [Jacobson & Weller, 1988] to describe faculty adoption patterns: [1] the use of computers for one purpose may encourage enthusiasm for further computer use, [2] that mainstream faculty may be limited adopters because of the lack of technical support and training, and [3] that colleague supported training is a viable way to encourage diffusion of computer technologies. Administration has to be convinced to let go of the infrastructure-driven “if you build it, they will come” approach to technology integration if they want to address the gap between early adopters and mainstream faculty. Critical mass alone is insufficient to drive further adoption. Faculty and administration have a deep mutual dependency; the top-down program advocate needs convincing exemplars to justify large investments in technology at a moment when funds are scarce, and the bottom-up project advocate and enthusiastic beginner needs a well-conceived and reliable working environment for successful implementation of innovative concepts [Noblitt, 1997]. To make the efforts of early adopters more widespread and their results used more comprehensively, incentives, training, support and reward structures “from above” are needed to build a strong human infrastructure [Foa, 1993] as well as providing the technological infrastructure [i.e., networks, hardware and software] to drive integration. IT investments for teaching have to be ahead of what is the state of the art in the world of work, as higher education prepares for the future. These ever-new investments cannot be left to uncoordinated departmental or individual initiatives, as they often exceed respective budgets [Bull, et al., 1994]. If the integration of technology for teaching and learning is a valued institutional goal, administration must recognize that in order to drive change they will have to address the reward system and commit to system-wide investment in IT. The key to diffusion will be training and support. Without investment in the human infrastructure nothing of sustainable value will be achieved [Foa, 1993]. One final thought: it may not be the case that early adoption and excellent teaching qualities exist in the same person. Universities must include an emphasis on excellent teaching in their technology integration plans. Early adopters of technology who are also excellent teachers have much to contribute to this planning process. [Kearsley, 1996] suggests that excellent teaching should be our first priority, because adopting technology will not improve poor teaching. He argues that without excellent teachers, technology will not enhance learning to any degree. If cases are found where early adoption and excellent teaching exist in the same individual, then it is worth profiling this expertise for the benefit of other faculty members who wish to develop both their technology and teaching knowledge and skills.

JUGEND AM NETZ (JAN - http://www.jugend-am-netz.de) is a project to bring youths in the age of 11-25 together using modern communication media. Participating youngsters built a network to exchange their opinions on various topics and help each other by providing information. JAN runs an intranet of different widespread dial-in nodes in the project area. Determining their contributions the young people practice their ability to present certain issues using internet technology. JAN already shows synergetic effects:
• Project members offer regular lessons on computer and internet providing interested youths with needed information.
• In special lessons female project members teach girls interested in computer-related topics.
• JAN cooperates with enterprises by educating their apprentices in the new communication media and offering the possibility of presenting the enterprises in the World-Wide-Web.
• Regular meetings let the project members meet each other personally initiating further activities.
JAN's friendship-network grows...

Abstract: Developing effective multimedia learning packages requires expensive equipment, is labour intensive, and requires expertise in a number of areas which teaching staff who are experts in particular subject matter areas are not likely to possess. This paper describes a grant-funded project which is using a team approach to cost effectively bring together human and machine resources necessary to developing high-quality interactive multimedia learning tools. Participants are expected to produce small prototype learning modules. In pursuit of this goal they attend workshops, have access to hardware needed in development, are provided with the authoring software of their choice, and receive individualized assistance.

1. Introduction

Methods of encouraging interactive learning that are self-paced yet can evaluate and document learners' understanding of key concepts are highly desirable. In most subject matter areas there are key concepts and principles that must be taught over and over again to large numbers of students or which are difficult for students to grasp without the use of sound, graphics, or moving images. In these situations, lecturer time could be saved and students would be more likely to comprehend difficult concepts if they were given a well-designed learning resource that they could access in their own time and use at their own pace. Computer-driven interactive multimedia has the potential to address these needs in education.

Technology enthusiasts claim that computer-assisted learning tools and, in particular, interactive multimedia, have definite advantages over other media of instruction- they can provide a multisensory learning environment, promote a more active form of learning, offer more independent learning, and provide simulations of complex scientific or social processes that are difficult or even impossible to demonstrate in classroom situations.

Clark (1991) argued that effective computer-based instruction depends not on the technology itself, but on the conscious and creative application of knowledge about learning and instruction in designing the multimedia programs. Gilbert (1995) suggested that effective implementation of interactive multimedia technology in universities requires the commitment of the institution to the infrastructure, the commitment of the staff members to the approach, and the availability of information, help, and support from various campus organisations (for example, computing services, educational/instructional development services, the library, etc.). On the other hand, domination by the technologists in the development of materials may be detrimental to implementing interactive multimedia instruction. Hansen and Perry (1993) argued that a lot of technology-based instruction failed because of the technologists' tendency to create their products for rather than with the users. It
follows that the design of tertiary education CAL (computer assisted learning) materials needs to be influenced by input from educational specialists as well as subject specialists.

Potentially, subject specialists (content experts) who are familiar with the stages of interactive multimedia software development, can contribute to more efficient and effective production. They would (1) understand the preliminary steps needed in software design, (2) appreciate the precision needed when filling out storyboards, and (3) understand the logical structures which need to be programmed in order to implement question-and-answer routines. Since they have the best understanding of both the content of the software and the intended users, content experts taking a leading role in CAL production can help to ensure both subject and educational validity of the product.

This paper will describe a project funded by the Hong Kong University Grants Committee through The Hong Kong Polytechnic University (PolyU) which is intended to develop university subject specialists’ knowledge about and skills in interactive multimedia production. An overall model of the project will be explained, progress to date will be given, and modifications based upon what has been learned in the first cycle of the program will be discussed. It is hoped that this information may help other universities undertake similar activities.

2. The Project

The project, Multidisciplinary Applications of Computer Assisted/Multimedia Learning Resources was funded with HK$600,000 (US$77,000) obtained through a Learning and Teaching Development Grant from the Hong Kong University Grants Commission through PolyU.

The aim of the project was to assist over 25 academic staff members to develop working prototypes of interactive multimedia software useful to the learning processes of their students. In doing so, it was expected that these subject specialists would gain knowledge and skills in development of educationally-sound modern technology software which would make them better informed about aspects of this complex and time-consuming activity. Past experience of the team leaders has proved that many subject experts become involved with CAL materials development without having adequate knowledge of the commitments and skills involved and some become overwhelmed with the workload. Unacceptable results include projects that are never finished, or are of questionable educational value. The present project hopes to prevent this by encouraging small-scale prototype development in which each participant is able to test the concept and design of their idea before they embark upon a large-scale commitment.

The time frame of the project spans eighteen months; this includes six months of meetings and workshops, ten months of development activity, and two months for CD production.

[Fig. 1] graphically depicts the people and other resources contributing to the project. Input to the project comes from workshop leaders (L), a research assistant (A), and software/hardware resources (R). Subject specialists (S), benefiting from the aid of the workshops and collaborative work with the other personnel, produce small but working prototypes of programs which have the potential to be expanded later into full CAL tools. The “deliverable” from the project is one (or more) CD-ROM “Prototype Sampler(s)”.

![Figure 1: Project model](image-url)
Subject specialists participating in the project come from eight university departments. CAL topics range from *A computerised construction planning game* from The Department of Building and Real Estate to *Therapeutic art in healing (pain expressed through art)* from The Department of Applied Social Studies. A complete list of participants and projects is available from the project's web site: (http://etu618.edu.polyu.edu.hk/Umbrella/Calmenu/Calmenu.html).

"Leaders" of the project were three staff members from The Educational Development Unit and one Research Assistant. Combined expertise of this group includes curriculum development, learning theory, educational environments, CAL development, user-interface design, computer programming, and miscellaneous technical skills such as filming and digitising video segments.

As microcomputer use at PolyU includes both PC and Macintosh platforms (in approximately 90% to 10% respective percentages), resources purchased for the project were intended to cater for both platforms. The Research Assistant has been given both a Pentium-based PC which includes full video and audio facilities, and a PowerMac (9500), along with a full complement of drawing and authoring tools. The project also funded each participant an authoring tool; Authorware Professional was the overwhelming choice, with some members choosing ToolBook. One obvious efficiency of this project was the saving in costs by bulk-purchasing software.

3. The Blueprint

All project participants were given a “blueprint” which helped them to organise the information and ideas necessary to create an educationally sound tool. The blueprint is the template overlying each participant’s sub-project. It is a fill-in form which prompts subject specialists to consider a wide range of areas from both educational theory and technical development perspectives, in planning their prototype. The blueprint incorporates the following categories:

1. concept map
2. learning objectives
3. target students
4. description of software required
5. media components
6. interactions intended
7. interface design
8. screen design
9. storyboard format

The blueprints were to be filled out over the course of the workshops. The intention was that when the blueprints were completed, the process of storyboarding could be conducted which would then lead to the programming phase of development.

The experience of the authors is that many academic staff who want to develop interactive multimedia materials lack both the requisite knowledge of educational theory alluded to by Clark(1991) and skills in the technical procedures involved; these procedures range from storyboarding and screen design to authoring, digitising, etc. Workshops were specifically designed to inform participants of the sequences of steps involved in the whole CAL software development process. Five two-hour workshops were conducted. Each workshop covered specific areas that subject specialists who were relative novices in multimedia/CAL development needed to know. These workshops were intentionally associated with the blueprint and included information and activities designed to help the participants complete portions of their own blueprints.

The first workshop demonstrated examples of CAL programs. These programs ranged from simple text-based computer-directed styles to more current multimedia with highly interactive structures.

The second session was titled “Design Issues” and introduced concept maps which are intended to be used to structure and organise a program’s components. These maps can take the form of diagrams, drawings, flowcharts, tables, or outlines. There was also discussion concerning the understanding of target students and setting learning objectives.

The third workshop gave an overview of authoring languages. Three example programs, each written from the same sample concept map were demonstrated. The three authoring languages used were Authorware Professional, Director, and ToolBook. A follow-up of this session was a one-to-one session for each participant with the Research Assistant; these sessions lasted approximately two hours each and gave the subject specialists a closer “feel” for one or more languages. Following these sessions, project members were expected to choose which authoring languages they would ultimately use for their prototypes.
The fourth workshop dealt with interactive multimedia user-interface design. Included in this workshop were topics such as the design of the amount of interaction which was incorporated in a program, screen design, and navigation issues.

The final whole-group workshop dealt with storyboarding. Example storyboards, both blank and filled-out, formed the basis of this session. Following this workshop, smaller more specialised sessions were planned and presented on an “as-needed” basis. Examples of these include Digitising Videos and Incorporating Sound. Works-in-Progress sessions are also underway.

During the present programming phase of development, one-to-one consultation sessions are occurring. These are meetings with the Research Assistant for assistance with programming problems, clip-art libraries, etc. as well as meetings with project leaders regarding such issues as screen design and reinforcement feedback.

4. Present State and Predicted Results

At the time of this writing, the project is fourteen months old. Already, the progress of participants covers a wide range- there are five working prototypes. Other project members have been hindered by the inevitable demands of lecturing commitments, vowing to make progress during the summer “holidays”. However, a wide variety of progress, results, and even the dropout of a few members was anticipated.

An anonymous project evaluation questionnaire has recently been distributed to project members. So far, returns have been received from half of the participants. These results expressed overwhelming satisfaction with the basic understanding and skills gained for creating CAL resources. Members also expressed satisfaction with the software and personnel resources available to them. Furthermore, they were in agreement with the high amount of time commitment required to produce computer programs. The authors concede that the half who have not yet returned questionnaires are likely to agree with the demands of software development, but also would be expected to have more negative attitudes to various components of the project than those who did make returns. Following are results of selected items:

1. Please rate the usefulness of the following aspects of the project:

   - Providing you with a basic understanding of the various knowledge and skills required to create computer-assisted/multimedia learning resources.
   - Helping you recognize the potential benefits of CAL packages.
   - Helping you understand the commitments required (time, effort, and cost) for developing CAL packages.

2. Which of the following statements best represents your view towards developing computer-assisted/multimedia learning resources for your own teaching?
   a. I think that it is a challenging and rewarding task, and I am definitely interested in getting involved in CAL/MM development in future.
   b. I think that it is useful and interesting, but I do not plan to be involved in such development in future.
   c. I don’t find it particularly interesting and rewarding, and I will not be interested in getting involved in these developments in future.
