From item 2. above it is clear that respondents have found the development of resources a challenging and rewarding task, and that they are definitely interested in continued involvement in future. The benefits of the project, from the participants’ perspective, are evident in the evaluation results which were succinctly summarized in the written comments from one of the members:

1. mastering the techniques of developing a CAL program,
2. sharing experiences with colleagues having the same interest in developing CAL programs,
3. self satisfaction from work done with recognition from colleagues and students,
4. developing a deeper interest in the hardware and software for producing CAL programs.

However, participants also reported that they have encountered problems and difficulties. Heavy workload and inadequate technical support are the two things that most participants identified as the major obstacles to their progress and continued involvement.

It is predicted that three groups of participants will emerge from this project. One group will find that interactive multimedia development is vastly different from what they expected. It is hoped that many of this group will at least be better-informed consumers of this modern technology. A second group may want to be involved in multimedia production, but as participants rather than as leaders of projects. They should have the experience to be better-informed for the job of directing others to perform tasks such as screen design and programming. Finally, it is anticipated that some enthusiasts will emerge from this project; this group will be those who enjoy a deep involvement in the design and technical aspects of development. At the completion of the project, an analysis will be made to determine if these (or indeed, other) groups form.

One surprise facet of this project which was not anticipated is the integral part the World Wide Web has taken. It was decided to build a web page on which project information would be placed. This page has evolved into many folders of files which comprehensively document the following:
1. project data such as aims and rationale,
2. references including scanned articles, relevant web sites, and conferences,
3. a discussion channel for notices and participants' communication,
4. participants' information,
5. prototype descriptions (projected to include prototype delivery).

With increased world wide web delivery capabilities, it is anticipated that the prototypes will also be installed on the project's web pages.

Based upon demands from PolyU staff members, a second project is currently underway. There are seventeen participants, inclusive of workshop leaders. Two significant changes arising from the questionnaire are (1) the workshops were "telescoped" to be conducted within two months, leaving longer production time, and (2) the second project will involve the exclusive use of Authorware Professional.

5. Summary

The potential of interactive multimedia technology in education is recognised by many. Because of the specialised and local nature of many university subjects, the development of these teaching aids often needs to be performed "in-house". However, CAL software development is a complex, labour-, and time-intensive activity. This paper described an efficient model for training academic staff to become knowledgeable and experienced in software production. Regardless of whether staff who participate in these activities become enthusiastic, "hands-on" developers, participants in larger software-development projects, or never partake in software development again (but are intelligent consumers of available packages), all should benefit from their involvement in the production of prototypes.

Abstract: CAL (Computer Assisted Learning) software can be designed using the same principles of teaching which apply to the design of traditional teacher delivery. Software can be a simple page-flipping delivery system, or can incorporate components associated with active learning. Likewise, CAL software can vary according to the amount of control and "advice" given to the learner. Compromises can be made concerning the complexity of the educational environment produced with corresponding differences in the complexity of the programming used to produce the software. A program intended to teach principles of molecular biology is an example of software which attempts to incorporate components of both receptive and constructivist learning. It is designed to incorporate a certain amount of intelligence but in doing so, also introduces the question of fairness to different users.

1. Introduction

While computers continue to increase in memory capacity, speed, and multimedia delivery, the most critical factors in educational software design are concerned with the incorporation of interactivity into the CAL environment. Just as university teaching can vary from uni-directional, didactic lecture presentations to student-centred environments in which the learners inquire, discuss, discover, and generally contribute to their own learning, educational software can be designed which follow a similar range of models.

This paper describes a range of CAL software models and issues such as control, interactivity, and ease-of-programming. It also introduces a "compromise model", used for a package currently under development, which is intended to teach students principles of molecular biology, incorporating three activities - Concepts, Practice, and Assessment. The paper will also consider the difficulties involved in attempting to build some "intelligence" into the Practice sectors, particularly the irony of designing software which can actually disadvantage the "good" students.

2. A Linear Approach to Software Design

The lecture style has a long-standing tradition in university settings. This one-way didactic teaching method is based on a model where a subject expert presents information to students. This information can be relayed verbally or in text form, with the result of this information being transcribed into students' notes. Advantages of this expository teaching style include efficiency (often with a teacher-to-student ratio of one-to-hundreds) and the relative ease of preparation and delivery. However, it can be argued that a good text could replace this teaching method with the favourable end result of less errors in the students' resultant written material (lecture notes would rarely be edited to the accuracy of a textbook).

The simplest and by far the easiest-to-program CAL software model has a linear, sequential structure. It follows a book metaphor where typically, the reader begins on page one and reads pages in order until the end of the book is reached. A computerised book may have the advantage of incorporating multimedia objects on each page, but the essential structure of this model as shown in [Fig. 1] is the electronic equivalent of a lecture. Control is determined by the order of the content, the user simply clicking a "next page" button. Presentation software such as PowerPoint could be used for creating and delivering such a book. James et al (1998) describe how beginning educational software programmers tended to design linear systems.
3. An Unstructured Model

The opposite approach to learning from the one mentioned above is one which gives students complete control of their information acquisition. Handing a student an encyclopedia or giving access to the World Wide Web are two examples of placing unrestricted learner-control tools in the hands of the student for a potentially rich, active, investigative environment.

[Fig. 2] shows graphically a typical hypermedia software model which, like the electronic book, is a simple point-and-click environment, but which allows complete user-control. The user can traverse any part of the structure, limited only by the buttons available at each node. A structure like this is still relatively easy to program using any authoring tool (such as HyperCard or ToolBook) which allows node (card or page) creation and linking between nodes.

![Figure 2: Unstructured hypermedia software](image)

While the amount of control may be different for each of these teaching methods, the commonality is the lack of interaction between computer and user.

4. The Ideal Model

An idealistic teaching model would be based on a “tutoring” concept; the program would ask the user a question, accept any answer and give expert feedback, ask another question, etc. Unfortunately, this all-wise, infinitely-patient, intelligent tutor [Fig. 3] would require a level of artificial intelligence which would increase the programming complexity immeasurably.

![Figure 3: The Intelligent Tutor](image)

It has long been recognised that there is more value in a “deeper” learning approach to education than that which is represented by the “expository” model. Laurillard (1993), in her comprehensive analysis of teaching in higher education, suggests that an active-engagement approach as advocated by educational psychologists Piaget and Bruner, is as relevant to university students as it is to younger learners. In practical terms, an environment such as this contains more learner-directed investigations (from the “hypermedia model”), combined with a significant amount of interaction (from the “tutor model”).

In designing computer assisted learning tools, it is reasonable to attempt to design software which involves learners in the most powerful educational environment possible. Latchem et. al. (1993) advocate basing
software design on sound pedagogical principles such as constructivism where students work in a knowledge-construction environment designed to be interesting, challenging, problem-oriented, and sometimes experimental.

The issue of control is fundamental to constructivist learning. In discussing the amount of control in CAL software, Schwier and Misanchuk (1993) caution that different learners have different amounts of control requirements. High-achieving students apparently benefit from having higher degrees of control whereas less-able and sometimes more naive students require more direction and structure to be administered by the computer program. It follows that educational computer software will be more adaptable to a range of students if it is flexible enough to allow different amounts of control by the users, although from a practical programming perspective, this is difficult to achieve.

Current interactive multimedia software often contains hypermedia knowledge structures. These are nodes of information (for example, screens of information), connected together by links (often in the form of buttons pointing to other screens). According to Muffoletto and Knupfer (1993), hypermedia enables students to explore information resources and can provide them with the opportunity to actively use newly-discovered information in the production of new knowledge. Jonassen et al (1991, p237) agree that “hyper environments” are “among the best examples of constructivist learning environments”.

Assuming that more powerful learning environments as discussed above can be programmed into CAL systems, Csete and James(1996) have proposed a conceptual framework for designing an instrument to encourage learner control and engagement. This framework is in the form of a template with three components: (1) a window for the presentation of basic (and new) information, (2) a menu of learning options, and (3) a “safe” learning workspace for experimentation and the application of new concepts, principles, and skills in a non-threatening environment. Within the third template component, it is expected that learners will be encouraged to try new things, repeat activities, and explore “what if” scenarios. Rather than a completely free, open, and 100% learner-controlled environment, the viewpoint was that there will be a “guided discovery” situation where the program shares control with the learner. Lowyck and Elen (1991, p214) label advocates of this compromised position “mild constructivists”.

“Mild constructivists argue that, though self-regulated learning might be the ideal, most learning involves the interaction between internal (cognitive) and external (e.g. instructional materials) monitoring and that learning processes can be initiated both internally and externally.”

A CAL program which has a modified hypermedia design, consisting of nodes connected by links including components of guidance from and interaction with the program, is consistent with this compromise.

[Fig. 4] shows a conceptual model of a CAL program which has a general sequential structure of units, but within each unit there is (1) information delivered to the student, (2) an environment where the student can investigate, and (3) “intelligent” interaction between the student and the program. A model such as this attempts to incorporate constructivist opportunities and interaction within a guided-delivery system.

![Figure 4: A “mild constructivist” model made up of three-part units.](image)

The content component is similar to a sequence of one or more nodes in the “lecture” model, each node explaining a concept using text, diagrams, pictures, animations etc. The investigation component can vary, but
typically will be an activity where the students make decisions based on what they understand of the content. It should be noted that activities such as these often require sophisticated design and programming skills.

The "intelligent" interaction consists of a "dialogue" which can be programmed using logical structures (e.g., if-then-else statements). This component addresses the concern expressed by Latchem et. al. (1993) that a majority of interactive multimedia systems are a "shallow" result of a simple menu-and-selection philosophy of interaction. They also see a potential for a more Socratic environment, posing questions and challenges. This view is supported by Larkin and Chabay (1992, p170) who propose, "Never tell when you can ask".

Larkin and Chabay caution, however, that designing interactive programs is a difficult task- the programming logic and possible pitfalls can be seen in the following example. The result of a well-designed comprehensive dialogue can be worth the effort, the alternative being what Bates (1995) describes as a lack of flexibility leading to student frustration when reasonable responses are not "recognised" by the computer.

5. Example Case

In early 1996, the Hong Kong Polytechnic University allocated Hong Kong University Grants Commission funds for projects which implemented interactive multimedia technology in teaching and learning situations at the University. A sub-project of one of the successful grant applications is called Molecular Biology which is intended to develop a teaching tool to aid third-year students to learn DNA technology. The philosophy behind the design of this project is to create CAL software which is consistent with the "mild constructivist" model given above. It incorporates high-resolution graphics and animation, and was authored using Micromedia Director. [Fig. 5] is a snapshot of a sub-menu of the program.

![Figure 5: A Sub-Menu of the Molecular Biology Project.](image)

The Concept part delivers subject content to the student; an example page is shown in [Fig. 6a]. This particular page gives an animation demonstrating how temperature affects DNA strand separation.

![Figure 6a: Example Content Page.](image)  ![Figure 6b: Example Activity](image)

The Practice option provides a problem-solving environment with appropriate user-computer interaction. [Fig. 6b] displays an activity where the student is expected to specify three temperatures using temperature...
slides. When the temperatures are set and the Start button pushed, the computer will report appropriate feedback to the student. This feedback is in the form of a written report. [Fig. 7] is a diagram displaying the logic the computer program will follow in determining feedback to the student's temperature settings (D, A, and P). Each of the seven possible reports will be a unique "intelligent" response to the temperatures which the student specified (note that in the actual package there are sixteen reports available, rather than seven). If the user sets all three temperatures correctly (D = 95, A is between 40 and 50, and P is between 70 and 75 degrees), Report 5 is given and control then leaves this routine, progressing to the next step in the program. If incorrect combinations of temperatures are specified, an appropriate report is given and the user has the opportunity to specify a new set of temperatures.

While the logic described above appears to be reasonable, the designers have a dilemma: assuming that the six "incorrect" reports are information-rich for each respective combination of temperatures, it could follow that the "good" student who gets the correct temperatures upon the first (or even second) attempt would have learned something else from some of the incorrect reports. If this is so, then the student was disadvantaged by leaving the routine following their correct input. Designers are cautioned therefore, that perhaps a more "fair" routine would look like that shown in [Fig. 8] where all students have the opportunity to gain from a variety of situations, in this particular case, from investigations arising from different incorrect temperature settings.

Example questions which would generate reports could be:
Report 1: What would you expect to happen if the Denaturation temperature was set to less than 95?
Report 2: Good! Did you also know that "de-oxy" means "removing oxygen"?

Figure 7: Logic Depicting Possible Feedback.
Figure 8: A More Incremental and Fair Routine.

The inevitable tradeoff with this structure however, is that all students must go through all possible settings, increasing the time of sitting by most students and more importantly, minimising the individuality of program runs.

In the spirit of the active learning approach however, guidance could be given in a more open-ended manner; for example "Investigate a wide range of temperature settings" could result in a variety of reported results as in effect, the student would be instructed to traverse the whole structure of [Fig. 7]. However, this would favour Schwier and Misanchuk's (1993) "high-achiever" students. A designer wanting to incorporate an "all things for all people" philosophy could cater for both types of students by adding another selection page with two buttons, one labelled "Sequential path approach" and the other "Open-ended approach".

6. Conclusion

Just as there are different teaching methods and styles, CAL software can be designed to reflect different teaching philosophies. Active learning approaches can be incorporated into computer programs to promote more effective learning, but there will be a tradeoff between more powerful learning tools and programming practicalities. Furthermore, it is not possible to build the "perfect" CAL program because of the differences between learners and hence, their learning styles. Perhaps the most serviceable educational software designs are accomplished by incorporating both guided and self-discovery components. In all cases however, interactive software designs must include components of intelligence and fairness to all learners.

Self-Directed Learning of University Students Using a Hypermedia on English: Spectral Analysis of Their Performances

Véronique JANS

Attached to the Department of Educational Technology (STE) of the University of Liège (ULG) - Belgium
E-mail: V.Jans@ulg.ac.be

Abstract: Today we are witnessing an explosion of the learning resources on the one hand and on the other hand a need for continuous learning [Leclercq & Denis 95]. In this context autonomous learning will take an increasing part of the educational process and people will turn more and more towards computerised products. As educationists, we study how and what people learn by exploring these resources... to be able afterwards to offer them helps to improve their learning strategies... and outcomes.

For one year, we have been conducting a research on learning strategies with a CD-Rom on English. Our research has been attempting to study the benefit of a punctual self-directed learning experience with a hypermedia in the appropriation of a foreign language. Our two main research questions are:

1. What is the evolution of each student’s “spectrum of performances” between the pretest and the post-test ?
2. Which learning strategy does he/she use and what is his/her efficiency ?

Context

In the current context of self-directed learning, people turn more and more towards computerised products...

We start from the idea that a lot of commercial tools do exist on the market and are actually used. As educationists we have no control on their diffusion but we can turn the situation to best account and formulate recommendations concerning their use. That is why we study how and what people learn by exploring these computerised informational resources... to be able afterwards to offer them helps to improve their learning strategies... and outcomes.

Research Object and Questions

For one year, we have been conducting a research on learning strategies exhibited by students using a hypermedia on English (as a Foreign Language). Our main research question is: “What is the benefit of a punctual self-directed learning experience with a hypermedia in the appropriation of a foreign language ?”

More precisely, we attempt to answer the two following questions: (1) What is the evolution of each student’s “spectrum of performances” (see [Concept of “Spectrum of Performances”]) between the pretest and the post-test ? (2) Which learning strategy does he/she use and what is his/her efficiency ?

Progress of the Experiment

Pretest
Our main objective is to measure the impact of self-directed learning by exploring three English lessons in the CD-Rom “L’anglais d’aujourd’hui en 90 leçons” (a “Studio Multimédia” product). Therefore, last year, 28 students registered in the first year of the licence in Educational Sciences received a pretest containing 55 items (short open-ended questions) on English notions. These notions represent 55 “opportunities to learn” (OTL) precisely located in the hypermedia lessons. Students had to complete the test and accompany each of their answers with one of the six following “confidence degrees”.

<table>
<thead>
<tr>
<th>Interval of the probability axis</th>
<th>0-25</th>
<th>25-50</th>
<th>50-70</th>
<th>70-85</th>
<th>85-95</th>
<th>95-100</th>
</tr>
</thead>
<tbody>
<tr>
<td>Codes for confidence degrees</td>
<td>0</td>
<td>1</td>
<td>2</td>
<td>3</td>
<td>4</td>
<td>5</td>
</tr>
</tbody>
</table>

Figure 1: confidence degrees

The reasons for this (asymmetric) segmentation of the probability axis have been explained elsewhere [Leclercq 83 & 93] and are related to what is currently known of the human capacity in discriminating different levels of doubt (or partial knowledge).

Self-Directed Learning Session

At the beginning of the self-directed learning session, students received directions for navigation and got familiar with the possibilities of the hypermedia. Later, students explored individually three lessons of the hypermedia (n° 25, 35 and 40) during one hour as a maximum. Half of the students received back their pretest during the self-directed learning session with a short feedback on their answers (correct answer/incorrect answer); the other half did not receive anything. This experimental design aims to compare learning strategies of students with “objective learning needs” and learning strategies of students with “subjective learning needs”. The first situation is similar to school situation; the second one to everyday life.

After the self-directed learning session, students were given a self-assessment questionnaire on their degree of appreciation of the self-directed learning session; on their initial objectives; on their learning strategies; on their feeling to have learned something; on their computer literacy; on their practical experience in self-directed learning...

All the learner’s actions in using the hypermediated lessons were video-taped with the help of a “Maxi Converter Pro” system, a hardware converter that allows to display the computer screen on a television screen and/or to record the tracks on a video cassette.

Post-test

Students received the same 55 questions as in the pretest. The post-test was not given immediately after learning, but postponed, since students have not had the learning session at the same time and because we prefer to measure long-term effects of self-directed learning.

Analysis of the Results

Concept of “Spectrum of Performances”

Too often the answer to a question is considered in a binary way: it is correct or incorrect without any concern for the learner’s conviction [Gilles 96]. Nevertheless, pioneers like [De Finetti 65], [Van Naerssen 66], [Shuford et al. 66], followed by a lot of researchers [Bruno 93], [Dirkwzager 93], [Fabre 93], [Gilles 96], [Hunt, 93], [Jans 95], [Jans & Leclercq 97], Leclercq 83 & 93], [Plunus 96], [Van Lenthe 93] recommend that researchers deal with different states of partial knowledge to study learning.
The expression of doubts with the system of confidence degrees enables to take account of these different states. [Plunus 96] and [Leclercq, Gilles & Jans 97] defined 6 of them, represented in a "spectrum of performances":

<table>
<thead>
<tr>
<th>... with Confidence Degree ...</th>
<th>Incorrect answers ...</th>
<th>Correct answers ...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Central value of confidence zone</td>
<td>98 90 78 60 38 13</td>
<td>13 38 60 78 90 98</td>
</tr>
<tr>
<td>Unknown ignorance</td>
<td>X X</td>
<td></td>
</tr>
<tr>
<td>Simple ignorance</td>
<td>X X</td>
<td></td>

<td></td>
</tr>
<tr>
<td>Simple knowledge</td>
<td>X X</td>
<td></td>
</tr>
<tr>
<td>Perfect knowledge</td>
<td>X X</td>
<td></td>
</tr>
</tbody>
</table>

![Figure 2: 6 states of partial knowledge]

The student’s “spectrum of performances” can be defined as the distribution of his answers according to their type: from incorrect answers with a high confidence degree (the worst or leftmost part of the spectrum) to correct answers with a high confidence degree (the best or rightmost part of the spectrum), passing through errors with doubt and correct answers with doubt (intermediate states).

**Notion of “Ideal Spectral Evolution”**

A spectral analysis for a test will be called “static spectral analysis” when it concerns a fixed state. A “bi-static spectral analysis” compares two states (two spectra), for example a pretest and a post-test, i.e. the global evolution of the performance, but not question after question (that is the object of the dynamic analysis).

In our experiment, two spectra for each student are drawn: the first is related to his/her pretest performances; the second one concerns his/her post-test performances, so that bi-static spectral analysis will be possible. [Fig. 3] illustrates the kind of “couple of spectra” (pretest and post-test) ideally expected:

![Figure 3: example of “ideal spectral evolution”]

The following observations are expected:

<table>
<thead>
<tr>
<th>Incorrect Answers</th>
<th>Correct answers</th>
</tr>
</thead>
<tbody>
<tr>
<td>PRE No matter what the content is, they should always be accompanied by a low confidence degree (CD)</td>
<td>No special expectation. According to the test content (easy or difficult for the student), he/she will know a bit or more partially, with CD between 0 and 5. In our example, they are distributed uniformly.</td>
</tr>
<tr>
<td>POST Their number should decrease, mainly answers with a high CD. The curve should present an escarpment more pronounced on the right (J-shaped curve.)</td>
<td>They should be more numerous and more confident. They should also present a J-shaped curve.</td>
</tr>
</tbody>
</table>

... with Confidence Degree ...

![Figure 2: 6 states of partial knowledge]

The student’s “spectrum of performances” can be defined as the distribution of his answers according to their type: from incorrect answers with a high confidence degree (the worst or leftmost part of the spectrum) to correct answers with a high confidence degree (the best or rightmost part of the spectrum), passing through errors with doubt and correct answers with doubt (intermediate states).

**Notion of “Ideal Spectral Evolution”**

A spectral analysis for a test will be called “static spectral analysis” when it concerns a fixed state. A “bi-static spectral analysis” compares two states (two spectra), for example a pretest and a post-test, i.e. the global evolution of the performance, but not question after question (that is the object of the dynamic analysis).

In our experiment, two spectra for each student are drawn: the first is related to his/her pretest performances; the second one concerns his/her post-test performances, so that bi-static spectral analysis will be possible. [Fig. 3] illustrates the kind of “couple of spectra” (pretest and post-test) ideally expected:

![Figure 3: example of “ideal spectral evolution”]

The following observations are expected:

<td>They should be more numerous and more confident. They should also present a J-shaped curve.</td>
</tr>
</tbody>
</table>
The escarpment increase is mainly due to a 
realism increase.
The escarpment increase is mainly due to a 
competence increase.

Table 4: expected spectral evolution

Quantification of the Four Hemispectrum Shapes

The escarpment or steepness of the two "curves" (strictly, histograms should replace the curves; we decided to join the tops of histograms in order to facilitate the comparison between pretest and post-test) can be quantified [Laveault & Grégoire 97] with the asymmetry coefficient (skewness). This mathematical function characterizes the asymmetrical degree of a distribution according to the mean. A positive asymmetry means a distribution with its "tail" moved forward the right side of the graph (i-shaped curve). A negative asymmetry means a distribution with its "tail" moved forward the left side of the graph (j-shaped curve).

The skewness index equation is:

\[
\frac{1}{n(n-1)(n-2)} \sum \left( \frac{x_i - \bar{x}}{s} \right)^3
\]

Here are the skewness coefficients computed for the four curves of our example. If the series of intervals of our six confidence degrees were symmetrical, the skewness of the right side pretest curve would have been 0.

Table 5: skewness coefficients

Categorization of Individual Cases

Our first experimentation led us to distinguish 6 types of students according to their "spectrum of performances" and their "performances card", i.e. their pre- and post-test results, their (absolute and relative) gains, their indices and graphs of realism, their skewness indices: (1) outnorming students (overcompetent or undercompetent); (2) ideal students, aware of their (important) progresses; (3) stationary students; (4) radicalized students (at post-test); (5) weak students, aware of their progresses; (6) students unaware of their progresses.

Different clues can help to explain the evolution of the "spectrum of performances". They are related to: (1) the subject's learning strategy (duration of the exploration; lessons really explored; consulted screens; number of "seized" opportunities of learning ...); (2) the learner him/herself (his/her initial competency; his/her objectives; his/her motivation to explore the hypermedia; his/her computer and hypermedia literacy; his/her satisfaction after the learning phase ...); (3) the learner's knowledge of pretest performance (objective feedback or subjective impression?).

Detailed results are analysed in a previous article [Jans 97]. This paper presents only one example, Student 11, an "ideal" student, with his realism indices and his realism graphs.
Figure 6: Student 11’s “spectrum of performances”

<table>

</tbody>
</table>

Table 7: Student 11’s “performances card”

Figure 8: Student 11’s “realism graphs”

We defined an « ideal student » as a student who makes progress in the two expected levels:

1. **in his knowledge of English**: The curve of his post-test “goes up” towards the right (peak at C5). His relative gain is high (37%).
2. **in realism**: In this case, St.11 does not increase his realism index at the post-test, but this index was already “very good” at the pretest, referring to [Gilles 96] norms.

Interviewed, St. 11 declared he appreciated the self-directed learning session. The English level suited him very well. He did not have the opportunity to consult his pretest before the learning session. Nevertheless, his process of navigation in the CD-Rom was efficient, seeing that the rate (55%) of his “seized opportunities to learn” is higher than the mean of the group’s rate (45%).

**Conclusions**

There does not exist something such as “the only one good way to explore a hypermedia”. Moreover, students are characterised by what [Denis & Leclercq 94] called “mathetical ambivalence”, i.e. the need to rapidly
change from an autonomous learning situation (let me try, let me search, let me create) to a dependent situation (tell me, show me, correct me) and vice versa. The hypermedia “L’anglais d’aujourd’hui en 90 leçons” allows these reversible shifts.

One kind of problems encountered by a hypermedia user concerns the navigation in the great mass of information. In collaboration with the CNRS - IRPEACS of Lyon, we are developing and experiencing new tools to facilitate the navigation in a hypertext [Zeiliger et al. 96 & 97].

The analysis of the first results stressed interesting recommendations to carry on with the research into this field. The second part of our research project will aim to compare the impact of self-directed learning on the one hand and of collaborative learning in the other hand of university students navigating in hypermedia. That’s why, this year, 30 students were asked to experiment the two situations in English learning. Different indices such as the evolution of their “spectrum of performances”, their (absolute and relative) gains on competencies, their satisfaction,... will be analysed and compared according to the two experimental conditions.

It is hoped that from this research recommendations could be drawn about learning with hypermedia to attain objectives that the learner (or the learners’ group) has assigned to himself.

“Netview” – a Qualitative Method in Networking Interviews

Sisse Siggaard Jensen, Associate Professor; sisse@d1hl.dlh.dk
Research Center for Education, Information and Communication Technologies
The Royal Danish University of Educational Studies, Denmark

Abstract: This paper identifies differences between the traditional face-to-face interview and the face-to-interface networking interview. It is based on results from the Danish project “Blaagaard ONLINE” (1989-93) and a casestudy of the project “Interkomm+” - a networked version of the Communication Studies at the University of Roskilde in Denmark (1995-). “Netview” and “Reflection-in-Interaction” are concepts introduced to qualify the development of new qualitative methods adapted to field research in networking. The invitation is to cooperate and to apply interdisciplinary approaches bridging the sciences of education and software design. A web design of netviews is outlined, and the need for teamwork in research and design is emphasized. The design is to be implemented in evaluation of ongoing projects within education and in-service training in Denmark.

Introduction

This paper will be a presentation of the new methodological problems, which we will have to deal with in the future development of networked education. The major claim is that we need an interdisciplinary approach to bridge software design and system development on the one hand and the reflective practices of learning and teaching on the other. An interdisciplinary approach is necessary to break through the walls between the “soft” and the “hard” sciences to focus on the human actors in learning. The crossing of these borders is vital if we are to meet the demands for networked and hypermedia learning environments of a high quality. To initiate the dialogue and the sharing of ideas this paper is focused on some of the problems in the development of qualitative research methods. They hopefully have such qualities as to exemplify the major claim and call for an interdisciplinary approach. Presently we are “short” of qualitative research methods to analyze and evaluate the specific qualities of hypermedia and networking environments and the learning cultures within these. “Netviews” is the preliminary term chosen for the networked “equivalent” to the research interview and the development of a method of netviews is one of the ways in which to deal with the demands for quality. To initiate a dialogue on this new method the paper presents:

- Results from carrying out networking interviews and the ensuing problems of method.
- “Netviews” - a tool and design for networked research interviews in hypermedia learning environments as seen from the “inside” and from the view of the participants.

Results from Early Networking Observations and Interviews

In BlaaLINE (Blaagaard ONLINE) – a Danish project within teacher education - research and observations were carried out on teaching and learning in computer-conferencing in the late eighties and early nineties after a period of evaluating different computer-conferencing systems. In the process of carrying out these observations it was realized that the new environment had a profound influence on educational, organizational and social roles in teaching and on the processes of teaching and learning. In the early observations research was concerned with issues such as: the amount of student responses in different computer-conferences; the amount
of discussion threads within conferences; the amount and frequency of student activity compared to teacher instruction and among students, etc. In other words data were collected on a quantitative basis and methods applied along the quantitative line. But the sense of understanding the environment diminished the more the observable activities were studied and "counted". There was an increasing "transactional distance" separating observations from the observed environments. So the method of qualitative research interviews was introduced to be complementary to the counting of activities. Little by little the focus of the interviews was on the group of teachers in the early networking communities and their reflections on how this new environment had influenced their roles as teachers and the qualities and the barriers they had to meet with. From 1989 until 1993 a series of networking interviews were carried out trying to identify the qualities of teaching and learning in computer conferencing and to "configure" the future demands on teachers competencies within networked learning environments. Electronic discussion lists were chosen as the means of distribution and they were chosen within subject areas such as education and communication in computer conferencing (CC) and in computer-mediated communication (CMC). The respondents were pioneers in these areas. [Jensen & Jensen 1993a, Jensen 1993b]. In the process of carrying out the networking interviews it was gradually realized that the procedures and the concepts of the qualitative research interview also changed profoundly in this new environment. The reason for this is to be found in the following two related phenomena:

1) Events of communication in networking seem to combine the qualities and the different styles we find in oral and written communication.
2) Interaction and the events of communication in networking are complex phenomena of double-layered transaction combining the interaction between the user and the interface (face-to-interface) with the events of communication between human actors.

The differences between the oral and the written styles are reflected among other things in the distinction between the questionnaire and the interview. The questionnaire is used to collect quantitative data and short comments on a subject in question, and the research interview is a way of gaining insight into the interpretations and viewpoints of respondents and their reflections. The questionnaire is a tool for "outside" evaluations and it needs to be strongly standardized, as there is no common context among the researcher and the respondent. These "decontextualised" qualities of written communication in the questionnaire are in line with the common cultural understanding of traditional textual qualities. In contrast to this the interview stresses the qualities of oral traditions and the "events" and situations in face-to-face communication and it appreciates the cues in metacommunication. In the process of an interview the researcher and the respondent create a common context along with the continuous negotiations of meaning and interpretation. Each of the participants in the interview "reads" the common context and interprets the ongoing interview-situation. The cues in metacommunication such as tone of voice, intonation, gesture and facial expression are essential in the process of shaping these interpretations. The negotiation of communication in an interview is a double-layered process of transaction. In one layer the negotiated content and the related context are produced while the second layer is concerned with the interpretation of the way in which content and context are negotiated [Kvale 1996]. The interview is visualized in [Fig.1].

![Diagram of interview process](https://example.com/fig1)

**Figure 1: Interview.** The interview is a face-to-face view in synchronous communication. The research interview is a mutual view of the interviewer and the respondent. In the traditional interview-situation the respondent and the interviewer create a common context through negotiation of content and in interpretation of the context - the communication layer (L1) - as well as simultaneously negotiated interpretations of the interview-situation as such - the metacommunication layer (L2).
The networking research interview is influenced by some of the procedures and qualities from the style of writing and the decontextualised features commonly associated with the questionnaire. But it is different from the questionnaire because it keeps the open and non-standardized format and the intention of gaining insight into the "inside" perceptions of the respondents and their viewpoints and interpretations. The content and the contexts of the interview are created in the process of the interview whereas the questionnaire is filled in according to the predefined and standardized categories and the foreseen way of working with the results.

*It seems that the dynamics of the interview in networking environments is quite different from both the questionnaire and the traditional interview. It is open and unfolds itself during the process of negotiation of meaning very much as it is the case in an interview, although the events of communication take place in writing, which relies on asynchronous communication. Starting with an open and opening question the process might speed up and unfold in a day or it might develop within weeks or months and it could be "located" in a global environment.*

In the networking interview there is also a double-layered process, but it is different from the traditional interview. As earlier mentioned the networking interview is characterized by the related interaction with the interface (face-to-interface) and the events of communication between human actors, be it teachers, writers or students. In software design, i.e. HCI, it is often emphasized that interaction with the interface is a kind of "transactional communication" between the user and the designer [Andersen 1990, Greenbaum & Kyng 1991, Suchmann 1991]. Thus the networking interview is very complex, because of the multiplicity of "participants" in the interview process. *In the construction of contextual situations and in the negotiation of meaning we have to deal with both the interviewer, the respondent, the designer and with the separate interview situations and their different but related contexts. Some of these characteristics are visualized in [fig. 2].*

![Figure 2](image)

**Figure 2: Networking Interview.** The networking interview is a face-to-interface view in asynchronous communication. In the networking interview-situation the respondent and the interviewer negotiate and interpret the context from within different situations - the communication layer (L1) - as well as simultaneously from within different contexts - the interaction layer or the face-to-interface layer (L2).

The Problems of Version in Networking Interviews

When confronted with these differences the complexity of networking interviews became obvious and the need for new methods to deal with this complexity was realized. The perspective in the ongoing research and the "visual angle" were then changed from the global "birds eye view" in networking interviews to a "zoom-in" perspective on the use-in-practice situations. Focus was on related transactions of face-to-interface interaction and the events of communication between human actors in the networking environments. The idea was to get as close as possible to face-to-interface interaction and the method applied was the Video Interaction Analysis.
(VIA) which is based on the use of video observation as an analytical tool [Jordan 1994].

One of the overall problems that occurred again and again during the analysis of the logged files with the interview dialogues was the question of “version”. It was difficult to establish whether the responses in the dynamics of an interview were “first version” responses or to what extent they were reviewed and edited and as such “late versions” of the initial response. The interaction layer in the networking interview was “invisible” and the asynchronous nature of the interview opened up a “transactional distance” within the interview. The respondent had the opportunity to reflect on, edit and revise the responses in a way that is unknown in the traditional interview. While carrying out the networking interviews the dynamics of responses was “speeded” in a call for short answers closely linked to the subject in the subject-lines of the emails. The subject-lines were used as a key-feature in structuring the networking interview sessions. In the printed version of the interviews the overall style was categorized as either primarily oral or written based upon parameters such as length of comments and frequency and intervals. But even though the styles very often bore resemblance to the events of oral communication, it was not possible to prove the responses to be first versions such as it is the case in a conversation and in an interview.

The concern about problems of version in the interview dialogues was confirmed when the transactional processes were video analyzed [Jensen 1994]. During the video analysis it gradually became evident that reactions in the computer-mediated dialogues were heavily reviewed, edited, evaluated and very often shortened or otherwise changed before they were submitted. There were frequent changes of the “focus“ in the dialogues: from networking dialogue to interface interactions and then again to a “traditional” dialogue with colleagues or workgroups in the physical environment with phones ringing, coffee breaks etc. In other words, it proved to be a quite different context of dialogue and situation in the networking interview.

In the traditional interview the layer of metacommunication serves to actively catalyze the focus and concentration “on and in” the interview situation and the ongoing process of negotiating meaning and interpretation. In comparison to this the layer of interaction between the user and the “system” environment (face-to-interface) in networking interviews seems to be distracting and the asynchronous nature of the events of communication creates different situations from within which the interview is to be carried out.

Design of “Netviews” and the Concept of “Reflection-in-Interaction”

The video observations dates back before the general development and diffusion of the web and hypermedia environments. They were carried out in the early years of the global spinning of the web (1993-1994) and not within hypermedia environments such as web-sites. But in the meantime the relevance of qualitative research methods of networking interviews has increased as the web has made networking cultures and their capacities visible for everyone. There is a shift from networking cultures as pioneering and experimental cultures within rather “closed” communities to the general integration of these cultures into society.

The underlying assumption in this paper is that the analysis of networked and hypermedia learning environments is to be carried out from the “inside” of the environment and with a focus on human actors. Networking cultures are coded with contexts created by the significant use of signs and symbols. They live by the actions and events of communication by human actors who are relying on a new set of values, conventions and rituals. The instrumental view on networking capacities as just a new technological infrastructure will leave us with no comprehension as to the new phenomena and the possibilities in relation to education and learning. To unfold their potentials and perspectives we need to understand the codes and contexts of these new cultures. In networking cultures as in any other culture we can learn a lot from asking and listening to the human actors and the way they interpret their own actions. The interview is one of the very important ways in which to gain this insight. So, in stead of “canceling” the interview as a rich and qualitative research method in networking cultures and environments, we need to develop the concepts and the way we think about interviews and the methods by which we carry them out. The “hybrid” and preliminary terms of “netviews” and of “reflection-in-interaction” are suggested as conceptual tools for the rethinking of networking interviews. The concepts of
netviews and of reflection-in-interaction are visualized in [fig. 3], which is superimposed on the figure of the networking interview.

![Diagram](image)

**Figure 3: Netview.** The netview is a multiplicity of face-to-interface views of the interviewer, the respondent and the designer. A common context is designed on the basis of reflexive strategies such as "reflection-in-interaction" in a hypermedia environment on the web.

The designer (D) is introduced as the “third part” in netview situations and the dotted line suggests the construction and design of a new and common context within the networked interview - “the netview”. In netviews the design of face-to-interface interaction is in a hypermedia environment such as the web and it is designed to catalyze the focus of reflections in and on the interview situations. Hyperstructures and link facilities are important tools in the creation of interactive written dialogues and in the construction of a common context. Netviews are based on the asynchronous nature of networking, independent of time and place, and on the capacity of storing interaction and communication. The method prospers from the asynchronous communication as it opens up the possibilities of a process analytical approach [Borgnakke 1996] to interview situations.

In the present expansion of the web hypermedia environment are integrated into commercial and public affairs. In the wake of this there is a growing interest in surveys and inquiries into patterns of usage and the identification of segments and target groups of commercials and in marketing. The interests of commercial and marketing sectors have produced a new kind of software to “detect” the patterns of user movements within web-sites such as the program “WebTrends”. The focus of interest in these programs is on the identification of “hit-lists” to decide on activities in which to invest. Tools for the logging of navigation patterns and different priorities within web activities are also of great interest to the analysis of learning situations especially if they are combined with the capacities to visualize priorities and patterns. In a Dutch hypermedia project, such tools for visualization have been developed although within a slightly different context [De Bra 1997]. The application of such software in hypermedia environments are important improvements of the methods to be applied in networking “field” studies, but only if it is combined with netviews as a tool and a method for interpretation and for the reflections of human actors.

Web environments support the integration of different representations and of face-to-interface interaction based on association and reflection. The web netview is designed in a hypermedia landscape as a "world" of digitized sources selected and organized by the interviewer and the designer. Together they create a common context framed by an interface supporting dialogue, exploration and interaction. The netview thus facilitates processes of reflection-in-interaction and of narratives as respondents travel through the hypermedia landscape of linked sources, following their impulses and associations. Patterns of respondent movements within the website are logged and so are the narratives and traces of interaction deposited as the traveler moves along. It is visualized in [Fig. 4]. The design and concept is heavily influenced by ethnographic approaches, methodological traditions of research into social history, theories on reflection and on human-computer interaction and methods in participatory design. In a netview the roles of the interviewer and the respondent are changed. The respondent
leads the interview in creating a context to be jointly explored by the interviewer and the respondent or by a community of respondents. It develops in recursive patterns of dialogue and design.

The conclusive concept in netview design, and in this outline, is “reflection-in-interaction”. It necessitates an interdisciplinary approach as it integrates theories and knowledge areas from within educational and reflexive strategies [Schön 1987] and from HCI and theories on participatory design. It is an important precondition for the analysis of qualities in education and learning within hypermedia networking. To qualify the development of methods and design in netviews based on the concept of reflection-in-interaction, we need to promote teamwork and to emphasize the need for cooperation between researchers from within the sciences of participatory and collaborative software design and from the educational sciences. In current research activities the method of netviews are applied to the Danish project “Interkomm+” [www.komm.ruc.dk/interkomm] - a networked version of the Communication Studies at the University of Roskilde – in a casestudy. The web version of netviews is to be further developed in future evaluations and analysis of Danish projects within teacher education and in-service training on a national basis initiated by the Danish National Center for Technology Supported Learning.

Abstract: We present and discuss the results of a project in which seven teams of elementary school students were involved in designing and implementing interactive multimedia resources in science for younger children. We found that students improved significantly in their science understanding and programming skills. We discuss the benefits and problems of integrating science content with multimedia design and discuss why the quality of dynamic and interactive components in students' multimedia production proved to be a better indicator of students' learning than the quantity of multimedia produced.

In recent years there has been a surge of interest in the use of multimedia in educational computer applications. Developers have added sound, graphics, photographs, and video to applications that were previously dominated by text. Various research efforts investigate ways in which multimedia features such as video [e.g., Cappo & Darling, 1996; Rubin, Bresnahan & Ducas, 1996], graphics [Rieber, 1994], or combinations of features [e.g., Jackson et al., in press] can contribute to students' learning. One underlying premise of most research is that providing students with multiple representational formats in a content domain helps to build their understanding and addresses the diversity found in students' learning and thinking approaches.

While these multimedia features potentially add value to applications, less attention has been given to approaches that provide learners with the opportunity to design and program their own multimedia software applications. To take a closer look at the potential of multimedia design for learning, we examined the cases of seven design teams that were involved in creating interactive multimedia resources about astronomy. We examine various program functions and the multimedia content of the final software products. Furthermore, we investigate how the team products themselves reflect the contributions of their individual authors. The purpose of these analyses was to illuminate some of the knowledge that young students have about multimedia design—as expressed in their products and in their interface design—and in which ways designing multimedia afforded learning opportunities for them.

Theoretical Background

Learning through designing multimedia applications is part of a larger effort to provide children with rich learning experiences [e.g., Brown, 1992]. It proposes software design as a new model of integrating programming with other learning that goes beyond learning programming for its own sake [Harel & Papert, 1991]. Software design requires students to consider interface design issues, deal with content aspects, and create, debug, and maintain their programs. In designing their own applications, students reformulate their knowledge by creating and implementing external representations in their software.
Multimedia features of software can facilitate this process, as they allow students to use and combine various representational formats in one medium.

While knowledge reformulation is an important feature of learning through software design, personal expression of one’s ideas is another. With the increasing proliferation of commercial education and entertainment software, students have become accustomed to a software production level that makes extensive use of multimedia features. While students might have a wealth of experience in using multimedia applications, they have little knowledge about making multimedia software. Creating multimedia applications is a complicated and collaborative enterprise. In research and commercial contexts, groups of professional designers, programmers and content specialists work together for several months (Lammers, 1986). Several studies have used this approach to study the thinking and learning of young software designers [Blumenfeld et al., 1991]. One series of projects focused on children designing instructional software for mathematics (e.g., Harel, 1991; Kafai & Harel, 1991) and instructional games in science and mathematics [e.g., Kafai, 1995; Kafai & Yarnall, 1996]. While these studies made special use of programming as a vehicle to foster children’s learning of content, other studies used platforms such as hypermedia and authoring environments [e.g., Lehrer, 1991; Carver, 1991; Spoehr, 1995]. In this particular study, we decided to focus on the nature of the applications created by the students. We used the final computational artifacts as a starting point for investigating what kind of learning opportunities in science and programming was afforded by the design of an interactive multimedia resource and how this was related to individual students’ contribution to the multimedia product.

Research Context and Participants

The project took place in an urban elementary school that functions as the laboratory school site for UCLA. The participating classroom was equipped with seven computers, one of each was set up as a workstation for the seven table clusters. An integrated class of 26 fifth and sixth grade students participated in this project (10 girls and 16 boys of mixed ethnic background) ranging between 10 and 12 years of age. Students were grouped in seven teams. One week before the start of the project, students were given an introduction to the main features of the Microworlds™ Logo programming environment. The assignment was to build an interactive multimedia resource about astronomy for younger students. Students worked 3-4 hours per week on the project for a period of 3 months, spending 46 hours in total of which 23 hours were dedicated to programming. Science instruction and programming time were combined. For this paper, we concentrate on the final software products which were analyzed in regard to the nature of their functions and the contributions of individual team members. The main data comes from a classroom activity conducted toward the end of the project in which each team met and determined which individuals should take credit for which parts of the final product (e.g., text, graphics, and animations).

Results

All seven teams finished a multimedia information resource at the end of the project. Our project observations documented that the completion process was not an easy one. For one, students had considerable problems in the beginning sharing work and computer resources, as each team consisted of 3-4 students each, but only one computer was available to all the team members. Furthermore, many students were learning Logo programming as they were designing their multimedia resource. While this provided an authentic context for students’ learning, it also limited students’ expression in the beginning to simple page designs. Later on, students started including animations of the life cycle of stars or the planet movements for lunar and solar eclipses. As for its science inquiries, each team posed several questions such as “Is there life on Mars?” or “What do we know about Black Holes?” which they intended to follow up in their science research. As the project progressed, these questions changed in focus and range. Some students reformulated their questions, while others added new ones which usually were more specific such as “What is the Big Bang?” In terms of the effectiveness of the overall
intervention, we found that the design project was successful as a vehicle for both science learning and Logo programming development. To assess students' improvement in their knowledge of science content, we administered pre- and post-tests in astronomy. Our preliminary analysis showed significant differences for the pre- and post-tests in students' understanding of astronomy (Pre-Test: 31.5, Post-Test: 37.2, df 25, t: 5.65, p<0.05). Students' understanding of Logo also improved (Pre-Test: 13.3, Post-Test: 18.6, df 24, t: 4.38, p<0.05). In addition, in terms of programming skills, many students started out at ground zero, knowing no Logo at all.

Evaluation of Educational Multimedia Software: Team Contributions

Each interactive multimedia resource consisted of a set of interrelated screen pages that were linked together with the help of buttons or clickable objects that could be activated through a mouseclick. Some of the screens had combined media elements such as text and graphics while others worked only in one medium, text or graphics. The number of created screen pages differed considerably for each multimedia design team; yet this was not a good measure of production value because screens differed in their functionality. We defined three categories of screens: content screens, quiz/feedback screens, and information/navigational screens. Table 1 provides an overview of the distribution of the different screen functions.

Content screens represent some piece of knowledge about the field of astronomy. They can take the form of text, pasted pictures, drawings, or any combination of those three design elements. The larger category of content screens was also broken down further to specify content animation screens. Content animation screens (CA) contain animations or simulations that exemplified dynamic aspects of the solar system such as the lunar eclipse, the life cycle of a star or effects of gravity. Only in one instance was the player given the possibility to set the parameters for a game-like animation (team 3).

Many groups in the project decided to include Quiz/feedback screens to complement their multimedia resource. Quizzes usually asked questions about the content displayed elsewhere in the product but occasionally introduced new material. Most quiz screens contained one or two multiple-choice questions with buttons linking the user to feedback on his or her response. Feedback screens consisted primarily of simple pages exclaiming “right!” or “wrong!” in a very large font. Only in a few instances were users provided with additional information, as in the question “Can Martians Dance: Yes or No?” The answer page in either case replied “There is no right or wrong answer to this question, because we don't know if there are Martians on other planets” (team 6).

Another type of screen common to most group products was Information/navigational screens that provided information about the designers themselves or displayed the title of the software and subtitles of topic areas, such as, “This is the Planets Section!” Other screens contained buttons or turtles which linked to different topic areas and provided information to the user on how to navigate the software, such as a table of contents. The graphical arrangements on these pages differed considerably. While in a few instances students took advantage of a graphical representation of the solar system as an entrance to different planets, many others just placed a variety of buttons on the page.

To summarize the design efforts by the teams, we see that students made extensive use of multimedia. A pervasive feature of all software applications is that students tried hard to emulate commercial software models. A comprehensive analysis of all seven final versions of the educational multimedia resource showed that all of them used “Point&Click” as their main mode of advancing through the program. They provided menu options, had navigational features such as title screens, introductions, content overviews and final screen and credit messages. In the instructional component, students (with the exception of one team) provided limited positive and negative feedback and sometimes explanations. But students' software did not provide the player with a “Quit” option, a feature that either many designers did not have time to implement or did not consider important. Furthermore, “Help” options were absent as well. Being beginning interface designers, the students were able only in a limited way to foresee their users' needs.

Evaluation of Educational Multimedia Software: Individual Contributions
While all students contributed to the final versions of their software, the levels of individual effort among the students in any group needed further examination. We decided to use the final artifacts themselves to not only document effort and equity, but also to examine the ways in which individual contributions to each group's final product have different affordances for product appearance, individual credit-taking, and learning benefits. To create a score commensurate with students' experience, we created a “design differentiated score” by looking at the types of screens created by individuals in the context of their total contribution. For that purpose, we used the three types of screens defined above, content screens, quiz/feedback screens, and information/navigational screens. Student differentiated scores for each type of screen were created using the same values as the raw scores. To create design differentiated screen type scores for each student we added up all their points for each category of screen. Thus, a student with a raw score of 8 screens might have 4 content, 3 quiz/feedback, and 1 information/navigational screens.

KEY: CON=content screens; AN=Animations; IN=Info/Navigation; QU=Quiz/Feedback

After examining the differentiated scores (see table 2), it appeared that they explained much of the deviation from expectations that showed up in the objective scores. Looking at screen types seemed to be a much more viable measure of participation than total screens. Students who created the most
content screens and content animations were the same as those who displayed the most leadership, spent the most time at the computer, and showed the most developing astronomy knowledge. In the group products where the student with the most total screens was not the same as the most dominant and knowledgable student, we saw that the one with the highest raw score created mostly quiz/feedback and information/navigational screens. This finding is interesting not only because it lends support for measuring individual performance and contribution by some deeper means than merely counting the number of pages created, but it also provides a window into which types of screens are valuable for what purposes. In the following section, we discuss how the different screen types afforded different modes of thinking and learning benefits, and served different personal goals.

Discussion

Working on different multimedia functions served different goals for the designers, in both science content and multimedia learning. While informational/ navigational screens presenting tables of contents, title pages, or personal information about the designers may not necessarily contain science content, they have definite value in terms of technological fluency. Making tables of contents, main title pages, and topic area title pages requires taking the perspective of the user and considering what he or she would find most helpful in navigating the software. Navigational screens are not by nature devoid of content, as illustrated by the comparison of the solar system model title page and buttons title page shown earlier, but many of the information/navigation pages designed by students in this study had little or no content. The process of making such pages is relatively easy, since no animations are required, no astronomy research is required, and little programming is necessary other than linking buttons.

Quiz/feedback pages afford several benefits from a software design perspective. For one thing, the type of drill-and-practice quiz designed by most groups is a “quick and dirty” way to add interactivity to the software. In fact, when asked by researchers why they were making a quiz, the students often responded that it was because the users would want more interactive features. Making a quiz takes relatively little time, when all that is required is a series of questions with buttons leading to pages that say “right” or “wrong.” Another benefit is thus that students who felt that their contribution was too small were able to increase the number of pages they created by adding a quiz on some topic at the last minute. From a science learning perspective, making quizzes does not allow the designer to experience the maximum benefits of the software creation process. Most quizzes in this project were a disjointed set of questions with little or no relation to one another, followed by feedback pages which gave no explanations of the correct answer. The process of designing a quiz such as the ones we saw may not help the designer develop systemic understanding in science, since a quiz only requires that he or she know the right answers to a series of unconnected science facts.

Content/animation screens are the most difficult to create, but they also afford the most learning benefits, both in terms of technological fluency and systemic understanding. Even the most basic kind of content page, one with only text and/or pictures, requires deeper levels of thinking about astronomy than the disjointed kind of knowledge represented by a quiz. Because students had to think about their users, 3rd and 4th graders, they had to write all the text sections in their own words and explain astronomy phenomena in language that younger students would understand. This consideration discouraged practices such as cutting and pasting of text from the Internet or copying word-for-word from books. Opportunities for even deeper thinking about users, programming, and the subject matter are afforded by more elaborate content pages, which use animation to depict some astronomy phenomenon. Creating animations requires the designers to learn Logo beyond relying on the basic point-and-click controls of the Microworlds system, because they have to direct the turtle in complex patterns and series. Most importantly, animations afford remarkable growth in systemic understanding. They require the designer to comprehend something well enough to create a model of the whole phenomena, as opposed to merely possessing a descriptive understanding of “what happens.”

From the preceding analysis and discussion it is clear that instructional multimedia development is a challenging enterprise for young software designers (as it is also, incidentally, for most professionals). One could argue that the concurrent learning requirements might have hindered more than
helped students. On the other hand, while schools traditionally introduce these subjects sequentially, we see a special synergy in learning them together at the same time. For one, it is difficult to imagine a course about multimedia design without students being engaged in designing media about something. Design has to be situated within a particular context or domain, so that designers as well as users can judge the value of their implementations. Furthermore, situated multimedia design provides an opportunity for the learners/designers to approach subject matter from a different vantage point than their own. Instructional design, as implemented in this project, affords particular learning possibilities not only for the designated user of the instructional material but also for the instructional designer. We found that interactive and dynamic aspects of screen designs provided a good indicator for learning that integrated the programming and science. The development of instructional animations facilitated students' better understanding of systematic aspects of science while it led them at the same time into more sophisticated programming and vice versa.

Designing multimedia software presented students with complex issues, some of which became evident in the previous discussions. Students needed to coordinate multiple demands in designing and implementing their work. Based on our observations and analyses, we found that elementary students' experiences and associated conceptions do not adequately prepare them for managing long-term, less well-defined design projects, which require more flexibility and iterative planning strategies. Furthermore, we found that students need more support in their collaborative work if the design situation is to be an effective learning context for each individual team member. It is obvious that the transition from a multimedia consumer to a multimedia producer is not an easy one. Yet the potential benefits make it a worthwhile learning experience.

Abstract: This paper shows how concept maps, a tool utilized rather widely these days, can be advanced to new horizons using computer-based approach. The authors discuss general structure of concept maps, their use as dynamic instructional tools, and then present a model for implementation of computer-based concept maps in college-level science courses. Most advanced concept maps are generated using multimedia authoring software and can be either qualitative or quantitative in nature. Such computer-based concept maps, located either on a computer in a classroom or on the Internet, can become a very powerful and unique tool contributing to other learning techniques and assessment methods.

Concept Maps: An Introduction

A concept map is defined as a graphical knowledge representation which hierarchically links concepts. Novak (1984), a leading authority on concept mapping in education, proposed that different learners structure their new current and new knowledge in a variety of ways, therefore validating use of concept maps in teaching and learning.

Joseph Novak stated that

a good curriculum design requires an analysis first of the concepts in a field of knowledge and, second, consideration of some relationships between these concepts that can serve to illustrate which concepts are most general and superordinate and which are more specific and subordinate. (Novak, 1979, p. 86).

If the instructor's role is to guide the learner in creating new meanings and deeper levels of conceptual understanding, then concept mapping can be an effective instructional and assessment tool to use in undergraduate lower division science courses. Knowledge is accumulated in a continuous fashion, and developing connections between prior and new knowledge is critical to the learning process.

In a traditional concept map design, the most general or most important concept is placed at the top of map, and concepts on lower levels are subsequently more detailed. Key concepts are connected by links that have descriptive words on them explaining the relationship between concepts. Concepts maps, by their visual presentation, have traditionally been used as very effective vehicles for organization of concepts within the domain. Traditional concept maps were of "paper and pencil" type, and were used mainly to organize qualitative or conceptual knowledge. Thus, in rethinking course curriculum at the undergraduate level, the number, organization and plan for the systematic development of concepts are worthy considerations in terms of curriculum restructuring necessary for improved student performance.

As concept maps evolve, there are variations in their development, discussed by Shavelson et al (1994), including free-form versus hierarchial, concepts' position on the map, collaborative effort by a group of students. These variations provide for greater instructional flexibility as well as for more diverse learning experience. In the last
decade, a noted increase in interest in and use of concept maps has resulted in the identification of many valuable instructional purposes for mapping. Concept maps are particularly useful as tools to:

1) plan and analyze instructional units of study, thereby identifying gaps in the curriculum
2) facilitate lesson planning and related activities
3) serve as an "advance organizer" for students to improve notetaking skills or as a guide to enhance student textbook comprehension.
4) serve as meaningful collaborative learning experiences
5) use as an alternative form of assessment.

A Model for Implementation of Computer-based Concept Maps in College Science Courses

An advent of computers, word processing and flow-chart software, as well as later developments in multimedia authoring software enables instructors to push the limits of usefulness of traditional concept maps far beyond "pencil and paper" representation. It is worth noting that in this respect the following stages of software development can be identified:

1) Non-dedicated word-processing or flow-chart software allowed for passive creation and use of computer-based concept maps
2) Software dedicated to generating concept maps results in production of more responsive and interactive computer tool
3) Multimedia authoring software for fully interactive knowledge building and assessment using computer-based/multimedia concept maps.

This article presents initial approach undertaken in implementation of concept maps in college-level science courses, and creates a model suitable for implementation in any science courses for computer-based knowledge building and alternative assessment using concept maps. Since this represents significant evolution of concept maps, we will refer to them as (c)omputer-(b)ased qualitative and quantitative (k)nowledge (m)aps (CBKM).

Software

For the purpose of this model, software from above mentioned stages 2) and 3) is used. Software dedicated to generating concept maps such as Inspiration ® (or comparable) is used by students almost exclusively. Instructors use Inspiration® for knowledge maps presented or developed during classes. These presentations are very effective and lead to interesting interactions when presented on a large projector screen. The set of standard knowledge maps as well as the ones developed during classes is uploaded on the Internet under the course's Web page.

Multimedia authoring software such as Authorware® by Macromedia (or comparable) is used by instructors to prepare highly interactive software used by students in- and/or out-of-classroom to build new knowledge, form linkages, and to build critical thinking and analytical skills. Multimedia authoring software enables instructors to provide students with an interactive study tool that provides them with an instant feedback, where each one of superordinate or subordinate concepts, linkages and propositions is a hyperlink providing immediate response or guidance. In addition to having such developed and customized software place on computers in science computer labs or individualized study labs, this software can be made available on the Internet.

Student Software and Concept Map Training

A session dedicated to concept maps and computer software is necessary for student involvement. Such training can take place either during the one of the first classes or during a lab period. Students have to become familiar with operational definitions of terms such as: concepts, propositions, principles, theories, relationships, hierarchy, cross-links, and general-to-specific examples. Then, utilizing subject matter from the first chapter of a textbook, students should become engaged in creating concept maps in groups of 2-3 persons. The authors of this article
found in teaching concept maps to many students and college instructors that a typical response indicated very positive reception of this tool. About one-hour hands-on orientation into the concept of concept maps, their role, and advantages is sufficient for college student to become proficient in constructing them and using appropriately. Additional twenty-thirty minutes is needed for a student to master software, and this is gained when working on first concept maps.

**Implementation**

It is an established phenomenon that concept maps can serve to align curriculum and instruction. Additionally, growing research evidence points to utilization of concept maps as assessment tools. Shavelson et al (1994) and Wallace & Mintzes (1990) provided extensive analyses of its use as a research tool to assess student conceptual change. Carefully designed implementation CBKMs can facilitate a very effective accomplishment of the following:

1) Assessment of student prior knowledge of fundamental concepts upon initial attendance of the first general chemistry course.
2) Building new knowledge, providing linkages, and the "big picture".
3) Building critical and analytical thinking skills
4) Assessment of new knowledge, critical thinking, and ability to manage data
5) Formative (ongoing) evaluation as well as summative evaluation (end of instruction).
6) Collaborative learning experiences
7) Information management

**Assessment Items: Examples of Qualitative and Quantitative Knowledge Maps as applied in Alternative Assessment of Students' Prior and New Knowledge**

*Example 1: Assessment of prior knowledge of fundamental concepts.*

**Problem:** Organize the concept map for the concept of matter using: mixtures, pure substances, compounds, elements, heterogeneous mixtures, homogenous mixtures

Use terms as propositions: "can be separated by physical methods into", "may be present as".

**Response:** One of possible representations indicating students knowledge of this fundamental concept would be as indicated on the Concept Map 1 below:
Example 2: Organizing quantitative new knowledge for a "big picture" and understanding of relationship among quantities and constants in stoichiometric calculations.

Problem: Present a comprehensive representation of stoichiometric relationships in a chemical reaction of 0.5 mole of sodium chloride with an appropriate amount of hydrogen chloride.

Response: Concept map 2.
Figure 2: Concept Map 2

Conclusions and implications.

Computer-based, qualitative and quantitative knowledge mapping is a tool that can be used by both instructors as well as students to meet the challenge of planning, organizing, teaching and learning. Computer-based knowledge mapping assists students in fulfilling quality outcomes in learning science. Used traditionally, concept maps provide concrete visual help to organize information to be learned. Science instructors for lower division courses at colleges who have been exposed to this tool are finding that they provide a logical basis for deciding which main ideas to include in a course. Computer-based knowledge maps can be as large as the entire course, one or more unit, or even a single class period.

It has been shown before that traditional concept maps are valid vehicles for documenting and exploring conceptual change (Wallace & Mintzes, 1990). This proposed model of computer-based qualitative and quantitative knowledge maps that is currently used as a pilot in a limited number of chemistry classes, in conjunction with authors experience in practical using concept maps, have provided convincing evidence that many instructors would be able to present more continuous learning experience for their students, who in turn would benefit from CBKMs as described above. Computer-based knowledge maps can be a powerful tool, that contributes to the other learning techniques and assessment methods, and addresses both knowledge and its organization.

kakizaki@cse.kyutech.ac.jp

Abstract: This paper proposes an automatic presentation animation generating method in a virtual environment. This method generates 3D animation based on a speech text that explains objects in the environment, and this animation shows a presentation performed by an agent in the virtual environment. In order to generate the animation automatically, we categorize the presentation motions of the agent into three classes, pointing, moving, and gesturing. Based on this categorization, our system extracts words from the explanation text. In order to determine what the target object is and to extract detailed information about the object, the system accesses a scene graph that contains all the information about the virtual environments. The system can find the object based on its characteristics that are explained in the text, and can then extract information about the object such as its size, position, and weight. This information is used for determining details to generate the agent's motion.

1 Introduction

Animation is one of most powerful tools in the broad area of education. It improves both desire to learn and comprehension of an object of students. However, it is not easy for teachers to create animation for their classes. In this paper, we propose an automatic presentation animation generating method in a virtual environment. This method generates 3D animation based on an explanation text, and the animation shows presentation performed by an agent in the virtual environment. In many cases, ordinary animation is used to show physical and mathematical simulations. Our animation, on the other hand, shows the explanation of something in the virtual environment.

Presentations are very important activities in educational, academic, and commercial settings. Many presentations are often performed in many different places. However, these kinds of ordinary presentations have several limitations. For example, students wishing to attend a presentation must go to where the presentation is being held. Animation performed by a presentation agent in a distributed virtual environment, however, can resolve these problems easily. Thus, a student can access a service presented in a virtual environment setting from anywhere and at anytime. A screen shot of the service is shown in Figure 1.

The use of animation performed by a presentation agent has many advantages. However, the motion authoring and programming of the agent have to be done as a 3D basis [Vince 92], so it is often very difficult for teachers less familiar with these procedures. In order to avoid difficulties, an automatic motion generating method for agents [Wavish 97] is introduced. The input information of the system is an explicit description of the motion. This method makes the system generating motions easy, but the author still has to describe the motion clearly. This work is also not so easy for those less technically oriented. Therefore, the development of easy authoring method is strongly required to make the presentation method popular.

The method we introduce in this paper realizes easy authoring for animation performed by the presentation agent. The input information in our method is in the form of an explanation text that the agent will speak. This kind of explanation speech text is usually written by the people who want to make a presentation. Therefore, it has the advantage that any individual can prepare his or her own presentation text without too much trouble. The motions performed by the agent, however, are not expressed explicitly in the text, which means our system has to guess the motion. Our system executes a guess based on the explanation text and the scene graph that contains information about all of the objects in the virtual environment.
2 Presentation in the Virtual Environment

As already mentioned, conventional presentations are usually performed in person, but such presentations have many limitations. A presentation in a virtual environment by an agent, on the other hand, has many advantages. In this section, we discuss the advantages of the presentation agent in the distributed virtual environment.

2.1 Time and Space

Live presentations performed by persons are the standard way to present. However, these presentations have a drawback in that both students and teachers must meet at a specific location and at specific time. Such a limitation can create problems for both parties. Teachers usually spend much in the way of time, energy, and money towards a presentation, which leads the teachers to want to show the presentation to many students. Similarly, if students want to see a particular presentation, they may have difficulty attending it if the presentation's location and schedule do not match their own.

2.2 Viewpoint

If we want to avoid some of the limitations of a live presentation, we might use recorded media such as videos and slide-shows. However, such a presentation is recorded as a 2D basis. In such media, the viewpoint is fixed at the time of creation and the student can't move their viewpoint to where they want. A presentation in the virtual environment, on the other hand, is performed as a 3D basis. This gives the opportunity to shift their viewpoint to any location they choose.

2.3 Environment

In ordinary presentations, the variety of visual aids of the presentation environment is restricted by many practical elements such as money, time, space, and so on. However, in a presentation in a virtual environment, the teacher is able to prepare any kind of environment he or she can imagine. This method is especially helpful if an object that the teacher wants to explain does not exist in the world, the virtual environment then becomes an ideal environment to do this presentation.

2.4 Repetition

It is usually required that a presentation be performed many times. However, performing an ordinal presentation many times is difficult, because additional expenditures in effort and cost are required for each presentation. In virtual environment presentations on the other hand, such additional effort and cost are not required. The agent just replays the presentation when necessary.
3 Animation Generation of Presentation

In this chapter, we describe animation generation method for a presentation agent.

3.1 Classification of Motion

In order to generate the motions of an agent automatically, we have to know what the agent’s motion is in a presentation and when the motion is performed. We believe that the primary objective of presentations is to show target objects clearly, then to talk about their features. Based on the objective, we classify the essential motions of an agent into three categories, as follows.

1. Pointing
2. Moving
3. Gesturing

We understand that presentation behavior is constructed from these motions, shown in Figure 2. In this section, we introduce the motions and discuss how can we guess the motion from the explanation text, and what kind of information is required for the motion generation.

![Motion Categories](image)

1: Pointing  2: Moving  3: Gesturing

Figure 2: Motion Categories.

### 3.1.1 Pointing

Pointing is a motion that the agent uses to indicate a target object. In a presentation, we usually point to an object that we are referring to, and it is this pointing motion which is used to identify that specific object for the student. We believe the agent should perform a pointing motion when the target object is referred to in the explanation text.

The motion is basically performed by the agent’s index finger, but the pointing motions have some versatility for example, an agent can:

- Point to an object with its index finger.
- Point to an object with an opened hand.
- Hold the object with a hand.

These pointing motions are performed in different ways depending on the situation. For example, if the target object is small, light weight, and near the agent, the agent could hold the target object in its hand. The decision table for the pointing method is shown in Table 1.

<table>
<thead>
<tr>
<th>The number of object(s)</th>
<th>Position</th>
<th>Weight and size</th>
<th>Pointing method</th>
</tr>
</thead>
<tbody>
<tr>
<td>Single</td>
<td>Far</td>
<td>-</td>
<td>Index finger</td>
</tr>
<tr>
<td></td>
<td>Near</td>
<td>Light and small</td>
<td>Hold by hand</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Heavy or large</td>
<td>Point to with opened hand</td>
</tr>
<tr>
<td>Multiple</td>
<td>-</td>
<td>-</td>
<td>Point to with opened hand</td>
</tr>
</tbody>
</table>

In order to generate the pointing motion, the system basically has to know which object the agent should point to. In addition, the system also has to know the direction and the distance of the object from the agent. Moreover, in order to make this variety of pointing motions, the system has to know the size and weight of the object. The system extracts this kind of information from the scene graph of the virtual reality system, which will be described later.
3.1.2 Moving

Moving is a motion that the agent does to move from one position to another. Moving is usually performed by the agent to locate itself near the target object that will be explained. In the explanation text, the requirement of a moving motion is not explicitly expressed. However, the system can guess the motion from the explanation text, as to when and where the agent has to move.

In the case of the explained object being near the agent, the agent does not have to move. The agent just points to it and continues the explanation. In a different case, in which the explanation text refers to a distant object, demonstrative adjectives such as, "this" and "these" are used; the agent has to move near the object before the explanation will start.

In order to generate the moving motion, the system basically has to know what the object is that the text is currently explaining. In addition, the system also has to know the direction and the distance of the object in relation to the agent. The system also extracts this kind of information from the scene graph of the virtual reality system.

3.1.3 Gesturing

Gesturing is a motion that we use a great deal in live presentations, and it is a motion that we use to increase the power of expression in a presentation. Gestures are usually performed in conjunction with words such as adjectives, adverbs, interjections, and verbs. Therefore, the agent might perform such appropriate gestures when these types of words appear in the explanation text. We show some examples of gesture below.

- Counting on fingers.
- Explaining size or length with fingers and hands.
- Explaining shape with fingers or hands.
- Explaining motion with fingers or hands.

In this method, gesturing motions are decided upon only from an explanation text, so gestures that are associated with a particular word always appear with those words. However, we sometimes use different gestures for the same words. For example, in the case that we talk about something large, if an object’s size is really large, we will open our arms to explain the size. If the typical size of an object is very small, but the object we explain is relatively large, we will open our index finger and thumb to explain the size. In order to create these gestures, the system has to know the typical size of the target object. The system also extracts this kind of information from the scene graph of the virtual reality system.

3.2 Scene Graph as Database

As described in section 3.1, each class of motion needs not only the information from the explanation text, but also any extra information to generate the motion appropriately. In the real world, determining a target object from its specific features and getting some information related to that object is very difficult for a computer, because the computer usually does not have the information about objects in the world. In virtual reality systems on the other hand, information about the objects in the environment is stored in a database called the scene graph [Hartman 96, Wernecke 94, Sense8 96]. Therefore, it is possible to determine a target object from its specific features and to get some information related to that object.

The scene graph was originally designed for real-time 3D graphics system. The scene graph contains data about the objects in a scene, such their shape, size, color, position. Each piece of information is stored as a node in the scene graph. In the scene graph, these nodes are arranged hierarchically in the form of a tree structure. The 3D graphics system traverses the tree structure to get information, and renders appropriate scene based on the information.

The concept of the scene graph is very popular for constructing virtual reality systems. In the virtual reality system, the scene graph is extended for simulation. The scene graph for the virtual reality system contains not only data for rendering, but also contains data for simulation and human interface such as weight, and name. Therefore, the scene graph for a virtual reality system would have the following kinds of information about objects:

- Shape
- Size
- Color
- Position
- Weight

721
If we know some characteristics about an object, we are able to look up the object using this existing information in the scene graph. The system extracts these characteristics from the explanation text, and following that, the system traverses the scene graph to look up nodes that have appropriate characteristic. If the node is found, an object that contains the node in the sub-tree becomes a candidate of the target object. After fixing the target object, the system is able to extract additional information from the scene graph to generate the agent's motions.

3.3 Explanation Text Parsing

In our method, primary motions of the agent are generated from information about the explained object. Therefore, the system has to decide what the explained object is. The process is realized by the system by picking up a noun clause that mentions a target object in the explanation text. Therefore, our system doesn't understand the meaning of an explanation text, rather the system just picks up a word or words.

Sometimes, a target object is referred by a pronoun. In this case, the system make an anaphoric reference and refers to the previous noun as the description of the target object. The explanation text is constructed from well-developed and well-formed sentences. In the sentences, a target object is described clearly, so picking up a noun clause is usually not difficult.

The text parsing system also picks up words, such as verbs and interjections, to generate appropriate gesturing.

3.4 Scene Graph Access

The target object is basically referred to by a noun in an explanation text, as the following example will show:

*I will talk about a cup*

In this case, the system picks up the noun “cup” and looks for the object by using the scene graph database. The cup is found in the scene graph, and the system knows its position. Based on the position, the system calculates its direction and distance from the agent. If the object is near, the system generates a pointing motion in the agent. If the distance is far from the agent, the system generates moving motion in the agent. If many objects are listed, the system chooses the nearest object to the agent. This system decision is based on the heuristics that presenters usually present the object nearest to them.

The target object can also be referred to by a noun with adjectives, as shown below.

*I will talk about a red cup.*

In this case, the system also picks up the noun “cup” and looks for the object by the scene graph database. As a result, several objects are listed, and the adjective information “red” is also used to determine which object is the appropriate one. Consequently, the system generates the motion of the agent.

We can explain characteristics of a target object, also in this way, as shown below.

*This cup is large.*

In this case, the system first, makes a list of all cups existing in the virtual environment. Next, the system calculates the average size of these cups. After this processing, the system generates an appropriate degree of gesture to explain the characteristics.

3.5 Motion Scheduling

The motions that the agent should perform are generated according to the explanation text. Therefore, the order of the motion sequence is defined by the explanation text, and this sequence is performed sequentially. However, the raw sequence of motions has some problems, so a motion scheduling phase is required.

The main purpose of motion scheduling is shown below:

1. To synchronize motions with the speech
2. To permit motions overlapping

Presentations in virtual environments are performed with speech and motions. It is imperative that these motions synchronize with the speech. For example, if an agent talks about an object, the agent should already be pointing at this target object. In order for this to occur, all motions performed by the agent must start in advance of the pointing reference. These kinds of adjustments are performed by the scheduler.

In order to synchronize motions with the speech, another kind of adjustment is also important. The duration time of the motion is extracted from two sets of data. One is the typical execution time of each motion, and the other is the pronunciation time in the explanation text. In our system, management of duration time is performed in each sentence. If the total duration time of motions is longer than that of pronunciation, silent time of speech occurs. In a
presentation, silent times of speech are often awkward and are undesirable. Therefore, the scheduler tries to reduce these silent times.

To do this, the scheduler tries to overlap some motions in a sentence to reduce a silent duration. Pointing and moving motions can always overlap, because pointing motions use hands and arms, and moving motions use legs, so both motions are able to be performed at the same time.

On the other hand, gesturing and some of the other motions sometimes cannot overlap. We believe that the importance of gesturing is lower than that of pointing and moving. Therefore, if the motion of gesturing conflicts with the motion of pointing and moving, the gesturing motion is not performed.

4 Implementation

We have developed an experimental system on the SGI's CosmoPlayer. CosmoPlayer is a VRML browser, and it can be programmed with Java language. VRML and Java are platform independent technologies for the WWW, so the presentation on the system is able to be distributed anywhere in the world.

The system is constructed in two parts, one is a virtual reality system that realizes the virtual environment, and the other is a motion generation system. We show the system overview in Figure 3. Each part of the system is constructed from some sub-systems.

![Figure 3: System Overview](image)

5 Conclusion

In this paper, we introduced an automatic animation generating method for a presentation agent in a virtual environment. It generates an agent's motion from an explanation text and from information that is held in a virtual reality system. Our method makes it possible for teachers without a technical background to create individualized presentations in a virtual environment.

References

Abstract: This paper describes a school experiment where the development of children’s conceptual models of the selected astronomical phenomena had been examined. During a learning and teaching period the objects of the learning by the guidance of a teacher in class situations were the planets, the solar system, the Earth and the sun. The pupils were Finnish second graders on an average eight years old. During a break and one day after school, the children could use the pictorial computer simulation, PICCO, independently for four weeks. As a main result it could be stated that most of the children’s conceptual models in this domain area developed quite a lot during the learning and teaching period. However, some children’s models remained vague. The results support the theoretical model of the formation of children’s conceptual models in the circumstances where seven year old children explored the phenomenon using PICCO independently and spontaneously according their own interest without a teacher’s teaching.

Introduction

This paper describes a school experiment where the development of children’s conceptual models of the selected astronomical phenomena had been examined. During a learning and teaching period concerning the Earth and space, children had possibilities to use a pictorial computer-based simulation, PICCO. The phenomena which was included in the teaching period were, amongst other things, the planets, the solar system, the Earth and the sun, the alternation of day and night and the succession of the seasons. These subjects were learned by the guidance of a teacher in class situations. During a break and one day a week the afternoon the children could use the PICCO program independently. The selected phenomena in PICCO was the variations of sunlight and heat of the sun as experienced on the earth related to the positions of the Earth and sun in space. The pictorial computer simulation shows the effects of the variations of sunlight and the heat of the sun on the earth in nature, and the origin of those variations caused by the interrelations of the Earth and sun as a part of the solar system. The school experiment had been carried out with Finnish second graders, the children’s ages being about eight years old. Altogether, there were 22 children, and the research period during which the children could use the PICCO program took four weeks.

Conceptual Development in Astronomy

In several studies it has been suggested that children in everyday situations form conceptions in physics and astronomy which differ from the conceptions of scientific theories in question and seem to be robust and difficult to reconcile with currently accepted scientific knowledge. Vosniadou, for example, has concluded, on the basis of her findings, that “children start their knowledge acquisition in astronomy by constructing an intuitive cosmological model of a flat, stationary Earth in a geocentric solar system in which the sun and moon move in an up/down direction and cause the day/night cycle. Eventually this intuitive model changes to that of a spherical Earth, which rotates around its axis and revolves around the sun in a heliocentric solar system in which the day/night cycle is caused by the axial rotation of the Earth and not by the movement of the sun and the moon.” In her findings Vosniadou has observed that “the process of conceptual change from these intuitive models based on a child’s everyday experience to scientific models is a slow and gradual one and is characterized by the emergence of various misconceptions of scientific explanations. Misconceptions are caused when students try to reconcile the scientific concepts with their experiential beliefs.” In current research there have been attempts to find the ways by which children could be guided in the formation of conceptions and the change of misconceptions. [See e.g., Vosniadou 1991, 1994; Vosniadou and Brewer 1992, 1994.]
Aim of the Research

The aim of this research was to investigate to what extent the use of the pictorial computer-based simulation, PICCO, together with the classroom teaching could support and help children in the formation of conceptual models of the phenomena in question.

In this research a conceptual model is seen as a mental construct concerning a certain natural phenomenon. The conceptual model of the natural phenomenon forms a basis for the cognitive action referring to the phenomenon in question. The more developed and integrated a conceptual model is, the better the basis it gives cognitive action concerning the phenomena in question. A conceptual model is formed from concepts and their interconnections which concern events, objects, properties and relations. The object of the present research was to study, especially the changes in a child's conceptual model concerning relations in the phenomenon in question.

Before and after the research period the children's conceptual models were elicited by using specifically designed procedures for this investigation. The eliciting of a conceptual model was achieved using procedures aimed at stimulating a recollection of the natural phenomenon in question. A child modelled the natural phenomenon from the basis of recollections and images through action, pictorially and verbally using different tasks. The modelling took place by showing, drawing, modelling and explaining. The phenomenon forms the wholeness which contains many, integrated phenomena and their interconnections. The main interest in this research was to study a child's conceptual model of the selected phenomenon, emphasizing relations and their changes in a child's conceptual models concerning the phenomenon in question. Regarding the natural phenomenon in question, attention was paid to the variations of sunlight and heat of the sun on the Earth, the interconnections of the Earth and sun in space, and interrelations of phenomena on the Earth and in space. In addition, attention was paid to the size, form and distance between the Earth and sun.

Description of the Pictorial Computer-Based Simulation - PICCO

The pictorial computer simulation concentrates on the variations of sunlight and heat of the sun as experienced on the earth related to the positions of the earth and the sun in space. In the simulation it is possible to explore the variations of sunlight and heat of the sun and their effects on the earth in a natural environment. It is also possible to examine the origin of these phenomena from the basis of the interconnections and positions of the earth and the sun in space. The simulation concentrates on phenomena which are close to the everyday experiences of children, such as day and night, seasons, changes in the life of plants and birds etc. The simulation program has been implemented in such a way that the knowledge structure and theory of the phenomenon are based on events appearing together with the phenomenon in question, and these events are illustrated. In the simulation all events and necessary elements are represented as pictures and familiar symbols. At the earth level the pictorial simulation represents the surrounding world, its phenomena and objects in a very natural and realistic way. In exploring the phenomenon at the space level the interrelations of the earth and the sun are represented with the help of an analogue model. The selected place on the earth from where the phenomenon has been modeled and simulated for a computer is the suburb of Lentävänniemi in Tampere, in Finland. The children who participated in this research live in this area. Therefore the exploration of the phenomenon with the pictorial simulation takes place in an environment familiar to the children.

The exploration of the phenomenon starts in Lentävänniemi on the 1st January at midnight. On a big screen is seen at that moment a dark, snowy, winter landscape in a direction of the south. The exploring can be continued by using icon pictures under the picture of the landscape, for example, a clock, a pictorial calendar, a picture map with different points of the compass and a space shuttle. The exploring of the phenomenon can be continued in many ways hour by hour, day by day, month by month, at different points of the compass and so on. At any moment it is possible to take a space shuttle and to look at the interrelations and positions of the earth and the sun at the space level. At the space level it is also possible to explore the interrelations and positions of the earth and the sun by using icon pictures which show the time in the same way as at the earth level. At every moment it is possible to choose how to continue exploring. Exploring can proceed at every moment using the existing alternatives.

When exploring at the space level the earth rotating around its axis and revolving around the sun on its elliptic orbit appears on the screen. The plane of the earth's orbit is shown as viewed from directly above this plane. When exploring the phenomenon at the earth level the following may appear on the screen: the changes of darkness and lightness daily with an accuracy of one hour, the sun's positions in the sky every
hour, the place and time for the sunrise and the sunset every day round a year, typical plants, birds and animals according to seasons and so on. With the help of the icon pictures, binoculars, magnifying glass and microscope it is possible to explore flowers, trees, leaves, insects, birds, spores, animals and so on in more detail. On the screen a selected object is seen as bigger. At the space level with the help of a telescope it is possible to look at the earth at a larger size so that, for example, Finland is seen more clearly. From this picture of the earth it is possible to continue further and to see the map of Finland, and finally an air photo of Tampere. In the simulation it is also possible to explore the mutual size of the earth and the sun and to get an image of the distance between them. Also the position of the earth in the whole solar system can be seen on the screen. The pictorial computer simulation is constructed so that it is very easy to use and it does not presuppose an ability to read or write. A pictorial computer simulation [Kangassalo 1991] is described in detail in the articles by Kangassalo [Kangassalo 1992, 1994, 1996].

Conceptual Change after the Learning Period

Before and after the learning period the children's conceptual models of the phenomena were at very different levels. As a main result it can be stated that most of the children's conceptual models in this domain area developed quite a lot during the research period and the direction of the construction seemed to occur towards the currently accepted scientific knowledge. However, some children's models remained vague.

In seven children's conceptual models, the alternation of day and night and the succession of the seasons on the earth level were seen to be as a result of the Earth's rotation around its axis, when the Earth is revolving at the same time around the sun. Eight children had difficulties in reconciling the Earth's rotation around its axis with the Earth's revolving around the sun. In four children's conceptual models, some connections between the phenomena on the earth level could be seen connected with the interconnections of the Earth and sun in space. In their conceptual models, either the succession of the seasons or the alternation of day and night could be seen connected with the position of the Earth and sun. In three of the children's conceptual models the spherical earth rounded in one place or revolved around the sun although the order, continuity and regularities of the seasons on the earth level had not been organized.

The results are mainly in the same direction than in the preliminary theoretical model which is based on eleven first-graders spontaneous and independent exploration of the phenomenon using PICCO four weeks. In the preliminary theoretical model [Kangassalo 1997] the main noticeable direction in the construction of the children's conceptual models, when using PICCO, tended to be as follows:
1. The Earth began to revolve around the Sun.
2. Seasons were organized in the surrounding world and connected to the positions of the Earth and the Sun in space. The connections varied from weak connections to developed connections.
3. The alternation of lightness and darkness on the earth was seen to have resulted from the turning or revolving of the Earth in the Earth's orbit.
4. The alternation of lightness and darkness and the succession of seasons have been seen to have resulted from the rotation of the Earth around its axis once every 24 hours while the Earth revolved around the Sun, a circuit around the Sun taking place once a year.
5. In conceptual models in which before the use of the simulation the Sun revolved around the Earth, after the learning and exploration period, the Sun no longer revolved around the Earth.

Abstract: The purpose of this study is to construct a Companion Agent Learning Environment within the framework of a multi-agent system. The expected result is that by installing the Computer Companion (as one of agents), a real (human) student will be able to get a deep understanding of his/her own ability for problem-solving through observation and reflection. For such a learning process, recognizing the state of the peer agents accurately (meta-cognition ability) is required. For supporting the enhancement of meta-cognition ability intelligently, it is required to build a model which shows how a real student recognizes the state of companion agents. Therefore, the main purpose is to build a companion agent's understanding model. Based on this model, we constructed a system that evaluates a real student's meta-cognition ability and thus intelligently supports the enhancement of meta-cognition ability.

INTRODUCTION

The purpose of this study is to construct a Companion Agent Learning Environment (CALE) within the framework of a multi-agent system. The expected result is that by installing the Computer Companion (as one of agents), a real (human) student will be able to get a deep understanding of his/her own ability for problem-solving through observation and reflection. For such a learning process, recognizing the state of peer students accurately (meta-cognition ability) is required, as a student learns behavior which he judges to be necessary for himself from the state of companion agents, recognized from his actions in a Companion Agent Learning Environment. If a student lacks the ability, he learns a wrong behavior, but at the same time, he can learn a correct behavior from errors made by peer student. For these reasons, we have developed an agent based mechanism for enhancing meta-cognition (i.e. monitoring the state of companion agents and also monitoring the recognition process).

For intelligently supporting the enhancement of meta-cognition ability, it is required to build a model which shows how a real student recognizes the state of companion agents. Therefore, the main purpose is to build a companion agent's understanding model. Moreover, the system visualizes this model so that a real student can be conscious of the real state of the companion agent, who's state he was trying to recognize, and may notice his own misunderstandings. In this way, this system supports the improving of the meta-cognition ability by making a real student redo the recognizing process, this time with more chances of success.

In this paper, we describe the fundamental components of a CALE, a method of modeling a companion agent's understanding model and the visualization of its model for supporting the enhancement of meta-cognition ability.
META-COGNITION ABILITY

THE EFFECT OF LEARNING BY ENHANCEMENT OF THE META-COGNITION ABILITY

Figure 1: A Model of Interaction in a Cooperative Learning Environment

[Fig.1] represents an interactive model among the students in a cooperative learning environment. There are two ways for a student to learn in a cooperative learning environment as follows.

1. an acquisition of problem-solving knowledge by way of Meta-Cognition.
2. a fixing of problem-solving knowledge by way of Reflection.

1. is learning by observing a peer student solving and explaining a problem. A student acquires the necessary knowledge from understanding the state of a peer student, by observing his behavior. So, if a student cannot recognize the state of a peer student correctly, the effect of the cooperative learning will be reduced by a half. For this reason, it is necessary for a student to recognize a understanding state of a peer student correctly in a cooperative learning environment. 2. is fixing of problem-solving knowledge by way of reflecting upon the structure of one's own knowledge. An effect of an acquisition of problem-solving knowledge is not to be expected by reflection, but an effect of acquiring skill within the knowledge which a student already has. Reflection produces such an effect by not only problem solving and explaining, but also by using meta-cognition. So, for a student, being conscious of meta-cognition facilitates the fixing of problem-solving knowledge by way of Reflection.

COMPANION AGENT LEARNING ENVIRONMENT

We construct a CALE as in [Fig.2] for supporting the enhancement of the problem-solving and meta-cognition ability. The system has two agents. One is the Computer Companion (CC), which has incomplete knowledge in the subject area. The Computer Companion aims to enhance the problem-solving ability of a real student (RS) and himself through collaborative dialogue with the real student according to a Dialogue Model (i.e. by putting questions to each other, solving a problem together etc.). The dialogue of the Computer Companion has two objectives as follows.

Figure 2: Companion Agent Learning Environment

- the enhancement of the problem-solving ability of the real student and the Computer Companion.
- getting information on how the Computer Companion's state is recognized by the real student.

In this study, we propose a dialogue model to make the Computer Companion behave as stated by the above two objectives. This model is formalized in predicate calculus to make it clear what the Computer Companion should do in each situation. We first describe the predicates used in the dialogue model. There are three kinds of predicates. The first kind shows a state of a problem such as `problem(P)` (P is the current problem). The second kind shows a situation of learning such as `agent(A)` (A is an agent who solves the problem). The last kind shows an action of each agent such as `explainA1 (A2, Operation)` (agent A1 explains to agent A2 about Operation his own problem-solving knowledge). In this research, we prepared about twenty
predicates and formalized a dialogue for each agent. For example, when the Computer Companion asks a question to the real student, one of the dialogue models is,
\[
\begin{align*}
&\text{problem}(P) \land \text{prob\_cond}(P, P\_\text{cond}) \land \text{agent}(CC) \land \text{not}(\text{Know}_{CC}(P\_\text{cond}, \text{Operation})) \land \text{not}(\text{Neg\_Know}_{CC}(P\_\text{cond}, \text{Operation}))) \\
&\quad \land \text{ask}_{CC}(P, \text{Operation})
\end{align*}
\]

The intended meaning of the model is that the Computer Companion asks a real student how to solve a current problem \(P\) when it couldn’t solve it and it doesn't know that the real student couldn't either.

The system adds and deletes primitive predicates in a working memory for recognizing the state of dialogue in a CALE whenever any agent does something. The Computer Companion behaves just right (i.e. points out, explains, asks a question etc.) in each situation defined by the dialogue model and the current working memory contents.

The other agent is the Facilitator Agent that is an expert in a subject area. The Facilitator Agent intervenes in the CALE only when a student asks for its help. The Facilitator Agent doesn’t act, except when students reach an impasse and go in a wrong direction in the learning process. The reasons is that the educational effect in a cooperative learning environment is reduced to nothing, if the Facilitator Agent intervenes every time. So, the Facilitator Agent rejects any help message from a student in any other but critical situation. In this research, we formalized the interventions of the Facilitator Agent in predicate calculus in the same way as we formalized the behavior of the Computer Companion. Moreover, analyzing the dialogue between the Computer Companion and a real student, the Facilitator Agent builds and evaluates a Companion Agent’s Understanding Model.

**SUPPORTING THE ENHANCEMENT OF THE META-COGNITION ABILITY**

**MODEL OF UNDERSTANDING A COMPANION AGENT**

The Facilitator Agent infers information on how the Computer Companion's state is recognized by a real student from the applied knowledge reasoned in the above way and the situation of dialogue obtained from the working memory. The way to infer the information is to use production rules which have conditional parts, including applied knowledge and dialogue situation [Kasai et al. 1997]. One production rule, which gets information about the meta-cognition of a real student, is defined for each action of a real student and of the Computer Companion (expanding a problem, observation, question, explaining and pointing something out). For example, one rules is,

\[
\begin{align*}
\text{if} & (\text{explain} \land \text{reduce} \land \{\text{open}\} \land \{f_m\}) \\
\text{then} & \{\text{not\_know}(\text{Rule}_n)\} \\
\text{else} & \{\text{know}(\text{Rule}_n)\}
\end{align*}
\]

This is a rule applied in a situation when a real student explains to the Computer Companion away of solving a problem. In this rule \(f_m\) is applied knowledge deduced by the Facilitator Agent and \(\{\text{open}_n\}\) is the operation list of the problem-solving knowledge \text{Rule}_n. It is possible to represent problem-solving knowledge by a problem-solving tree as in [Fig.3]. Problem-solving knowledge is defined by a set of one node and its child nodes in this problem-solving tree.

![Figure 3: A Problem-Solving Tree](image-url)

In this way, the system gets information on how the Computer Companion's state is recognized by a real student in each state of the dialogue.

**THE METHOD OF SUPPORTING THE ENHANCEMENT OF META-COGNITION ABILITY**
THE CONTROL OF A COMPUTER COMPANION'S DIALOGUE

A Computer Companion's dialogue is controlled when the information of about the meta-cognition of the real student is diagnosed as a mistake. The diagnosis is done by making a comparison with the actual problem-solving knowledge of the Computer Companion by the Facilitator Agent. When the information of about the meta-cognition of the real student is diagnosed as a mistake, its result is changed into the predicate "mis(Operation,How)" (misunderstanding about Operation's problem-solving knowledge such as showed by How) and sent to the Dialogue Control in Computer Companion. Then, the Computer Companion acts so that a real student can notice his own misunderstandings by means of a dialogue with the CC. In the following we show an example about how the Computer Companion actually acts when a real student's cognition is a misunderstanding.

When a real student explains something to the Computer Companion, the system diagnoses that the student's understanding about the CC's state is 'don't know', while the CC's actual state is 'know'. Then the Computer Companion answers to the student's explanation "I have already known this!!". Such a dialogue with the Computer Companion can make a real student be conscious of meta-cognition. Moreover, it gives a hint to the real student to notice that his own cognition actually a misunderstanding.

VISUALIZING THE MODEL OF UNDERSTANDING A COMPANION AGENT AND COMPUTER COMPANION

In this paragraph, we describe how to visualize a Model of Understanding a Companion Agent and how this model is displayed for a real student. The system displays the model as a problem-solving tree as in [Fig.4].

This problem-solving tree branches into sub-goals (i.e. mathematical fraction reducing, adding of fractions etc.). With this display, it is possible for the real student to confirm how the peer agent's state is recognized by himself at a glance. Each node of this problem-solving tree is a button which explains how the system reasons about this information, i.e., how a peer agent's state is recognized by a real student. This explanation has the educational effect that the real student reflects upon himself and evaluates each behavior for his own use. This function can support a real student in taking suitable decisions depending upon the state of a peer student in a cooperative learning environment.

Whenever the Facilitator Agent discovers a misunderstanding, the system changes the color of the button that has a sub-goal which includes this knowledge as shown in a right upper part of [Fig.4] so that a real student may notice immediately that he is recognizing the state of a peer agent mistakenly. We expect that the real student will try to ascertain the misunderstanding and will try to do the recognition, again.

In the above way, it is possible to expect that the real student is conscious of how the Computer Companion's state is recognized by himself and will try to ascertain a knowledge recognized mistakenly.
correctly again. But the result obtained after the second recognition is not necessarily always correct. According to circumstances, recognizing may reach an impasse, because a real student cannot recognize things accurately however often he may try. For this reason, we appended a function of visualization of the actual model of the Computer Companion and of the Companion Agent's understanding model as shown in [Fig.4].

If the system always visualizes the actual model of the Computer Companion, the educational effect of this study will be reduced to nothing, because the opportunity of recognizing the state of the Computer Companion from dialogue with him will be missing. So, we control the visualization of the Computer Companion's state with the following rule:

```plaintext
if (remodel(X_i, X'_i) & misunderstanding(X_i) & misunderstanding(X'_i))
  then Manage(visual(Sub_goal))
  else Unmanage(visual(Sub_goal))
```

`remodel(X_i, X'_i)` means that a recognition $X_i$ about a knowledge $i$ is renewed as a new recognition $X'_i$; `misunderstanding(X)` means $X$ is recognized as knowledge, mistakenly; `visual(Sub_goal)` is a button to visualize the problem-solving tree of the `Sub_goal` which includes a knowledge $i$. With this rule, the system can judge that recognizing reaches an impasse when the real student can't recognize the same knowledge contents correctly for the second time, and will pop up a button which indicates a problem-solving tree if pressed by the real student, so if the demand exists. With this function, it is possible for a real student to understand the degree with which he misunderstood the Computer Companion's state by comparing his own recognizing state with the actual state of the Computer Companion, but can be activated only when recognizing reaches an impasse.

**CONCLUSION**

In this paper, we have described a CALE with the purpose to support the enhancement of the meta-cognition ability. For supporting the enhancement of this ability, in this research, the Facilitator Agent builds a Model of Understanding the Companion Agent, which shows how a real student recognizes the state of the Computer Companion. Moreover, we have described the way to support an enhancement of this ability by using a Companion Agent's Understanding Model. For the visualization of this model and the actual model of the Computer Companion, we can expect that the ability of recognizing a peer student's state is enhanced by being conscious of how he recognizes himself and modifying the misunderstandings.

Here we have to say, it is necessary to experiment this model first, in order to prove that this system can actually build a Companion Agent's understanding model accurately and can support the enhancement of the meta-cognition ability.

**REFERENCE**

Abstract: Visualizing the contents to be learned about an instructional material is an effective way to facilitate learning. However, the effectiveness is not always obtained only by looking at the visualized representation. The knowledge visualization accordingly requires learners to devote more attention to it. Considering the context of learning a text, this paper gives an effective knowledge visualization called Diagram Tailoring, and demonstrates an intelligent learning system. This system presents part of a diagram as a visual representation, and encourages learners to construct the whole diagram so that their attention can be devoted to the visualized representation. This paper also describes an experiment on Diagram Tailoring. As a result, we have ascertained that partial diagram presentation makes a contribution to retaining knowledge to be learned from a text. Diagram Tailoring can be consequently viewed as an available way for allowing learners to obtain the intrinsic fruitfulness of knowledge visualization.

1. Introduction

Visualizing the contents to be learned about an instructional material enables learners to make sure knowledge which they are learning from the material, and to realize what has not been understood. Such knowledge visualization can be viewed as a fruitful way to facilitate learning [Merrill et al. 1992; Larkin and Simon 1987]. However, learners may only glance at the visualized representation, and may not elaborate on their knowledge with it [Barnard and Sandberg 1996]. In order to certainly get good results for learning with knowledge visualization, therefore, it is necessary to focus their mind on the visualized representation [Cox 1997; Kashihara et al. 1996].

This paper proposes an effective knowledge visualization which encourages learners to construct a visual representation by externalizing knowledge which they learn. In general, the knowledge externalization does not always occur because what to and how to externalize are often unclear [Chi et al. 1994; Cox and Brna 1995; Kashihara, Hirashima, and Toyoda 1995b]. Alternatively, the representation construction is not so easy because the learners may make excessive mental efforts which cause cognitive overload [Kashihara, Hirashima, and Toyoda 1995a]. In order to overcome these difficulties, we consider presenting part of the representation to be finally constructed. This corresponds to visualizing part of knowledge which they would learn. Such partial knowledge visualization gives the learners the directions what to and how to externalize, and contributes to reducing their mental efforts to complete the whole visual representation. In addition, moderate mental efforts of the representation construction will lead them to devote more attention to the visualized representation. The partial knowledge visualization can be consequently viewed as a fairly available way for allowing learners to obtain the intrinsic fruitfulness of knowledge visualization.

The technical issue in the partial knowledge visualization is how to decide which part of visual representation should be presented according to each learner. Considering the context of learning a text describing computer vocabulary, we have proposed an adaptive knowledge visualization called Diagram Tailoring [Kashihara et al. 1996]. This paper gives an overview of Diagram Tailoring, and demonstrates an intelligent learning system which accomplishes it. In this system, learners are encouraged to construct a diagram as visual representation. In order to facilitate such diagramming, the system presents part of the diagram so that the learners can elaborate on their knowledge with the presented partial diagram. This paper also describes an experiment on the basic idea of Diagram Tailoring which we have made compared with the whole diagram presentation. As a result, we have ascertained partial diagram presentation makes more contribution to retaining knowledge to be learned finally from a text.
We will first explain the knowledge visualization in learning a text in the next section.

2. Knowledge Visualization

2.1 Context

In this paper, we consider that learners learn a number of text describing computer technical terms in related order. In this situation, the learners are expected to identify the difference between and to classify the new term and the known terms they have already learned from the previous texts. Completing such an integration process can be viewed as building up a knowledge structure in mind [Chan et al. 1993]. Such knowledge-structuring process facilitates and deepens learning of a given text [Kashihara, Hirashima, and Toyoda 1995a]. The knowledge structure represents the contents which learners are expected to learn from a text.

2.2 Visual Representation

We provide a diagram such as IS-A hierarchical network with tables to visualize a knowledge structure finally constructed. Figure 1 shows a diagram which consists of three technical terms. A node in the diagram indicates a technical term, in which its name is described. The attributes with values which characterize the term are described in a table attached to the node. A link shows the relationship between nodes. There are two predefined links: difference link and is a link. Each link possesses its own table. This table describes the attributes which have different values between nodes.

![Diagram](Image)

Figure 1: A Diagram

A text given to learners is represented as a sequence which consists of several units. Each textual unit gives a textual description of what attributes and values a component (node or link) includes. The text shown in Figure 2 has a textual unit sequence which consists of Duplex system (indicated by Node-11) and is a link between Duplex system and Fail-safe control system (indicated by isaLink-1).

The design purpose of duplex system is to enhance the reliability of the system. This system has two control sequences, called main control system and sub control system. These systems operate concurrently. The main control system usually executes online processing, and the sub control system executes batch processing as background processing. When the main control system fails, the online processing is kept on the sub control system. The cost of operating duplex system is high. (Node-11) The duplex system is a kind of fail-safe control system. The fail-safe system has two control sequences which operate concurrently. In the system, the failure recovery, operating, and cost are not considered. (isaLink-1)
2.3 Representation Construction

The diagram construction process involves the following three mental operations: textual unit extraction from a text, related knowledge retrieval, and inference. These operations are externalized by making tables attached to nodes or links. The first operation requires learners to focus on keywords in the text to identify the components corresponding to the textual units. The second operation requires them to recollect related knowledge. The third operation requires them to distinguish and classify the identified textual units and the recollected knowledge to generate nodes and links. To generate a link, they particularly need to compare a node with the other node. The comparison involves discriminating, categorizing, or instantiating the attributes. To generate a node, they also need in some situations to differentiate and in other situations to generalize or specialize attributes (or values).

The amount of the mental operations can be viewed as cognitive load. There are three kinds of load in diagramming: the load of textual unit extraction, the recollection load and the inference load. Confronting each load contributes to retaining the knowledge structure built up [Kashihara, Hirashima, and Toyoda, 1995a]. However, the diagram construction is not so easy for some learners since it may impose cognitive overload on them. Therefore, we need to adapt the load to each learner. This adaptation corresponds to Diagram Tailoring.

2.4 Partial Knowledge Visualization

The basic idea of Diagram Tailoring is to present part of a diagram to reduce the load of constructing the whole diagram. The important point is how to decide which part of the diagram should be presented.

A diagram to be constructed consists of three parts: the part to be composed by extracting keywords from a text, the part composed by recollecting related knowledge, and the part to be inferred. We call these parts, text-scope, knowledge-scope, and inference-scope of the diagram. The basic procedure of Diagram Tailoring is as follows. When learners are expected to have difficulty in constructing a diagram, the text-scope is presented as partial diagram. When they are expected to have more difficulty, the knowledge-scope is also presented in addition to the text-scope. This intends to reduce the textual unit extraction load or recollection load, and to focus their still more attention on the inference scope. The inference operation requires the learners' attention not only to the inference-scope but also to the text-scope and the knowledge-scope. It is therefore the most important operation for calling the learners' attention to the diagram. That is why reducing the inference load is not considered.

3. Knowledge Visualization System

3.1 Interface

We have already implemented an intelligent tutoring system with a graphical user interface shown in Figure 3. Looking at a text, learners can construct a diagram by mouse-selecting NODE and LINK buttons. They can also use tables attached to these components as supplementary means. The attributes and their values to be described in the tables are prepared as menus. The learners can select words from the menus and put them into the tables.

When the learners reach impasses, they can receive supporting information by pushing Q/A button. The occurrence of the impasses is recognized when they are asked or an interval between the operations is longer. Although some learners may also make mis-diagramming, the system does not currently distinguish the support for their mis-diagramming from the impasse support.
3.2 Framework

We will next give an overview of Diagram Tailoring. The detailed explanation of Diagram Tailoring is omitted in this paper [See Kashihara et al. 1996].

Providing a number of computer technical terms in related order, the system exercises learners in constructing a number of diagrams. In the exercise, the system builds up and updates learner models representing the capabilities of textual unit extraction, recollection, and inference. These capabilities are diagnosed according to the number of impasses which learners cause in text-scope, knowledge-scope, and inference-scope of a constructed diagram. In other words, the fewer impasses learners result in, the higher their diagramming capability is. The learner models are used for Diagram Tailoring.

In the diagramming exercise, Diagram Tailoring is executed for each diagram construction. The system first decides a diagram as learning goal in consideration of the technical terms a learner has known. The system next generates a text including some components in the diagram. The system also estimates the diagramming process that the learner is expected to perform with the text and existing knowledge. Considering his/her diagramming capability and the diagramming load estimated from the process, the system then decides which part of the diagram should be presented.

The learner is next asked to complete the whole diagram. If the learner reaches an impasse, the system provides the supporting information as a text or as another part of the diagram. Using the monitored information, the system updates the learner model to adapt Diagram Tailoring for the next diagram construction in the diagramming exercise.

3.3 Examples

Let us show an example of Diagram Tailoring as shown in Figure 3. In this example, we assume that a learner has known the term of Dual system, and the system generates the text as shown in Figure 2. When his/her capability of textual unit extraction is diagnosed as low, the system displays the text-scope of the diagram as shown in Figure 3. In this case, the learner is encouraged to recollect Dual system and to infer the node of Fail-safe control system and the is a link between Dual system and Fail-safe control system although he/she does not need to extract keywords from the text. If his/her capability of recollection is moreover diagnosed as low, the system displays still more the node of Dual system in addition to the text-scope, and he/she is encouraged only to execute the inference operation. In this way, Diagram Tailoring individualizes a displayed diagram according to learners' diagramming capability.
4. Evaluation

In this section, we will explain an experiment on the basic idea of Diagram Tailoring that we made. The main purpose of the experiment was to ascertain if completing a diagram with the presented part of the diagram is more effective for learning than just looking at the whole diagram without diagram construction. The learning effect was measured by retention of the diagram [Barron and Atkins 1993]. Tailoring the partial presented diagram to each learner is not considered in the experiment.

A diagram was composed of three nodes as shown in Figure 4 (a). Each node included 4 attributes. Each link included 2 different attributes between nodes. Subjects were 14 graduate and undergraduate students. We set two conditions. These were as follows: (1) the whole diagram presentation, and (2) the partial diagram presentation. In order to make each subject learn a text on each condition (within-subject design), we prepared two similar diagrams although these describe different domains. The influence of the domains on the results was counterbalanced.

![Diagram Presentation in Experiment](image)

**Figure 4: Diagram Presentation in Experiment**
The experiment was done with the system as follows. The system first displayed a text which described a node indicated by Node-a, and required a subject to carefully read it. The aim of this careful reading was to make him/her acquire knowledge about Node-a.

On the first condition (Condition-1), the system next displayed a text which described all components of the diagram and the whole diagram such as Figure 4(a). The subject was then required to carefully read the text and to look at the diagram.

On the second condition (Condition-2), the system displayed a text which described Node-b and Node-c, and the partial diagram including Node-b and Node-c such as Figure 4(b). The subject was then required to complete the whole diagram by recollecting Node-a, and by inferring other components. When the subject reached impasses or made mistakes, he/she was given correct attributes with values. Learning on each condition took the same time (about 30 minutes).

After two hours, a retention test was conducted. In this test, each subject was requested to reconstruct each diagram with the system. The perfect score was 21. Table 1 shows the average score and standard deviation of the retention on each condition. The average score on Condition-2 was quite higher than the one on Condition-1. In addition, we performed an analysis of variance on the retention test. The result indicated that there was a significant difference between the average scores (F(1, 13)=28.52, p<.01). From this result, it was ascertained that the partial diagram presentation accompanied by the diagram construction made more contribution to reinforcing the retention of the visualized diagram than the whole diagram presentation.

Table 1: Scores in Retention Test

Nevertheless, there were four students on Condition-2 whose scores of the retention test were less than 10. This indicates that the presented partial diagram and the diagramming operations required are not adapted to them. This finding implies that it is necessary to tailor the partial diagram to be presented according to each learner.

5. Conclusion

In this paper, we have claimed that visualizing knowledge should be accompanied by letting learners construct the visual representation. Following this claim, we have proposed a knowledge visualization with representation construction called Diagram Tailoring in learning a text. This paper has also demonstrated a system which has been already implemented. The system provides a graphical user interface in which learners can externalize knowledge learned from a text to construct a diagram. In order to facilitate the diagram construction, the system presents part of the diagram properly with the learner models which represent their capability of diagramming. The Diagram Tailoring technique makes the knowledge visualization more effectively since it leads the learners to devote attention to the visualized representation. In addition, we have evaluated the partial diagram presentation compared with the whole diagram presentation. As a result, it made more contribution to retaining knowledge learned from a text.

In our future work, we will apply the Diagram Tailoring technique to other learning contexts to make clear the limitation.

A Mechanism for Knowledge-Navigation in Hyperspace with Neural Networks to Support Exploring Activities

Mizue KAYAMA & Toshio OKAMOTO
The Graduate School of Information Systems, University of Electro-Communications, JAPAN.
e-mail : {kayama,okamoto}@ai.is.uec.ac.jp

Abstract: We propose a mechanism for the knowledge navigation based on the sub-symbolic approach to decide the appropriate navigation strategy. A neural network was used as a navigation strategy decision module in that system. Hypermedia is a tool for user-driven access to information. Adaptive hypermedia is a new direction of research within the area of user-adaptive systems. It provides an effective learning environment, where users can acquire some knowledge by exploring the hyperspace in their own way. Still, users often tend to "get lost" in the hyperspace. Often, we have cases of redundant or sub-optimal path. To improve these undesirable redundancies, we have to construct a sophisticated hypermedia system which can identify the user's interests, preferences and needs and give some appropriate advice to the user in his/her exploring learning process.

Introduction

In this paper, we propose a user model that represents exploring activities in hyperspace and a mechanism based on a sub-symbolic approach, to decide appropriate navigation strategies. Hypermedia is a tool for user-driven access to information. It provides an effective learning environment, where users can acquire knowledge by exploring the hyperspace in his/her own way. But, users often tend to get lost in the hyperspace. Often there appears the phenomenon of redundant information access. To improve these undesirable effects on users, many researches have been working to construct sophisticated hypermedia systems which can identify the user's interests, preferences and needs and give some appropriate advice to the user in his/her exploring learning process.

Adaptive hypermedia is a flexible system which infers the learning goal of the current learning state, by using the exploring history, the structural characteristics of the hypermedia a.s.o. As a result of its inference, this system changes its own performance to adapt to the user. Brusilovsky classified the adaptive hypermedia systems from the point of view of the methods and techniques of adaptation [Brusilovsky 1996]. According to his paper, the methods for adaptation are of two types. One is the content-level adaptation. This method changes the contents of the node which the user will refer in next step. This type is also named adaptive presentation system. The other one is the link-level adaptation. This method changes the links in the current node. This is also named adaptive navigation support system.

We have developed an adaptive educational hypermedia system based on the sub-symbolic approach with two types of adaptation, the link-level adaptation and the content-level adaptation. In cases of educational use, usually, as the exploring aim of students is usually fixed by a teacher in advance, frequent interactions with the system may be obstacles for the free exploring learning of a student. This paper also describes the training procedure of the neural network and its result. The paper is structured as follows. In the next section we describe the indicators that evaluate the users' exploring activity in hyperspace and the goal and content of each navigation strategy. The details of the hyperspace structure, which is expected to be the environment of the exploring learning process, are presented in this section. In third section, the configuration of the navigation system is described. In fourth section the structure and the learning of the neural network, the expertise of the navigation and the learning results of the network are described. In fifth section the validity of our navigation system is described and in a concluding section we give some final remarks.

Hyperspace structure
Student exploring states

In this research, our purposes in giving guidance to the students for navigation towards their learning
The goal is to support the smooth progress of the exploring study. As a result of the observation of the exploring behavior of students and after interviewing them, undesirable cases, which are likely to happen during the learning process, are classified as follows.

- *blind in hyperspace*
- *lost in hyperspace* [Nielsen, 1990]
- *redundant or sub-optimal references in hyperspace*

*Blind in hyperspace* are the students who do not know how to follow the links to go to the target nodes. The target nodes are not read before. The students can not infer the relation between the current node and the target nodes. *Lost in hyperspace* are the students who do not know the relative position of the current node and referred nodes. *Redundant or sub-optimal references in hyperspace* are taken by students who follow a longer path than necessary to go to the target nodes or to achieve their learning goals.

Two types of data are needed, to distinguish between the students who are in the undesirable learning states we described above, and the other students. They are physical information on the exploring activity (e.g. reading or reference time, number of referred nodes, topics a.s.o) and semantic information on the exploring activity (e.g. degree of importance of the referred node, degree of relation between two nodes a.s.o). From these information, from the behavioral features of students in undesirable states and from the structural model of the hyperspace, we defined six indicators which represent the exploring activities in hyperspace [Kayama et al. 1997]. The labels and meanings of each indicator are shown in Table 1.

The needs of the students who are in undesirable states are considered to determine the strategies which will support their smooth progress during the exploring study. The structure model of the teaching material and the methods of presentation of the needed information are also considered, in order to develop the six knowledge navigation strategies. The labels and functional details of these strategies are shown in Table 2. Our system makes its adaptation by using both methods, the link-level adaptation and the content-level adaptation. To the first type of adaptation belong UOS and REH, to the other type MEC, FEC and CEC. The adaptability of our system is increased by including both types of adaptation.

### The structure model

This teaching material is organized as a two class model. The first one is a node class, which is a real hypermedia. The second one is a topic class. The nodes which have a semantic relation to each other are included in the same topic. This structure depends on the teaching style of each teacher, not on
The contents or domain of the hypermedia system. The components of the teaching material (e.g. topic, node and link) are also depend on the educational point of view of the teacher (e.g. learning goal). Figure 1 represents the structure model of the hyperspace. The attributes of each component of the hypermedia system are shown.

A topic has two attributes. One is the set of nodes which are included in it. The other one is the ideal ratio of referred nodes (IRR). The IRR is calculated as the ratio of the minimal number of nodes, which are needed for understanding the point of a topic, to all nodes in the current topic. A node has four attributes. They are identification number (ID), degree of importance (DI) and the standard and minimum necessary time for reading (SNT, MNT). The ID is a unique number in a hypermedia. Stored, this attribute shows the exploring history of a student. DI is defined as the degree of contribution towards the achievement of the current learning goal. Its values are integers from 0 to 5. SNT is the standard time necessary to understand the contents of the current node. This time is used to evaluate the exploring behavior, to judge whether it is effective to achieve the current learning goal or not. SNT is a useful indicator that evaluates the effectiveness of the node for the user and is used to evaluate the exploring behavior quantitatively. The last attribute, MNT, is the time needed for just glancing at the contents. These two attributes are represented in seconds. The minimum value is 1(sec) and the maximum value is not limited. A link has only one attribute, the degree of relation (DR) between two nodes. DR is defined as the strength of the relation between the contents of linked nodes. Its values are integers from 1 to 5. This value is used to evaluate the efficiency of referring that link between the nodes.

The knowledge navigation system which we have developed supports an educational hypermedia system with all of the attributes mentioned above. So, the teacher who wants to use our navigation system needs to arrange his/her hypermedia which is used as a teaching material. There are no limitations or rules to set concrete values for each attribute. Using those attributes of items of the hyperspace, we describe the formulas of each of the indicators mentioned above.

System configuration

Our navigation system has five modules and two databases and is shown in Figure 2. These modules are named as follows:

- the exploring data recording module (EDRm)
- the exploring activity evaluation module (EAEm)
- the navigation strategy decision module (NSDm)
- the definite contents building module (DCBm)
- the navigation guide visualization module (NGVm)

The databases are the history exploring database (HEd) and the hyperspace structure database (HSD). The system interferes only when the user wants to be guided in determining his/her next exploring activity. The prototype system is working and the selected theme for the teaching material is "The positioning at tennis (for doubles)".

Each exploring state (ID and reference time) of a student is recorded by the exploring data recording module as a piece of the history exploring database. When a student requests navigation guiding from the system, the exploring activity evaluation module develops the model of the current
state of the student. This model is expressed by the six indicators which were mentioned in the second section. The student model is handed over to the next module, the navigation strategy decision module, which contains a neural network as a classifier engine. Only one navigation strategy is selected by the navigation strategy decision module from the output of the neural network. The calculation mechanism of this module is described in the next section. The definite content of the navigation guidance information is created in the definite contents building module by using the strategy determined by the neural network engine and the knowledge of the hyperspace attributes from the hyperspace structure database. Then, the results of the processing are shown to the student by the navigation guide visualization module as the current navigation guidance information.

Figure 3 shows an example of navigation guidance information. The guidance message and recommended nodes are given to support the decision about the student's next exploring activity.

Navigation strategy decision module

The algorithm and input data of the neural network

In this research, a sub-symbolic approach is taken to develop the navigation strategy decision module. To infer the appropriate navigation strategy, the expertise on knowledge navigation is learned by a supervised neural network. This expertise is formed by the pair of learning state of the student and adapted strategy, which should help him/her find the right exploring path.

By using this sub-symbolic approach with the neural network, it is possible for the system developer to improve the flexibility and the generality of the mechanism of the navigation strategy decision processes. In case of using a sub-symbolic approach, the extraction of the expertise is equivalent to the collecting of the training data for the neural network. The training phase of the neural network means the arrangement of the expertise. These embedded processes make the task of experts and system developers easier. The neural network which is used as the classifier engine in our system is a supervised multi-layer feed-forward model. The engine learned pairs consisting of possible student states in exploring learning and the appropriate navigation strategies, by using the back-propagation (BP) learning rule. The BP is one of the most famous supervised learning rules. The input pattern is the student's learning state and the output pattern is the corresponding navigation strategy.

Extracting expertise on navigation from experts

The pairs of learning state and navigation strategy are prepared from the results of experiments whose subjects are experts in the given field of education. These five are all educational experts who have made hypermedia teaching materials and used them in their classes. These pairs of data are teachers' expertise on navigation. We call this expertise the navigation knowledge. The extracted knowledge is used as training patterns for the neural network. In preparation for this experiment, experts are given the explanation of the means and the ways of calculation of each exploring indicator, and the ways of navigation for each navigation strategy. Experts' understanding of the indicators and navigation strategies is confirmed by researchers. At the experiment, according to the questionnaire method, the sets of learning states are gathered from experts. The experts are required to answer in pairs of learning state and suitable navigation strategy. Also, the experts attach to each learning state grades for the indicators. During this process, learning states which are not needed to express a certain strategy are allowed to be included in the experts' answer. In this way, we reduce the mental
load of experts during the extraction of their expertise.

In the process of arranging the results of this experience, all learning states are classified. The results are looked at Table 3. The learning states extracted are the ones computed by selecting the answer of the majority from the collected results. The rest of the data are classified as being redundant states for the navigation.

Table 3 : The extracted navigation knowledge

|     | 
|-----|-----|-----|-----|-----|-----|-----|
| Redundant | 390 | UOS | MEC | FEC | CEC | REH | R  |
| Necessary | 399 |     |     |     |     |     |    |
|       | 9   | 81  | 60  | 90  | 18  | 81  |    |

The neural network structure

This network has three layers. The input layer has twelve units. One indicator is assigned two units so that three grades of evaluation can be expressed. The output layer has 7 units. These represent the six navigation strategies and the redundant output. The number of the hidden layer units are determined by successive training simulations. The final number of neurons in this layer is the number which assures the highest performance. Moreover, other parameters are needed to be tuned in order to achieve a better efficiency of the network. These network parameters are the learning rate and the momentum. The fine-tuning parameters of the network are 1) number of units in the hidden layer is 16, 2) learning rate is 0.3 and 3) momentum is 0.5.

All of the navigation knowledge is learned by the neural network. It means that this trained neural network can decide upon an unique appropriate navigation strategy for each exploring state at the rate of 100%. The trained neural network is used as the classifier engine of the navigation strategy decision module. The learning process of the network is the process of implementation of the navigation strategy decision module. When the navigation strategies are changed or the relation between the learning state and the appropriate navigation strategy is changed, the system developer has only to retrain the neural network. The training of the network has to be done before replacing the old inference engine with the new one.

Examples of the user model

An investigation was made on several real users to evaluate the appropriateness of the student model. The real users were graduate and undergraduate students who have played tennis for a few years. To evaluate the appropriateness of the student model in our system, we have been recording data about users' exploring activities and about the navigation guidance information for fourteen days. Data which we have recorded are 1) the student's exploring state when he/she requests the system to give a navigation guidance, 2) the name of the navigation strategy applied for the user, 3) the shown navigation guidance (guidance message and recommended nodes or topics), 4) the node IDs which are accessed in the next step and 5) the reason for having demanded navigation guidance. 25 users have used the navigation system during this experiment. Navigation guidance was requested in total for 154 times. The mean time of learning with our system was 37 minutes per student.

Hyperspace structure of the teaching material

A fragment of the new hypermedia structure on tennis is shown in Figure 4. The topic layer (in the rectangle) is represented as a tree structure. The gray-outed part is a node layer.
Appropriateness of the student model in the navigation system

Path in Figure 4 shows an actual path of students' exploring. The nodes with the circled numbers express the nodes searched by the students. The students who follow the path are searching for items relevant to each node one after another. Taking this Path, we describe the results of the evaluation of the exploring activities of our system. As results, 1) the values of six exploring state indicators, 2) the applied navigation strategy, 3) the shown messages for navigation guidance, and 4) the recommended nodes (or topics) are shown.

Path: (1 - 2 - 3 - 4 - 8 - 9 - 10 - 7)
This path shows a searching for nodes which are relevant to the previously accessed node, one after another. The navigation guidance was demanded when there were no interesting nodes any more or when the user could not find any more nodes related with his/her learning goal. The result which the system estimated is as follows.

As a result of referring the nodes which were of related contents one after another, the RSUT has become high and RFT has become low. The low value of the VR is due to the low importance of the accessed nodes. The navigation strategy which was applied to this student is the FEC. The navigation guidance information for the student is shown in Figure 5. The shown navigation message was "You have referred nodes on many topics. How about learning more details on a specific topic?". The topics of the accessed nodes were recommended as a next destination to explore.

Conclusion

The exploring behavior which needs navigation guidance is collected from the results of the observation and the interview of the exploring students. Then, indicators which express the students' exploring states and the navigation strategies are constructed. The user model is developed by using these indicators in our navigation system. The navigation knowledge is extracted from education experts. Their knowledge is structured as pairs of exploring state, navigation strategy. The learning states which represent redundancies are considered in the process of pruning of input data. The expertise is learned by a three layer feed-forward neural network. As a result, the navigation strategy decision module in the navigation system is created.

Evaluating Collaborative Learning using BBS focusing on questions of learners

Michiko Kayashima
Department of Art, Tamagawa University, Japan
kayasima@lit.tamagawa.ac.jp

Abstract: The goal of this study is to find out the cognitive activities which can act as a measure for evaluating whether collaborative learning develops effectively or not. I propose that one of these activities is learners' spontaneous questions. I describe a question model and report the evaluation of two case studies which use it. In each case, study students were given different tasks. One is creating a HomePage for virtual audience, the other is for real audience. As a result, this study has pointed to the influences that a task has and how it may help promote cognitive activities.

1. Introduction

The socio-cultural approach has influenced education. Learning theory has changed from "transferring knowledge" to "constructing knowledge" (Scardamalia & Bereiter 1996). The latter means aiding learners in constructing knowledge for themselves rather than transferring knowledge by giving self-sufficient drills and practice tasks. The socio-cultural approach considers that learners are active rather than passive participants.

In this academic shift, there are many case studies of collaborative learning which have been designed to assist learners to construct knowledge for themselves. They include collaboration with experts, collaboration with peers, cooperation and so on. In Japan, most of the case studies is called "project learning". In project learning, learners are given puzzles or problems to solve and summarize collaboratively. However, during project learning learners limit themselves to gathering information, instead of actively solving the task. This is not the proper role of project learning. Project learning should lead to educational effects, such as gaining new knowledge, acquiring new skills for problem solving and so on.

On the other hand, there are several case studies of collaboration which have reported positive expectations (Scardamalia & Bereiter, 1991, Scardamalia & Bereiter, 1996, Merril, Reiser, & Merrill 1995). These case studies suggest that there are activities which are related to effective collaborative learning, such as conflict between learners, learners' explanations and so on.

The present goal of my study is to find out the cognitive activities which can act as a measure by which one can evaluate whether collaborative learning develops effectively or not. Questioning is one of these activities, specifically learners' spontaneous questions. Learners' questions can be observed; these questions represent the learners' cognitive activities. What learners ask others or themselves allows them not only to obtain information from each other's answers but also to progressively organize their necessary existing knowledge structures during the production of their questions. Questioning enables learners to externalize to others how they understand the concept underlying their questions and how it is integrated in their existing knowledge structures.

However, spontaneous questions only occur if some conditions are met. One of the conditions is that a learner is not left as a passive learner, that is a learner takes the initiative for the task in hand, and, in so-doing, learners should learn the knowledge and skills that are necessary for doing it, furthermore learners should spontaneously produce diverse primitive questions during their learning.

In this paper, I describe a question model which can act as a measure for evaluating collaborations, and I report the evaluation of two case studies which use it. In each case study, students were given different tasks. One was writing a report for virtual audience, the other was for real audience. When they had spontaneous questions, they participated into the collaborative learning between different academic departments using BBS (Bulletin Board Services), by which I can observe the students' questions and the tutoring techniques. In part two, the further analysis of questions which learners asked in the previous case study and a question model are described. In part three, two case studies and the evaluations will be described.

2. Understanding cognitive activities through questioning transformations

Recent studies of successful tutoring demonstrate tutors' tutorial guidance such as sophisticated strategies, techniques and so on. This guidance allow an extremely effective style of learning (Merril, Reiser, Merrill, and Landes 1995). Therefore, it is undoubted that the tutors' guidance might improve the students' cognitive activities.

In my previous case study, which was cross-aged tutoring (Kayashima 1997), tutors criticized vague questions and recommended better ways of formulating inquiry. Tutors aided tutees to formulate inquiry, rather than simply offering the necessary knowledge. This advice transformed some of tutees' questions into questions to confirm their hypotheses. This advice implies that tutors monitored what cognitive activities tutees did through their questions, such as tutors recognizing a vague question as a question which tutees asked before
they thought reflectively. In addition, the questioning transformation implies that this advice improved tutees' cognitive activities. Hence it may be possible to understand learners' cognitive activities by such analysis of their questions as tutors analyzing. Furthermore, the analysis may lead to a standard question model which represents learners' cognitive activities.

2.1 The analysis of questions

I can analyze and categorize tutees' questions into “questions that request information” and “questions that confirm interpretation”. Questions that request information are questions that ask others to give their interpretation without attempting to integrate it themselves. For example, “let us know about ...”. These questions asked tutors to explain “simply” or “using effortless interpretation”. These imply that although tutees were aware of some necessary knowledge, they did not attempt to integrate it into their existing knowledge structure. This activity does not involve a reflective activity.

Questions that confirm interpretation are questions that learners ask in order to confirm their own interpretation(hypothesis). For example, one of the students in the study, when involved in learning about the binary system, asked the following : “I suppose that all information is represented as one or zero. If so, is hiragana or katakana\(^1\) represented as one or zero?”. This implies that the tutee attempted to integrate a new concept into her existing knowledge structures. However, her cognitive activity was not sufficiently developed and her knowledge was not enough to confirm her own interpretation. Therefore she asked others to confirm whether her interpretation was correct or not. Questions that confirm interpretation mean that tutees depend on others' cognitive activities and others greater knowledge instead of their own.

At the beginning of the tutoring, all students asked questions that request information. However, some of the students shifted to questions that confirm interpretation after the tutors criticized and advised. Here is an example of a tutor’s piece of advice; “I guess you are unsure about how to ask for help. When I was a junior student, I asked questions like yours... You should make uncertain things clear when you ask somebody”. This advice, that instructed students on how to ask questions, guided learners to try to integrate a new concept into their existing knowledge structure by themselves.

2.2 The Question model

The above-mentioned questions bring out that the ascent to cognitive activity is made in two basic phases. The novice learner takes the first phase toward the awareness of some knowledge. The second phase brings about the integration of some knowledge into their existing knowledge structure. The second phase is an ascent to higher level than the first phase. These are shown in Table 1.

<table>
<thead>
<tr>
<th>kinds of question</th>
<th>ascent to cognitive activity</th>

</tr>
</tbody>
</table>

Table 1 Kinds of question and cognitive activities

Nelson and Nares developed a definition about meta-cognition(Nelson & Nares 1994): A monitoring is a meta-level (meta-cognition) that obtains some information from an object level(cognition), and a controlling is a meta-level that revises an object level. In the first phase, learners could do their monitoring, that is, obtain some information from an object level according to the definition. However, they failed their controlling, that is, could not revise an object level such as their existing knowledge structure. Hence they asked others for help in revising it. Others' advice should enable some of learners to revise it. In the second phase, learners did their controlling, that is, attempted to revise an object level. However, they failed their monitoring, that is, could not evaluate information from an object level. Hence they asked others for help in the evaluation of their controlling. Others answers should enable some of the learners to evaluate their controlling.

\(^1\) Both Hiragana and katakana is Japanese character.
This mechanism implies that learners’ meta-cognition, which includes a monitoring and a controlling, is done by others’ help and steadily develops. Hence questioning represents what cognitive activity learners need, that is, what cognitive activity learners could not work when they asked. This is consistent with Vygostsky’s claims: “Every function in the child’s development appears twice, on two levels. First, on the social level, and later on the psychological level; first, between people as an interpsychological category and then inside the child, as intrapsychological category” (Vygostky 1978 p.128). These ideas are shown in Figure 1.

3. The analysis of the two case studies

I describe two case studies and report the evaluation of them which use a question model. In each case study, students were given different tasks. One is creating a HomePage for the virtual audience, the other is for the real audience. Each study lasted for 13 weeks.

3.1 The outline of the two case studies

One of the case studies was set up in the autumn semester of 1996 and the other was in the spring semester of 1997. The autumn case study consisted of 34 junior college students who belonged to the Department of Art. The spring case study consisted of 64 junior or senior college students who belonged to the Departments of Art, Engineering or Agriculture, who had no computer literacy and no knowledge about HTML (Hyper Text Make up Language). There were 13 lessons. One lesson was 100 minutes. In the first 5 lessons, students learned computer literacy and HTML. In the final 8 lessons, the students were divided into groups of four to do project learning.

3.2 The different tasks

We designed two tasks. In the autumn, students interacted with a virtual audience and the students in the spring case study interacted with grade five students. These are shown in table 2.

The task in the autumn case study was to create a HomePage for a “virtual person” who is planning to buy a computer and is willing to spend 500,000 yen. The task in the spring case study was to create a HomePage explaining university students’ answer to grade five students’ questions about computers. As the elementary school was not connected to the internet, they communicated to the university students with a video tape exchange. They exchanged video tapes twice. The first time the fifth graders introduced themselves and asked questions about some computer mechanisms they did not understand. In response to this, the university students introduced themselves and promised to answer the questions as clearly as they could. The second time, the university students sent a copy of the HomePage they had created to clearly answer the questions about computer mechanisms. In response to this, the fifth graders sent a video tape in which they criticized the HomePage.

Table 2 task design and source of help
There were two sources of help for the university students. The first source was teachers and cooperators who do not belong to the university. The students could ask questions and receive comments from them through BBS. The other source was students at the Departments of Engineering and Agriculture. They created a terminology HomePage for the students at the Art Department to explain computer technology. The students in the spring case study created their own HomePage while referring to the terminology HomePage given to them. They could also ask those other students questions. The autumn case study could only use the first source but the spring case study could use both sources.

3.3 What questions were asked?
Many questions were asked in these two case studies. In the autumn case study, some of the university students asked questions that request information such as “What kind of computer should we buy for computer graphics?” or “What is a modem?” in the first lesson. After 3 months they still asked questions that request information such as “We can’t get a PowerMacintosh with more than 8MB of memory and more than 350MB of memory on hard disk. Should we get the PowerMacintosh6100?”

In the spring case study, the university students had to answer questions such as “Do Tamagochis work on the internet?” Some of the university students then asked their sources questions that request information such as “Can you tell me the architecture of Tamagochis?” in the first lesson. However, they received vague responses from their sources like “Tamagochis have computers in them”. Then the university students referred to the terminology HomePage and asked more specific questions that request information. For example, “If memory and a CPU were incorporated, how would these affect Tamagochis?” After 3 months, their questions were transformed into questions that confirm interpretation such as “We read your explanation about Tamagochis’ mechanisms. We think there are many functions programmed in a Tamagochi. Is that true?”. This transformation occurred without the tutors’ advice on how to ask questions.

4. Conclusions
The article has proposed and modeled that students’ spontaneous questioning is one of various cognitive activities which can act as the measure of evaluating collaborative learning, and reported the evaluation of two case studies which use it. The analysis of questioning revealed that questioning is related to learners’ meta-cognitive skills. However, the present question model, which includes only two categories, is not enough to observe learners’ complicated cognitive activities, because questioning is also related to the conversation rules in certain circumstances. Therefore I need a more specific, detailed analysis of questioning and to build a more sophisticated question model.

On the other hand, the evaluation of the two case studies indicates that the design of a task affects learning. These have suggested that the “non-virtual”, the genuine interaction in the spring case study with the elementary school students and the students in the science departments who can aid as the external knowledge, led students to develop their own cognitive activities. A more detailed analysis of this result should be given in the future.

An Interactive Graphing Tool for Web-based Courses

David M. Kennedy
Multimedia Education Unit, The University of Melbourne, Australia, d.kennedy@meu.unimelb.edu.au

Paul Fritze
Multimedia Education Unit, The University of Melbourne, Australia, p.fritze@meu.unimelb.edu.au

Abstract: This paper reports a project involving the development and formative evaluation of an interactive Web-based learning tool. The interactive graphing tool (IGT) permits students to sketch a graph on screen using the mouse and responds to a wide range of common graph types including logarithmic, exponentials, curves, and straight lines. The IGT facilitates an iterative approach to understanding graphical representations of knowledge by actively involving students in the construction of these representations and multiple modes of feedback. The examples provided in this paper relate to reaction kinetics and chemical equilibrium in undergraduate chemistry. However, the graphing tool is applicable to many other academic disciplines with similar needs to foster the development of student understanding of graphical representations of knowledge.

Introduction

Over the past few years two components for delivering courses via the WWW have emerged—the server-side applications (e.g., WebCT®, FirstClass®, TopClass® and Melbourne IT Creator®) and the client-side applications with which the learner interacts. While considerable efforts have been invested in developing course management software which functions from the server-side of course delivery to facilitate the linking of course content, Web pages, logging of student activity and reporting of student interactions only minimal (institutional or commercial) efforts have been made on developing pedagogically sound applications on the client or student-side. There remain two important issues affecting the application of new technologies which are crucial if there are to be any lasting improvements in student learning outcomes and the success of on-line courses. They are the:

- need to embed sound educational pedagogy into on-line courses; and
- facility for the content provider to be provided with sound pedagogical tools which are simple to implement.

This paper addresses the need for course designers (usually a lecturer appointed because of her or his content expertise rather than computer programming ability) to have available educational tools which engage students actively in learning and are simple to deploy. At the Multimedia Education Unit (MEU) in The University of Melbourne work has been focused upon developing generic learning tools which reflect sound educational pedagogies which are easy for non-programmers to use and implement. The interactive graphing tool (IGT) is one element in a suite of educational tools being developed by the MEU as part of the Learning Engines project [Fritze & McTigue 1997]. The remaining sections of the paper discuss the basic functionality of the IGT and the results of formative evaluations with students and academic staff.

The Design of the IGT

The IGT and Student Learning

The interactive graphing tool (IGT) has been designed and used within a framework that links the literature on student learning to that on understanding symbolic representations of scientific phenomena. The IGT is designed to actively engage students in constructing relationships between time-dependent data. For example, the macroscopic properties of matter and the symbolic representations used by chemists to represent those processes. While this paper focuses on the formative evaluation of the IGT, the use of such a learning tool must be seen as being incorporated into a computer-aided learning module which is merely part of a variety of
curriculum experiences. In considering the design of any interactive learning tool it is here that the principles underlying constructivism are invaluable. These principles can be summarised as follows [McNaught, 1993]:

- Students have prior well-formed frameworks of ideas about many of the topics they study in science.
- Learners build up personal, internal conceptual maps as a result of interactive processes between each learner and her or his environment.
- Our frameworks embrace our sociocultural environment as well as our physical environment.
- Learning occurs as an active construction of meaning as a result of reflection on experiences.
- 'Reflection' is one of those concepts which deserves to be reflected upon. It does not just mean thinking over an experience, but implies a conscious integration of experience into an existing framework.
- The process of reflection is not purely rational; motivation and interest are essential.

Any computer-based learning tools we build in order to assist student learning must require students to actively interact with new material in ways which require reflection. It is not sufficient for students to understand an argument or explanation in a detached way. They need to make decisions in their work which show clearly what their own knowledge constructions are. This has serious implications for the design of IMM where there has been a heavy reliance on recognition rather than construction in the design of question or problem formats. It is our belief that IMM will only assist student learning when the tasks we design are based on the constructivist principles outlined above. The IGT has the potential to:

- engage the student actively in the construction of knowledge,
- allow for a variety of student inputs,
- provide an iterative approach to learning,
- provide immediate and appropriate feedback, and
- be simple and straightforward for a lecturer/teacher to embed in computer-based media.

In many text books and IMM packages graphs are used widely to explain relationships between variables. The use of animations of graphs are widely used to explain how relationships vary over time, so that three variables are illustrated. However, students do not build these relationships themselves; they observe the developer’s image of them. At best, they may be asked to select between various graphical representations in a multiple choice question.

It has become clear to us that giving students IMM which included a learning tool by which they can build they own images of the relationships between variables and then get feedback from the computer about how useful their images are would be a real advantage in enhancing their learning [Kennedy & McNaught 1997].

IGT Structure

The IGT has been developed in ShockWave® using Macromind Director®. The graphing tool is a ShockWave object which requires a Web browser (Netscape Communicator) with the current Shockwave plug-in installed. In a Web environment it has the potential to provide students with the opportunity to express the relationships between variables in an active learning environment which provides appropriate feedback, and can be linked to multiple representations (e.g., video images of chemical processes or animations) of scientific concepts.

All curves drawn by the IGT including logarithmic and exponential shapes are simulated by the use of Bézier curves [Plant 1996]. The range of current default curve styles are shown in [Fig. 1]. Each curve has a default set of values which include the start and end points, start and end angles, an optional critical point may be defined, and a mid point. A wide range of curve shapes can be generated by changing these parameters. In chemistry the range of curves that can be simulated include those used in reaction kinetics, chemical equilibrium, and pH titrations. The location of the pen tool is shown at the top of the graph and is updated as the student draws the graph. Errors are corrected by using the eraser tool or redrawing the graph.
Formative Evaluation of the Interactive Graphing Tool

Goals of Formative Evaluation

This study focused on two groups—students and academics. The specific goals of the formative evaluation with students focused on:

- their responses to the general on-screen layout, navigation and behaviour of the IGT (in particular the mechanics of using the mouse to draw the curves);
- comments on the nature and function of the feedback provided;
- the difference between the IGT and other forms of CFL representations of graphical information including static graphs or animations of graphical information;
- perceptions of the IGT as a tool to influence their learning outcomes;
- the difficulties encountered in using the IGT; and
- how the IGT might be improved.

The focus for academic staff was on all of the above plus the ways in which the IGT might be used in particular academic disciplines:

The Studies

The students who took part in the formative evaluation were self selected from first and second year undergraduate science (all names are fictitious). All were experienced users of the first year ChemCAL computer-aided learning package [McTigue et al. 1995] developed at The University of Melbourne. Students were paired and asked to complete four small modules—a tutorial module to gain experience in using the software, followed by three modules which investigated kinetics and chemical equilibrium. Students were asked to comment on each of the broad areas listed above as they worked through the modules. The first author was present at each session (to observe, ask questions and assist if the software crashed—it didn’t) and all student responses were recorded using audio tape. Written notes were taken during and after each session—which required approximately 35 to 45 minutes per pair.

The academics who took part were either involved in courseware development at the university or known to the first author. The evaluation data was generated by the use of a questionnaire. This was the less successful of
Abstract: The advent of the WWW and a rapidly growing number of networked multimedia capable PCs in labs and homes created a new wave of ambitious educational projects. This paper presents first use experiences with FernUniversität's Virtual University concept. The core of this comprehensive teaching model consists of a rich collection of multimedia course materials particularly designed for interactive and computer supported distance learning. Main objectives include reduced communication periods, motivation enhancement through active learning, and improved insight into complex structures and processes through visualization, animation, and multiple presentations. The approach is exemplified with a highly interactive course on distributed software engineering. This example also serves to demonstrate the need for synchronous collaboration tools exploiting the structure and semantics of the course materials communicated.

1 Introduction

Traditionally, European distance teaching universities used prepackaged self-instructional correspondence courses supplemented by video and audio cassettes that allowed their students to study at the time and location of their choice. This teaching model can now be replaced or enhanced with multimedia, interactivity, electronic communication, and custom navigation and annotation; the course material can be published over communication networks; and the elapsed time of about six weeks between sending out homework assignments, receiving the students' solutions and returning the corrections to them— all by snail mail— can be reduced tremendously by using email and other forms of electronic document exchange. In some cases, for example, in a programming course, Internet technology can be used to perform corrections interactively with the help of remote compilers and testing tools. All this is currently taking place in FernUniversität's Virtual University project [http://vus.fernuni-hagen.de/].

In networked learning environments interactivity allows students to manipulate input data, parameters and thresholds of real-time simulations or animations. Learners may also influence the progress and output of process or algorithm visualizations. They may experiment with their own solutions to course-related problems and access virtual or remote laboratories. Such features are likely to raise the attractiveness of the learning material and enhance the students' motivation by letting them apply and experience what they have learned to problems of their choice. Flexible navigation and annotation mechanisms allow them to find their own tour through the educational material and associate it with their personal notes. Active links to related material of the Web allows interested students to deepen their knowledge at their own pace and time. But interactivity has a second meaning with respect to learning being considered as a social process. Distance teaching and training have always suffered from a lack of personal communication, face-to-face collaboration, and positive and negative reinforcement through tutors and fellow students [Krämer 97b]. Today there is a chance to support some elements of this social process by extensive use of email, chat tools, virtual classrooms [Maly et al. 97], collaboration support for geographically dispersed teams [Krämer & Wegner 97], and smart inquiry systems. Combined appropriately they enable new forms of online tutorial support and remote group interaction, both tutor with students and students with students. Currently we are implementing an enhancement enabling synchronous interaction over a distance within a consistent, representation-independent object model.
the two evaluation processes—the major problems being time constraints on the academics and significant cross-platform and software issues (discussed later).

The Modules

All of the objects which are part of the Learning Engines project are designed to communicate (e.g., text input or user interactions) with each other. In [Fig. 2] there are two objects on screen. The top one which is shown in [Fig. 2] as a straight line graph is the IGT. The lower one is the Tutorial Item Set (TIS) object. This contains the text of the question (left box in [Fig. 2]) and generates the comments box (right box in [Fig. 2]). The IGT facilitates sketching graphs on screen using the mouse and the TIS object contains the question scripts and the functionality to respond to input from both students and the academic. The two learning tools facilitate an iterative approach to developing student knowledge constructions between non-graphical and graphical representations of knowledge.

Figure 2: Screen capture of the prototype Interactive Graphing Tool

Figure 2 [Fig. 2] is a screen capture image of one screen. The straight line is illustrative of a response by a student. The question being asked of students is:

**Question 1 (question 1 of 2).**

The reaction: \(2 \text{N}_2\text{O}_5(g) \rightarrow 4 \text{NO}_2(g) + \text{O}_2(g)\) has been shown to be first order in terms of the \(\text{N}_2\text{O}_5\). The reaction has a rate law which may be expressed as:

\[
\text{rate} = k [\text{N}_2\text{O}_5]
\]

With the pen tool provided, draw a graph of the expected change in \([\text{N}_2\text{O}_5]\). Factors such as; Where does the graph start?, Where does it finish?, What is the shape of the curve?, became immediate problems for students to solve. This is quite unlike selecting from a series of possible answers as in a multiple choice question. The feedback to the student depends upon input (what the student sketches) and
comments defined by the content expert. The tutorial item in this example has been scripted to respond to the following components of any curve drawn by a student including the:

- start point (0,0) and end point (100,100) of the curve;
- start angle (>70°) and end angle (defined by the general form, decay1) of the curve;
- general form (decay1) of the curve (see [Fig. 1] for the generic shape of a decay1 curve).

Feedback can be as complete or as minimal as desired by the content expert. In the current version multiple levels of feedback may be specified in the TIS object. The TIS object analyses key parameters of the student input provided by the graph object and provides the appropriate response in the Comments box in [Fig. 2].

Student Formative Evaluation Results

The formative evaluation carried out with students in this instance has indicated that students find this type of task more challenging than conventional multiple choice selection problems. Construction is much harder than recognition. Quotes from student interviews support this statement.

DK  How is this different from other experiences of CAL materials of dealing with graphs—materials you have already used?
Anne  You have to actively participate. A lot of time with other CAL materials (either static displays of graphs or animations), you watch it, you take maybe 5% of it in. With this you actually have to sit there and work it out... This is much more active.
Mike  With the little movies they have in the current CAL labs there’s no real insurance that you comprehend what you are seeing.

The navigational issues and general layout of the two learning objects did not result in any problems. After minimal practice, all students were able to sketch a desired curve shape using the mouse. The feedback and the visual representations of the IGT were seen to be a very positive aspects of the software. For example.

DK  How is this (the IGT) different? This is the kind of question you would find in a book.
Anne  You are visualising it instead of just seeing a bunch of numbers in front of you.
Mike  Being able to see it (the graph you draw) helps out, rather than just the equation.

At the conclusion of the modules students were asked to their impressions of the IGT as a learning tool. In particular “How is this approach different to that you have seen in multiple choice questions, static displays, or animations of graphical representations of graphical information?”. Some of the responses were:

Nick  I think it’s good for students. I’m surprised to say that because it actually makes it harder for them in that they really have to learn (think) about what they know.
Mike  This (the approach to graphing using the IGT) makes it into something that is a serious learning tool.
Anne  ...if you do have a problem with it (the graph you are trying to sketch) you can’t readily go and ask for feedback (with a book or static display).

Formative evaluations from academics

The comments from the limited number of responses from academics tended to focus on issues of implementation within a specific academic discipline (e.g., physics staff require sinusoidal curves which are not currently supported), the need for specialised symbols in the text, and the issues of software compatibility. The latter is a non-trivial problem for those involved in developing Web-based pedagogical learning tools. The internet is not a mature technology. Standards for hypertext markup language (html), computer operating systems, and even internet browsers are problematic. For example, the two major internet browsers have implemented the current version (4.0) of html differently. However, In response to the question “How is this approach different to other forms of representing graphical information, static displays or animations”, an illustrative response is:

Rose  The primary difference must be that students can trial their own answers and get feedback on same.

Problems And Solutions

A number of perceived deficiencies in the current iteration of the software were articulated by the students and academics. These problems included the lack of information on the axes and suitable scales, the initial graph drawn disappears once a new graph is started, and the graph disappears if the screen display is altered (e.g., scrolled in a manner to hide the graph object).

The authors were well aware of the first problem however it was not possible at the time to have this implemented. It will be part of the next iteration of the IGT. The second issue will be implemented in the near future. It is envisaged that once a student response has been checked and found to be not correct, that response will fade to 50%, then 25%, of the original while the student has a second or third attempt respectively. The
third issue has been addressed by Macromedia. The latest Shockwave plugin preserves information on the screen. A cross platform font has been developed which facilitates the use of the IGT on a Macintosh or a PC using Netscape Communicator®.

Future Directions

The current work of the project is focused on the development of the authoring interface for lecturers and implementing the changes recommended by students and academics. Improvements currently being implemented include the ability to customise the types of curves recognised for different disciplines and pop-up menus to select the graph set appropriate to the particular content discipline.

The expectation is that the number of graph types recognised by the software will be increased as will be the degree of customisation of the graph types recognised by the software. There is no intention to have the IGT display or respond to sinusoidal curves or curves which are drawn right to left.

While the examples provided in this paper relate to reaction kinetics and chemical equilibrium in undergraduate chemistry, it must be stressed that the interactive graphing tool is applicable to many other academic disciplines with similar needs to foster the development of student understanding of graphical representations of knowledge. It is anticipated that the graphing tool will be used the future in other contexts—in subjects that also have a need to link the macroscopic behaviour of objects or materials with graphical representations of knowledge. Discussions have been held with lecturers from pharmacology and physics and the requirements of these subjects have been addressed in the current iteration of the IGT. The comments from students in this study were very positive however, studies are currently ongoing to ascertain any changes to student learning.

Abstract: This paper reports the results of a study of the development of an innovative learning element designed to be implemented in a computer-facilitated learning (CFL) module. The learning element is an open-ended, short answer, text question tool (TQT) designed to be used in Web-based courses or incorporated into hybrid Web/CD-ROM systems. The TQT object facilitates the development of extended question-and-answer problems which overcome the limitations of the multiple choice question format. The TQT facilitates an iterative approach to developing student knowledge constructions of knowledge. The examples provided in this paper relate to questions developed for the Department of Anatomy, Faculty of Medicine at The University of Melbourne. However, it must be stressed that the TQT is applicable to many other academic disciplines with similar needs to develop student understanding of specific content domains.

Introduction

The development of the Text Question Tool (TQT) is an additional component of the Learning Engines project—work being undertaken by the Multimedia Education Unit (MEU) at The University of Melbourne to develop simple Web-based learning tools [Fritze & McTigue 1997]. The project is developing a number of generic learning tools for the implementation of Web-based, CD-ROM or Web/CD-ROM hybrid course materials. A number of these tools have already been produced including an a concept mapping tool, tutorial item set tool, and an interactive graphing tool [Kennedy, Fritze, & McTigue, 1997]. The Text Question Tool is designed to be a generic question tool which facilitates the construction of computer-facilitated learning (CFL) modules or Web-based courses. The functional aspects of the TQT are the:

- facility to allow students to type in short text-based answers in a field in a Web page based upon a question item;
- ability of the TQT to search for key words or phrases defined by the lecturer;
- ability to provide feedback to students based upon the number of key words or phrases found in the text string typed in by the student; and
- facility to respond to student requests for Hints, spelling of terms, and expert answers to the question.

Faculty members from the departments of Chemistry, Physics, Anatomy, Pharmacology and Economics at The University of Melbourne were surveyed to determine the needs of delivering on-line tutorials. While the needs of each academic discipline were varied, the TQT was perceived to be fundamental to the implementation of Web-based courses. The department of Anatomy is participating in the development, design and the formative evaluation of the TQT. The design of cognitive tools for student learning is an outcome of a theoretical framework developed to link what is known about sound educational practice with the design of interactive elements to incorporate into multimedia courseware [Kennedy, Fritze, & McTigue, 1997; Kennedy & McNaught, 1997].

The Text Question Tool and Student Learning
The TQT fulfils a number of educational requirements not available in current Web-based courseware tools. These are:

- allowing a student to express more complex concepts and ideas in her or his own words and receive immediate feedback in a Web-based environment;
- providing an environment in which students can refine and reflect upon their understanding of concepts which is non-threatening;
- allowing the content expert to decide the content matter and the appropriate form and language of the answer. It is the lecturer who decides the key words, hints and expert answers pertinent to a particular content domain; and
- providing an opportunity for students to learn in an environment which is supported by a sound educational framework.

A non-functional example of the look-and-feel of the TQT object with examples of questions may be found at <http://www3.meu.unimelb.edu.au/meuweb/staff/dkennedy/TQT.html>. The TQT has been through a number of iterations in discussions with academic staff from the department of Anatomy using the scenario-based approach. Scenarios have been chosen because they "are grounded in the work activities of prospective users; the work users do drives the development of the system intended to augment this work. Thus scenarios are often open-ended and fragmentary; they help developers and users pose new questions, question new answers, open up possibilities" [Carroll 1995], p. 5.

**Example of a scenario in Anatomy**: The student reads a question—in conjunction with a range of resources (e.g., an series of anatomical images, a video clip of the initial phases of the procedure, or images of the radiological perspective) from the lower back in the Interactive Anatomy (IA) database—and is required to link the procedure with the underlying anatomical structures. For example, the insertion of a needle for a lumbar puncture requires an understanding of the anatomical structures the needle must pass through, the angle of insertion, and how far the needle must be inserted in order to obtain cerebrospinal fluid. The student is required to apply her or his anatomical knowledge in order to solve a clinical problem—which determines the success or failure of this procedure.

**Teaching and learning**

The advent of the World Wide Web (Web) and the shift to delivery of courses via the Web has provided the impetus to develop pedagogically sound learning tools for student learning. It has become clear that merely placing lecture notes on the Web is not sufficient for student learning to occur. However, there is a lack of suitable interactive learning tools which are Web compatible to actively engage the learner. A major purpose of any learning tool should be to provide teachers and lecturers with the facility to match the desired educational outcomes of a Web-based course with the learning elements which have the greatest potential to achieve those outcomes. For example, studies from many institutions over a period of many years "have drawn attention to the wide gap between the rhetoric describing the qualities lecturers say they want in their students’ responses, and the tasks they set" [Biggs 1989], p. 15—however, the on-line learning tools which actively engage students are currently very limited. The TQT is potentially one such tool. A general schematic view of the TQT is shown in [Fig. 1].

In the Interactive Anatomy project the TQT will be used to:

- develop the ability to analyse clinical problems by utilising students’ knowledge of anatomical structures,
- link procedural knowledge with anatomical knowledge, and
- promote active learning.

In addition the TQT can be utilised in this project and other academic disciplines to:

- provide a mechanism for self-assessment,
- develop procedural knowledge, and
- facilitate the development of descriptive terminology.

There are a number of components in the TQT environment. They include:

- a field into which the student can type an answer to a question,
- the hints assigned by the lecturer,
- the spelling helper,
- the expert answers, and
- the facility to print a record of a students’ responses and self-assessment to disk for later review (by the student).
Student Learning

Learning is the way in which an individual changes the way s/he conceptualises the world. Teaching involves a lecturer constructing learning opportunities for students. One of the major difficulties in the design of computer-facilitated learning (CFL) is the gulf between the instructional or educational design of CFL and what the research literature indicates is good teaching practice [Ramsden 1992]. There is considerable evidence that students need to be actively engaged in knowledge construction through a variety of learning experiences [Laurillard 1993]. The need to make learning environments as rich as possible to enhance students' ability to construct knowledge and resolve conceptual difficulties is fundamental if courseware is to be a significant part of course delivery in the next 10 years. Only limited examples exist where CFL has replaced part of the traditional approach to academic learning in higher education. At present there are very few learning tools of the type being developed by the MEU (Learning Engines, [Fritze, & McTigue 1997]) available for lecturers to construct learning opportunities which actively engage students. The self-assessment component of the TQT is one valid method of determining the 'distance' between the student response and the expert answers provided by the content expert.

The TQT is not intended to:

- supplant conventional examinations (formal assessment) although it may be possible to do so in the future,
- address syntax, grammar or content other than in a very fundamental way (key words), or
- address open-ended essay type questions.

Figure 1: The structural view of the TQT

A Functional View of the TQT

A functional view of the current iteration of the TQT object is shown in [Fig. 2]. The structure of the authoring environment is critical as the tool is to be used by lecturers with limited computing experience. Design of the authoring environment is guided by work carried out as part of Learning Engines Project. A key component of the intended authoring environment is the ability to incorporate graphics, animations etc., as
sources of question objects. Currently, the functionality of the TQT is linked to a database. The lecturers have a
proforma which sets the:
- the key words, spelling terms, expert answers, and hints for students; and
- structuring of questions with multiple forms of media (video and images from the Interactive Anatomy
database).

Question: Define a term, express an idea, or interpret some information.

![Diagram of TQT object](image)

**Figure 2**: A functional view of the TQT object

**Current Development and Evaluation**

Preliminary work on the TQT has been completed. The development of the TQT is focused on the
Interactive Anatomy project currently nearing the end of its first of two years in the Medical Faculty. The first 8
of 16 PhotoCD disks have been completed. Currently the design team is developing the first two modules for
use with students in 1999. The TQT will be incorporated into interactive tutorials on CD-ROM which will
facilitate the development of anatomical knowledge in a case-based clinical approach. Student evaluations of the
modules will take place in early 1999. A screen capture of the prototype is shown in [Fig. 3].
**Sample Questions and Answers from the Interactive Anatomy Project**

The Interactive Anatomy CD-ROM project is a large interactive multimedia project at the end of its first year which is part of the restructuring of the curriculum in the Medical Faculty. In each question the student would be told to type her or his answer in the text entry field to answer the question. Information in the Help section for the student will include:

"These are technical questions requiring technical answers. You may get hints of keywords, check your spelling in the Spelling Tool or look at the expert answers after your first attempt. Once you have reached a decision, check your answer against the expert answer(s). You will be told how many of the key words or phrases you have entered which are appropriate to the question. You may try again if not satisfied or check your answer against the expert answer(s) provided and estimate your mark. These results can be saved to disk and printed out later."

Two example questions are shown in [Tab. 1].

**Summary**

This project differs from the investigations into artificial intelligence and full text recognition and analysis of text by computers in a number of important ways. Firstly, it is not intended that the TQT would be semantically coherent, that is, be able to analyse a student response as an experienced teacher of the subject matter. There is
considerable evidence (discussed earlier) that this level of complexity is not required in order to significantly enhance student learning. The second major difference is the assessment of student answers. The students are expected to assess their own answers and provide a mark or grade for their future reference. In the future it may be possible to construct a basic marking algorithm based upon the number of key words or phrases used; however, this is not perceived to be an educational requirement—students can learn without formal assessment. The TQT is an interactive learning tool which has the potential to enhance student learning.

Abstract: Most of previous authoring systems have at least the following two problems for producing multimedia titles or coursewares. The first problem is a separation between authoring and planning. Since many authoring systems provide only authoring facilities, users have to manually plan titles. The second problem is an insufficient management of objects used for authoring titles. For instance, since many authoring systems do not provide retrieval facilities for finding objects, users have to remember all of the objects to be used. As a solution of these problems, we present a co-operative multimedia authoring system called Grimtor that can be used for not only authoring but also planning titles. To support the co-operative authoring environment, Grimtor allows a hierarchical structure: titles, scenes, and cuts. A title can be planned in terms of the hierarchical structure and a page for each cut can be created independently by an author. Grimtor also provides authors with a hybrid user interface metaphor so that they can easily construct titles.

1. Introduction

Most of multimedia authoring systems are mainly used for authoring titles. However, the production of multimedia titles is not only an authoring task. It also includes several tasks: planning, data preparation and maintenance, task control, and so on. Since the previous multimedia authoring tools provide only authoring facilities to authors, they have to manually handle other tasks for producing titles. In addition, since many authoring systems do not sufficiently maintain objects used for authoring titles, users often have difficulties to find out wanted (or planned) objects. In this paper, we present a co-operative multimedia authoring system called Grimtor that provides both authoring and planning facilities. Grimtor also provides authors with a hybrid user interface metaphor so that they can easily construct titles.

User interface metaphors are increasingly becoming a prominent part of commercially available software [Carroll et al 1988] [Madsen 1994]. In authoring systems, user interface metaphors are specially important to authors. They are often classified as three categories: book/page metaphor, timeline metaphor, and flowchart metaphor [Koegel 1994]. Toolbook [Aymetrix 1994] is one of the popular authoring systems that adopt a book/page metaphor. The user of Toolbook constructs a book that consists of a series of pages. Each page may have one or more objects such as lines, circles, buttons, graphic, text, and so on. These objects are activated by associated procedures that are programmed in a scripting language, called OpenScript. In a flowchart-based authoring system (for example Authorware [Authorware 1992] and IcornAuthor [Koegel et al 1992]), authors create the paths that a user could take by placing icons on a flowchart and linking them to other icons. A timeline-based system (for example, Macromedia Director [Macromedia 1994]) allows authors to organize time-based media such as audio and video along the timelines.

Grimtor has a hybrid user interface metaphor that integrates all of the three kinds of user interface
metaphor: flowchart metaphor, timeline metaphor, and book/page metaphor. For the planning process, Grimtor adopts a flowchart metaphor, since a title can be easily planned in a form of flowchart. For the authoring process, Grimtor allows users to use both timeline metaphor and book/page metaphor, since users usually like to use a timeline metaphor or a book/page metaphor depending on the types of authoring objects.

Grimtor is a client/server-based model. The client part consists of a planning module and an authoring module. The server part consists of a database module and a communication module. Using the database module, Grimtor maintains all of the information about objects used in the processes of authoring and planning so that authoring and planning processes can be properly integrated. [Fig. 1] depicts the running environment of Grimtor.

2. Planning for Co-operative Authoring

Recently, some of authoring systems [Fujikawa et al 1991] [Ogawa et al 1990] allow structured authoring in order to provide users with different views of a title, for example a hierarchical view and a channel view [Hardman et al 1993]. Grimtor supports the co-operative authoring environment that allows structure-based composition of titles: titles, scenes, and cuts. We suppose that a title consists of scenes and a scene consists of cuts. Therefore, a title can be planned in terms of the hierarchical structure and a page for each cut can be created independently by an author. In the process of planning, author constructs a title map as shown in [Fig. 2] that describes a scene-flow of a title. Similarly, each scene is planned using a scene map that represents a cut-flow of a scene.

Grimtor provides each cut with a storyboard [Koegel and Heines 1993] in which a background picture, appearing characters, occurring events, and etc. are explained. [Fig. 3] depicts an example of a storyboard for a cut. In the process of planning, Grimtor allows users to assign objects to a cut and to make a path (i.e., a hyperlink) from a cut (or a scene) to other cut (or other scene). It is convenient for users to assign objects to a cut during the process of planning, since users can easily find out the objects that are needed to construct the cut. In Section 4, we will explain more about integration of planning and authoring.
3. Authoring based on a Hybrid Metaphor and an Object Database

For the authoring process, Grimtor allows users to use both timeline metaphor and book/page metaphor. Users usually like to use a timeline metaphor or a book/page metaphor depending on the types of authoring objects. For example, when users synchronize video with audio, in a book/page metaphor-based system they usually write a program (a script) for the synchronization. It is not easy for users to write such a program. In this case, it is much easier for users to use a timeline metaphor. In Grimtor, the book/page metaphor-based authoring system is just Toolbook, while the timeline interface is implemented. When users are authoring using the timeline interface, the result is displayed in a Toolbook window. [Fig. 4] shows an authoring environment for a cut. The top window in the left of [Fig. 4] depicts the timeline interface and the bottom window in the left of [Fig. 4] shows Toolbook window.
For the process of authoring, Grimtor supports a retrieval system to manage objects to be used. This retrieval system has an object database in a server so that users can register and retrieve their objects in the database. Users can register objects during the both processes of authoring and planning. When users assign objects to a cut in the process of planning, these objects are automatically registered into the database. The right side of Fig. 4 depicts an object list window in which the registered objects in a cut are listed. Using the object list window, users can easily find out objects that can be used to construct the cut.

Another convenient authoring feature of Grimtor is that users can easily put some actions on objects without writing scripts. For example, suppose that a user wants to make a circle object in a cut as a button such that when the button is pushed down, jump to other cut. To do this, a user can choose the push-down-action in the action list provided by Grimtor. Then, the user makes a jumping event from a cut to other cut. Making a jumping event will be more explained in the next section.

4. Integration of Planning and Authoring

As described in the above, if users assign objects to a cut in the process of planning, then these objects are automatically registered into a database. When users are authoring, from the database they can easily find out objects assigned in the cut and construct the cut with these objects. This is one way to communicate a planning process with an authoring process. Using this kind of communication, one person can plan a scene (or a title) that contains cuts and distribute the cuts to authors so that they can independently construct the cuts or objects registered in the cuts. In this way, Grimtor can support a kind of co-operative authoring.

Another connection between planning and authoring is to make a path (i.e., a hyperlink) among cuts (or scenes). In Grimtor, every cut and scene can have incoming interfaces and outgoing interfaces. Every path coming to a cut (or scene) has to come in through the incoming interfaces of the cut (or the scene). Every path going from a cut (or scene) has to go out through the outgoing interfaces of the cut (or the scene). Fig. 5 depicts incoming interfaces and outgoing interfaces of a cut.
To make a path from an object to a cut (or a scene), users first declare an outgoing interface of the cut (or the scene) that contains the object, and make a connection between the object and the outgoing interface. Then, users set a jumping event to the object such that when the object, for example, is clicked twice, jump to other cut, actually an incoming interface of the other cut. This linking method gives a restriction such that it is not possible to directly jump from an object to a cut (or a scene). However, this restriction allows users to make a hyperlink among objects during the both processes of planning and authoring. Since Grimtor maintains all of the information about incoming and outgoing interfaces for every cut and scene in a database, if users once define incoming and outgoing interfaces, then they can simply make links by making connections between the interfaces without seeing specific objects in a cut.

5. Conclusions

We design and implement a co-operative authoring system called Grimtor. Grimtor support not only authoring facilities but also planning facilities. In the planning, users can make a plan of a title that is associated with the authoring process. Therefore, according to the plan, authoring tasks can be distributed to many people. After finishing authoring tasks, some people can integrate the tasks into a title. Grimtor also provides users with a hybrid user interface metaphor so that they can choose their preferable metaphors. In future, we attempt to find a tutor model for planning and authoring so that teachers can easily develop multimedia coursewares.

Interactive Simulation Based Tutoring System with Intelligent Assistance for Medical Education

Kinshuk, Reinhard Oppermann, Rossen Rashev and Helmut Simm

Abstract: This paper presents a tutoring system for the ear domain in medical education as an application of the Interactive Simulation based multimedia system (InterSim). The InterSim approach is based on the principles of cognitive apprenticeship. It enables exploration of the subject domain and acquisition of both domain knowledge and skills through multimedia based interactions, especially interactive simulations. With its main focus on cognitive skills acquisition, the system adapts to user actions and supports learning activities with intelligent assistance in the form of guidance and dynamic feedback as well as system assessed testing.

1. Introduction

Acquisition of domain competence for any professional discipline includes both domain knowledge and skills. While the analytical disciplines focus on domain knowledge, the task oriented disciplines emphasise skill based competence. For successful learning in the task-oriented medical profession, learning in a work environment is an essential part of curriculum supplementing the learning in an academic institution. While the academic learning provides the core knowledge that is relatively weakly situated and more abstract in nature, the work environment facilitates the learning of task related skills that are specific and strongly situated. Computer based educational systems provide benefits of both approaches by facilitating learning in the form of observation, imitation, feedback and evaluation in a simulated environment that provides the necessary context for adaptation, enrichment and refinement. The components of multimedia technology such as animations, explorations and simulations provide all the necessary ingredients for learning both the domain knowledge and skills and thus may help the learner in becoming an expert or at least a fluent practitioner in the field [Baumgartner & Payr 1996].

This paper discusses implementation of a tutoring system for the ear domain being developed under the InterSim project. It benefits from the cognitive apprenticeship approach and aims to provide knowledge of the structure and functionality of a human ear as well as the skills involved in diagnosis and treatment of auricular diseases. The basic domain knowledge in the InterSim project is provided by tutoring and explorations whereas the acquisition of advanced knowledge and related cognitive skills is achieved through simulations with the help of repetitive learning process. The system complements other educational media (such as traditional lecturing, texts etc.) used by medical students and doctors in continuing medical education. Since the primary focus of the system is on advanced knowledge, it is simulation oriented and provides intelligent assistance throughout the learning process. It judges a learner’s need and adapts to it, provides interactive feedback and makes recommendations without obstructing the active learners in self-exploration at will. It provides authoring facilities to add and document real cases, serving as a communication medium among doctors besides assisting teachers in case-based teaching.

2. Characteristics of the InterSim System

The InterSim educational multimedia system can be used in and outside educational institutions and is suitable where the constraints of space, time or resources limit the possibility of regular institutional access. It may be combined with other means of education to suit different learning environments such as classroom based, open, and distance learning. The system facilitates competence not only in domain knowledge but also in
related cognitive skills that are difficult to obtain in absence of ‘hands-on’ training in real working environment. The learning environment follows the cognitive apprenticeship model [Collins et al. 1989] that fulfils the requirements of both academic and situated learning. The system is activity oriented and supports acquisition of cognitive competence in both knowledge and task oriented performances. It should be noted that interpretations and decision making are also regarded as activities. The following are the characteristics of the learning environment.

- **Modelling**: In this environment, the learners can study the task solving patterns of experts to develop their own cognitive model of the domain as related to the tasks, tools and solutions. The technical support provides guided tours (demonstrations and simulations) and textual explanations. The learners can work with the tutorials and perform interactive imitations of the demonstrated simulations.

- **Coaching**: The environment allows the learners to solve tasks on their own by consulting a tutorial component. The technical support provides exploration tools for the learners to search for possible solutions, try them out and to solve any attendant problems. The technical support also provides consultation facilities for solving notorious errors.

- **Fading**: The environment’s tutoring activity is gradually reduced in line with a learner’s improving performance and problem solving competence. The technical support provides a learner with adapted intelligent assistance in the form of recommendations and support throughout the learning process. Such assistance is based on the learner’s progress in understanding the subject matter and thus the novice learners are provided with a much higher level of assistance.

The InterSim system, incorporating the above learning environment, is beneficial with respect to various socio-technical factors. The system provides a risk free simulated environment for explorations by a learner without the fear of harming a fellow human and includes real world scenarios based on actual patients. Such systems are applicable to a wide geographic area, since multimedia techniques facilitate the adoption of multilingual support with little effort. After the initial prototyping investments, systems based on the InterSim approach are likely to prove economically viable as they offer immediate savings in terms of human and laboratory resources and a longer life cycle due to well established domains and low rate of subject matter obsolescence.

### 3. InterSim Tutoring System for the Ear Domain

The system aims to facilitate acquisition of competence in the subject matter by providing basic and advanced knowledge of the domain as well as the associated cognitive skills. The skills are sought to be developed in a constructivist manner through repetitive learning process whereas knowledge is reconstructed from what learners do in their experiential worlds [Akhras & Self 1996]. The learner is able to explore various paths in the learning process in an exploration environment and the system extends assistance as adapted to the learner’s degree of domain competence.

The system not only facilitates self learning by medical students and doctors but also enables knowledge sharing among doctors as it provides tools to add and document real cases within the system. These cases also become available in the system’s simulation environment for learner observation and exploration similar to the “master” solution for an apprentice in any cognitive apprenticeship system.

### 4. The Main Functional States of the InterSim System

The InterSim system provides learning according to the demands of the domain, for example, the ear domain requires a deep understanding of the structural and functional aspects so the learning strategies emphasise visual and spatial learning aids. Since the exploratory learning approaches (simulation based) are implemented in combination with the logical approaches (rule based path determination towards the solution), the learning in the InterSim system is based both on **learning by doing** and **learning from other's experiences**. The system can be set by a user into three main functional states:
1. The Learning State enables access to all the learning contents of the system and provides immediate (dynamic) feedback on user actions with a view to facilitate active learning.

2. The Assessment State is for testing a learner's learning and retention of the domain knowledge and skills. The system allows a learner to make mistakes and provides a delayed (static) feedback after the work is assessed.

   As [Routen 1992] observed, "There are advantages with both forms of student monitoring. Static feedback perhaps is less obtrusive ... while dynamic feedback prevents students from making gross errors and getting completely lost."

3. The Case Authoring State provides authoring facilities to doctors and teachers for adding real life cases to the system.

4.1 The Learning State

   The Learning State initially instructs the knowledge of the domain and progressively enhances a learner's competence in the application of that knowledge in working environment. Various multimedia techniques are used to enrich the learner-system interactions, for example, animations, simulations, hypertext links, sensitive image-maps etc.

   Although the learning process takes place in an integrated exploration environment, it is conceptually divided into four sub-processes within the system. The aim of the system is to make the distinction between these sub-processes as transparent as possible for a learner. The learning process is not assumed to be sequential in terms of these sub-processes and smooth transition to any sub-process is allowed from any point within the system, subject to a learner's state of domain competence. The four sub-processes are discussed below.

1. **Coarse grained instruction dominated learning**
   The learning activities are concerned with the basic knowledge of the subject matter and obtaining an overview of the domain, for example, structure and functionality of the ear, with the help of tutoring and guided tours. The system employs textual explanations, demonstrations and guided explorations for this type of learning.

2. **Fine grained knowledge construction**
   The learning activities target the domain at a detailed level to acquire an advanced understanding of specific areas. The system utilises intelligent interactive simulations to support this type of learning. For example, a learner learns about sound energy loss from outer ear to inner ear through interactive simulation of the energy loss occurring in air to fluid sound transfer, thus improving the understanding of the role played by ossicles in reduction of such losses.

3. **Cognitive skills development**
   The learning activities relate to acquisition of competence in the cognitive skills. These skills are acquired in a constructivist manner through training in a repetitive learning process. An example in the ear domain is the development of skills related to the diagnosis of ear diseases and prescribing appropriate treatments. However, the system design is currently limited to development of cognitive skills and excludes the development of physical skills which requires senso-motoric training.

4. **Application of the acquired knowledge and skills**
   The learning activities, based on cognitive apprenticeship, aim to identify and correct any misconceptions acquired or gaps left in earlier learning. The system presents different problems, including notoriously difficult cases recorded in the field, for the learner to attempt diagnosis and solution. The learner is able to evaluate the problem solving procedures employed and match the interaction strings with those of others such as a peer learner or an expert. The system also provides appropriate feedback and comments on the efficiency of the learner's approach to the problem resolution.

4.2 The Assessment State
In the Assessment State, the learner is presented with problems similar to those faced when applying the acquired knowledge and skills within the Learning State but have to solve them without any assistance from the system. On submission of the solution, the system assesses it in comparison with its master solution and provides static delayed feedback based on the deviations from the master solution. The learner is tested for acquisition and retention of the knowledge and skills and on achieving success at this state of learning, acquires confidence to apply them to real life situations.

4.3 The Case Authoring State

The system provides authoring facilities for doctors and teachers to add real life cases to the system. They can document the cases and share them with each other, thereby using the system as a means of communication and also to build up a repository of cases that might help in further research and developments. The system provides access to these cases for learning and assessment purposes as already discussed and the teachers can also employ the documented cases to provide case-based teaching away from the system, if so desired.

5. Intelligent Assistance and Dynamic Feedback

The system provides intelligent assistance at various stages of the learning process and adopts adaptive behaviour according to learner needs. The exploration-space-control methodology [Kashihara et al. 1997] is employed to facilitate a proper learning and assessment environment for all types of users. According to this methodology, the users within the Learning State of the system are able to use several dedicated interaction support tools through suitable graphical user interfaces to explore the learning space, thus reducing cognitive overload that normally accompanies a large exploration space. Within the Assessment State, the implementation of exploration space control assists in selecting suitable problems to match the individual user's level of learning. To facilitate quick analysis of the learners' performance and progress of learning, the system constructs individual learner models and based on user actions continuously updates them.

An important example of intelligent assistance using exploration space control is the concept of “main path” and “excursions” which the system employs within the Learning State. While interacting with the system, the learner would explore along a main learning path linking a sequence of learning units and the system provides intelligent support and guidance geared to the main path. Whenever the learner needs to deviate from that path to some loosely related units, the system allows such excursions but limits the span of the information resources presented in these excursions by tailoring them to make them relevant to the main learning path. The learner is able to remain in these excursions as long as necessary but the system maintains a subtle reminder for returning to the main learning path by always providing a return button. The learner can cancel a previous main path and convert the current path into the main learning path but this process needs explicit user intervention. The further exploration avenues in an excursion are not emphasised to ensure that the learner does not get distracted and lost in the hyperspace of excursions. For example, a learner, exploring the structure of the middle ear, would be able to get an excursion in “physics of sound” to understand how the sound travels through the mechanical linkage of ossicles but the information presented in “physics of sound” is tailored for better understanding of sound travel in the ossicles. On the other hand, the learner, whose main learning path may be concerned with the “physics of sound” is able to get the knowledge presented in a wider context. This is not to say that the information is inaccessible or hidden in the excursions, but system’s focus and presentation styles are different for “main path” and “excursions”.

The interactive messages provided by the system to the learners are also adapted to the situation and a learner’s current needs. There are two kinds of dynamic feedback messages provided by the system.

a) Handling messages are context adaptive navigational aids to the learners to help them identify various interactions available in the system. This is an important aspect since the learning in task oriented disciplines depends on learner’s interactions with the system and on the amount of useful exploration. For example, the learners may keep exploring the aspects which are not relevant to current learning theme, and hence may not benefit from the system as much as they would if the explorations were made in proper direction.
b) Learning messages are concerned with the subject domain and are driven by the learner interactions. The system infers the state of knowledge and competence from these interactions and evaluates against the defined learning criteria for particular units. Based on the learner model, the system also provides suitable recommendations for further explorations. For example, if the learner has studied the animation depicting the movements in the middle ear, the system updates the learner model to reflect completion of this activity and if the learner model indicates that the functionality of the ossicles has not yet been learnt, the system would recommend its learning at that point.

The intelligent assistance also helps the learners at the level of interaction with the system. In the Learning State, it provides a subtle strategy to widen the learning perspective. For example, in the healthy ear units, pictures of various parts of the ear contain sensitive image maps indicating various constituents. When the learner takes the mouse pointer over any sensitive region, the boundary of that constituent gets highlighted, and its name appears at the mouse pointer. If necessary, the system also provides a hint that more information can be obtained by clicking on that region. If the learner single clicks, a short descriptive message appears on the screen motivating the learner to explore a bit further and learn more about the constituent. On double-click of mouse by the learner, the system either transfers the learner to a detailed description of the constituent or recommends going to an intermediate learning unit which connects the learning of that constituent with the current learning unit. This strategy not only facilitates a gradual acquisition of concepts by the learners but also provides motivation for successive explorations. This implementation further helps the learners in the simulation based fine grained knowledge construction where learning is predominantly based on explorations.

6. The Cognitive Apprenticeship Emphasis of the System

The InterSim system employs various techniques in order to benefit from cognitive apprenticeship approach. A learner can learn the subject matter through observing various animations and textual explanations. The process facilitates development of learner’s own cognitive model of the domain. The learner can then try to imitate the observed processes with the help of simulations and interactive feedback and thus take the necessary corrective measures with the help of the system’s coaching. Once the domain’s knowledge is grasped, the learner can practice its application to various problems in a problem solving environment and the system gradually reduces its assistance with a view to build the learner’s confidence.

Various simulations are provided in the malfunctioning and disease related units of the system where the learners can observe, analyse and reflect on the normal and abnormal behaviour of the various parts of the ear by altering various environmental and disease related parameters [Fig. 1]. Learners can attempt to solve various problems presented by the system to practice the application of their knowledge and skills while the system evaluates their solution and provides feedback to rectify any misconceptions.

The cognitive apprenticeship approach has also been emphasised by allowing the teachers and expert doctors to document and add real life cases to the system. These cases let the learners observe real life problems and their resolution by experts just as an apprentice observes a “master” accomplishing tasks.

7. Conclusion

This paper described an implementation of a tutoring system for the medical domain with a major emphasis on interactive simulations. What differentiates this system from the currently existing systems is the intelligent assistance to the learners to facilitate interactive and dynamic support wherever required.

There are systems which provide exploration environments where a learners can explore the subject domain without any interruption by the system. These systems are usually based on a hypermedia approach where various simulations, textual explanations and other teaching aids are embedded within a hierarchical structure. There are also relatively passive systems which provide domain knowledge to the user in an environment where the interactive assistance is limited to navigational aids or search facilities. However, the literature does not indicate any serious attempts where intelligent assistance has been provided within a simulation based system for the learning of both domain knowledge and cognitive skills. The InterSim approach attempts to fill this gap and the tutoring system for the ear domain is an implementation of this approach. Besides intelligent
assistance, the InterSim approach adopts cognitive apprenticeship principles for attainment of competence in the cognitive skills, due to distinctive suitability of the cognitive apprenticeship approach in a task oriented discipline such as medicine.

Abstract: Since 1993, the Critical Thinking Cooperative (TC²) has initiated projects with school districts and universities throughout British Columbia, Canada. To date, the main emphasis has been on Social Studies with the exception of some recent work in language arts; however, no research has examined the application of this model to computers, specifically, CD-ROMs and children who experience problems with reading. This paper investigates this application of the model, concentrating on the intellectual tools (background knowledge; criteria for judgment; critical thinking vocabulary; thinking strategies; habits of mind), and discusses the author’s data with remedial readers as they work through CD-ROM adventure games.

Introduction

Critical thinking through technology has not been a major area of research in the last ten years nor has critical thinking been used extensively with struggling readers. This paper will examine the use of critical thinking through CD-ROMs to increase reading strategies in remedial and reluctant readers. First, I will outline the three major components of the critical thinking model adopted: (1) community of thinkers; (2) critical challenges; (3) intellectual tools, explaining how each forms an integral part of the model. Then, I will exemplify the five intellectual tools: (i) background knowledge; (ii) criteria for judgement; (iii) critical thinking vocabulary; (iv) thinking strategies; (v) habits of mind (see Figure 1). Next, I will demonstrate how this model and these tools can be applied to CD-ROMs in the area of Remedial Reading. Specifically, examples from a popular CD-ROM adventure game, *Indiana Jones and the Search for Atlantis*, will be shown and I will walk through each of the elements of the TC² model by modelling the questions asked of the reluctant or struggling reader. Special attention will be given to the interaction between the reader and the teacher so it is clear that the role of the teacher is, initially, the sage on the stage while the ultimate role of the teacher is to be the guide on the side to create an independent reader. The paper will end with a rationale of why this technique appears to be effective for this type of reader by presenting data from my on-going research and emphasizing the importance of having reluctant and remedial readers read small pieces of text over an extended period of time rather than having them read large reading passages and give up.
The TC² model [Bailin, Case, Coombs, & Daniels, 1993] has been used extensively in Social Studies [Case, Daniels, & Schwartz, [Eds], 1996] and recently, in Language Arts [Kitchenham, 1998, July], but to date, it has not been adopted in technology studies. The TC² model proposes that there are three components which will promote critical thinking in the classroom [Bailin, Case, Coombs, & Daniels, 1994]: (1) community of tools; (2) critical challenges; (3) intellectual tools. A community of thinkers is a classroom in which reflective inquiry is valued and that is driven by the premise that critical thinking is not the work of an individual but rather relies on other like-minded individuals [Vygotsky, 1987]. The critical challenges are the problematic situations set for the students to complete and are guided by four questions (Does the question or task require judgement?; Will the challenge be meaningful to students?; Does the challenge address key aspects of the subject matter?; Do students have the tools or can they reasonably acquire the tools needed to competently address the challenge?). These challenges appear to be based on an information processing model [Piaget, 1970]. The intellectual tools will be discussed in the next section, [Intellectual Tools].

**Intellectual Tools**

The intellectual tools component is a fundamental element of the TC² model of critical thinking. There are five intellectual tools: (1) Background knowledge is the information about a topic required for thoughtful reflection. (2) Criteria for judgement are those criteria or grounds for deciding which of the alternatives is the most sensible or appropriate for the critical challenge. (3) Critical thinking vocabulary is defined as the range of concepts and distinctions that are helpful when thinking critically. (4) Thinking strategies are the repertoire of strategies, heuristics,
organizing devices, and algorithms that may be useful when thinking through a critical thinking problem. (5) Habits of mind are the values and attitudes of a careful and conscientious thinker [McDiarmid, Manzo, & Musselle, 1996].

It needs to be stressed that the TC² model, in general, and the intellectual tools, in particular, are grounded in educational psychology theories and, therefore, are very reliable. Vygotsky’s zoped, or zone of proximal development, is prevalent in the model as the student is moved from his present ability level towards his potential ability level with the assistance of a more experienced reader and thinker [Vygotsky, 1987]. In addition, the notion of scaffolding thinker [Vygotsky, 1987] is built in the model since the student works through various levels of mastery and builds on his own background knowledge in an attempt to beat the computer. It is, without a doubt, an information processing model and finds support in the Piagetian notion of child development [Piaget, 1970]. Lastly, it is built on the idea of a taxonomy and includes many of the higher order thinking skills and concepts argued the pioneers of educational taxonomies [Anderson & Sosniak, 1994].

Application to CD-ROMs and Struggling Readers

This model, as applied to reluctant and remedial readers, is quite successful. The primary method of delivering the model to the student is through question and answer emphasizing the five intellectual tools required. Although it is not necessary to include all five tools when applying the model to competent readers, for struggling readers, it is far more advantageous if the teacher attempts to include each of the five intellectual tools.

Initially, the teacher discusses the background knowledge needed to understand the game. Specifically, the teacher and the student review (or teach) the characteristics of an adventure CD-ROM such as a quest to be performed by a main character, puzzles to be solved, decisions for which a strategy or tool would be required to master a particular level, and the need to remember codes to go back to starting points in the various levels of the game. In many cases, the reader is quite familiar with these characteristics but they need to be brought to the forefront so that the student remembers them throughout the game. For the more inattentive (e.g., ADD) or distractible students (e.g., ADHD), the qualities of a CD-ROM adventure game are displayed above or beside the computer monitor. In this way, the teacher can make several references to the characteristics as a memory cue or can point to them whenever the student does not remember them. Within the background knowledge concept would the notion that content and procedural knowledge would be transferred from one adventure game to another. In other words, if a student knew that scanning the rooms in the adventure games, Myst and Riven, meant finding necessary clues and artefacts in that game, then he may be more inclined to apply the strategies and knowledge to Indiana Jones and the Search for Atlantis.

In addition, the criteria for judgement are continually reviewed. For the most part, the student and teacher go through a series of five “generic” questions:

- Is my estimate accurate?
- Is the interpretation plausible?
- Are our sources reliable?
- Is the conclusion fair to all?
- Is my proposal feasible?

In the case of Indiana Jones and the Search for Atlantis, the student might consider whether Indiana Jones would need to take a “logic” route, a “fist” route, or a “team” route and estimate the pros and cons of each route. He may go through an inner-speech dialogue [Berk, 1992] weighing working with Sophia (“team”) versus fighting his way through the game (“fist”) and decide that working with another person would slow down Indiana Jones (i.e., plausible interpretation). The
reader might consider his sources very carefully by looking at a clue book, talking to other players, checking for websites, or considering his past performance in the game. The issue of fairness is quite clear in the "team" route as Indiana has to make many decisions which jeopardize both his and Sophia's lives so discussing the choice with the teacher before executing it is paramount and continuously emphasized throughout the session. Lastly, the student is asked to make predictions at virtually every screen and level of the game and to evaluate whether the proposed prediction is feasible. In Indiana Jones and the Search for Atlantis, he needs to decide in which order to perform certain tasks or which of the objects he possesses would be useful and how to use it in a logical or creative manner.

Throughout the sessions, the student is cognizant of any critical thinking vocabulary that may be used in the course of the game. For example, in the "fist" route, the student may notice through "direct observation" that he should hit the soldier first and continuously or Indiana will tire while his "inference" may be that the more times he gets in a fight without a rest, the faster Indiana will "die" and the game will be over. Other key vocabulary would include "logic," "informed decision," "generalization/overgeneralization," "educated guess," "extrapolate," and "cooperate."

In addition, the thinking strategies needed to master the game, such as decision making models, information organization, and role taking, are either modelled by the teacher or discussed between the teacher and the student. Clearly, in Indiana Jones and the Search for Atlantis, decision making models are a constant. As stated earlier, the player has to decide which of the three routes to take which, in turn, dictates various paths and levels already programmed into the game; which tools to use in which order; whom can he trust and who is an enemy; which responses in which order will get the answer to a puzzle; which response to a friend or enemy will result in success or failure; and the list goes on. When Indiana is in the maze, an information organizer such as drawing a rough sketch of which rooms contain certain machines or artifacts is extremely helpful in remembering how to get out of the rooms without running into soldiers. And role taking is also an excellent thinking strategy for this CD-ROM. Whenever Indiana has to make a major decision, the teacher encourages the student to put himself in Indiana's shoes and to think through what may happen or what Indiana may be feeling which may, in turn, affect how he will react. In short, the student tends to use higher order thinking skills [Anderson & Sosniak, 1994] and hypothetical reasoning [Piaget, 1970].

Lastly, there are the four habits of mind: (1) open-minded; (2) fair-minded; (3) independent-minded; (4) inquiring attitude. Throughout this game, the student is encouraged to pursue his own hypotheses for what might happen based on a choice he makes (e.g., leaving Sophia by herself, knowing that she could be kidnapped); however, he is also expected to consider evidence which refutes his hypothesis and to make a new hypothesis, using the new evidence (i.e., open-minded). Often, the teacher will pose an alternative point of view to the student (e.g., Sophia may be able to help Indiana work out how to get the knife from the knife-thrower in Algiers), expecting that the student will argue or accept the new view, temporarily (i.e., fair-minded). In this challenge, the student sometimes will not accept the new hypothesis (i.e., independent-minded); however, he must always supply concrete evidence for why he is standing behind his view (e.g., last time, Indiana was trapped when he went into the machine room). Consistently, the reader must question his own claims (i.e., inquiring attitude) and be willing to seek justification, when needed (e.g., taking a balloon versus the camel to cross the desert).

Rationale

Now, to why this technique seems to be effective for the struggling reader. Based on my
on-going research, there are three salient reasons this technique is so successful: (1) the reading material; (2) the familiarity of the genre; (3) the series of mini-successes which build to the major goal.

Based on my ten years of working with struggling readers, I feel confident in saying that most reluctant and remedial readers do not like to read for long periods of time. When they do read, it is usually material which is pleasurable for them and chosen by them. The reading material in *Indiana Jones and the Search for Atlantis* is between the grade three and grade seven reading levels (based on a modified Fry readability formula), but more importantly, the passages are quite short so that the struggling---either reluctant or remedial---reader believes that he is receiving manageable sections of text. In fact, the student reads about 10 to 12 words in each line of dialogue so with four lines of dialogue, the student reads approximately 2000 words over a thirty-minute period. In addition, much of the dialogue has an immediate payoff so that the reader knows that he will be moving on in the game whereas in many books and short passages, the reader has to wait a long time to see the evidence of his hard work of slogging through the text. The familiarity of the Indiana Jones movies and videos also adds to the overall understanding. Lastly, the reader tends to feel empowered as he is making many of the decisions in reading even though the teacher has both direct and indirect input.

Many children are familiar with the genre of CD-ROM adventure games and therefore, the teacher is beginning with a framework with which students are already comfortable. In my private practice, I have discovered that over 90 percent of the struggling readers know that the CD-ROM adventure game frequently involves a quest, it has some form of puzzles, and that the player must always be ready for surprises—not to mention, remembering to save the game a lot! My latest observations of children working with the next generation of *Myst*, indicates that *Riven* may be even more successful based on the child's familiarity with *Myst*. Lastly, the remedial and reluctant reader knows that good will overpower evil as long as he knows how to get there.

Adventure games are based on a building-blocks, or scaffolding [Beyer, 1997] concept. As the player learns more strategies, acquires more tools, codes, or artifacts, and learns from his mistakes, the pace of the game increases but also, the level of the game increases. That is, the game allows the player to receive a series of successes which enables him to move toward the end goal [Vygotsky, 1987] of winning the game and “beating the computer.” For a struggling reader, seeing tangible evidence of these victories in the form of moving through a level faster the second or tenth time or knowing that a particular response will cause the villain to react in a certain manner is absolutely crucial.

**Conclusion**

In sum, the TC² model, using popular CD-ROM games, clearly increases the reading strategies of remedial and reluctant readers. Paramount is the confidence these readers have after several hours of working with the genre. There are other strategies. The remedial student understands the importance of anticipation and prediction which are major elements of the reading process; he increases his sight vocabulary and has many words reinforced throughout the game; he learns the importance of metacognitive (inner) dialogues. The reluctant reader tends to become a risk-taker and will attempt to sound out or guess at unfamiliar words; he will read voluntarily even if it is only for a slightly longer time; he often makes predictions based on previous passages or prior knowledge. Both the remedial and reluctant reader also learn about the importance of sources for clarification. Thus far, this model and the use of CD-ROM adventure games has proven to be more successful than any technique I have used in the past.

Abstract: This paper discusses courseware authoring for CALAT, a Web-based intelligent CAI system, mainly from the standpoints of courseware design support. CALAT has the ability to adapt to individual learners, dynamically selecting the material to be presented based on each learner's comprehension and other parameters. Most of conventional adaptive intelligent CAI systems required spending a much time and having know-how for courseware authoring, making it difficult for specialists in the field of learning to create courseware. In our system, a design method based on courseware knowledge structured around learning goals and a scenario was introduced to overcome these problems. This paper describes the authoring tool for creating this courseware knowledge in the design step, providing 1) visual editing for courseware knowledge, 2) spiral-type designing support, 3) automatic generation of courseware. An experiment in which subjects used the prototype authoring tool to create courseware, showed that the spiral work flow consists of a few different types of circle and the tool is working effectively in the courseware design process.

1. Introduction

The use of computers as learning support systems goes back many years to the days of drill-based systems that were little more than page-turning machines. In time these developed into intelligent CAI systems, able to adjust their contents to individual learners based on comprehension success and other learner-specific factors. The research devoted to intelligent CAI systems, however, has traditionally focused on obtaining a detailed model of student characteristics and developing teaching strategies accurately pegged to this model [Wenger 1987]. Creating courseware for these systems requires nearly the same degree of effort and know-how as for system development. By no means is courseware authoring something that can be performed easily by instructors whose specialty is in the particular field of learning rather than programming. Recently some authoring systems are trying to make it easier to create courseware for intelligent CAI [Brusilovsky 1996][Murray 1997].

In the field of software engineering technology, meanwhile, the integrated development tools, which cover all development stages such as the analysis, design, implementation and make possible to build software in spiral-type, has lately attracted considerable attention. It is reported that the trusty software can be developed rapidly, making prototype repeatedly. There are few tools supporting spiral-type design in the field of courseware creation because the importance of the methods might not be recognized yet.

We have been developing CALAT, a Web-based intelligent CAI system [Nakabayashi 1995]. The aim of CALAT is achieving both a high degree of adaptation to individual learners and a courseware authoring system that can be used readily by specialists in the courseware field even without system or programming skills. The basic idea is integration of both the ease of courseware creation in frame-based CAI and the capability of adaptive behavior in intelligent CAI. The frames, that is, are presented to the learners like frame-based CAI, inferring from the courseware knowledge attached to each frames in order to achieve the individual adaptation. The visual authoring tool for creating the courseware knowledge provides the functions for not only data entry but also courseware design, supporting spiral-type design methods for rapid courseware development.

In the following sections we give a brief introduction to CALAT and explanation of the courseware structure. We then present an authoring tool for supporting the courseware design step and describe its evaluation in actual courseware creation.

2. Courseware Structure

2.1 Outline of CALAT System

CALAT (Computer Aided Learning and Authoring environment for Tele-education) is a client-server type distributed intelligent learning system using the World-Wide Web, which provides intelligent CAI services.
Students using a Web browser such as Netscape Navigator or Microsoft Internet Explorer simply access the CALAT server. By presenting their own ID, they can enjoy the CAI services from anywhere in the world, at any time. All the courseware is located on the server. While the student is on line, the server monitors "Next screen" requests and exercise results, determines the next material to be presented, and sends the screen images and audio information to the student terminal. The learner's comprehension is measured based on practice exercises, and on this basis the system selects and orders the materials presented to each learner. A learner who is relatively slow to comprehend is therefore given detailed, repeated instruction and practice, with remedial lessons as needed, whereas a learner who is quick to grasp the contents is moved along at a more efficient pace.

This system is configured of courseware knowledge, which is the systematic knowledge in the particular field of learning, teaching strategy knowledge relating to how instructors impart learning, and student information keeping track of each learner's comprehension of the material and other learner-specific factors. Of these, the courseware author need be concerned only with courseware knowledge; the others are provided in the system itself as generalized knowledge not dependent on the courseware contents. Input by learners is passed to the teaching strategy part, where teaching strategy inference is carried out based on the courseware knowledge and student information, and the material to be presented to the learner is decided. The student information itself is continuously updated by the teaching strategy part so that the latest learning status is always reflected.

2. Courseware knowledge

Courseware knowledge consists of the multimedia materials (expression layer) presented as courseware "scenes" to the learner, and courseware structure knowledge describing the logical structure of the courseware itself (logical layer). The latter knowledge is essential information making up intelligent CAI courseware. The expression layer and logical layer are of course different in representation, but ideally they should describe the same contents. In reality, however, the logical layer descriptions tend to be highly complex, imposing too great a burden on most courseware authors. An important requirement in courseware authoring is to realize a high level of teaching effectiveness while defining courseware structural knowledge that allows for ready implementation. Our system describes the courseware structural knowledge as follows [Fukuhara 1995].

1) Learning goals: The learning goals list the knowledge to be taught to students, in specific statements such as "be able to do x" or "understand what y is." This is also called "what" knowledge. Once the courseware subject is determined, the list of learning goals should be practically the same regardless of the courseware author.

2) Scenario: The scenario defines the courseware story (what will be taught in what sequence). It corresponds to the chapter and page arrangement of a book. This is also called "how" knowledge, and will likely be different for each courseware author even if the field is the same. In our system, chapter and page of book is called "Section" and "Element", respectively.

3) Relational information mapping the scenario to the learning goals: This information defines the correspondence between the learning goals and the scenario sections and elements. Since one element may teach two or more learning goals and one learning goal may correspond to two or more elements (taught in different ways), the two have a many-to-many correspondence. A relationship is likewise defined between each of the questions asked in a practice exercise and the learning goals they cover.

4) Relational information mapping the scenario to multimedia materials: Defined here is the screen information presented to students on each element of the scenario. In CALAT the relation to screen information is designated as a URL (Uniform Resource Locator), so potentially any multimedia information available on the Internet could be designated [Maruyama 1996].

In the process of conveying knowledge (for example, when writing up a plan or a report, or writing a book), the above systematization of knowledge into learning goals and a scenario occurs quite naturally. In many cases the learning goals may not be laid out explicitly, but we can always expect them to exist in the thought process. This kind of courseware structural knowledge is both natural and clear-cut, so it enables an individually adaptive learning environment to be provided with little burden on the courseware author.

3. Courseware Authoring Tool

3.1 Courseware creation procedure

When courseware is created for CALAT, there are four main steps: (1) courseware planning, (2) courseware design, (3) data entry (multimedia materials preparation), and (4) evaluation.

1) Courseware planning

Determine the intended users of the courseware to be created and the primary learning goals.

2) Courseware design

Carry out the following steps in order. Of these, 2-2) and 2-4) may be carried out in parallel.
2-0) Gathering information: Obtain and study information on the courseware field.
2-1) Organizing the learning goals: Make a list of things to be taught (learning goals).
2-2) Designing the scenario: Decide the courseware story (sequence in which the learning goals are to be presented; the chapter-section arrangement) and then make the relation between the scenario and learning goals.
2-3) Creating exercises: Make exercise problems for each learning goal, and define their relation to the learning goals.
2-4) Making drafts of the multimedia materials: Create a rough sketch of the scenes to be presented to students, and define the relation between scenes and the scenario.
2-5) Testing: Check the courseware data to make sure it is complete and consistent.

3) Data Entry (Multimedia materials preparation)
Create the scenes presented to students using tools for each of the media used. Note that materials created by others can be reused by pointing to information resources elsewhere on the Internet as URL.

4) Evaluation
Evaluate the courseware by prospective users and also check it not to have wrong descriptions by expert in the field of learning.
In the following section, we mainly describe the support functions for courseware design step.

3.2 Tool for Courseware knowledge design
With the original authoring system used for CALAT, all courseware design is done on paper. The courseware author, following the procedures outlined above, organizes in table format the courseware knowledge consisting of learning goals, scenario, practice exercises, and the correspondence between learning goals and scenario, etc. Only after this work is completed and found to be free of any inconsistencies is the design information entered in the authoring system, using table-based editors. This approach, however, has certain drawbacks.

a) At the design stage the courseware author has to go through a repeated process of trial and error to refine and develop the courseware knowledge. For example, arranging the learning goals and scenario involves repeated breaking down and grouping in order to achieve the desired results, yet the process of refining the courseware knowledge during the design stage is not given any support functions.
b) Since system entry takes place only after the design is completed, the courseware operation cannot be checked until the final stage of authoring. In other words, the steps of design, entry and evaluation proceed sequentially in a so-called waterfall development style, making it difficult for the courseware author, let alone others, to get a good grasp of the overall courseware image at an early stage.

We therefore implemented the following two courseware design support functions to alleviate these difficulties [Kiyama 1997].

3.3 Design information editing tool
The courseware design tool is highly visual and fully integrated. The tool, as shown in [Fig. 1], consists of an
outlining function (left part of the screen) and detail design function (right part). The outliner shows the learning goals (lower part) and scenario hierarchy (upper part), while the detail design function displays the detailed attributes of each learning goal and scenario division (upper part) and scene draft (lower part). The outliner enables the moving of any part up or down the hierarchy or to any place, insertion and deletion, the making items void temporary and so on. It is therefore useful for refining the learning goals and scenario by changing the breakdown and grouping as necessary. The detail design function already has default values set for each of the attributes, making it possible at the initial design stage to create working courseware simply by editing with the outliner, without having to make any other entries. Data entry for attributes can be made as the design work proceeds and details become fleshed out. In this way a spiral-type RCD (Rapid Courseware Development) design approach is realized, enabling courseware operation to be checked as soon as the basic and essential information has been entered, followed by a gradual refining and improving of the quality. In addition, the knowledge mapping (relating learning goals to scenario and relating scenario to multimedia materials) is carried out visually, with the scene draft shown and edited in the same window as the scenario attributes.

3.4 Automatic generation of courseware knowledge

Even with the courseware design tool, there is still a large amount of information to be created, compared to a traditional Frame-based CAI system. Automatic generation of courseware knowledge is another possible way of advancing RCD. Here automatic generation means creating courseware knowledge based on other existing courseware knowledge, for example, generating a scenario from the learning goals. The results of the automatic generation process do not have to be perfect; it is assumed that the courseware author will make corrections and adjustments as necessary.

We indicated a courseware design procedure that starts by listing learning goals and then creating a scenario. That, however, is simply a typical approach. Observing the actual courseware authoring tasks, we can see that there are three possible cases described below. The automatic generation input and output are different for each case.

[Case 1]: A specialist in a given field creates the courseware from scratch.
The courseware author should be able to list the learning goals easily, but in many cases will find the task of making a scenario difficult or troublesome. In this case support can be given for generating the hierarchical scenario structure from the learning goal structures. The relation between learning goals and scenario sections is 1-to-1 simply.

[Case 2]: Courseware is created based on textbooks and reference works.
The author can make use of the existing table of contents and organization for the scenario, but may need help drawing up learning goals and mapping them to the scenario. Here support is given for automatic generation of learning goal structures from the scenario layers. The relation between learning goals and scenario sections is 1-to-1 simply.

[Case 3]: Courseware is created based on actual test problems.
The author can readily prepare exercise information, but the problem will be organizing the courseware sections corresponding to the exercises, creating explanations and other parts of the scenario, and mapping learning goals to the scenario. Support functions will take the form of automatic generation of the scenario organization from the test problem configuration, and generation of information mapping scenario explanation pages to learning goals based on the learning goals of the answers and problems. Each question may be categorized in a few groups.

Obviously, courseware generated in these ways will not be very good courseware. These functions can, however, serve the purpose of providing the courseware author with an initial design proposal as part of a spiral design process.

4. Evaluation

4.1 Experimental approach

The authoring tool has a function for saving the operation log as a file. The subjects were asked to use the tool in actual courseware authoring, then the recorded logs were analyzed.

The environmental issue of "acid rain" was assigned as the courseware topic. The subjects first received a brief (approximately one hour) explanation of the courseware creation procedures as described preceding chapter, and of the authoring tool operations. Then they were given another hour to practice with the tool in order to master its use. After they had learned how to work with the tool, they were handed a 12-page textbook on acid rain and asked to be creating courseware. Their task was limited to the courseware design steps, including scene draft creation, and did not cover multimedia material creation. The finished courseware consisted of from 20 to 30 scenes, equivalent to about one hour of courseware when filled out with narrations.
and the like. Three subjects were involved in the experiment, consisting of one (A) with no courseware authoring experience, one (B) with experience both in courseware authoring and with the use of the tool, and one (C) with courseware authoring experience but no experience with the tool.

4.2 Results and analysis

[Fig. 5] reconstructs the courseware design steps based on a subject's log information. The lateral axis shows the number of operations (elapsed time), while the vertical axis shows the individual processes (sub-processes) within the overall design process. These sub-processes consist of (1) setting learning goals, (2) making a scenario (sections), (3) making the scenario elements, (4) making exercise elements, (5) mapping the scenario to the learning goals, (6) creating scene drafts, and (7) testing the courseware.

In each of the subject's logs a spiral design pattern is to be discerned, by which they move back and forth among the sub-processes. The spiral consists of larger cycles and smaller loops within the cycles. A large cycle runs from the start of courseware authoring or revision to the completion of testing. In the case of subject A, in cycle C1 a courseware prototype was created, and in cycles C2 and C3 the courseware was revised to improve its quality. The scale of C1 is rather large (around 800 operations), whereas cycles C2 and C3 were only about 300 operations each. The smaller loops within the cycles consist of efforts to acquire, organize and refine the knowledge in repeated trial and error. For example, for subject A, cycle C1 consists of four small loops, L1 through L4, of around 100 to 300 operations each.

(L1) Learning goals → Scenario (sections) →
(L2) Learning goals → Scenario (sections, elements) →
(L3) Mapping scenario to learning goals → Learning Goals → Scenario → Scene draft
(L4) All sub-processes

When asked about the process of courseware authoring, subject A explained the approach as one of first
deciding the broad outline of the scenario based on the most important learning targets (L1), then coming up with other related targets to make a more detailed scenario (L2), further refining (adding and revising) the learning targets in the process of mapping the targets to the scenario (L3), and finally shaping the courseware by changing the presentation sequence, etc., in order to make it easier to follow (L4).

In the process of designing courseware, moving back and forth among sub-processes is a highly natural approach. The experiment showed that a spiral work flow is applied also when using this tool. This is one indication that the tool is working effectively in the courseware design process.

Subject (B), who had previous experience with the tool, exhibited an absence of wasted operations, with fewer overall operations and a lack of meaningless transitions between processes. Yet the number of cycles and loops differed little from subject A, a rank beginner (3 small loops and 3 cycles). This suggests that the tool can be useful regardless of whether the user is experienced or not.

Subject (C) took a different approach from the others, starting not from learning targets but from the scenario writing step, then listing the learning targets. The sequence of sub-processes may well differ depending on the author and the subject matter; but this tool lends itself naturally to a diversity of courseware authoring approaches, making it possible to start from any desired point.

An analysis was also made of the courseware refinement process. This tool supports a trial-and-error approach to designing courseware, with operations for changing and moving the learning targets and scenario sections or elements, for grouping elements or breaking them down, and so on. [Tab. 1] shows the number of times refinement operations were used and their percentage of the total operations (subject A). Apart from L4, L3 was highest in number of operations (54) and percentage (16%). The reason for this result is likely that the initial design stages (L1, etc.) are used mainly to extract knowledge and do not require very many refinement operations, whereas the subsequent stages involve more trial and error. The percentage of refinement operations in L4 was the highest at 57%, but these were used for shaping the courseware and are not to be considered pure trial and error.

5. Conclusion

An intelligent CAI system using the World-Wide Web is attracting attention as a system that makes possible individually adaptive learning at any time or place. A conventional intelligent CAI system, however, requires a similar degree of effort and know-how for courseware authoring as for system development, and does not enable courseware authoring to be carried out practically by instructors or other experts in the field of learning. The authoring methods described here makes use of a courseware knowledge structure consisting of learning goals and scenario, and enables courseware with a high level of individual adaptation to be created readily by specialists in the courseware fields. For efficient courseware creation, we have proposed a visual authoring tool for supporting courseware design step in which the spiral-type design and knowledge refinement operations are required. Analyzed the design process when using this tool, it was found that spiral work flow consists of 3 circles and 3 or 4 smaller loops for one hours of courseware. Issues for the future include devising ways of reusing existing courseware and resources on the Internet, and creating a framework for courseware evolution.

Using a modular construction kit for the realization of an interactive Computer Graphics course

Abstract: In [Klein & Hanisch 1997] we described the concept and realization of an interactive computer graphics course combining lectures, example applets, programming exercises, documentation etc. within a common sophisticated web-based framework. This course allowed for adequate teaching of topics that require both, visualization and interaction. Although it greatly simplifies teaching and learning of the various contents extending the course is still difficult for several reasons: the restricted reusability of its programmed components, the complexity of the particular applets, the complicated low-level programming of the applets and various inhomogeneous API's.

Recently, new platform independent software component models like JavaBeans appeared that allow to write reusable components and compose them in a visual builder tool into new applications. In this paper we describe how we used such models to transform the existing course into a modular construction kit consisting of components of teaching text and program classes. The program classes consists of Java Beans which can be composed together into an application using a Visual builder Tool.

Although the components are used for the generation of a computer graphics course they are much more general and might also be used for the generation of other extendable and interactive Web-based courses.

1 Introduction

Visualization and interaction are the major topics of current computer graphics. Teaching this issues using only traditional teaching methodologies and tools, such as blackboards, slides, and even videos cannot provide real-life examples. Only in real-life settings teaching can react flexible on the different questions occurring during the discussion of a certain subject and as in physical research, computer graphics problems and challenges can only be recognized through the exploration in experimental setups [Owen 1994]. In computer graphics such experiments consist of interactive programs which allow to manipulate parameters and animate and visualize complicated algorithms. Working with such a program not only helps to illustrate problems but also to motivate students. Furthermore, providing the student with these programs enables him to repeat the experiments, to build up his own settings and to deepen certain aspects. This greatly improves the consolidation of lectures at home. As a major goal of the exercises the student should learn to implement the graphics algorithms dealt with lecture [Naiman 1996].

In the meantime the World Wide Web (WWW) together with embedded Java programs (applets) and Hypertext provides an appropriate framework to generate common interfaces for the integration of all elements of interactive teaching courses, such as lectures, programs, exercises, and consolidating literature references and there is already a number of computer graphics courses [Calgary/CS 1994, Owen 1995, Cornell/TC 1996, Shabo et al. 1996, Klein & Encarnação 1997] that benefit from these techniques including our own web-based interactive computer graphics courses "Computer Graphik spielend lernen I & II" [WSI/GRIS 1996/97].

Although our course greatly simplifies the teaching and the learning of computer graphics topics, extending the course is still difficult for several reasons: the restricted reusability of its programmed components, the complexity of the particular applets, the complicated low-level programming of the applets and various inhomogeneous API's. Recently, new platform independent software component models like JavaBeans appeared that allow to write reusable components and compose them in a visual builder tool into new applications. In this paper we describe how we transformed the existing course into a modular construction kit. This kit contains on one hand tools to integrate components of teaching text into one Hypertext document containing links to corresponding Java-applets and vice versa, and on the other hand it contains software components that can be composed together into demonstration application by teachers and students. A similar approach was chosen by Wernert [Wernert 1997].
He describes a unified environment for presenting, developing and analyzing graphics algorithm based upon IRIS Explorer, a modular visualization environment which provides a visual data flow language and allows user to link computational modules in order to create visualizations. A further similar approach is described in [Land 1994]. This nice system allows high level programming (network wiring) to analysis problems to more traditional coding of new modules. But there are also some drawbacks. First of all IRIS Explorer is not platform independent and only available on high-end PCs and SGI-workstations. Second the application cannot be interlinked with a WEB-based environment like our own course. For students even more interesting are the financial costs of a commercial system like IRIS Explorer, AVS or IBM Data Explorer.

The rest of the paper is organized as follows: in section 2 we first give an overview over the existing courses. In section 3 we discuss the challenges we were faced with extending and improving the course. The section 4 of the paper describes the construction kit and the software architecture that we used to meet that challenges. This section includes the component based programming environment (JavaBeans) and the compilation tools developed to integrate the different parts of the course as well as examples how to generate an applet using existing building components. We conclude with section 5.

2 The Course

2.1 Contents

The course contains the following topics: Computer graphics hardware, raster algorithms with aliasing and anti-aliasing, 3D-transformations, visibility, color, local illumination schemes, modeling techniques, simple animation, texture mapping, global illumination techniques (ray-tracing, radiosity), and volume visualization, distributed into two courses. Both are based on, or related to, the books [Encarnação et al. 1996a, Encarnação et al. 1996b] and corresponding written for the Fernuniversität (Correspondence University) in Hagen, Germany.

2.2 Structure

A hypertext page [WSI/GRIS 1996/97] provides an unified interface to our Web-based computer graphics course. Starting at this page one can follow links to hypertext pages containing or referring to:

1. the instruction manual and editorial of the course itself,
2. the course text (script),
3. an index of all available applets and the application interface (API),
4. the programming exercises and
5. links to external documentations and sources.

The instruction manual first gives a short introduction to the course, hints for private studies and provides a list of symbols used throughout the course. In addition it gives a short overview over the design of the course, the programming architecture, the file structures and last not least it reports known bugs, such as the different behavior of certain applets on different browsers. This list of known bugs and comments can be extended by the user. The external links provide the student with tutorials e.g. for HTML and Java, public domain software, other Web-based courses and further useful stuff.

2.2.1 Course text, applets and API

The whole course text is available as hypertext and is presented in an own browser window. The contents and structure of the hypertext is the same as the one of the original course text. The hypertext contains not only cross references to figures, tables, literature, exercises and footnotes but also links to corresponding applets, to the API and a number of videos and slides that were shown during the lectures. If the user follows a link to an applet or a video, it is started in another browser window. Vice versa the hypertext pages containing the applets also provides links into the course text. In such a way the user working with an applet can immediately get the corresponding theoretical background. In addition, to each applet there is a fourfold kind of documentation made available: An introduction, details on its features, a guided tour covering its essential topics, and general information on its programming architecture. The latter one also contains links to the API. Since the classes of the API also provide hyperlinks to applets that demonstrates their usage in real examples and hyperlinks to the course text (like e.g. Camera), the course text, the applets, their documentation and the API are fully interconnected. Note that all these elements are shown simultaneously in their own browser windows (cf. Fig. 1).
2.2.2 Programming exercises

In the programming exercises the students complete the code of a given Java-applet. The Java source code of the environment is available as a hyperlink and can be downloaded by the students. A comprehensive written instruction is available for each exercise in the form of hypertext pages. In order to read it the students need to use a Web-browser, such as Netscape Navigator TM or Microsoft Internet Explorer TM. Since one of the aims of our course is to make the students familiar with graphics programming, it is important to provide them with sample programs to work with. Therefore, in addition to the instruction for each exercise a small programming example is provided. Since all these components of the course are integrated into a common interface, permanent switching between the theoretical background information, the description of the exercises, and the source code of the latter is possible and greatly supports the students during the completion of their programming tasks.

2.3 Course Summary

The described course environment increases the learning success of students through a common interface integrating lectures, programs, programming exercises, user support, and related literature references, thus optimizing the coordination among these basic parts of a course. It realizes a graphical system that contains all the basic functionality that modern 3D graphics system share, yet staying simple enough so that the basic concepts and mechanisms can still be easily understood by the students. It enables students to deepen the different contents of the lecture and explore the different algorithms.

The course provides different approaches: either to start with the theory using the script and to complete it with examples and programs or to start and motivate with examples and then take a closer look on the theoretical background. Its object-oriented design and implementation provides a simple and modern programming concept. Furthermore, the use of Java as programming language assures platform-independence.

Using our course teachers and students are enabled to theoretically and practically prepare, catch up on, and deepen the lectured course. There is no need to provide for and install a variety of software packages to be able to run the practical examples at home. Moreover, interested students are able to extend the examples.
3 Extending and modifying the course: The Challenges

3.1 Connection between course text and the applets

The current course contains about 70 highly sophisticated applets covering all topics of our graphic course. A drawback of the current situation is that a single applet provides too much functionality. For example, the applets on BSpline-Curves contains the BSpline curves itself, the BSpline basis-functions and the knot-vectors. Reading the part about BSpline-basis functions and invoking the corresponding link the student get the whole applet. Instead of being focused to the basis functions the student is distracted by that functionality of the applet which is irrelevant in the current context. To get more focused references, also the small components of our applets must be provided as autonomous applications.

On the other hand extending the framework of a course the teacher should be able to use already existing components to generate new applets in an easy and fast manner.

3.2 Generating new applets

The strict object oriented design of our Java-applets simplifies the programming of new applets and classes. Many of the existing classes can be reused and extended. Nevertheless, to generate new applets still requires low-level programming. Students or teachers not familiar with the existing classes have to wade one’s way through the jungle of hierarchical APIs, instead of concentrating on the structure and concepts of the algorithms. As already shown by a number of authors visual programming greatly aids in developing and debugging code [Wernert 1997, Lotufo & Jordan 1994].

3.3 The programming exercises

Since the low-level programming is too time consuming without visual programming our students only complete already existing applets. The drawback of this kind of programming exercises is, that most of the students are not able to understand the overall structure of the program. Although they successfully implement the missing parts there remains a bad feeling. Again, this problems can be solved using a visual application builder in combination with low level programming and studies of existing code.

4 The construction kit

4.1 The hypertext

The ingredients for the hypertext were the course text as Latex source with images, the applets and the exercises. In the first step we manually created an applet resource file containing all information necessary to automatically generate all hypertext environment of an applet. This includes the applets' documentation and keywords used to generate hyperlinks into the course text. The actual pages containing all HTML-tags for the applet (header, hyperlinks to the documentation or course text and applet parameters) are then automatically generated by a Perl script. This guarantees an easy-to-modify and unified outlook of all applets and saves an immense amount of time in the design of these pages.

Subsequently those applet resource files are used by a further Perl-script to automatically generate an index of all applets. Aside from hyperlinks to the applets this index page contains their titles, introductions and motivating images.

In an independent step the original Latex source was modified. As a first step links to the different applets are placed into the course text. As a second step anchor points named by the headers of sections and subsections of the course text were automatically inserted. This anchor points are later on referred by hyperlinks of the corresponding applet pages. The names of the anchor points are copied into the corresponding applet resource files. After these two steps we used the program LaTeX2HTML [Drakos 94] to convert the course text into an HTML format, which still contains the unprocessed anchor tags. These tags are processed in a further step by an additional Perl-script which generates the special course text structure developed for our course. This structure allow for folding and unfolding the hierarchy of the chapters. For each text page on the lowest level of the hierarchy automatically links to the previous and next text page as well as links to all predecessors in the hierarchy.

4.2 The applets

In the realization we put special emphasis to a common, easy-to-use interface of the applets. This is especially necessary as the whole course contain a variety of different topics and the functionality of the applets differs greatly. Some of the techniques we use are same colors for the same context, same outlook of labels and control elements with identical meaning and same mouse control. Very important for the design of the applets for teaching
purposes is a clear structuring of the visible information. At a first glance the student must be able to recognize
the topic of the applet, the key elements of the teaching content and the connectivity between them. Therefore, the
visual part of the applet containing these information must attract his attention more than special control elements
to steer certain parameters. Otherwise, the applet would overwhelm the student by a forest of equivalent choices.

4.3 The Beans

As stated in its specification [Hamilton 1997] a JavaBean is a reusable software component that can be manipulated
visually in a builder tool. The components can either be an object with or without graphical interface. Typical beans
in our course are

- interface components that extend the standard Java AWT.
- mathematical and geometrical utility components like vectors, matrices, triangles, spheres etc.
- 2D- and 3D canvases also extending the standard Java components.
- 2D- and 3D scene graph for high-level graphics primitives and scene descriptions
- already programmed 'high-level' beans like image filters, function parsers, editable curves, etc.

Due to the strict object-oriented design of the Java classes used in our course, their conversion into Java beans was
straight forward.

4.3.1 Examples

![Figure 2: Left: Building a simple applet demonstrating black white image filter in the Bean Box. Unfortunately,
the current version of the BeanBox does not display the already established links between the components. Right:
Composing three beans into a new applet demonstrating Bézier Curves together with affin combinations and Bern-
stein polynomials.]

Like in a visual data-flow language beans can be visually composed into new customized applets. The left side
of Figure 2 shows the generation of a simple applet that demonstrates the conversion of a gray-value image to a
black-white image. The user can define the threshold value. To generate the applet the image loader, two image
beans for input and output image, the value panel and the black-white filter are loaded into the application builder.
In this example the data-flow is defined by so called property changed events. The property changed event of the
original picture (invoked by loading it) is propagated to the black-white filter that expects a reference to the input
image and resolves an property changed event with an reference to the output image. Last but not least the property
changed event of the value panel changes propagates the threshold value to the black-white filter and invokes it.
After designing the applet in the application builder it can be compiled into a new applet.

The right side of Figure 2 shows the construction of a more complex applet demonstrating Bézier curves. Its
main building blocks are three simpler beans, one realizing affin combinations between two points in 2D, one
bean displaying the Bernstein polynomials, and one bean containing the Bézier curve itself. Each bean already
implements all basic interaction to manipulate their contents. Several interface components link the beans together.
In such a way the functionality of data-flow languages are available to build up new Java applications. Using this
paradigm teachers and students can easily develop their own new beans and integrate them into the course using
already existing components. Nevertheless, there are still cases like the implementation of new filters in which new beans must be implemented in the traditional way.

4.3.2 Discussion of design problems

One of the design problems of data-flow languages is how to manage the complexity of program networks. In our approach this problem can in most cases easily be solved by grouping several beans into new ones and customizing their appearance within the builder tool. We made use of these techniques throughout the whole course. The problem of propagating data through the network that is inherent to most other systems based on the data-flow concept does not occur, since different modules may share the same data in memory.

5 Conclusions

In this paper we briefly describe our WEB-based computer graphics course. This course contains various Java-applets allowing the students to explore different topics in computer graphics. We presented a new approach based on JavaBeans to design new applets using existing components in a visual builder tool. These high-level approach is of advantage for both, the teachers extending the course and students in doing their programming exercises. Due to the strict object oriented design of the Java classes used in our course, their conversion into Java beans was straight forward.

The advantage of this approach is that it combines the power of visual programming and of the data flow concept with the platform independence of Java. The resulting programs are not stand alone applications but may be integrated into hypertext. In addition all development components are available for free.

Geometry and Education in the Internet Age

Ulrich H. Kortenkamp and Jürgen Richter-Gebert
Institut für Theoretische Informatik, ETH Zürich, Switzerland, E-mail: kortenkamp@inf.ethz.ch

Abstract: Interactive Geometry is a major tool in modern geometry education and various software tools are available. We discuss the requirements of such tools and how they can be fulfilled. We also explain how a geometry tool can benefit from the Internet and present Cinderella’s Café, which is an internet-aware geometry tool with a high mathematical background.

1. What is interactive Geometry?

In all modern secondary school curriculae geometry plays a major role. Besides its drawing skill training purposes it is used as a tool for teaching mathematical and logical reasoning. Unfortunately, the second, much more important goal, is sacrificed for the first, since accurate drawings are needed for correct reasoning.

As an example, let us consider the well-known statement that the three altitudes of any triangle meet in a point. In order to convince himself of the validity of this simple statement a student has to draw an example of it. Unfortunately, in most practical cases the three lines will not meet in a single point. Due to little drawing inaccuracies the altitudes will miss each other slightly. This is not very instructive; even worse, it confuses instead.

A high level of discipline and practice is necessary to benefit from the understanding a correct drawing can serve. A computer drawing program that supports access to geometric constructions can help. It can serve as a geometric pocket calculator and relieve the student from the routine work. Such a program helps to achieve the second goal that was mentioned above: the thought-stimulating effect of geometry.

2. Key features of Interactive Geometry Systems

Interactive Geometry Systems (IGSs) differ from usual computer aided drawing (CAD) software. In contrast to CAD Systems (which are well suited to produce a single static picture) Interactive Geometry Systems consider a drawing as a dynamic entity. They provide not only access to geometric objects like the intersections of lines or perpendiculars to given lines. They, in addition, memorize all construction steps that led to a final picture.

As a first application you can use an IGS to produce drawings that are exact with respect to the restrictions a pixel oriented display or printer bears. But in fact you gain a lot more than exactness: Since the IGS keeps track of the whole construction sequence, it can redo the construction for another set of starting points, so you can actually move single points and watch the influence on the rest of your drawing. Going back to our example you are able to verify the fact that the three altitudes meet in any triangle not only for one, but for a large set of triangles. Let us summarize the key features of IGSs.

2.1 Dragging Objects

The “draggability” of complete constructions stresses the most important, because most interactive part of Interactive Geometry Systems. This is more than a tool for getting a “feel for geometry” — which is already significant —, this is even a method for proving geometric theorems. A conjectured theorem (like the altitude theorem for triangles) can be explored by moving the free objects (in our case the vertices of the triangle). If the theorem “seems to be true” (that is, it is true for every single drawing one creates), it is generally true with an
extremely high probability. Here “high” means, that it is much more likely that the computer fails during execution of the program (due to hardware or software failures), than that the theorem is false. This theoretical background of this method is currently under development by the authors and uses tools from randomized polynomial checking [Kortenkamp & Richter-Gebert 98b, Ibarra & Moran 83, Schwartz 80]. In addition, under certain conditions a low number of examples (a so called test set) is already sufficient to prove the conjectured theorem in general, without depending on randomized proving [Hong 86b, Hong 86a, Deng et al. 90].

2.2 Macro Operations

In order to facilitate constructions IGSs offer the definition of macro operations. Repetitive tasks like constructing the perpendicular bisector using two circles and their intersections can be bound to a macro that issues the necessary steps automatically. This leads to concepts like geometric programming languages. Unfortunately, this also brings up new theoretical problems inherent to this, like the ambiguity of the intersection of two circles [Laborde 97], or, even worse, the intersection of two conics, which has not been resolved satisfactorily yet [Kortenkamp 98].

2.3 Loci

While macro operations are a constructional tool, tracing the movement (locus) of a point while moving a free object is a more investigative tool. How Loci are offered to the users differs a lot among the currently available IGSs (as of now, there are two major systems offering Loci, Cabri II [Laborde & Bellemain 97] and Geometer’s Sketchpad [Jackiw 97], as well as some minor ones.) The spectrum ranges from simple point position recording, which gets erased whenever a new point is moved, along more sophisticated techniques that offer connect-the-dot-algorithms and are able to be viewed under different additional motions, up to almost fully automatic, high-speed drawing routines, that try to find the complete range of positions a dependent object can take. As in the case of macro operations, several ambiguities arise, and to be resolved they require a solid mathematical theory.

2.4 Additional requirements for IGSs

The described features alone are not sufficient for a geometric tool to be applicable in education and research. Let us mention a few additional requirements, which should make a good IGS, but are not available throughout all IGSs.

To use the constructions in publications one needs high-quality output in any resolution (e.g. Postscript) and the possibility to use different colors and styles for the construction elements. When used with presentations (for example with a beamer as a “geometric blackboard”), the screen output must be configurable to give a good visualization of the construction (points must be big enough to be seen!).

On the user interface side the creation of constructions and macros has to be very simple. A magnetic mode that automatically detects incidences between points and lines or conics should support the user. The interface has to be configurable; if a teacher wants to allow circle and ruler only as construction tools, nothing else should be available.

And finally, a text-based output and input of the construction sequence should be available. This gives the opportunity to check a construction and to fully understand it. The value of this text-based I/O is indisputable, but nevertheless there is no support for it in most IGSs.
3. Cinderella’s Café

Cinderella’s Café is a new IGS we would like to present in this context. It features all the necessary components of an IGS mentioned above, and adds some other features that have not been available before.

3.1 Using most general approaches to geometry

A key component in every geometry system is the mathematics used, e.g. how the dependent objects are calculated. By using the most general approaches possible (as shown below) Cinderella’s Café becomes a more general, simpler and consistent tool for doing geometry on a computer. A general approach to powerful mathematical concepts is the systematic elimination of special cases. This opens the possibility of more user interaction, makes programs more reliable and robust by eliminating possibilities of programming mistakes (“bugs”), and allows higher execution speed. We would like to present two examples of this paradigm.

3.1.1 Complex Numbers

Consider the following situation: You draw two circles that intersect each other in two points. Next you join these two intersection points by a line [Fig. 1], the so-called radical axis of the two circles. By moving the circles you can move this line. It will always be perpendicular to the line connecting the centers of the circles and at a distance to each center that reflects the ratio between the radii. But: What should happen in an IGS if you move the circles apart? The two intersections disappear, and so does the radical axis? Or, even worse: You are not allowed to move the circles in this way? Check it out with your favorite IGS, and find out which approach it takes.

From a mathematical point of view, one would rather expect the following behavior: The radical axis, which is still defined for non-crossing circles [Coxeter & Greitzer 67], moves consistently and continuously the whole time.
This could be achieved by defining a basic operation "Radical Axis" which does a computation independent from the crossings. However, the desired behavior is inherent to the described construction. An IGS should be able to detect this without introducing additional concepts. Therefore Cinderella’s Café takes the following approach: Recall that the two crossings are the common solutions of two quadratic polynomials, which happen to be real when there are two visible intersection points, and which are complex otherwise. Thus carrying out the calculations in the field of complex numbers always gives us two complex intersections, whose connecting line happens to be real (since the two solutions are conjugates of each other), and this is exactly the radical axis.

This small example shows that the introduction of complex number calculations greatly simplifies geometric constructions by eliminating “vanishing” intersections.

3.1.2 Geometric Calculations in Projective Geometry

In the Euclidean Plane almost all pairs of lines have an intersection. More precisely, two lines intersect if and only if they are not parallel. This becomes an issue when dealing with interactive geometry. Two lines which had an intersection might become parallel, when some objects of the construction are dragged. In Euclidean Geometry this introduces another problem: Whenever one calculates the intersection of two lines one has to check whether they are skew or not. But what happens to another line which is defined by this intersection and another point? The line should become a third parallel, but instead (if we stick to the paradigms of euclidean geometry) it disappears, because its defining points are not defined anymore. How can we avoid this dilemma?

Projective Geometry, a powerful theory that has been developed already a hundred years ago, helps us to solve the problem. By embedding the Euclidean Plane into the Projective Plane we add the “points at infinity” lying on the “line at infinity”. First of all this eliminates the necessity of a special treatment parallels. In projective geometry every pair of lines has an intersection. When lines become parallel, their intersection lies on the introduced line at infinity. Moreover, the calculations that are needed to obtain the intersection are greatly simplified and unified (and not vice versa, as one could expect). For this we use homogeneous coordinates, i.e. we model the points of the Projective Plane by the one-dimensional linear subspaces of $\mathbb{R}^3$, represented by a spanning vector, and we
model the lines by two-dimensional linear subspaces, represented by their normals. Note that scalar multiples of these representing vectors are identified [Fig. 2]. Now the calculation of the intersection of two lines reduces to calculating the cross product (or vector product) of two representing vectors in $\mathbb{R}^3$. The same holds for the calculation of the line connecting two points [Stolfi 91, Coxeter 92].

3.2 Multiple Views

We just sketched how to carry out calculations in the projective plane. How can one visualize the new, non-euclidean objects, or even input them? For this, Cinderella's Café offers the possibility to view a construction in a multitude of different Windows. So it is possible to have an overview of a scene and a detailed view of the same scene (zoom in) at the same time in different Windows. All windows are fully functional, that is, you can move or add elements in either window, and all windows are synchronized, that is, you can see the effects of one operation immediately in all windows.

Since it is not possible to zoom out so much that you can see the elements at infinity, another approach has been taken. It is possible to view a construction in a completely different model, for example, in the "spherical double-covering model of the projective plane". Here the Euclidean Plane can be imagined as being shifted to the $\{z = 1\}$-plane in 3-space. Then the complete scene is mapped onto the unit sphere by a central projection. Thus the points at infinity may be found at the equatorial circle at $z = 0$ on the sphere. Cinderella's Café allows all the operations of the euclidean view also in the spherical view. The additional possibility of rotating the view of the sphere simplifies the exploration of geometric objects and constructions [Fig. 3].

1This is the same as identifying the linear subspaces by their intersections with the unit sphere
3.3 Euclidean Geometry support

Since most IGSs are to be used in secondary school teaching it is desirable to have a strong focus on Euclidean Geometry. In the last section we described how to avoid the pitfalls of Euclidean Geometry by using complex Projective Geometry. One might expect that by the introduction of the line at infinity and its associated points we lost the special role of infinity that is needed for "proper" Euclidean Geometry. This is not the case.

We just keep in mind (or in memory) that there is a special line — which does not need any special treatment —, and we can use it to do euclidean constructions. Let us take parallels as an example. When we like to construct a parallel \( \ell_P \) to a given line \( \ell \) we proceed as follows: Take the line at infinity \( \ell_{\infty} \), calculate the meet of \( \ell \) with \( \ell_{\infty} \), and let \( \ell_P \) be a line through this intersection, chosen specifically to the needed other properties of \( \ell_P \) [Fig. 4]. We can carry out all the calculations in homogeneous coordinates without any care for special situations. The user is not bothered with these technical details, since all internal operations that are needed to construct the parallel are encapsulated within a macro.

Another example are circles. Since circles depend on euclidean measurements, one might expect that it is not possible to find a projective description of them. However a circle is a special conic, which can be defined by five points. A classical observation of Poinclet shows that all circles have two points in common — which have complex (!) coordinates. So our two mathematical concepts (Complex Coordinates and Projective Geometry) just do fine in modeling Euclidean Geometry [Klein 28].

3.4 Hyperbolic Geometry and beyond

Currently, most IGSs provide support for the Poincaré-model of Hyperbolic Geometry only via a sets of macro operations. The multi-view approach of Cinderella’s Café allows for a “native” support of Hyperbolic Geometry. In the same way as with spherical views one can add a hyperbolic view that provides full functionality [Fig. 5]).

By this we can avoid the usual pitfalls in designing macros [Kortenkamp 98, Laborde 97]. But we are also given the opportunity to create new views, either traditional ones, or completely new ones. All views share a
common computational kernel, and one can concentrate on adding just the translation from abstract objects to their visualizations. The interface for this will be made public, so it is possible to share new views in the community.

3.5 Measurement of Angles and Distances

Since we mentioned circles, we have to discuss measurements as well. Despite the fact that the educational value of doing measurements within IGS is questioned [Kortenkamp 98], it is a feature desired by current curriculae.

Any measurement has to be carried out with respect to some scale. Here the point is not that it is possible to zoom into drawings while still having the correct distances. The situation is much worse: The definition of distance and angle is bound to the type of geometry we are using. Since projective geometry is a common basis for doing euclidean, spherical, and hyperbolic geometry (among others), we do not want to restrict ourselves to euclidean measurements. The unified approach to different measurements is Cayley-Klein geometry, as featured by Cinderella’s Café.

Cayley-Klein geometry defines angles and distances as multiples of logarithms of certain cross ratios. These cross ratios are calculated with respect to certain fundamental conics, which are the defining conics of the geometry used [Coxeter 92]. So we have a “pluggable” measurement, which supports all our needs (and even more).

The same fundamental conics play a role when we define circles by a center and a point on the circle, or when we define perpendiculars. Both these objects come in different flavors, since they are heavily dependent on the measurement chosen.

While Cinderella’s Café supports simple calculations to be performed with the measurements taken, it does not allow to mix different geometric units. So it is not possible to add an angle and a distance, or to assign the area of a triangle to the length of a segment. This is an intended restriction, since it would lead to results which do not reflect any geometric situation.
4. Using the Internet in Education

These days there is a great effort to connect schools to the Internet. There are various arguments for that, but there are few high-quality Internet-aware educational tools. Having this in mind, Cinderella’s Café has been designed to fill this gap.

4.1 Choosing the right language

Portability and simplicity have been the reasons for choosing JAVA as the development language of Cinderella’s Café.

The program has to be highly portable across platforms in order to make it accessible on a wide range of systems, since it should be possible to use it with all the computer systems currently installed in schools, academic institutions, and at home. This has been made possible by using the language JAVA, developed by Sun Microsystems/Javasoft. This language is available on all major platforms, e.g. Windows 95, Mac OS, Solaris, and Linux.

The execution speed of JAVA was a major concern, but benchmarks showed that the performance is satisfactory even on Intel 486-based systems.
4.2 Instant availability

As an additional benefit we get instant availability of Cinderella's Café via the World-Wide-Web. It is possible to enhance webpages with interactive geometric content without having the user to install any software besides a JAVA-enabled browser. At our website [Kortenkamp & Richter-Gebert 97] you may find some examples [Fig. 6] as well as a complete demo-version.

Users of Cinderella's Café are able to create examples and export them directly into their own webpages. So everybody might use Cinderella's Café to enhance their webpages, which may be (interactively) viewed by anyone having access to the Internet. The visitor does not have to install any software for this, and there is no royalty fee.

4.3 Example databases

Currently there is work in progress to build up example databases which reflect the different curriculae. Thus in the near future a teacher or student may benefit from ready-made constructions. This underlines that it makes sense to provide connectivity to schools and other academic institutions, if you have software like Cinderella's Café that uses the additional possibilities one encounters.

4.4 Interactive exercises

Another new and exciting feature of Cinderella's Café is the possibility to prepare exercises for geometric constructions. The teacher can construct a sample configuration and mark the set of starting objects and the desired object to be constructed. Then he or she can export the exercise together with a restricted set of tools. For instance, one can imagine to give the exercise to construct the perpendicular bisector with a ruler and a compass. You only need one construction with Cinderella's Café in order to create an interactive exercise sheet.

The solution of the construction exercise is checked automatically by Cinderella's Café. This non-trivial task, which has not been available in any IGS before, is done via a new randomized theorem prover developed by the authors [Kortenkamp & Richter-Gebert 98b, Richter-Gebert 95]. So the student is not tied to the particular construction the teacher had in mind, but is free to find any construction that leads to the desired result. So the program can be used as an educational tool without restrictions on the creativity of the student.

5. Conclusion

We presented Cinderella's Café, which is a new IGS with a high mathematical background. It supports highly consistent interactive manipulation of geometric constructions. This is achieved using the most general mathematical models whenever possible, in order to avoid the necessity of special treatment of degenerate cases.

The software package is very well applicable in education and presentation since a lot of features not known to other IGSs is included. Since the program is written entirely in JAVA, it is highly portable and Internet-aware. The additional possibilities of the network are used to enhance the software by offering direct export into webpages and the creation of interactive exercises. Thus it gives the Internet the necessary content to make it suited for educational purposes.

In this article we explore some of the possibilities of multimedia technology and networked learning environments. To illustrate our position, we argue with a sample online course on Distributed Software Engineering [Krämer 97a]. In our discussion we focus on two issues: Section 2 sketches our approach to the design of this course and reports on lessons we learned during its evaluation. Section 3 describes our approach to use a shared workspace system to support joint work of distributed project teams and learner groups. We conclude with some general observations we made at FernUniversität during two test runs of a preliminary version of a comprehensive online teaching platform with a limited community of students.

2 An Interactive Online Course on Distributed Software Engineering

The course "Distributed Software Engineering" is the second part of a two-semester course on software engineering issues. It is particularly dedicated to three characteristics of many computer-based process control applications: reactivity, distribution, and safety. The course introduces new terms and requirements specific to distributed software that is embedded in technical applications and has to satisfy high dependability requirements. Sample applications include computer-controlled manufacturing systems, industrial control systems, process automation, (mobile) communication systems, and pipeline-control software in petrol industry.

To illustrate the different steps of software development, a simple production cell serves as a general case study [Fig. 1]. The production cell includes electro-mechanical actuators and sensors that monitored and controlled by a distributed program. Major course objectives are to confront students with the intricacies of distributed and non-sequential software systems and endow them with the capability to recognize realistic abstractions and modeling ideas for given development tasks. We also want to teach them suitable specification, design, programming, and validation techniques and raise their awareness to scrutinize correctness and adequacy of specifications and programs with rigorous means. Further pedagogical aspects of this course are described in more detail in [Krämer 97a].

![Figure 1: A virtual production cell](image)

2.1 Structure and Design of the Online Course

The online version of the course is a structured program of study whose skeleton consists of a hyper-linked set of HTML pages. These pages include interactive animations, simulation packages, videos, and light weight software tools. The course consists of the following teaching units:

**Introduction to Distributed Software Systems.** In this lesson we develop main concepts of distributed application programs such as concurrency, resource contention, synchronization, or deadlock with different use cases. These use cases are visualized in terms of a distributed virtual book store. We
chose the HM-Card authoring system [Maurer & Scherbakov 96] to integrate animation, text, sound, and interactive user input in this unit. The didactic method used is guided discovery and exploration [Khan & Yip 96].

Case Study and Safety Analysis. The introduction of our general case study includes a short video showing a real production cell in action. This cell operates under strong safety constraints in a German metal factory. Throughout the course we use an interactive 3D-model of that production cell [Fig. 1]. The virtual production cell was developed in VRML and Java and is operational under a VRML 2.0 browser plugin like SGI's Cosmo player.

This virtual production cell serves for several purposes: a) students can study the behavior of each individual machine and understand the synchronized interplay of neighboring machines with the help of a panel controlling the cell's actuators individually. b) As software safety is of primary concern to that course, the students then have to find eight different sequences of production steps leading into eight different hazardous situations. A typical example is a robot arm being extended and directed towards the press. Any attempt to move the cheek of the press in that situation would lead to the destruction of both press and robot. The student's attempts to find such sequences are recorded, normalized and compared with a predefined set of correct answers to provide positive and corrective feedback. During our study days held on campus at the end of the course, we develop hazard analysis models using fault tree analysis and state machine hazard analysis [Leveson 95]. We use selected student solutions of the distributed cell controller to analyze their flexibility in coping with possible hardware failures that were revealed during this post-development system safety analysis. c) An automatic mode shows the virtual production cell in correct action. It demonstrates the behavior of a correct solution that avoids all hazardous situations and exploits the maximum of concurrency in all production steps. d) After having developed their distributed control program towards the end of the course, the students can link their program with the control interface of the virtual production cell to get visual feedback on the behavior of their own solution. All kinds of safety violations that may happen now are visualized and recorded.

Requirements Analysis and Specification. The students' insight into the problems gained through manual interaction with the virtual cell machinery and the detection of hazardous situations provides the ground for the formalization of behavioral requirements and safety constraints.

Design. A light version of a Petri net editor written in Java allows them to edit and symbolically execute their Petri net design of the machine controllers' intended behaviors at home. A model checker, a tool for reachability analysis, and other verification tools for Petri net designs operational on our Unix server can be accessed remotely through CGI-Interfaces. We are currently working on a interface between the net tool and the virtual production cell by which the transitions of the student's net design are synchronized with the execution of corresponding operations (e.g., extend-arm(L)) at the control interface of the virtual cell. This mechanism would allow them to get visual feedback on the behavior of their solution early at the design level.

Distributed Programming. Distributed programming is centered around a Java version of the graphical design tool for Darwin [Ng et al. 96]. Program development starts with the transformation of the student's design into a course program architecture which is then developed into a hierarchy of interacting program components. The students finally have to develop Java code for the leaf components of their architecture to obtain an operational solution. This code controls and surveys the actuators and sensors of the virtual production cell, respectively.

Further subjects of this course topic are concepts of distributed programming languages, synchronization and communication mechanisms, and middleware standards and platforms. Remote procedure call, marshalling, message brokering and other core mechanisms of current middleware systems are visualized and animated by means of an interactive introduction to CORBA. Students can learn the different steps of a CORBA-based programming methodology by working through predefined and guided examples. In addition, they can define their own problems, design corresponding interface specifications and develop code by accessing our CORBA environment remotely.

2.2 Evaluation

This and a previous version of the online course have been tested with a small population of students. During summer semester 1997 an evaluation study was undertaken. The study served to measure the
effectiveness of the use of new technologies including the Internet, the World Wide Web and multimedia. The hypothesis we started with was that teaching/learning effectiveness can be influenced by a number of independent factors including:

- design and presentation of the course material;
- degree of the students' previous experience with computers;
- time spent by students online.

In the sequel we sketch the conceptual framework used for the evaluation and summarize major results.

**Method.** During course development prototype solutions were regularly presented to peer colleagues to receive early feedback on the quality of the online course material. During the test run of the online course with students a summative evaluation relying on pre- and post-test [Calder 95] was performed. Two kinds of questionnaires were handed out the students. The first one for the pre-test aimed at identifying the students' expectations of the new teaching model. The post-test questionnaire helped to determine their overall judgment and criticism. The twelve questions contained in the first questionnaires were replicated in the post-test questionnaire. In the latter further standardized and open-ended questions were added to allow the evaluation of specific issues on the course design, the human-computer interaction, or understandability. The standardized part of the questionnaire was analyzed by means of statistical analysis, while the open-ended part was analyzed using qualitative content analysis.

**Results.** Due to the relatively small number of students that participated in the user trails, we can only draw tentative conclusions from this first evaluation. All students found the online, interactive teaching model attractive and challenging. Most participants expressed the feel that the new mode helped them increase their skills and knowledge on the subject matter of the course. The correlation of effectiveness as a measured variable and several other measured variables including design of multimedia courseware, preferred mode of study, or time spent working online revealed that the effectiveness was mostly influenced by the design of the material. Conversely, the students' time spent working online added very little to the effectiveness variance.

The qualitative content analysis of the open-ended questions showed the students' preferences and dislikes concerning the use of multimedia courses. It also generated a number of suggestions for enhancements. A great majority of students found that the new learning model had positively affected their study patterns as they were actively involved in the acquisition and development of knowledge. In particular, students liked the possibility to put hands on things in animations and simulations. The search and navigation facilities and the availability of course material were also found useful. Requests for enhancements included the demand for: more interactivity, exercises, animations, simulations, and video clips. Also an improved, more professional layout, more visualizations of self test examples, and less online text material ended up high on the students' wish-lists.

Measurements of students' access behavior revealed that the lengths of online sessions were disappointingly short. We assume that this is particularly due to relatively high telecom fees in Germany and many other European countries. Therefore we decided to distribute heavy course material, especially video clips, sound files, software tools and utilities, on CD-ROMs, while those components that are like to change more often and are smaller in file size are maintained on our Web servers.

3 **Synchronous Collaboration Support**

Software engineering is a subject that should not be studied merely theoretically. An important asset of such a course is practical training in teamwork with small but realistic projects. In the past we had to constrain such experiences to the short period of practice days students spent together in our labs. Today, the Internet enhanced with suitable cooperation technology allows us to extend the time of collaboration and support distributed learning groups.

Collaboration in distance learning shares many features with groupware, also called computer supported collaborative work (CSCW). As a first step in the direction of collaboration support between remote students, we defined distributed project teams and set up a shared workspace for each team.
using GMD's BSCW platform [http://bscw.gmd.de/]. The team members were asked to use the functionality of BSCW to prepare joint specifications and designs prior to attending the practice days. To some extent this experiment failed, largely for two reasons: At the beginning CSCW seems to impose an additional burden on its users as it requires quite some discipline of documentation and communication. Usually it takes a while until the advantages of a disciplined team work are recognized. A real deficit of the platform in its current state is, however, the lack of synchronous collaboration support. Students had liked be be able to discuss properties of shared design objects or clarifying difficult passages of course materials through synchronous communication.

Whiteboards and chat tools were of lesser help here because they assume a poorly structured material as typically encountered in initial brain-storming sessions. The course material, requirement specifications, designs or programs, however, are well-structured documents bearing a potential for controlled navigation and small-grain annotation of individual document parts. Whiteboards and chat tools also suffer from insufficient concurrence control. For example, one participant might start to sketch an architectural design of a software solution, while, all of a sudden, someone else changes the context by scrolling the page on zooming into some detail of another object presented.

To diminish these problems, we borrowed structures and methods from both database research and current multi-media course development in the design of mechanisms supporting communication through gesturing at a shared drawing, images, pieces of text, animations or simulations [Krämer & Wegner 97]. Their intended advantage was that proposed changes would be made easily visible, evaluated and further developed in give-and-take discussions over technical media.

A sample collaboration scenario may illustrate our approach: Mary, John and Barbara have teamed up to form a distributed project team during the course Distributed Software Engineering. The problem our three students are currently concerned with is the development of a design solution for the safe control of the behavior of a robot used as a transport component of the production cell [Fig. 1]. The behavioral design of the robot controller is supposed to be delivered in terms of Petri nets. Mary has produced a preliminary design she wants to discuss with her peers [Fig. 2]. Hence she initiates an online team meeting. As the common work context she has been setting up her design solution and the course unit introducing the case study.

![Diagram of Petri net design of the arm controller](image-url)

Figure 2: Finger on the Petri net design of the arm controller

John's first reaction is that he has difficulties to understand the essentials of Mary's proposal finding it overly complex. To clarify the issue, Mary sets a logical finger on the relevant part of the problem description in the corresponding course unit. In addition she also points to the place enabledMagnet in the net and explains that this place served exactly the purpose to ensure that pieces held by this arm can only be dropped by the gripper of an arm if that arm was extended. Obviously this place could only be set by an occurrence of transition extend. While saying this she moves the finger to the left lower transition of the net. In this moment Barbara jumps in and says: Do you remember the specification of the safety constraints we developed four weeks ago to formalize the safety requirements?". She opens another window and puts a new finger on the appropriate predicate in the premise of the formula presented in the new window and continues: These two subexpressions correspond to the case in which the places out, hold and enabledMagnet are marked and transition drop is enabled. John's reaction is: Ah, now
I got it. Let’s keep these relationships in our records so that we can easily reconstruct them. He pushes a key combination to materialize the pointers (fingers) as links in the team database.

4 Conclusions

We strongly believe that distance learning can be improved with the help of new technologies. But, as we have argued, the traditional distance education model is not without shortcomings. Personal communication via phone, fax, and e-mail are no substitute for an eye-to-eye discourse. Students lose the opportunity to scrutinize facts or processes through extended conversations with tutors and peers. Remote teachers find it hard to verify that a student has actually learned the subject in, say, the same way traditional teachers can gauge progress and clear up misunderstandings. There is little regular hands-on experimentation and no access to physical objects, models, simulations, and instruments in computer and engineering labs. There is little support for cooperative learning and joint problem solving.

As one of the many examples aimed to improve that situation, we outlined the design of an interactive online course taught at FernUniversität Hagen. This course exploits various possibilities of multimedia technology to convey knowledge about the challenges, principles, techniques and tools for building distributed software systems. We provided preliminary evidence that our hypothesis holds true from a systematic quantitative and qualitative evaluation of this and other courses that was pursued in the context of a European project on open and distance learning. We then identified requirements needed to have shared pointing to objects in distributed work scenarios besides the typical functionality of CSCW systems. We sketched an approach to provide cursors, here called fingers, that can be positioned on logical objects rather than on their display representations. A simple use scenario served to illustrate the basic idea. Technical details of its implementation are described in [Krämer & Wegner 97]. A prototype implementation is currently in work.

Abstract: Reading a hypertext document differs from reading a book in many ways. The most important difference is the non-linearity of the hypertext document. Non-linearity means that the pages do not appear in a clear order but in an order that is controlled by the reader. Therein lies a big advantage of hypertext against linear media [Jones 87]. But the non-linearity causes one of the biggest problems of hypertext, too. The phenomenon of „getting lost in hyperspace“, as Jeff Conklin named the readers disorientation in [Conklin 87], and the growing cognitive load are wellknown problems which were often discussed and are still not completely solved. This text shows an approach to solve both problems for internet based HTML hypertexts by providing an automatic generated visual document map to the reader. The map itself can be adapted to the readers needs very flexible, enables the reader to actively navigate in the document structure and reduces the cognitive load by giving preview information about the referenced pages.

1. Introduction

Two problems remain still unsolved for large hypertext documents:

- The reader still looses orientation when browsing the document. The pages appear from „nowhere“ and disappear to there again after reading. The underlying structure is not transparent to the reader. A cross-reference in the text can lead a beginner in one step to the last pages of the documents where he hardly understands any of the experts knowledge given by the author. Another question is, whether the reader really did read all pages or if he only scratched at the top of the iceberg.
- Non-linearity is said to be a big advantage of hypertext against traditional books because the reader can explore the knowledge space individually by deciding himself which page to read next. The problem with this advantage is that it also means an huge cognitive load for the reader. Before he can really decide which should be the next page, he has to read all available pages first, keep everything in mind and afterwards decide which page was the most interesting.

Approaches were made to prevent the reader form the named problems. Against cognitive load typed hyperlinks were suggested in [Trigg 83], implemented in the Intermedia System [Yankelovich et al. 88] [Utting et al. 89] [DeRose 89] and ported in a more flexible way to HTML and the Internet in [Kreutz et al. 97]. The link types show the kind of relation between the current page and the referenced page and thereby reduce the number of pages that have to be visited by the reader, because he can leave out the pages which do not match his own interest. A preview information suggested in [Kreutz et al. 97] as well helps to reduce the cognitive load, too, because the reader does not have to leave the current page to get information about the referenced page anymore. He just clicks on the link and gets an information window that displays a brief abstract about the destination.

Document maps are suitable to improve the readers orientation within the document, because they display the whole structure of the document. On the other hand very large and complex documents are hard to display and the diagrams are normally not very readable [Brandenburg 88] [Batini 85]. Maps are implemented in HTML documents very rarely so far. The maps implemented in Web based hypertext documents are mostly limited in size and detail depth. In [Kreutz 94] a visual navigation tool was introduced for ToolBook based hypertexts, that solved the problems of displaying even very huge structures and keeping the display flexible to readers adjustments at the same time. It also enabled the reader to actively navigate within the document structure. This approach proved to be useful in [Buchner95] which consists of approximately 2,000 pages and 10,000 links.
The next chapters show a way to provide a visual navigation tool within Internet based hypertext documents that is adjustable to the readers interests, easy to generate and maintain, and that includes the benefits of preview information, too.

2. Visual Navigation: An Overview

2.1. Index

Indices can be found in some documents today. They are implemented in two ways. Either as a central page that is referenced from each document page or as part of the browsers display where the index stays constantly visible. In most cases the latter approach makes use of Netscape's Frame-Concept. Because the display space of the browser is limited this approach leads to a limitation of the index itself, too. The first approach doesn't lack this limitation but is on the other hand not as elegant as the latter. The reader has to leave the current page and by this his context to get to the index page which then doesn't tell him were he was. He has to use the browsers Back-Button to get back to the originally page.

2.2. Maps

Maps are nothing more than a visual index. They too suffer the limited space of the browser display but their readability is in most cases better than the one of textual indices. Because maps are more graphically oriented they contain more graphical elements such as boxes and arrows. Therefore they need more space, too. To take the advantage of a better readable graphical display without taking the disadvantage of high space requirements, maps are often limited in width, depth or both. But the main disadvantage of maps is the lack of flexibility and the problem of maintenance. Huge graphics may show the complete structure and all links between all pages but they do not meet much of the requirements for good readability of graphs as described in [Batini 85]. Smaller graphs that do focus on special structure views support the reader better and are more readable but demand higher costs for maintenance to keep the graphics conform to an evolving document. Experiments showed further, that graphics that were called „good“ and „readable“ were in most cases those that were edited by hand. From this it follows that if the author wants to provide good assistance to the reader he can not rely on automatic graph layouts only. This again leads to higher editing costs.

2.3. Fish-Eye

The Fish-Eye view tries to reduce the space needed to display the complete structure. Therefore it shows the nodes representing the current page and its direct neighbours larger than nodes representing pages further away. Indeed it saves space but because of the changing sizes of the displayed nodes, the reader has problems with recognizing the documents common structure in the different presentations.

2.4. Wall

The Wall view [Lechner 94] (p. 53) is not implementable for Internet based documents. It shows the current page centered and compressed presentations of the precessor and the successor page. The problem is that in highly linked documents normally one can't tell which will be the next page. To give a pre- and postview might be helpful but it is questionable that a user can recognize the compressed page presentation. We prefer textual previews as introduced in [Kreutz et al. 97]. Such a textual preview is shown in [Hierarchical View].

3. Improved Visual Navigation

Our approach as maps and Fish Eye view tries to save space, too, but uses another way to achieve this goal. Instead of presenting one universal display we provide many different views on the document structure meeting the different readers intentions in looking at a document.
3.1. Complexity of Graph Algorithms

As described above producing good maps is a timeconsuming process. The maps then are not adjustable to the users needs. On the other hand automatic generation of maps does not lead to very readable maps or requires algorithms that are at least NP-hard [Sugiyama et al. 81]. The advantage of automatic automated maps is a by far higher flexibility. Therefor the first aim is to reduce the complexity of the algorithm or the complexity of the problem. [Kreutz 94] showed that efficient algorithms with linear complexity can be found by distinguishing different link types. We are sure that in all hypertext documents a main hierarchic structure can be found and with this at least two link types can be distinguished: hierarchical links and crossreferences. (A technique to introduce more link types into HTML based hypertexts is mentioned in [Kreutz et al. 97].) With the information about the link types more specialized algorithms can be used which enable us to provide views that can be adapted to the user's needs and that can be updated after an user interaction within less than one second.

3.2. User Adapted Views

If the reader wants to know, where he is in the document, he needs a hierarchical view that shows all needed information and hides all unneeded. If he wants to know which pages he can reach directly from the current page (which pages are directly related to the current page), he needs a map of all direct neighbours. Then again the reader might want to know where he had traveled so far through the structure, which pages he had already visited or which he hadn't visited so far. For each of these different questions he needs a special view.

All these views are specialisations of the same underlying one structure. Each of these specialisations itself is controlled by parameters by which the view can be individually adjusted to the readers needs. Because each view focuses on one specific question the algorithm to create the presentation does not have to cover all intentions of looking at a document. Therefor one can optimize it that much that the resulting presentation is good enough to be used in a document. This way we achive a „good“ and „readable“ presentation at low maintenance costs that behaves flexible to user needs.

4. Implementation

4.1. Goals

In our approach we focused on maximal flexibility in adjusting the display to the readers needs and interests and heavy performance. Each presentation has to be computed at runtime taking in consideration the readers adjustments. At the same time the implementation has to be platform independend as the documents themselfs.

4.2. Language

To meet this last goal Java [Flanagan 97] was chosen as the implementation language. Building browser plugins in C/C++ would have lead to much more browser specific programming which eventually had to be adjusted with every browser update and which would had to be compiled and shipped for every platform each browser supports. With Java we are able to implement the display tool without having to bother about platform dependencies. The command set of Java is sufficient to force browser actions. The Java based concept to achive preview informations which was introduced in [Kreutz et al. 97] could be adopted in this work.

4.3. Interface

To meet the first goal (flexibility) the design was kept very simple. It provides just an interface between the Web-Browser and the display tool [Figure 1]. Through this interface data is exchanged to specify the current document and the current document page in one direction. In the opposit direction the request for a new page is transferred to the browser. The kind of view (visual graph presentation) is specified by the user through the user interface of the graph viewer itself.
The simplicity of the interface and the specialisation of views also guarantee the performance to achieve goal two (computation at runtime). Algorithms with linear complexity for computing the graph layout were discussed and implemented in [Kretz 94]. They are used in this approach, too.

4.4. Browser / Display · Communication

A communication between browser and graph viewer is necessary to synchronize the user interactions with the displays. If the user moves to another page using the browser, the graph viewer needs to get informed about this and the graph layout has to be updated. On the other hand the browser has to move to another page if the user clicks on a node within the graph viewer. This communication [Figure 1] is initiated by a Java applet that is included in each document page. It is answered by the Java application that manages the structure display.

4.5. View-Modules

Different intentions to look at a document demand different presentations. Those presentations are computed by view modules at runtime, which can be docked to the graph viewer. The number of view modules is unlimited and each module holds methods for adjusting the display parameters to the readers needs. The modules communicate with a View-Manager and share one global representation of the documents structure in common.

5. Results

The Clinic for Diagnostic Radiology at the RWTH Aachen develops an HTML based Script for their medicine students where our View-Manager is included. The document consists of approximately 300 pages and 1,500 Links. The underlying structure is rather deep with up to 7 chapter levels. Two views are implemented. One to show the hierarchical structure of the document and one to visualize the neighboured pages to the current page. Both are discribed further below.

The inclusion of the applets into a document’s pages is done within a few seconds by the author. Further steps are not necessary. The applet itself can be down-sized to one single pixel. This way it doesn’t even appear visible inside the document.

The View-Manager is started automatically as soon as the first page of the document is loaded and stays visible as long as the document is browsed. The current page appears marked in the view window. By clicking on a chapter node with the right mouse button an extra window pops up that gives a brief description of the corresponding page. Clicking the chapter with the left mouse button loads the corresponding page into the browser.
5.1. Hierarchical View

The hierarchical view [Figure 2] presents the hierarchical structure of the document. It is a tree where the root represents the starting page of the document (i.e. an index page). This view suppresses all non hierarchical links like all kinds of crossreferences.

---

5.2. Neighbourhood View

The neighbourhood view focuses on another readers intention. Here the question is not „Where am I?“ but „Where can I go from here?“. The view generates the N-Context - the set of pages, that can be reached from the current page within N or less moves - and displays it in a cyclic order.
This view is also adjustable to the reader's interests. The reader can specify how extensive the N-Context should be. An N with a value of two or three has proved useful as they give some furthering information than an One-Context but do not include almost every node in the document like a Five-Context or Ten-Context does. The reader can also specify if only the shortest routes to the N-Context pages should be displayed, or all of them (A page may be reachable from the current page on different routes with i.e. two and three moves). If he decides to filter out the longer routes, the displayed graph gets a bit more readable and the reader sees the shortest ways to get to specific pages. If he decides the other way round, all links are displayed which enables him to overlook the general connectivity of one chapter / page with the other chapters / pages. This general connectivity reflects contextual relationships between the pages / chapters and is therefore of some interest.

5.3. Other Views

Three more views are planned for implementation. One in which the question is „Where do I come from?“, „Where did I go so far?“ and one that varies the hierarchic view into a Directory Tree which is wellknown from file select dialogs in many operating systems. The third view displays the reading history in a hierarchic way.

Further studies will show if there is a need for even more views. Considering that different hypertexts are based on different structures a need of more views seems to be justified.

6. Conclusion and Future Works

We believe that the Internet with HTML as its publishing standard will supersede the platform dependend publishing systems in the long run. Universities should make intense use of the hypertext medium to improve the quality of teaching and reduce costs at the same time. A good reader support is essential for a growth in acceptance of Web based hypertexts - especially for those with educational intentions. The text showed a solution to the two problems disorientation („lost in hyperspace“) and cognitive overload that existed in Web based hypertexts so far. The shown solution is currently included into a hypertext for medicine students.

To measure the benefits of the visual navigation to the reader an evaluation is planned. We are very confident that the visual navigation increases the usability of Internet based hypertexts and that it will become more commonly used in hypertext documents in the future.

Further improvements such as reader modelling and context dependend navigation were mentioned in [Kreutz et al. 97]. Future works will include these topics into the visual navigation, too. To support the author during the definition of the document structure currently an authoring system is under development. In the near future more View-Modules will be developed and docked to the View-Manager.

Abstract: This paper describes the automatic generation of questions for the Comprehension Test component of HELEN (Hypermedia Environment for Learning ENglish). The test is one of intelligent learning functions, and the test module converses with learners about the contents of sentences. Aims of the test are roughly classified into three categories: first, to train the use of grammatical knowledge; second, to confirm the understanding states of content; and third, to correct errors. A question generation module in the test generates questions according to the aims by using syntactic and semantic information, semantic structure of sentences, and a student model. For example the module generates questions which make learners use new words; which ask time and space relationships; and which use grammatical knowledge that the learner previously used incorrectly.

1. Introduction

In this paper, we describe 1) educational targets of the Comprehension Test in which a learner and a computer converse about the contents of English sentences, and 2) an architecture of automated question generation which reflects the educational targets.

The Comprehension Test is one of the intelligent learning parts which realize the learning functions of HELEN (Hypermedia Environment for Learning ENglish) [Kunichika et al. 95a]. HELEN is an authoring system for intelligent learning environments for English Learning. The aim of HELEN is to give authors who are not good at programming, a programming-less authoring environment. The authors can easily make up learning environments according to their educational intentions by selecting necessary learning parts from a prepared learning parts library.

The Comprehension Test gives a learner questions about the contents of sentences in a textbook. This kind of test is popular in language learning environments. However many of these systems provide quite limited answering capabilities such as selecting from choices or filling blanks; e.g. MARPLE [Teutsch & Vivet 93] and Dynamic English [DynED 97]. And even if systems allow learners to input answers freely, questions are prepared beforehand in almost all the systems; e.g. MARPLE and ALICE-chan [Levin & Evans 95]. Furthermore in the situation using the Comprehension Test in HELEN, learning is proceeded on learners' initiative fundamentally, so what the learners have studied vary, and it is necessary to generate questions automatically by considering both semantics of the sentences and the learner's understanding states about syntactic knowledge and the semantics. Moreover when systems generate questions, they should reflect authors' educational intentions.

In the second section, we classify educational targets of the Comprehension Test. Then in the third section, we describe the outline of its architecture such as the knowledge and processing flow of the Comprehension Test. Next, we explain how to reflect educational intentions. Finally we present our
2. Aims Of The Comprehension Test

Learning by using a learning environment created with HELEN proceeds on a learner's initiative fundamentally, so the learner can select how and what to learn. The test is designed to use after the learner has studied the contents of sentences by using the other learning functions.

The educational targets of the Comprehension Test are as follows.

(1) To master the use of grammatical knowledge

In general, each lesson in textbooks for novice learners has learning targets about grammatical knowledge. To confirm whether the targets are achieved, the Comprehension Test module makes questions which use particular grammatical knowledge such as new words or sentence structures, or questions which ask words used in a particular case.

(2) To acquire the ability to exchange information

This target means giving and taking information by using hearing, reading, writing and speaking skills. Note that HELEN does not support the speaking skill at present because to recognize speech in any situation is very difficult in present information processing technology. The Comprehension Test requires learners to use reading, hearing and writing skills; that is to say, the learners read sentences, hear questions and write answers. To achieve the target, the test function gives the learners questions which have moderate difficulty and ask about the contents of sentences. It is desirable to construct questions and answers by such a process as replacing words and phrases or summarizing of sentences, instead of using only words in textbooks. For example the questions which use synonyms of words in a textbook or ask the contents of some sentences are useful.

(3) To correct errors

Learners sometimes make errors syntactically or semantically. When a learner makes errors, rather than giving the correct information immediately, it is important that she corrects the errors by herself through dialogs designed to recall the correct knowledge. The errors are classified into two categories; one is past errors and the other is present errors. For correcting the past errors, especially frequent ones, systems should make questions which assess the knowledge the learner has learned from those errors frequently, and for correcting the present errors, systems should support correcting the errors immediately. To achieve this target, the Comprehension Test module makes questions by referring to a student model.

3. The Outline Of The Comprehension Test Module

In this section, we explain the information used for automated question generation and processing flow.

3.1 Information For Question Generation

The question generation module uses 1) syntactic and 2) semantic information, 3) semantic structure of sentences and 4) a student model. 1)-3) are extracted in the authoring stage, and 4) is generated in the learning stage. In this section we describe each information.

Syntactic information consists of a syntactic tree which expresses parts of speech and modification relationships of words and phrases, and the feature structure which expresses both grammatical functions of words and phrases and grammatical information such as sentence structure and idioms.

Semantic information consists of time and space information and the information about verbs, nouns and modifiers. [Fig. 1] shows the semantic information of the four sentences placed on the upper left-hand corner. One of the features of this expression is that each piece of information is stored separately and relationships of correspondence are expressed by links shown as arrows, so the module can easily use contexts to make questions which ask the contents of some sentences such as referring relationships by pronouns, or the time order of some events.

The structure of sentences is expressed as a semantic hierarchy, and it expresses the context such as changing topics and scenes. Experiments have been done to divide sentences automatically by considering topics, time and space information, and to make up a semantic hierarchy automatically by con-
think carefully.

4. Mechanisms Of Question Generation For Each Aim

The question generation module in the Comprehension Test treats the following three kinds of query forms.

(1) Questions using interrogative pronouns

This type of question is high level because a learner must understand the context such as referring relationships between words and time-space relationships, and have the necessary writing skill to construct an answer sentence.

(2) Alternative questions

This type is easier than (1) because if an answer follows "No", a learner must have writing skill but she can construct an answer by referring to the question.

(3) Questions asking a learner to point out errors

A learner reads a sentence describing the contents of the textbook, and then she answers whether the meaning of the sentence corresponds with the contents or not. This type is the easiest because the learner needs not construct a sentence.

To ask questions of types (2) and (3), the module should automatically generate sentences which are semantically incorrect. We have implemented the following methods.

(a) To use an opposite word
(b) To exchange the order of cause and effect or time relationships
(c) To replace an instance of a noun or a modifier in the semantic information

The methods of (b) and (c), especially, are quite natural and useful because these methods use information taken from sentences in the textbook.

Note that we are discussing difficulties of questions by considering the query forms and what and how to ask, and we will describe them in a future paper.

In the following part of this chapter, we describe how to form questions from the information described above in [Information For Question Generation] along with the authors' educational intentions.

4.1 To Master The Use Of Grammatical Knowledge

To confirm understanding states of particular grammatical knowledge such as new words and phrases and new interrogative pronouns, the question generation module makes a question of one sentence as follows [Kunichika et al. 95b].

(1) Using new words and phrases

"Words and phrases" include words, idioms and sentence structure. The module has information about the places where new words and phrases appear in each textbook. Using this information, the module transforms statements into questions which include new words and phrases. For example the module generates "Did John have breakfast at eight this morning?" when we assume a new word in the sentences in [Fig. 1] is "breakfast".

(2) Using interrogative pronouns

For conversation training using particular interrogative pronouns, the module makes such questions by referring to semantic categories and functions of words stored in semantic information. For example to train dialog using "Who", the module selects the agent "he" of the third sentence as the query part, and then generates "Who sat on a white bench in the park?".

4.2 To Confirm Understanding States Of Contents Of Sentences

To achieve the target the module makes questions which confirm whether or not the learner is able to answer questions even if they use synonyms, or is able to grasp the context.

First to make questions by replacing words, the module uses dictionaries of synonyms and antonyms. At present the module has information about synonyms and antonyms of verbs, nouns, modifiers, and prepositions and conjunctions used for expression of time or space information. For example by replacing "then" in the second sentence in [Fig. 1] with "after" and combining the first sentence with the second sentence, the module makes a question "What did John do after he had breakfast at
eight this morning?".
Next to make questions which ask the context of sentences the module can use the following ways.

(1) Using sentences of textbooks
The module uses interrogative sentences in a textbook. But if the sentences have pronouns, the module replaces them with referred words by tracing links in semantic information. For example we suppose an interrogative sentence “Do you like skiing?” is in a textbook and “you” in the sentence means “Tom”. The module makes questions such as “Does Tom like skiing?” by replacing “you” and selecting the suitable verb “does”, and “Does Tom dislike skiing?” by using the antonym “dislike” moreover.
(2) Using referring relationships of words and phrases
Referring relationships by determiners and pronouns are expressed as links in semantic information. To confirm whether a learner understands to what words and phrases refer, the question generation module uses the links. For example the module generates “Who went to West Park?” which asks for the word referred to by the pronoun of the second sentence of [Fig. 1].
(3) Using attributes of nouns
Semantic information of nouns is expressed separately for each noun. For example in [Fig. 1] two bicycles: one is the blue bicycle described in the second sentence, and the other is the red bicycle in the fourth sentence. They are not the same object, but they are stored into one entry as different instances. The word “bench” which first it appears in the third sentence and next in the fourth sentence, is the same object, so its attributes are stored into the same instance as shown in [Fig. 1]. Because modifiers which appear in various sentences are stored in one instance, the question generation module can make questions related to some sentences. For example by using modifiers of “bench” in [Fig. 1], the module makes “Did John sit on a small white bench in West Park?”. By using a modifier of another instance of “bicycle”, the module makes a semantically incorrect question “Did John go to West Park on a red bicycle?”.
(4) Using relative pronouns
The question generation module makes questions which use relative pronouns in the following order. First, the module selects both a main sentence and a subordinate sentence. Next, the module selects a relative pronoun by considering both the role of an antecedent in the subordinate sentence and a semantic category of the antecedent. And then the module inserts the antecedent, the relative pronoun and the subordinate clause into the main sentence. Finally, the module makes a question from the sentence. For example by using the third and fourth sentence in [Fig. 1], the module makes “What was there near the small bench which John sat on?”.
(5) Using time and space relationships
Time and space information are expressed as hierarchies as shown in [Fig. 1]. Inclusion relationship information is expressed, vertically, and partial ordering in time information and positional relationships in space information, horizontally. The module makes questions which ask relationships between nodes in the information. For example the module makes “When did John go to West Park?” which asks when the phenomenon in the second sentence in [Fig. 1] happens.
(6) Using information about transitions of scenes
To make questions which ask the transitions of scenes, symbolized by changes of topics, time and space, the question generation module uses semantic hierarchies of sentences as described in [Information For Question Generation]. As a hierarchy indicates in [Fig. 3], sentences in [Fig. 2] are divided between the second and third sentences. Furthermore by using information about continuance of words which express topic, time and space, the module decides the topics of the opening two sentences are “king”, “queen” and “have” which appear in the both sentences: appearing includes referring pronouns. For example the module generates “What did a king and a queen have?” by using the semantic reason for dividing, and “Who liked the baby girl?” to confirm whether a learner grasps a story by assuming the first sentence of a divided group describes the change of a scene.

4.3 To Correct Errors
This category has two meanings; one is to confirm whether a learner has correctly acquired knowledge mistaken in the past, the other is to correct errors in the previous answer. In this section, we describe the ways to make questions for the two types of errors.
(1) For incorrect knowledge in the past

To confirm the knowledge about words and sentence structure, which was mistaken in some test functions, the module makes questions which make a learner use the knowledge in an answer by referring to a student model. Grammatical information in the student model consists of understanding states of both words identified in a word test, and grammatical knowledge identified in the Comprehension Test. The natural language understanding module can identify 61 types of grammatical errors in the following two ways [Kunichika et al. 95b]. One is to use extra conditions in grammatical rules for natural language analysis, and this way is used for identifying word transformations. The other is to use buggy rules, and this way is used for identifying word order. As a result, the identified error type and concrete grammatical information are stored in a student model.

For example to confirm whether a learner who has made the error "countable noun with no article" uses an article for the countable noun "bicycle", the module generates "What was there near the small bench?" from the fourth sentence in [Fig. 1].

(2) For incorrect knowledge in the present time

When a learner inputs an incorrect answer, the module supports the learner from the viewpoint that the module makes the learner think carefully. As parents correct syntactic and semantic errors made by their children immediately, it is important for the module to support correcting errors immediately.

The module corrects syntactic and semantic errors as follows in the Comprehension Test: First, to correct syntactic errors, the module helps the learner in the following order: (a1) Telling the learner where she makes errors. (a2) Showing a correct example sentence. (a3) Showing the incorrect part of the answer and telling about the errors concretely. (a4) Explaining correct knowledge. (a5) Giving an example of a correct answer as the final way. Next, to correct semantic errors, the module supports in the following order: (b1) Telling the learner “Your answer is incorrect,” and giving the same question again. (b2) Giving the same message and a simplified question. (b3) Showing sentences of a textbook, which includes the answer, and giving the same simplified question. (b4) Giving an example of answers as the final way.

5. Conclusion

In this paper we described the targets of using a question and answer facility in the context of education, the kinds of questions to achieve the targets, and the methods of automated generation of them.

A short-term target of our research is to implement the question generation module which generates various kinds of questions automatically. We have already implemented a way of question generation from time and space information, and we are now implementing the other kinds of ways. After we have implemented them, we will evaluate a rate of both generated correct sentences in syntactically and semantically, and generated useful questions in educational use. The next step is to research educational use of the question generation module, that is how and what to ask in what order.

Abstract: An emerging model of learning as situated in social practice is challenging traditional methods of education that tend to isolate the student and abstract the learning processes and outcomes from the social and cultural practices that give them meaning. Approaches to learning and professional development are increasingly turning toward models of induction and apprenticeship. For teaching and learning processes these models emphasize learning from experience and the development of expertise as a process of progressive problem-solving and movement past present levels of competence. This paper describes an Internet-based journal system to provide access, support and sharing for the processes of learning to become a teacher.

Educators and learning scientists are coming to understand that learning is not a discrete process which can be abstracted out of social and cultural experiences, but rather that learning is a part of each human experience. Further, learning from experiences can best be understood when it is seen as situated in a community of practice [Brown, Collins, and Duguid 1989] [Lave and Wenger 1991]. The models of induction and apprenticeship are also aligned with a view of the professional as a reflective practitioner engaged in life-long learning. Donald Schon [Schon 1983] described professional practice as being engaged in a reflective conversation with an uncertain situation, taking stances, experimenting, and learning from the back-talk of the situation.

Following from these emerging understandings of professional education the College of Education (COE) at the University of Missouri-Columbia designed a new undergraduate teacher development program. The new program emphasizes:
1. learning from field experience (i.e. a substantial part of the program is situated in K-12 classrooms),
2. becoming a reflective practitioner (i.e., being challenged to articulate one's experience and learn from the backtalk of the situation.), and
3. induction into a learning community of educators (progressively more challenging responsibilities in teaching, developing habits and strategies for life long learning, and contributing to a knowledge-base of teaching and learning to teach.

Technology infrastructure
The COE envisioned a technology infrastructure connecting students to a common knowledge base and support structure even when dispersed throughout various school systems in the State of Missouri. Students would participate in field experiences in remote schools, communicating about those experiences, being supported as they made sense of the experiences, and building an appreciation and capacity to use a network of resources (human and archived) for engaging in reflective conversations with uncertain situations.

The three key elements for the initial implementation of the technology infrastructure are access, support, and a sharing service. Access was made possible by providing Macintosh Powerbook 1400's to all 290 freshmen students in the class of 2000 and approximately 30 faculty who would guide their first year curriculum experience. The Powerbooks have both ethernet and modem capabilities for making
connections to network services. Support issues are handled by multiple training session about using the technology, a special troubleshooting team created to address technical problems, and a newly designed physical space, called the reflector, for shared resources such as desktop systems, printers and check out for audio-video devices. The current paper describes the Interactive Shared Journal System (ISJS) designed, developed and implemented to support the sharing service for the new processes of teaching and learning.

ISJS is implemented on a Macintosh client and Silicon Graphics Indy servers. The clients and servers communicate over the internet using TCP/IP connections. Anyone who has access to the internet via a direct connection or a SLIP or PPP connection is able to participate, thus students can connect from any home or school location in Missouri and beyond. In addition the software supports the creation and editing of journal entries off-line for later upload when a connection is available. A custom server was created for connecting and maintaining a login to the journal system. The server provides communication between the client and an Oracle database. ISJS is a flexible system for the development and support of learning communities, but in the context of the undergraduate teacher development program it can best be understood as enabling three key processes: access to Internet-based resources, capturing experiences, and sharing experiences. These processes are undertaken in the context of a community made up of four roles:

- administrators, who are responsible for the system;
- mentors, who are responsible for instruction and modeling;
- students, who are responsible for articulation of experiences; and
- guests, who have limited access to public information

Access to Resources

When a student logs into ISJS with an id and password they connect to an intranet of information and communication services. Figure 1 shows the tools menu that greets users once they have successfully logged into ISJS. Users have access to an internal email system that allows for posting mail to internet-based accounts, but also enables an internal mail system for sending messages to other ISJS users via their ISJS login id. This feature will be especially valuable for K-12 students who do not have email addresses. Users can also invoke the Netscape browser from the Tools window. The News button and Resources button take the user to custom news readers and web pages. These features allow the faculty to craft special discussion or HTML environments for their students and their curriculum and have them directly available within ISJS. The inclusion of these first four services in the tools panel is primarily to organize and integrate these features in a single environment for the faculty and student.
Figure 1: Tools window provides access to shared services.

Capture Experience
When a student selects “My Journal” from the Tools window they open a list of existing journal entries. Figure 2 shows four types journal entries: Journal, Append, Source Task and Task. The Journal entry is used to represent an experience or reflection. An Append is a personal journal entry that is attached to another persons journal entry. For example, a mentor or other user might be reading a journal entry from a student. The reader can click the append button that allows for a new entry to be created and attaches it to the open entry. Source Tasks are created by Mentors as assignments and can be distributed to students and then monitored for progress. A Task is what the student receives from the mentor. The sections of the task created by the mentor cannot be modified by the student. The student can, however, insert his or her response to the assignment and indicate level of progress. The journal entries are organized by folders for the various groups that a user has joined or can be sorted by alphabetic title or by date. When entries are created or updated the author can set access privileges to be private, public or by group membership. Figure 2 shows the symbols for each of the four types of entries and illustrates that entries can be either public or private. In addition public entries can be organized by groups of users (not shown in figure).
A user can create a journal entry with the New button on the list window or directly from the File menu. A standard entry has several elements: a title, keywords, access privileges, an author, a body, and it may have appends. A source task has a distribution list, and a task has a progress status. A key design goal of ISJS was to enable mentors and students to express themselves with as much representation power as possible in order to facilitate articulation and communication. To this end we have created a journal entry as a set of media and link objects. Figure 3 shows a journal entry that includes text fields, a link to a web page, a link to another journal entry, an image, and a sound object.
This is a demonstration of some of the features of the hyper-media and shared journal system.

links can be made to other journal entries

Users can insert images.......

The Center for Technology Innovations in Education

Users can insert audio clips

Figure 3: Journal entry showing text, links, an image and a sound.
In addition entries can include attached binary files (e.g., an excel spreadsheet or video clip). The media objects can be imported into an entry through cut and paste from an open document or through a file access dialog if they reside as a file in computer storage. Objects can also be acquired on the fly by selecting an open web page or journal entry, or by using a media control panel for capturing sound through a microphone, a video still from a camera, or an image from a scanner. The object rich journal entry form can facilitate the student as they capture their experience and as they represent it. For example, a student on a classroom visit can capture images of the seating arrangement or bulletin boards, record audio of students reading text passages, or include links to web sites the students found or developed during class assignments. Fellow students or the instructor can not only review the students text descriptions of the experience, but can have a mediated tour of the experience, facilitating understanding and discussion.

Sharing Experience
The idea of capturing experiences can be extended by enabling the student situated in the experience to call up journal entries of classmates who have undertaken similar assignments. By comparing one’s “findings” with those of others, our student can “make better sense” of the experience. In this way, by allowing access to a dynamic community memory, ISJS scaffolds students as they take on progressively more challenging tasks in the community of educators.

ISJS is an archive of experiences, richly presented, that can facilitate being successful on challenging tasks, thus enabling the curriculum to provide progressively richer experiences for the student. Based on research undertaken at Apple Computer, electronic systems can augment the processes of taking on new challenges, sharing resources, and being guided to successful performance. [Laffey 1995] articulated the characteristics of a dynamic support system as the ability to change with experience, to be updated and adjusted by the performer, and to augment other resources found in the performer’s community. The archived experiences can become especially valuable when enriched by appendices from faculty, peers, or practicing teachers.

To build a learning community ISJS was designed to represent both users and their archived experiences. The system enables each user to create a personal profile that represents a type of business card from which other users can connect via email, view a personal web page, enter one’s journal or solicit a chat session. Figure 4 shows a profile window for a system user.
Figure 4: A profile window for a system user.

In addition to archived representations of experiences ISJS affords a live chat intranet. A faculty member or student for that matter could invite students to a chat session in the evening following a set of field experiences. Similarly a chat session could be invoked amidst a field experience to seek suggestions or help make sense of an observation. Users of the system can see who is on-line by asking for a list of people on-line. On-line users can be sent notes asking to meet in a private or open chat room.

Another form of sharing is for the faculty or mentor to structure an experience for a student. Instructors can create object rich source tasks that can be distributed to individual students or groups. Figure 2 shows a journal entry that a mentor has turned into a Source Task. Once an entry becomes a Source Task the mentor can use the Distribute button to assign the task to members of the community and the Review button to monitor progress in the completion of the assignment. A student receives the task in “My Journal”, but a pointer to the task is also placed in the “In-Box” to facilitate the students attending to the task. The In-Box also holds system email and shows when someone has created an append in one of your journal entries. Upon opening the task the student can report about the work they undertook to complete the task and also use a slider bar to mark their progress on a 0 to 100 scale. When the mentor reopens the source task he or she can review student progress and directly open the student task entry.

Conclusion.

ISJS provides an electronic support environment for many of the teaching and learning processes of learning from field experiences, of supporting reflective practice, and of sharing within a learning community. Our experience is showing that learning communities can be augmented by a technology infrastructure that emphasizes access, networking, and shared services. The pilot year of implementation with freshmen students in the undergraduate teacher education program has provided several markers of progress. Representing learning experiences in an electronic journal supports the articulation and sharing of experiences and the ability of faculty and students to derive benefit from field-based learning. ISJS also enables connections to resources and learning experiences that are otherwise inaccessible. For example, we have a cohort of practicing math and science teachers using ISJS with their students as the students undertake project based learning. ISJS is being used to help the preservice teachers “observe” project based learning via reading journals, and is beginning to be used to facilitate a conversation between the preservice teachers and the high school students so as to support the work of learning from their projects. Given some good beginnings, the pilot year has also shown that traditional methods are slow to yield to new approaches in a college of education and that many challenges remain to be overcome. One example of the strength of existing practices is that although ISJS affords the opportunity for a network model of sharing (e.g., communication among peers), almost all instances of ISJS usage of appends show a hierarchical model of sharing (e.g., students provide entries for review by faculty who then use appends to provide comments).

The coming year represents several advances in system use and utility. The freshman and sophomore classes of the teacher education program, including faculty, for a number of about 600 will use ISJS. A key system enhancement is to develop a second client based on the use of a web browser and JavaScript. This client will enable cross-platform use of ISJS. ISJS is a continuing effort to match innovations and advances in technology to the communication and sharing needs of a learning community.

Attitudes of University Students to Computing: An Australian Perspective

Sim Kim Lau
Ang Yang Ang

Department of Business Systems, University of Wollongong, Wollongong, Australia
Tel: +61-2-42214132, Fax:+61-2-42214474, Email: sim_kim_lau@uow.edu.au

Abstract: This study reports on the results of a study investigating attitude to computing for a large group of students undertaking an introductory information systems course in an Australian university. The focus of this study is to determine whether the following factors: age, gender, previous computing background and computer knowledge, influence attitude of university students to computing. Our results show that age and gender do not appear to significantly influence attitudes to computing. However previous computing background and level of computer knowledge do significantly influence attitudes to computing.

1. Introduction

The purpose of this study is to determine the attitude of university students to computing. We are interested in the following questions: “do age, gender, previous computing background and level of computer knowledge influence attitude to computing?”

With the above aims, the following four null hypotheses were formulated for this study:

1. There is no significant relationship between age and attitude to computing.
2. There is no significant relationship between gender and attitude to computing.
3. There is no significant relationship between previous computing background and attitude to computing.
4. There is no significant relationship between the level of computer knowledge and attitude to computing.

2. Methodology

A survey was conducted during the first class for students enrolled in an introductory information systems course in March 1997. The course teaches computer-based information systems in business organizations and practical hands-on lessons on word-processing and spreadsheet software.

The questionnaire is divided into two parts, A and B. Questions in part A are related to gender, previous computing background and level of computer knowledge. Previous computing background is measured in terms of number of years a student has used a computer. There are four categories: not at all, less than a year, between one and two years and more than two years. In this study, level of computer knowledge is defined as overall knowledge in word processing, spreadsheet and database software as well as programming skill. For each type of software and programming skill, students are asked to indicate what they believe to be their level of expertise in terms of none, basic, intermediate and advanced, each carrying weights of 1, 2, 3 and 4 respectively. The mean score, rounded to the nearest whole number, for these four questions is calculated to indicate the overall level of individual student’s computer knowledge. A mean score of 1 indicates no computer knowledge at all, 2, 3 and 4 indicate basic, intermediate and advanced levels of expertise respectively. Part A also consists of other questions such as age (less than twenty years old, equal to or more than twenty years old), faculty which the student enrols in (Commerce, Informatics and others), year of study (first, second, third and above) and mode of study (full-time or part-time).

Part B of the questionnaire consists of twenty-four questions related to attitude to computing. These questions (see Table 1) were adopted from [Francis, 1993]. A five-point Likert scale, ranging from “strongly agree”, “agree”, “not sure”, “disagree”, “strongly disagree” was used. The question can be either a positive or negative statement. For example: “I feel at ease when I am around computers” is regarded as a positive statement, whereas “computers make me feel uncomfortable” is a negative statement. Questions relating to
negative statements are coded in reverse order to those relating to positive statements. In this study, a positive statement is coded as 5 for "strongly agree", 4 for "agree", 3 for "not sure", 2 for "disagree" and 1 for "strongly disagree". On the other hand, a negative statement is coded in the reverse order (for example 1 for "strongly agree"). The attitude of each student is determined by calculating the mean score of the twenty four questions presented in Table 1. A student is considered to have a positive attitude if he or she has a mean score of 3 or more. Otherwise he or she is considered to have a negative attitude to computing.

3. Results

As the study involves bi-variate correlational problems, chi-square analysis is used.

3.1 Profile of Respondents

Five hundred and nine responses were collected, of which two hundred and seventy-eight were from male students and two hundred and thirty-one were from female students. There were four hundred and sixty-three full-time students and forty-six part-time students. There were three hundred and eighty-nine respondents enrolled in the faculty of commerce, whereas seventy-nine respondents enrolled in faculty of Informatics and forty respondents were from other faculties in the university. In addition, there were four hundred and thirty-two respondents who were first-year students, sixty-one respondents were second-year students, sixteen respondents were third- and fourth-year students. In terms of age category, there were three hundred and forty-five respondents who were less than twenty years old and one hundred and sixty-four respondents fell into the age category of equal to or more than twenty years old.

There were forty-five respondents with no computing experience at all, sixty-two respondents had less than one year of previous computing experience, ninety-four respondents had between one and two years of previous computing experience and three hundred and eight respondents had more than two years of previous computer experience. In terms of level of computer knowledge, one hundred and nine students considered themselves did not have any computer knowledge, two hundred and forty-three students were perceived to have basic level of computer knowledge, one hundred and thirty-two students were identified as having intermediate
level of computer knowledge and twenty-five students had advanced computer knowledge. Figures 1 and 2 show breakdown of age in relation to previous computing background and level of computer knowledge respectively. Figures 3 and 4 show breakdown of gender in relation to previous computing background and level of computer knowledge respectively.

**Figure 1:** Breakdown of age in relation to previous computer experience

**Figure 2:** Breakdown of age in relation to level of computer knowledge
3.2 Chi-square Results

Table 2 shows observed Chi-square values from comparisons between attitude and age, gender, previous computing background and level of computer knowledge. We conclude that there is no significant relationship between attitude to computing and age, and, attitude to computing and gender. However there are significant relationships between attitude to computing and previous computing background and, attitude to computing and level of computer knowledge.

4. Discussions

In this study, it is found that age has no significant relationship with attitude to computing. Studies have shown that although older students had less computing experience compared to younger students, they were less computer anxious. Older students also believe that they could benefit from computer technology and viewed acquisition of computer knowledge as desirable and favorable. On the other hand, younger students are more likely to use computers earlier in life than their older counterparts and therefore they are more likely to show positive attitudes to computers. It is suggested that although older students have less computer experience than younger students and they may be less confidence with computer, however they demonstrate positive liking for computer. Confidence with computers is often a result of computer knowledge and familiarity with the technology, thus age should not be a factor in influencing one’s attitude to computing. Attitude can change as a result of computer knowledge and experience with computer. Our results which show age does not influence attitude to computing is consistent with that reported by [Anderson, 1996].

Our results also show that gender does not significantly influence attitude to computing. This result is encouraging as female students are no longer perceived to have a less positive attitude to computing. In a previous study conducted by the authors in 1994 [Lau et al, 1995], gender was found to significantly influence attitudes to computing. The result presented here is consistent with studies conducted for undergraduate students undertaking introductory course in information systems or computing [see Anderson, 1996; Houle, 1996] in which gender factor was found to be not influencing attitude to computing. Thus it is encouraging to note that the result presented here together with others reported elsewhere may indicate that traditional gender stereotyping and attitude to computing no longer valid.

Our study shows that there are significant relationships between previous computing background and attitude to computing, and level of computer knowledge and attitude. These results are consistent with that reported in the literature as well as consistent with a prior study conducted by the authors in 1994 [Lau et al, 1995]. Evidence [see McInerney et al, 1994] suggests that increased computer experience diminishes computer anxiety. This is because computer anxiety and attitudes towards computers use are related [Bozionelos, 1997]. In another study [see Torkzadeh and Dwyer, 1994] also suggest that computer training increases user confidence. Confidence with computers can be attributed to familiarity and computer knowledge. Lack of computer knowledge results in high anxiety and negative attitudes. It has been shown that attitude to computing can be improved significantly with training. Thus in order to reduce the anxiety of students to computing, training may be an ideal way to overcome the negative attitude to computing. [Torkzadeh and Dwyer, 1994] show that computer user training does influence user satisfaction and user confidence. However it is worth noting that increased computer experience alone will reduce computer anxiety and thus ensure a more positive attitude to computing is a simplistic view [McInerney et al, 1994]. Further research in this area needs to be conducted to confirm this view.

6. Future research

There is no consistent view on whether attitude to computing change for better or worse after attending the computing course. [Barrier and Margavio, 1993] show that student’s attitude to computing do become worsen after a one-semester computing course. However [Torkzadeh and Koufteros, 1993] do not show any change in attitudes upon completion of a computing course. It is important to investigate student’s change in attitude to computing. As [Simon and Wilkes, 1997] point out having a good attitude will encourage a student to learn more. It is desirable that further research to be carried out to investigate whether students change their attitudes after completion of computer course. In this study students were asked to determine their perceived level of computer knowledge in terms of their capability in using application software (word processing, spreadsheet and database) and their programming skills. In order to obtain a more accurate measure of computer knowledge, a computing test should be administered to determine individual’s level of computer knowledge. A set of multiple-choice questions on computer concepts and applications can be used for this purpose [see Oliver, 1993]. Thus to investigate the change of attitude after one semester course in computing, a pre-test needs to be conducted at the beginning of the semester and then a post-test can be carried out at the end of the semester using a structured instrument.

As information technology becomes an indispensable organizational resource, top management expects its employees to be conversant with computer technology and to use the technology in all aspects of planning,
management and production operations. More and more organizations are also employing staff who are computer literate. Students from business and commerce courses are expected to be computer literate and proficient in computer software. It is not known whether professional expectation such as that described above plays a part in influencing attitude to computing. Future research should be carried out to investigate the relationship between professional motivation and attitude to computing.

7. Conclusions

In conclusion, our results show that there is no significant relationship between age and attitude to computing, and, gender and attitude to computing. However there are significant relationships between previous computing background and attitude to computing as well as between level of computer knowledge and attitude to computing.

Finally what can this study contribute to the educators, in particular educators who are involved in teaching introductory computer courses in tertiary education? As discussed previously with widespread introduction of computers in the workplace, a large number of organizations expect graduates they employed to be computer literate and be able to integrate their academic knowledge and computer technology into all aspects of their work. Universities have also included computer literacy as one of desirable attributes which students must possess when they graduate. Thus it is not surprising to see that introductory computing course has often become a compulsory unit in business degrees and programs. To this extent an introductory computing course often have large group of students with diverse background and computer skills. As indicated in this study, previous computer background and level of computer knowledge show significant influence on attitude to computing, thus educators should make deliberate efforts to find out if students possess any previous computer background. By finding out prior computer experience and level of computer knowledge, this can assist educators in planning the content, format of the course as well as assessment. As [Houle, 1996] points out that effective teaching requires detailed knowledge about the students as it impacts on students' motivation and desire to learn. It is hoped that by having detailed knowledge about students' previous computer background and level of computer knowledge and by planning a course which is appropriate to their level, it will improve students' motivation to learn more and to acquire computer skills which will be useful to them.

Abstract: Telelearning is no longer a new phenomenon in educational practice. The emergence of the Web in the field of education has created a new teaching and learning discourse as well as a new discourse community. It provides teachers and learners with powerful facilities to interact and to explore the world of knowledge whose access is no longer restricted by time and locality. Educators of different academic specialisations have used the Web as a superhighway for extending and expanding education. However, it is not smooth surfing as teleteaching in a virtual context can bring with it serious problems, particularly in an intercultural context. As learning cannot be divorced from its cultural context, teaching via the Web needs to take into account the discourse of learning which is sensitive to cultural imperialism. The superhighway can create cultural conflicts between learners and course providers if it fails to recognise learners' cultural identities.

The question 'What is teleteaching?' was raised by Daunt [Daunt 1997] at a conference when she attempted to examine how teleteaching and traditional face-to-face teaching differ in the current context of computer technology. In her view, the most common factor for teleteaching is that it involves the use of communications technology to interact with students in 'real' time. She explains why teleteaching is introduced:

Many educators are being thrust into the role of 'teleteacher'. This sometimes occurs because an organisation has investigated new and creative ways of delivering education to dispersed groups of learners. However, it often occurs because organisations must do more with less and teleteaching is seen as one way of achieving this. No matter what the motivating factor, teleteaching presents exciting new opportunities for teachers and students.

[Daunt 1997, p.105]

As the prefix 'tele' means 'far' or 'over a distance' as in 'telephone', 'telegram', 'television' etc, teleteaching can be said to be in contrast with face-to-face teaching. The discussion in this paper will focus on teaching via the Internet, primarily the World Wide Web.

While the constant search for an effective and enlightening way of teaching in traditional education is explored, a different force which challenges the current educational practice has emerged as computer technology has powerfully permeated society as a whole and education cannot be immuned from the computer-led revolution. The Web is undoubtedly a powerful force which may tricker a paradigm shift. The popularity of this conference is a clear evidence of its recognition in educational theory and practice. Terms such as virtual class, virtual school, telelearning and courseware are no longer special jargons.

The Web has become a familiar educational context for alternative teaching, particularly in tertiary education. Terms such as courseware, teleteaching (Daunt 1997), virtual class, and Internet-based teaching represent a new paradigm shift from face-to-face teaching. As the context of teaching has changed due to the recent emergence of the Internet, the role of a modern teacher has also changed. Tellah [Tellah 1997] suggests that the teacher's role is likely to change from the 'Sage on the Stage' to the 'Guide on the Side'. Roberts [Roberts 1997] argues that higher education is experiencing a paradigm shift, which occurs worldwide but faster in some...
parts than others depending on availability of resources, existing infrastructure and the stage of development reached. Moran [Moran 1997] refers to the new paradigm as a cult as she points out that this cult has “its own esoteric language and rites, ‘in’ groups and ‘out’ groups, and above all faiths in the intrinsic value of electronic communications”. The so-called paradigm shift brings along newly defined concepts such as flexible learning, independent learner, technologically-based learning style. For instance, according to Szewcow [Szewcow 1997] flexibility means ‘being able to learn a course/subject any time, any place, any pace and leave when you have satisfied your needs’.

Courseware and semi-courseware have been introduced by tertiary education institutions to cater for on-campus as well as off-campus students. These are across subject areas. However, science and technology subjects tend to dominate the new technologically dominated domain [Linn 1992; Hedberg et al. 1994; Lê 1995; Gibert 1996; Newmarch 1997].

Though the Web has undoubtedly provided its users an extremely powerful tool for communicative interaction via the superhighway, it also brings along problems, clearly identified or mysteriously hidden in a human context as the superhighway has to run through a global village in which villagers of diverse cultures live. There are always cultural boundaries and demarcations which are invincible. In the discourse of education, while we may feel proud of the incredible speed and wide range of interaction the Web has brought to telelearning, it also brings many problems of the human kind. Access to a treasure of valuable information is one of the main aims of the Internet. However, the information superhighway cannot ignore the dynamic nature of different cultural contexts through which it travels. As the context of cultures determines the discourse of education, it is important to recognize that the cultural background of the learner can have a more profound effect on education than does a courseware itself. In traditional teaching as well as teleteaching, the commonly held assumption is that unless students can relate the application of what is taught to their own cultural backgrounds, their learning is likely to be less than effective. This is the reason why it is important to examine critically the new discourse brought about by the Web so that we can understand and appreciate its full contribution to education and intercultural understanding while taking notes of its potential problems and dangers. Andrews [Andrews 1997] has recently pointed out the needs for implementing global education using new computer technologies:

The rapid uptake of telecommunications technologies is having a profound impact on the nature of teaching and learning at a local, national and international level. While expanding and enabling the globalisation of teaching and learning this globalisation has considerable implications for educational establishments. The challenge lies in providing a quality education to a client base that is not only geographically dispersed but also diverse in terms of age, culture, access, educational experience, expectations about learning and exposure to a range of teaching and learning methodologies and modes of delivery.

[Andrews 1997, p.5]

The issue of 'taking for granted' in society and education has re-emerged with great interest. This is partly due to new developments in discourse analysis and critical pedagogy. Recently, educators, particularly those who adopt the critical theory, have questioned current educational practices which reflect the dominance of certain ideologies implanted in the curriculum and most importantly their powerful control of the educational discourse. On this tenet, the hidden curriculum needs to be systematically exposed and critically examined in terms of coercion, social inequity and ideology imposition. It is argued that this is crucial as the Web with its own powerful superhighway travels through a vast land of diverse cultures. As learners' cultural backgrounds cannot be ignored in intercultural education, any telelearning involving learners of diverse cultures needs to tackle seriously curriculum issues in a Web-based teaching context. Teleteaching in an intercultural discourse needs to be culturally sensitive as it may create cultural conflicts between course providers and learners. Factors such as cultural assumption and definition, cultural norms in social interaction, learning styles and cultural attitudes to education etc. need to be in the consciousness of courseware providers. Failing to take all these factors into consideration, the superhighway will lose its educational mission as it can lead to educational conflict, particularly when the cultural gap between the educational provider and the receiver is wide and in many cases no conventional bridging can fill the gap. As the paradigm shift moves away from the focus on teaching and learners are no longer passive knowledge receivers, there have been various attempts in educational theory and practice to introduce innovative curriculum ideas to schools to improve learning conditions and teaching methodologies. A quick glance at papers presented at this conference shows abundant use of curriculum concepts such as constructivism, learner-centred, negotiated curriculum, humanistic approach to learning, learner empowerment etc. This is a fascinating direction in educational multimedia.

The popularity of the Web has brought various parts of the world together. Gradually it has created its own culture. From the educational viewpoint, learning interaction is no more restricted to a few classmates in a
corner of a classroom. The interaction has widened to include those from different geographical and cultural backgrounds. Teachers are no longer the only powerful source of knowledge and the library is no longer a building with many isolating walls and concrete boxes. In other words, the virtual world almost becomes a reality, not just an imagination. Teaching and learning via the Web present a different dynamicity in a different discourse. The new discourse of teaching and learning via the Web creates a different meaning making process which cannot be derived from the face-to-face tradition. The new discourse requires new ways of thinking, interacting, expressing etc. If educators seriously want to meaningfully embark on a new paradigm and accept a paradigm shift, they need a new consciousness.

To maintain meaningful intercultural education, particularly via the Web, it is important to take into critical consideration the meanings and assumptions that people in different cultures hold on fundamental concepts such as learning, teaching, curriculum, knowledge and relevancy etc. since these concepts are culturally specific. The reality facing a virtual class is that it cannot treat students as virtual learners. They exist in context and bring to the learning environment, whether it is face-to-face or via the Internet, a complex socio-cultural background which interferes with their learning and becomes a determining factor for their educational achievement. The fact that they are not visible in a face-to-face teaching does not mean that they do not exist. We cannot expect these students leave all their cultural backgrounds behind when they undertake a course delivered on the Internet. As stated, learning is embodied in culture. According to [Andrews 1997], not only students, teaching staff are struggling with the changes brought about by globalisation and the accompanying diversity of the student body. She points that while it is generally acknowledged that learners have different learning styles and expectations and teaching students from other cultures can be an ordeal for some staff and misunderstandings concerning cultural differences are not uncommon.

It has been argued in this paper that the real question facing Web-based education is that different cultures see issues differently and people engage in discussing those issues are culturally constrained. Therefore courseware developers need to take into account the cultural reality of a virtual class. Learners bring to their cultural identity which can strongly dictate teaching and learning styles, perception of the role of a learner and teacher and most importantly the classroom discourse. Thus, teaching cannot be treated as culturally independent.

The Web has provided distance education learners and teachers with an extremely powerful tool for sharing information in teleteaching. It also brings along problems in a human context. In education, there are curriculum issues in internet-based teaching which need to be dealt with, particularly from the intercultural perspective. Like face-to-face teaching, virtual classroom teaching in intercultural education needs to be culturally sensitive as it may create cultural conflicts between course designers, teachers and learners. Factors such as cultural stereotyping, cultural norms in social interaction, learning styles and cultural attitudes to education need to be taken into consideration. Otherwise the superhighway can lead to educational conflict, particularly when the cultural gap between the educational provider and the receiver is very wide. Davison [Davison 1997] is critical of the way in which the concept 'globalisation' is (mis)applied in intercultural education. He says:

The importance of personal knowledge of the people involved in any open, distance and flexible learning is sometimes lost in a context of 'globalisation' trends and a techno-idolatry often associated with it. And yet all education is a moral activity. It is concerned with people significantly affecting the lives of others and educators have a moral obligation to consider how their individual actions in the teaching/learning nexus might significantly affect the lives of those immersed in it.

[Davison 1997, p.113]

The serious problem facing Internet-based teaching is that different cultures see issues differently and people engage in discussing those issues are culturally constrained. In one culture, talking about sexual behaviour is encouraged in education while in other cultures, it is censored partially or totally banned. It is the question that Internet-based courseware developers have to take into account; otherwise a 'virtual classroom' in one cultural context may become a villainous classroom in another.

Ideology plays a crucial role in the development of critical theory as a central feature of the work of critical theorists, the ideology-critique. Ideology is therefore an important feature for critical theorists to expose the social imbalance of society. Interest in ideology leads to the understanding and sympathy for the culture of the oppressed. Critical theory operates by freeing people from coercion of ideology through enabling them to recognise the reality of their situation and thereby giving them more control over their own lives. In the critical theory viewpoint, educational practices are not themselves ideologically neutral. It reveals a context of cultural and political imposition. As Comber [Comber 1994] points out in literacy education:
Literacy practices are not in themselves neutral, but work culturally and politically to privilege particular kinds of literacies and therefore particular kinds of literate students. [Comber 1994, p 26]

From the critical theory perspective, education should seek to overcome false consciousness as individuals are caught up in a social context in which they are blind to inequities of their situation and can be exploited by the dominant class. It is interesting to apply the concept of hegemony from critical theory to the context of Internet-based teleteaching, particularly in relation to the multicultural education. Hegemony can be defined as "the whole body of practices and expectations: our assignments of energy, ordinary understanding of man and his (sic) world. It is a set of meanings and values which as they are experienced as practices appear as reciprocally confirming. It thus constitutes a reality for most people in society, a sense of absolute because experienced reality beyond which it is very difficult for most members of society to move in most areas of their lives" [Phillipson 1996]. In this way, there is a close link between hegemony and discourse community. The relationship of these two concepts is metaphorically seen as the mind and body matter. According to [Phillipson 1996], hegemony reveals 'the relations of domination and subordination, in their forms as practical consciousness, as in effect a saturation of the whole process of living - not only of political and economic activities, nor only of manifest social activity, but of the whole substance of lived identities and relationship, to such a depth that the pressures and limits of what can ultimately be seen as a specific economic, political, and cultural system seem to most of us the pressures and limits of simple experience and commonsense [Phillipson 1996]. As pointed out previously, the Web produces a new culture of learning and teaching and obviously it can create its own hegemony.

There is now a strong belief in Web-based teleteaching that teaching is not the process of acquiring new knowledge but fundamentally to make sense of knowledge and even to challenge it. Postmodernism encourages learners to question how the master narratives become constructed and how they influence their thinking and living experience. In addition the regime of knowledge should be challenged as it is 'there' in the curriculum because it is part of power. In Foucault's view, power and knowledge cannot be separated. Weedon [Weedon 1987] points out that social structures and processes are organised through institutions and practices such as the law, the political system, the church, the family, the education system and the media, each of which is located in and structured by a particular discursive field. If all those issues are ignored due to financially-driven principles and pure excitement with the magic of the Web, the culturally ill-perceived educational superhighway could lead to ideology imposition and cultural conflicts. It is not always easy to draw a line between imperialism and education.

**Conclusion**

We have just examined some moral dilemmas in telelearning, particularly in the context of intercultural education. The Web has permeated the field of education at various levels, ranging from primary to tertiary education and covering themes across subjects and specialisations. Internationally, the Web as a superhighway has brought people of different cultural backgrounds together and this conference is a good example of its achievement. However, how powerful this superhighway is, it is still so vulnerable in its teleteaching mission.

Advanced Technologies, Achievement, and Migrant Students

Dr. Patty LeBlanc
Assistant Professor of Educational Computing and Technology
Barry University-Orlando Center USA
pleblanc@bu4090.barry.edu

Abstract The purpose of the MECHA project is to develop, implement, and evaluate a comprehensive model for 1) promoting greater continuity of instruction for migrant students as they are served in different school districts and 2) assisting migrant students to achieve high academic standards through innovative uses of technology to enhance teaching and learning. Web based instruction, email, and two-way interactive technologies are used to provide instruction and feedback as students migrate so that each student has a seamless academic year. This project serves as a model for collaboration between government, school districts, universities, and industry partners.

The Migrant Education Consortium for Higher Achievement (MECHA) project is a collaboration between Barry University, Miami-Dade County Public Schools, Florida Public Schools' Migrant Education Program, public television, telecommunications industry partners, and school districts serving migrant children and youth in five states along the migrant stream of the eastern coast of the United States. This project is funded by the U.S. Department of Education, Barry University, DCPS, and industry partners.

The purpose of the MECHA project is to develop, implement, and evaluate a comprehensive model for 1) promoting greater continuity of instruction for migrant students as they are served in different school districts and 2) assisting migrant students to achieve high academic standards through innovative uses of technology to enhance teaching and learning.

The objectives of the MECHA project are:
♦ to develop a model for providing and monitoring a student's individualized learning plan regardless of time or place.
♦ to implement the model over a 5 year period and evaluate its effectiveness.
♦ to provide relevant and meaningful instruction which will result in higher achievement in the core subjects at all grade levels and reduce dropout rates for secondary migrant students.
♦ to expose migrant students and their families to a number of career options available to them.
♦ to disseminate information about the model to state and local agencies serving migrant families.

Dade County is located at the tip of the Florida peninsula. Because of its idyllic climate and long growing seasons, it is the site of many large farms and other agricultural-related industries. Dade County is the home base for approximately 1,089 migrant families and 2,787 school-age migrant children and youth [Florida Department of Education 1996]. The typical migration patterns for these farm workers is from Mexico to South Florida, Georgia, South Carolina, North Carolina, Pennsylvania, Virginia and back to Dade County. The pattern varies little from year to year, depending on weather, availability of housing and work, and educational opportunities.

Migrant students at all grade levels have been identified by M-DCPS as being at risk for school failure for a number of reasons: 1) inability to communicate effectively in English, the language common to American schools, 2) socioeconomic factors, and 3) disruption of education due to migration.

The problems associated with migration are obvious:
♦ disruption of and lack of consistency in educational services.
♦ isolation of students from their peers.
♦ lack of educational materials.
back-tracking (students have to be re-assessed at every new school due to lack of timely receipt or transfer of educational records).
- lack of time to complete school assignments due to the students' need to work or provide child care.
- lack of knowledge of systems and opportunities.
- the inability of migrant parents to support their children's educational progress due to time constraints and limited English proficiency.

Advanced telecommunications technologies afford students and school districts a way to bridge many of the barriers to educational progress found in the migrant community. These technologies allow any learner to take advantage of educational opportunities regardless of time or place. Our vision for the MECHA project is that migrant students can be involved in a consistent, individualized learning program regardless of where the student and his/her family are located, provided that appropriate supports are available and utilized. Innovative technologies have been built into the MECHA model in hopes that they will prove to be a prototypical approach to migrant education in other locations. The MECHA model was designed to address the critical concerns of educational programs in migrant communities as described in Table 1.

Table 1: Critical Concerns of Migrant Education and MECHA Solutions

Description of the MECHA model

Key elements of the MECHA model include:
- centralized coordination of instruction, monitoring, and reporting at Barry University.
- use of telecommunications technologies for instructional delivery, technical assistance, dissemination of information, teacher/student/parent support, monitoring, and reporting.
- collaboration with critical businesses, districts, agencies, and departments to provide comprehensive educational services to migrant families.
- parent education and support via instructional TV and telecommunications technologies.
- implementation of "best practice" in education applied to the distance learning environment.

The MECHA project is housed in Barry University's School of Education. The director of the MECHA project is responsible for coordinating all components of the MECHA program including:
Five migrant teachers were selected by the M-DCPS Migrant Education Program and are housed in South Dade in order to facilitate the planning and delivery of distance learning. The migrant teachers:

- were trained by the MECHA project staff in the use of telecommunications for the development and delivery of instruction using distance learning technologies.
- were assigned 20 families each to mentor throughout the entire academic school year and the summer (their community) in conjunction with undergraduate teacher interns from Barry University.
- will deliver instruction to the mainstream or migrant resource teachers at the remote sites via one or two way interactive video (live) technologies.
- coordinated the curriculum development component of the model to integrate educational technology in authentic and transparent ways.
- co-developed individualized learning plans (ILPs) for each of the migrant students in their community.
- collaborated with other MECHA staff in the delivery of web-based instruction.
- coordinated and supervised undergraduate interns who will work directly with students as mentors.
- were responsible for monitoring the academic progress of each of the migrant students in their community.
- were responsible for referring migrant students and family members to other social service agencies when appropriate.

A dedicated web server was purchased using USDOE grant monies. Its function is to serve as the WWW information link to the migrant student's home-base teacher as well as the virtual (online) teacher's lounge where the home-base and remote teachers can interact privately via email to plan, discuss, and evaluate the effectiveness of the program, its curriculum, etc. In addition, the server is used as the home for web based instruction and student home pages.

A web master was hired to design the MECHA homepage (http://mecha.barry.edu), maintain the server web site, and to assist teachers in the development of web based curricula. In addition, the web master is responsible for the development of a secured area for storing information about each student in the migrant program which can only be accessed by means of a password. Two hourly records clerks input information from the cumulative folders of each student in order to establish a web based tracking system for all DCPS migrant students.

Equipment and network support for provision of two-way, interactive video were purchased through grant money and industry partnerships and set up at Barry University and in South Dade. One other district receiving migrant students will be randomly selected each year for testing the viability of "team teaching" using live, two-way interactive video between the remote site and the home based teacher. Two-way, interactive technologies will also be used to deliver parent education, teacher development activities, and progress reports on students.

**Implementation of the MECHA Model**

One hundred families were randomly selected from among the 1,089 migrant families identified in Dade County to pilot the on-line, distance learning component of the MECHA project in year one. Selected families received a WebTV interface with a remote, a small keyboard, and a carrying case. This device was chosen through industry partnerships to provide an inexpensive, portable means of accessing and interacting with the Internet using a standard TV set for the display of information and a built-in modem for access.
Prior to their departure from South Florida, migrant students and parents were taught by the home-based teachers to set up and use the WebTV interface to access the MECHA web site, to conduct research, and to send email to their teachers or other members of their community. All family members were also instructed on staying safe on the information highway.

When a migrant student leaves with his or her family to follow the migration route, the WebTV interface goes along too. Upon arrival in the new location, the device can be easily hooked up, and the student can dial a local number to access his or her account with the WebTV network. Once logged on, the student can then type in the address of the MECHA web site to access materials, assignments, and related resources on the web developed by his or her teacher. Assignments can be submitted by email back to the teacher or undergraduate intern.

Collaborative projects may be assigned by the home based teacher which require other migrant students within the neighborhood to interact via email in order to complete the requirements of the project. In any case, the opportunity to collaborate with both teachers and peers via email is available to the student wherever he or she goes and provides a motivating purpose for learning. All content area instruction includes a strand on career education to introduce students to alternative career choices based on their aptitudes.

Using the WebTV, students are able to work during the day and study at night, on weekends, or during bad weather. Instructional timelines will become asynchronous depending on the needs of the individuals and the neighborhoods (a "virtual" work-study program!).

If the student does not have access to a telephone line in his or her home, the MECHA partnerships at both the home based and remote sites go into action to ensure access either through directly supplying the necessary equipment and wiring or contracting the work. The coordination of these services is the responsibility of the MECHA director.

Other family members can use the WebTV interface as time allows. The MECHA web site has links to related Internet resources, parent education programs/activities in the home language, and resources for younger siblings in the home.

Each of the students collaborated with his/her teacher to develop an individualized learning plan (ILP) before leaving the home base. This learning plan included web-based communications and activities that address the student's specific needs and interests. The home based teacher keeps an electronic portfolio of all of the students in his or her community.

In addition to the WebTV interface, each migrant family received a "6 pack" of useful CD ROMs from industry partners such as electronic encyclopedias, etc. for use at the remote school site or at the public library.

Finally, each child in the selected family received a Scholastic Literacy Place kit to take with him/her to the remote site for enrichment and independent work. This particular curriculum is especially appropriate for second language learners due to the whole language approach to reading with extensive literature, writing, and technology connections. Additionally, each unit of study has a focus on career education.

When video-based components are necessary to introduce, teach or explain a concept, home based migrant teachers videotape an instructional segment at the district's TV studio, and a) broadcast the segment using 2-way interactive technologies or b) compress and digitize the video to be put on the web site. In this way, the student only has to click on the web link to view the video on his/her computer before, during, or after completing the assignment.

When the family has to move to a new location, the equipment goes along with the family. This equipment will change and/or be upgraded as new technologies develop during the 5-year grant period.

Evaluation of the Project
Formative and summative evaluation procedures are employed to assess the effectiveness of the MECHA project. An external evaluator works closely with project staff and migrant students and parents to document the program’s activities, ensure effectiveness, and promote measurable gains in achievement of migrant students. The project’s funding period of 5 years lends itself beautifully to longitudinal study of program impact.

Evaluation of the program’s effectiveness can be assessed in the following ways:

- descriptive statistics on the numbers of migrant students and families served by the program.
- documentation of the implementation of the project and achievement of project goals.
- evaluation of portfolio data and quality of products developed during the course of the program along with an analysis of the achievement of the goals of the ILP.
- standardized test scores given by the district in the spring of each academic year will be compared over as part of a multiple-measures model of ascertaining scholastic growth over time.
- standardized test score gains of participating students will be compared each year to the test’s norm group gains (non-participating students).
- comparison of the drop out and teen pregnancy rates among participating students and a random sample of non-participating migrant students matched for age.
- focus group/interview data from participating teachers, parents, and students describing the most and least beneficial/effective components of the program.
- analysis of a sampling of email messages from students and parents; these thoughts and reflections should provide a rich source of anecdotal data.
- documentation of the types of parent education offered through the program and its impact.
- level of dissemination of information about the model to state and local agencies serving migrant families.

The central repository for information about the MECHA program, its implementation, effectiveness, and evaluation results is the MECHA web site. The information contained there can be updated daily. Student work can be published and displayed on the web site. Video data will also be collected throughout the entire program. This footage will be edited into a 1 hour documentary on the use of innovative technologies in migrant education to be broadcast on public television.

The collaboration between government, university, school districts, and industry partners has been crucial to the implementation and success of this project and serves as a model for other projects.

Abstract: This paper explores various issues on building a Web-database gateway. The ease of the Web interface and the versatility of a relational database make the Web-database connectivity a potent vehicle for activities that require dynamic interactions including business environment. Web design, CGI programming, database design and "middleware" approach for Web-database connectivity are discussed. Some examples of Web-database interface are available online at: http://business.ship.edu/WebDB/.

1. Introduction

The World Wide Web is a particularly useful vehicle for learning activities for students, low-cost corporate training and customer service for small firms, and other situations that require a sophisticated level of interaction and user participation. The majority of Web sites today, however, is designed for one way communication and serves static documents. The Web, although an improvement over the past technology, requires additional development to make it truly interactive.

The marriage between the Web and a relational database can provide powerful interactive tools for academic as well as business users. One of the main issues in using a database is the problem of accessing the data. Many database management systems provide a programming interface for computer languages such as C or Fortran, but these can be cumbersome for ordinary users. A Graphical User Interface (GUI) can make database access easier, but the implementation of such interface also requires programming expertise specific to a hardware platform, and most database users should not be required to know how to implement a GUI. This is where the Web technology can play a significant role. Web browsers provide a GUI that can be used to access various informations, including a database. Users can access a database by simply filling a Web form and pressing a submit button. The Web server executes CGI (Common Gateway Interface) programs to access and retrieve desired data. The returned data are displayed in an easily readable format. Furthermore, the Web's cross-platform support allows users of different types of computers (Win, Mac, Unix, etc.) to access a database from anywhere in the world. Information can be disseminated with a minimum of time and effort, with no compatibility problems.

The purpose of this paper is to discuss various aspects of building a dynamic Web-database gateway that can be used in business curriculum for interactive teaching and learning, tutorials, and corporate training. The technology of building a Web interface to a relational database is on the cutting edge. While there are some applications available, they are rarely designed for educational or corporate training purposes. There is a need for Web-based database development that can be applied to business curriculum so that students may understand how the Web and relational database technologies can be integrated and apply them in the business environment.

2. Web-Database Gateway
For a majority of Web sites on the Internet today, five things normally happen when a user visits the site. First, the user's browser software decodes the first part of the Web address called Uniform Resource Locator (URL) and contacts the Web server. Second, the browser provides the rest of the URL to the server. Third, the server translates the URL into a path and file name. Fourth, the server sends the document file to the browser. Fifth, the browser displays the document. As stated earlier, these static Web documents can come alive through the use of Web forms, CGI programming and relational databases. The mechanisms for such Web-database interaction are shown schematically in Figure 1. There are five major stages in this interaction. First, the user fills the form using the browser, requesting pertinent information. Second, the browser submits the request to the Web server. Third, the server executes one or more CGI scripts, accessing and querying the database. Fourth, CGI retrieves or produces a document. Fifth, the Web server sends the result to the browser for display. The Web server and database server can be hosted in a single machine or two separate machines connected through the Internet [Lin, Danielson & Herrgott 1996; Healy 1996].

Figure 1. Schematic of Web-database Interaction

For purposes of Web-based instruction and training, this process can be repeated until the objective of the user is accomplished. The Web forms and CGI scripts provide mechanisms that record input, relate it to previous inputs, and to return desired results for the user's browsing. This structure of Web-based instruction even allows periodic evaluation of activities. For example, multiple choice questions can be presented in a Web form, which are answered by students and submitted to the server for evaluation. A database server (or program) stores the data. The CGI performs the evaluation using the data and sends the feedback to the students. This Web forms-CGI-database combination can be used in a variety of situations that require interaction and user participation.

To design an effective Web-gateway for a relational database, the three major design activities must be performed, including Web form design, CGI programming, and database development.

2.1 Web Forms
Web forms are created as a graphical user interface to link users to a relational database via the Web. These forms are designed by giving a number of data fields in which users can enter information and/or choose options. The action and method elements embedded in a form decide how the data are processed. For example, potential customers can key in order information in an order form. These order data are assigned to appropriate data fields. When finished, potential customers click a submit button to send information back to the server script. A script is a computer program that is written specifically for each form (or user interface). Scripts present flexibility by allowing users to interact with form documents instead of just reading and providing information. By writing scripts, results of data input in a form can be sent to an appropriate person or linking data to server applications.

2.2 CGI Programming

Traditionally, communications between Web server and database application are conducted through CGI scripts. The CGI programs can be written for a variety of purposes. For example, externally, a business organization might present its product information on a Web site. The corporate database might provide a link to the internal sales, supplies, inventory, and pricing database tables, allowing customers to check on their orders. All these linkages are realized through the CGI programming. One CGI program may handle customer search function for checking product availability in the product database stored in the Web server. Other CGI programs may process password verification, database security, table opening, record updating, field calculation, and data transmission. CGI programming makes it possible for the operations such as opening and updating appropriate database tables to link form objects to a database structure specified in the database design. Visual Basic and Perl are frequently used as the CGI programming tools for Web-database connectivity [Hermann 1996].

One weakness of using CGI programming for Web-database connectivity is that the interface seems to suffer in a production environment, since the Web server must load, execute, and terminate a new CGI script for each user access (Lazar & Holfelder 1997). Recently, Web "middleware" using server-side scripts is gaining popularity. Unlike the traditional CGI programming, this approach improves the performance of a Web-database interface by more tightly integrating the Web server and relational database. This "middleware" approach to Web-database gateway is briefly discussed in the following section.

2.3 Database Design

A database is a collection of information stored in files. A database management system is a program that stores, maintains and retrieves information in a database. A relational database (as opposed to hierarchical, network or object-oriented database) stores and retrieves information according to user-defined relationships. A relational database composed with rows (for records) and columns (for fields) in table format. Compared with a flat file structure, database approach has the advantages of minimal data redundancy, information sharing, and data consistency. For larger databases, a client/server relational database management system such as Oracle, Sybase, Informix or Illustra can be used. For smaller databases, a PC-based database system such as Microsoft Access, FoxPro or FileMaker Pro can be used.

Microsoft Access, for example, can be used to create a relational database for Web-database connectivity. Access is used for small and medium size database, but it is known to be a flexible and powerful relational database management system. Much of Access' strength lies in the fact that the database's design and management take full advantage of the Windows GUI environment (Jones 1995). By using Access, the creating and maintaining database become much simpler. By enforcing referential integrity, Access allows minimum data duplication and maximum data sharing and data consistencies among database tables. The newer version of Access provides a link between the database design and the Web. However, Web pages that are created with Access are still static. A static page reflects the state of the database when the page is created. Subsequent changes to the database information are not reflected in the Web page. Therefore, CGI programming or Web "middleware" applications are required to dynamically access and maintain a relational database via Web.

3. "Middleware" Approach for Web-Database Connectivity

While the traditional approach of using CGI programming to provide a Web-database connectivity has a pedagogic value and is preferred by some people, recently there have been a steady increase in the number of
"middleware" developed by database vendors as well as individual programmers. A Web-database middleware is a programming tool for Web-database connectivity that reduces (or eliminates) CGI programming. These applications also tend to improve the performance of a Web-database connection by more tightly integrating the Web server and database. Some of the middleware are commercial programs; others are shareware or freeware. They are available for all platforms, including Unix (NetDynamics, Sapphire/Web, Oracle WebServer, to name a few), PC (Cold Fusion, iHTML, DB Gateway, etc.) and Mac (Tango, DataWave, etc.). A partial list of Web-database middleware products can be found, for example, in (Letovsky 1998).

There are several factors to be considered in choosing a middleware tool for Web-database connectivity [Lazar & Holfelder 1997]. They include:

- Portability of the development tool across platforms
- Ease of installation
- Scalability
- Portability of the development tool across Web servers
- Reusability of components
- Performance
- Security

4. Design Issues of Web Database Interfaces

Although a Web gateway to a database can overcome many disadvantages of conventional client-server databases, there are several limitations in the Web-database implementation using the traditional CGI approach. First, there is lack of mechanism for locking a record in the database. With a conventional client-server database system, when a record is actively used by one user, the record is locked until the user is finished with editing the record. To get around this problem, a timestamp can be included in each record so that CGI program may detect conflicting updates by different users [Healy 1996]. "Cookies" are a new mechanism that allows the browser to keep "state" information between calls to CGI program. Second, the Web-database implementation lacks field-level validation found in conventional database system. For example, a user is not allowed to enter text into a Zip Code field in a traditional client-server database system. However, in the Web forms-database interface, all information is sent at once when the user clicks the submit button. CGI program must be designed to handle all errors at once. Third, as with many other Internet applications, the builder of a Web-database interface faces security issues [Knauss 1996]. User authentication is a challenging issue because most Web servers run CGI scripts under a low-privilege user name. Database access rights must be carefully implemented in order to avoid potential abuse and corruption of databases. Some middleware tools mentioned in the previous section do overcome some or all of these problems.

5. Web Database Interfaces for Business Curriculum

The Internet is changing the way companies conduct their business. Businesses of all sizes can lower the costs by using "electronic commerce" on the Internet. Electronic commerce can not only facilitate the selling and buying of goods and services but also improve customer relations by eliminating the constraints of time and space [Kosiur 1997]. Today's students would be better prepared for the business world by understanding how business transactions are conducted on the Internet.

5.1 Web-Database Applications in Business

The versatility of relational databases and the easy access of the Web provide companies with the capability of providing value-added services for their customers [Swank & Kittel 1996]. There are numerous situations in which businesses can take advantage of the Web-database connectivity. Among the uses of Web-database applications for businesses are:

- Electronic store with comprehensive catalog
- Easily accessible product information, specifications, and price information
- Technical support through searchable knowledge bases and troubleshooting information
- Improved and low-cost customer services through Web forms. (e.g., the package tracking service on the FedEx Web site)
- Online registration, record keeping for special events (conferences)
- Employment records, payroll records, inventory information, sales trends, customer demographics, transaction rules, schedules, other internal information sharing

5.2 Building a Web-Database Getaway: An Example

As a simple example of Web-database connectivity, let us consider a firm's database that includes customer information, order status, product information, sales representatives and shipment. First, a relational database needs to be designed and developed. Since a database can contain multiple tables, information can be organized in several different tables, establishing the necessary relationships between the tables. For example, using a desktop database system, we can create several tables for the firm, as shown in Figure 2.

![Database Relationships and Structures](image)

Figure 2. Database Relationships and Structures

Next, several CGI programs need to be written to provide the connection between the database and the Web-based user interface. Finally, Web-based user interface that includes various Web forms need to be designed to access and retrieve data, and to report database query results to the user. Again, these tasks can be minimized if a Web-database gateway product is utilized. The details of this example and other examples can be found online at [http://business.ship.edu/WebDB/](http://business.ship.edu/WebDB/).

6. Concluding Remarks

A Web gateway to a relational database promises to provide a powerful interactive tool for both academic and business world. This paper discusses major issues involved in building a dynamic Web-database gateway to a database and how the new technology can be applied to academic environment, especially for business curriculum and corporate training. Three major components--Web forms, CGI scripts, and database design--are discussed.
Although a promising field, Web-database interfaces are not without limitations. For example, there exists no client-side validation for database work and handling simultaneous updates can be tricky, when the traditional CGI approach is used for Web-database interface. These and other issues including security presents challenges to Web-database developers. Perhaps such new technology as an object-oriented relational database or a client-side scripting language will provide answers to these challenges to enable a more robust implementation of Web-database interfaces.

Abstract: Current social systems are extremely unstable and educational systems based on the paradigm, in which people learn to prepare for their life during a certain period, can not function well anymore. People want and need education provided to themselves in their workplaces, home, or near learning centers. The current research discusses the image creation of virtual university as a new educational system. Above all, it describes the importance of image building based on stakeholders’ shared values and ideas, as a preparation stage before an actual design stage. As a framework for image-building, Banathy’s three-dimensional model is introduced. Then, an image of a virtual university is introduced as just one example. This image has been created based on the current researcher’s values and ideas, by applying Banathy’s framework.

I. Virtual University as a New Educational System

We as a society sit posed at the doorway to the 21st century. In this world, information and abilities will be shared globally through information and telecommunication technology, which weave educational consumers and providers together. We have to accept that the acceleration of social changes created by this technological change creates a new paradigm to which education should respond. According to Linda Harasim [Harasim 1995], we became to have a framework for time and space independent group interaction for the first time in the human history in new technology’s favor. "With the emergence of ISDN-based electronic highways to our homes and workplaces, we are rapidly approaching technical readiness for the Distance Education Network - a virtual university, school, or training department in which learners anywhere can interact with teachers anywhere." [Moore & Kearsley 1996]. This technology supports a nation to overcome economic, cultural, physical barriers against learning; and to create a new system which allows just-in-time education promoting continuous human development [Baker & Gloster II 1994]. Simply stated, the most powerful tool for changing the old paradigm is education based on information technology and further a virtual university, a virtual school, and virtual training organization as the network of learners and instructors which are not limited at specific geographical location.

As the idea of a virtual university becomes more familiar, so does the amount of on-line educational opportunities provided by various universities increase. As access to multimedia information gets faster and easier, a virtual university primarily existing in a cyberspace as bits and bytes is considered the next logical stage for distance learning.

II. Framework for Imaging a Virtual University

Markley and Harman’s research informs us that if old images from the old historical stage guide development when a new societal stage emerges, it hinders and delays societal development [Markley & Harman 1982]. In like manner, continued images in education also hinder the imaging of a newly designed education if we stay within the conceptual framework of the existing system and focus on the problems that the system has. We should now search for a new educational image that can lead our education for the 21st century. This image can be created based on the shared values and ideas of participants in the designing of this new educational system.
1. Importance of Value in Educational Systems Design

Designing of an educational system should be a transformation process based on 'values' rather than on 'goals' or 'purposes'. According to Checkland [Checkland 1981], value is the most important element of all societal systems' structures and processes, and shouldn't be ignored at the front-end of system design. This is due to the nature of values as 'preferred futures' that underlie visions and guide systems design inquiry. Therefore, any system design process must help stakeholders raise awareness of, articulate, and arrive at commonly shared institutional values. Values serve to guide and better the systems design process in education as follows [Lee 1995]:

Value as a collective sense: Clarified values enable stakeholders in educational systems design to understand each other so as to lead toward a collective sense of the purpose of a particular design effort. This might happen as clarified, shared core values reduce the disruptive potential of hidden agendas [Nadler 1981].

Values as a set of directions: Educational systems design is a dynamic and emerging process. As systems are continuously informed and re-informed by their environment, the designing of human activities is ongoing and never ending. In this complex process, values function as learned "principles and rules to help one choose between alternatives, resolve conflicts, and make decisions." [Rokeach 1973]. Accordingly, values guide in daily situations during the design of educational systems as "poles of attractions which give directions to whatever emerges"[Goulet & Dolbec 1991].

Values as standards and criteria: Any decision, performance, and behaviors in a system are based on values, that is perceptions and interpretations of what ought to be in the system. Therefore, values are standards and criteria [Rokeach 1973, Schlechty & Cole 1992, Reavis & Griffith 1992, Keeney 1992, Hechter 1993, Williams 1968] for judging a particular position, task, or behavior in an educational system and for deciding what should be measured and evaluated in organizations, as well as whether the system's actions are acceptable.

2. Framework for Creating Images of a Virtual University

When the design of a new educational image is created based on the clarification of values regarding a virtual university, its image can function as solid foundation in the actual 'design' stage. This research proposes Banathy's framework for creating images as a tool on which image options can be explored and synthesized in a holistic manner [Figure 1]. The following framework is constructed of three dimensions upon which we can reflect our values and ideas of a new image of an educational system [Banathy 1991]. "Which one of the options we select will depend upon our worldview and our view of the society, coupled with our perspectives on the societal functions of education, and our core ideas and values about education and human development."[Banathy 1991].

The Dimension of the Focus of the Inquiry

The focus of the inquiry provides the opportunity for designating the primary level of system design. The constituents of this dimension are (1) governance, (2) administration, (3) instruction, and (4) learning-experience. According to which level is selected as a primary level, there appears clearly different education models as described below:

If the learning-experience level is in focus, the learner is designated as the key entity and occupies the nucleus of the systems complex of education. The primary system function is the facilitation of learning. The primary system level is the learning-experience level, in support of which we design the other systems of the complex: the systems of instruction, administration, and governance. If the instructional level is in focus, administration and governance are to provide policies and resources for its support. The instructional system defines the content and method of instruction, and students are called upon to respond to it. If the administration level is in focus, it sets the goals of instruction, defines the
instructional content and method, and provides indicators for the use of resources. Governance sets broad policies and is called upon to secure needed resources. The governance level is in focus when the purpose of education is indoctrination and enculturation. Top decision-makers (in the government or in religious institutions) define policies and regulations, and mandate uniform curriculum and instruction.

**The Dimension of the Scope of the Inquiry**

The constituents of the scope of inquiry provide four different options from a very limited scope and narrow boundaries toward an ever broader, widening, and extended scope and, consequently, enlarged boundaries.

(1) Limited by the boundaries of the existing system. In this case, the inquiry may explore issues surrounding management, organizational communication, instructional effectiveness, staff development, school climate, etc. This narrow scope is typical with the goals of making the existing system more efficient or more effective. (2) Broadened to consider certain issues in the environment. With this options, we broaden the scope and make some changes at the margin of the existing system, and extend the inquiry in order to consider issues in the environment to which education might respond. The inquiry might focus on such problems as dropouts, teenage pregnancy, students at risk, economic competitiveness, smoking, etc. (3) Extended to include the entire community as the domain of design. The involvement of a wide variety of societal systems, organizations, and agencies is explored that might provide resources, arrangements, and territories for learning. (4) Marking the larger society as the space of design -- with the broadest scope and within the most extended boundaries. In this scope, we extend our inquiry into the larger society and re-vision education and guide the design inquiry based on our understanding of the evolving major societal changes and transformations. We seek not only to respond to these massive changes and transformations, but also to create a new image of education by asserting that education has a special and unique responsibility today to participate in shaping societal development.

**The Dimension of Patterns that Connect**

Four patterns may be considered that the educational system interacts with other social systems that can offer situations, resources and opportunities for learning and human development. These are information exchange, cooperation, coordination, and integration.

(1) **Information exchange between the educational system and its environment.** It means the least amount of interaction. It projects exchange between the school and the community, by providing information about the community for use by the school. Information might be developed about resources in the community that could supplement instruction. This pattern of interaction is the most frequent today. (2) **Cooperation with external system that strengthen the social functions of education.** It implies a pattern of interaction between the school and other societal institutions and agencies for the purpose of attending to complementary goals or sharing some resources. Participants in cooperative arrangements still maintain their autonomy but may enter into mutually advantageous relationships. (3) **Coordination as inter-organizational arrangement among the organizations of education with other social and human systems.** It shares ownership of an educational enterprise, which is mutually beneficial to the participants. It also implies giving up some autonomy and indicates longer-lasting commitments. Formal organizational arrangements are created for the accomplishment of shared goals of education and human development. (4) **Integration in which all social and human service systems become a system complex based on education and human development.** If integration is considered, the entity currently called as schools will become a constituent of the total educational community, which pursues learning and human development. Such a system would be designed from the integration of systems of the public and private sectors, community organizations, and various agencies that have the potential to offer resources and arrangements for learning and human development. Participating systems would integrate a portion of their resources and services into a new entity that would assume the responsibility for designing and carrying out the societal function of education and human development.
According to Banathy, the above framework enables us to accomplish the followings [Banathy 1991]: (1) Portray the image of the existing system as a 'base-line' against which to design or from which to depart. (2) Map the overall context within which to explore and create new images of education. (3) Consider and create various alternatives to the existing image of education, by creating alternative images. (4) Formulate criteria by which to select from the alternatives. (Criteria are formulated by considering the advantages and disadvantages of choices made of available options offered by the three dimensions and their constituents.) (5) Select from the various alternatives the most promising alternatives and describe it as the new images. Map the selected image into the framework. By so doing, we also define the boundaries of the system we intend to design.

III. An Image of a Virtual University

This research selects the following levels among various alternatives of the three dimensions of Banathy's framework as an option, which will enable us to create an image of a virtual university with the newest and largest perspectives:

1. The learning-experience level on the dimension of focus of inquiry
2. The overall societal context on the dimension of the scope of inquiry
3. Cooperation on the dimension of patterns of interaction

The image provided below reflects the current researcher's perspectives which were discussed in the preceding part of this paper. This image reflects the above mentioned levels in terms of a virtual university's relationship with the society, overall functions, the scope of learning experiences provided, the key organizational imperatives, types of intervention, and resources used. This image of a virtual university is introduced just as one example, based on the current researcher's perspectives. Arrangements and structures of a virtual university vary depending on stakeholders' perspectives of society, education and the human development of those participating in the system design.

1. A virtual university should be a 'purpose-seeking system'. A virtual university should derive its educational vision from its understanding of key emerging societal changes, define its policies and
purposes by this vision, and constantly seek out new purposes and boundaries in its environment. This university system should be open, and can co-evolve as a partner to its environment. For this to be true, it should place value on organizational flexibility that can cope with the knowledge explosion. By organizational flexibility I mean its ability to perform organizational learning and continuous organizational redesign.

2. A virtual university should provide lifelong education through coordination and integration with various human service systems. If based on the image of learning-centered educational system, we can and must design a comprehensive social and human service system in order to nurture and enhance human and societal potentials. Education as a societal system, in the largest perspective, is a collective integration of human activity systems that include considerations, resources, opportunities for children and young people to learn and develop as well as for adults continuously to learn and develop.

When based on this large scope of perspective, a virtual university will seek for other systems in community and the society in order to input resources and opportunities for learning and human development. A virtual university extends its inquiry for creating our new educational system into the outside society by constructing itself with a larger resource base. It is designed by integrating public, private, community, and institutional systems that have the potential for resource and organizational arrangements appropriate for learning and human development. The entity currently called ‘school’ will become just one constituent of an entire educational community that pursues learning and human development.

3. A virtual university should be an open learning community based on learning information technology. A virtual university expands opportunities for people to receive higher education by employing the newest information technology based on distance communication and personal computers for delivering educational services. It should demonstrate innovative and cost-effective approaches. It should be established on a solid foundation through the partnership with existing various higher education institutes, other educational providers, information technology hardware and software providers.

In a virtual learning environment, individual learners have chances to be recognized in their own jobs and academic areas, overcoming the limitations of time and locations. Learners will be able to take courses in their convenience on campus, home, libraries, or workplaces and offices; and to finish courses and earn credits according to the most appropriate and flexible time schedules. In addition, learners can enjoy a globalized learning environment. Learners will take courses from virtual universities all over the world. This feature itself will add special dimension to learning, and ultimately quality learning activities will be supported in a global virtual space.

4. A virtual university should provide organizations and environments in which learning-experiences are centered and supported. Learners in a virtual university are located at the center of the system complex. That is, the foremost function of a virtual university is to facilitate learning. It should be designed to respond the learning-experience level and then the instruction, administration, and institutional system to support the learning-experience level. Learners and learning resources managers should make decisions related to learning-experience. Various learning resources in the society need to be identified and developed. The structures and environment are established in the manner of promoting easy access and utilization by learners.

In a virtual university, wide and various learning styles and models such as self learning, peer learning, collaborative learning, social learning, and organizational learning are used and supported. In the meantime, a virtual university uses optimal and various tools according to individual conditions and needs. In this environment, learners are transformed from passive information consumers to active apprentices.

5. A virtual university should be humanized educational space. A virtual university should pursue the maximization of humanized educational spaces in which learners can enjoy a rich environment of learner-learner and learner-instructor interaction. Negative phenomena including a sense of isolation, lack of belonging, and “being out-of-control” occur more readily in a situation where learners are located at a distance to each other, than in traditional face-to-face or assembled education. In addition, the learning community is not a spontaneously occurring entity. Rather it is something, which requires planning and subsequent nurturing. We need special efforts on designing humanized, social interactions and organizational cultures. Through this, a virtual university can maintain learning communities of
space that is accessible to, comfortable with, and provides what people want.

IV. Conclusion

The era of acceleration and dynamic social changes has introduced new thinking, perspectives, technology, and new scientific approach. This eventually demands breaking out from the old thinking frame that we have experienced in the current education sector and changes in the ways of educational practices. "We should jump out from the system, explore educational changes and renewal from the larger vistas of the transformed society, and envision a new design."[Banathy 1991]. Although there is not a commonly shared understanding of a virtual university's entity yet, there have been various efforts along with the perspective extension of its need. What we need to create are the ideal models of the new educational system called a virtual university. Its design process should be based on the ideas of the complete 'transformation' of education, and this means the re-formulation of education at the social level.

This paper identifies learning boundaries and resources of a virtual university centered on learning-experiences. It also pursues a new education system design through 'integration' among human social systems. Yet, I should make clear that there are alternatives of various levels depending on who the stakeholders participating in designing the system are. In addition, what values and ideas concerning society and education they hold are important parts of this education.

The 'preparation' stage of creating the image of a virtual university will be followed by the actual 'design' stage. This image of a virtual university based on shared values and ideas will function as a shared understanding, a set of directions, and design criteria in the process of specification and design. We, however, should understand shared images can be revisited, changed or improved as needed, rather than fixed, due to the circular nature of system design.

Abstract: As need of distance learning grows more and more, requirements for development of high-speed network based real time distance learning system become spread. MHEG-5 is the fifth part of the MHEG standard and it defines a final-form representation for application interchange.

In this paper, we design and implement real-time distance learning system based on MHEG-5 standard. As we design that it contains session managing module to support multi user collaboration environments, it can provide real-time educational application such as videolecturing and distributed CAI. Also it can provide non real-time application such as bulletin board systems, video on demand, etc. And we can support effective student management using session managing mechanism for real-time user interaction handling.

1. Introduction

Distance learning is a new field that can overcome the limitation of previous education criteria[Campbell, Hurley, Jones and Stephens 1995, Dwyer, Barbeiri and Doerr 1995]. So requirements for development of high-speed network based real time distance learning system become spread. But, representing and exchanging educational multimedia contents are too difficult[Lockyer and Badham 1995]. MHEG-5 is the fifth part of the MHEG standard suite[ISO 1997]. The standard defines a final-form representation for application interchange so that the application only has to be developed one time. In this paper, we design real-time distance learning system on information superhighways based on MHEG-5 standard.

As we design the system contains session managing module to support multi user collaboration environments, it can provide real-time educational application such as videoconferencing and distributed CAI. Also it can provide non real-time application such as bulletin board systems, video on demand, etc. We design the MHEG-5 engine using MHEG-5 encoding/decoding class library[Lee and Wang 97a], so it can be easily modified when some modification needed. We can support effective student management using session managing mechanism for real-time user interaction handling.

2. Related Works

MHEG is an ISO/IEC and ITU standard for the interchange representation of multimedia/hypermedia information objects[ISO 1994]. Approved by ISO in 1995, MHEG currently receives very strong interest from most major actor in the interactive TV market, as the standard for set-top-unit high-level API. The developers can implement interoperable multimedia systems and information providers can implement open multimedia applications, using the MHEG standard[Hofrichter and Bitzer 1996, Cossmann et al 1995, Steinmets and Nahstedt 1995]

MHEG-5 is the fifth part of the MHEG standard suite[ISO 1997, Joseph 1995]. It was developed to support the
distribution of interactive multimedia applications in a client/server architecture across platforms of different types and brands. The standard defines a final-form representation for application interchange so that the application only has to be developed one time. [Fig. 1] shows MHEG-5 class hierarchy.

Figure 1: MHEG-5 class hierarchy

3. System Design & Implementation

In this paper, we use some session-specific mechanisms such as centralized controlling, multicasting, collaborating. We implement this system at 100base-T ethernet and Pentium-pro™ 200MHz Server as hardware environment. We use MS Windows NT TM 4.0 as operating system and MS Visual C++™ 5.0, Win32 SDK, MHEG-5 encoding/decoding class library as development tools.

3.1 Overview

[Fig. 2] shows overall system configuration.

3.2 MHEG Engine

In client side, MHEG-5 engine contains object managing module and presentation module. Object managing module has encoding/decoding module for MHEG-5 objects. Presentation module has object interpreter and interaction handler. Object managing module fills a role of interpreting and converting between MHEG-5 objects.
and internal objects. In presentation module, object interpreter reorganizes internal objects from object pool, and interaction handler processes link and action operations. We use MHEG-5 engine in [Lee and Wang 1996, Lee and Wang 97a].

3.3 Session Managing Module

In server side, session managing module has group managing module and event handler[Manthe and Mamuye 1996, Rodden and Blair 1992]. [Fig. 3] shows architecture of session managing module.

![Figure 3: Session managing module](image)

Group managing module operates as gateway. It authenticates and manages participated users. Event handler processes events that occur in each group. Group managing module creates appropriate group for user requirement, and manages those using group pool. Once event occurs, interaction handler catches that. If it cannot be handled, interaction handler sends it to event handler. Event handler processed that using group managing interfaces. Events handled by event handler require group-related operations such as create, destroy, join, and leave.

3.4 Servers

Courseware and BBS server has educational materials. We store courseware as MHEG-5 object representation form using MhegDitor[Leroy and Charbonnel 1997]. Students can browse these materials using MHEG-5 engine and presentation system. It appeared to students as tree-liked form, so students may select any content in a view. If there are some questions about materials, students may use bulletin board system or E-mail. For videolecturing and video on demand, media stream server stores movie files and supplies stream-related service. Using MHEG-5 representation form, movie files can be used during courseware browsing or videolecturing.

4. Learning Scenarios

In this chapter, we describe two learning scenarios that can be occurred when students use this system. The first case is using videolecturing feature of our system. The other case is using courseware-browsing feature. In order to testify the student administration ability in group, we designed the class with one lecturer and four student. And in order to testify functions of real-time application, we used MHED objects for videolecturing. These MHEG objects were made by MhegDitor 1.3 and edited by encoding/decoding class library for MHEG-5 objects[Lee and Wang 97a]. [Fig. 4] represents MHEG objects used by lecturer.
4.1 VideoLecturing

A student executes a client application to connect media stream server. Then login dialog appears, and the students inputs username and password. After login process, a session view appears to and the students. Then he/she selects a group that he takes interests in.

When the students participation succeeds, his/her participation is notified other students and lecturer in that group. Then, and the students can view lecturer's video stream and whiteboard. During videolecturing, lecturer can monitor participated students. Lecturer selects certain student to give token as the right of speech. The student who has that token speaks his/her opinion. After student's speech, lecturer owns that token for next right of speech. Also, a student requires token for his/her own right of speech. When lecturer draws some figures on whiteboard, these figures are shown to all participated students.

4.2 Courseware Browsing

A student executes a client application to connect media stream server. Then login dialog appears, and he/she inputs username and password. After login process, a group view appears to him/her. Then he/she selects a group that he takes interests in. When his/her participation succeeds, his/her participation is notified other students and lecturer in that group. Then, he/she can view lecturer's video stream and whiteboard.

During video lecturing, lecturer can monitor participated students. Lecturer selects certain student to give token as the right of speech. The student who has that token speaks his/her opinion. After student's speech, lecturer owns that token for next right of speech. Also, a student requires token for his/her own right of speech. When lecturer draws some figures on whiteboard, these figures are shown to all participated students. [Fig. 5] shows client application in lecturer side.
[Fig. 5] shows the example that lecturer sent additional information to students using whiteboard. These types of Session management facilities are enough to control the participated students. In this experimentation, we show that the designed framework can be used for applications that require efficient group management and control, and it can support to handle user interaction in real time environments.

In this case, a student also executes a client application to connect courseware and BBS server. Then login dialog appears, and he/she inputs username and password. After login process, a courseware view appears to him/her. Courseware view is represented by tree-liked form. Then he/she selects a topic that he takes interests in. Selected topic is provided as MHEG-5 application object. That has several or a number of scenes that compose of various multimedia presentations. Browsing courseware is same as hypermedia navigation. Students may have some questions about courseware when browsing. Then they can use both bulletin board system and E-mail. When a question registered, lecturer would read and reply answer to student for that question.

5. Conclusion & Future Works

Implemented system has several advantages. It can provide effective presentation and management for multimedia
information using MHEG standard. And we can use its user management facilities for real-time multimedia applications that should support real-time user interaction. Also encoding/decoding class library applies to various MHEG-5 based applications.

There is an important feature to enhance educational values of this system. Currently, we cannot provide student-evaluating facilities. We plan to implement integrated distance learning system that contains intelligent tutoring features [Lee and Wang 97b].

**Meta-Freedom in Hypertext:**
The Freedom to Limit Your Own Freedom

Abstract: Hypertext is fast replacing traditional linear text in many environments and documents, such as the World Wide Web and the on-line documentation packages supplied with many current software applications. Much of the discussion on the merits of hypertext, as well as its drawbacks, revolves around the extra freedom it affords the user compared to linear text documents such as books. In this paper we offer an analysis of some factors influencing how much freedom may be desirable for a given user in a given context and, in some cases, suggest a solution to the problem of too much freedom. Our guiding principle is not to limit users' freedom in any authoritarian and predetermined way, but rather to offer them one more level of freedom, called meta-freedom: The freedom to choose for themselves the amount of freedom vs. the amount of guidance for a given context.

Introduction

Hypertext is fast replacing traditional linear text in many environments and documents, such as the World Wide Web and the on-line documentation packages supplied with many current software applications [1]. Much of the discussion on the merits of hypertext, as well as its drawbacks, revolves around the extra freedom it affords the user compared to linear text documents such as books.

On the one hand, the user of hypertext is free to choose the order of traversing the various text modules, as well as the degree of detail in reading the material. For example, if a long and complex document is arranged in hypertext as a hierarchy of short modules, users are free to choose the order of traversing the hierarchy, as well as how many levels deep they wish to go. A closely related set of ideas—the advantages of hierarchical modular design and presentation—are elaborated in computer science in relation to structured programming [Dijkstra 1972] and in mathematics in relation to structured proofs [Leron 1983, Leron 1985].

On the other hand, users are often overwhelmed by the amount of freedom they have in traversing the various nodes in a complex hypertext document, and may wish for more guidance. In other words, users are sometimes willing to surrender the total freedom (and concomitant confusion) and hand over some control to an outside agency. Here is Romiszowski’s (1997, p. 32) description of the problem of too much freedom:

One major user problem in many currently available hypertext systems is described as “lost in the hyperspace” effect [Edwards & Hardman 1989; Yankelovich et al. 1988]. The readers navigate in a non-linear pattern from one “node” of information to another, following potentially interesting or relevant “links,” and soon lose their bearings, as if in a maze, unclear as to where they have arrived in the domain of study and why they are there.

---

[1] Much of what we say is equally applicable to hypermedia in general, but for simplicity we will stick to hypertext.
In this paper we offer an analysis of some factors influencing how much freedom may be desirable for a given user in a given context and, in some cases, suggest a simple solution to the problem of too much freedom. Our guiding principle is not to limit users' freedom in any authoritarian and predetermined way (that would be defeating the very spirit of hypertext and the web), but rather to offer them one more level of freedom, called meta-freedom: The freedom to choose the amount of freedom vs. the amount of guidance in a given context. In the talk we will discuss in addition how this facility could be implemented in practice and give some examples from our own practice in web-based instruction. Meta-freedom, if properly implemented, is empowering rather than limiting the user, since it offers more choices rather than less. There is a seeming paradox here: How can we deal with the confusion due to too many choices by adding even more choices? However, the answer is implicit in the above definition of meta-freedom: the new choices are control choices, allowing users to set the optimal amount of guidance in accordance to their own preferences.

The price of freedom: The need to make control decisions

Let us consider the allocation of mental resources (time, energy, attention, memory, etc.) of a user reading—and trying to make sense of—a complex document. We'd like to compare the allocation of these resources when the document is organized in hypertext vs. linear form. We note that while concepts, ideas and mental structures in general are structured in non-linear webs [e.g., Minsky 1985], the activity of reading is largely linear. Thus in the process of communication through text, writers and readers must go through some linear representation of their target ideas. Since there are many ways to linearize a complex structure, the relevant questions for us here are what is an optimal linearization for a particular individual in a particular context, and who is in charge of making the decisions involved in the linearization process (called control decisions).

In the case of books, the author has made for the reader all the control decisions regarding the level of expertise and detail, and the order in which the material should be followed. True, readers often skip and skim, but this happens despite the linear nature of the medium, not because of it; the structure of the medium carries the default expectation (which, however, is seldom obeyed), of reading sequentially and fully from the beginning to the end.

The idea of hypertext, in contrast, is exactly to leave all the control decisions to the reader, hence the glorified extra freedom. The great idea behind hypertext is that there is no single best linearization, and each reader should be free to decide what's best for him or her. "Because each individual's knowledge structure is unique, based on his or her unique set of experiences and capabilities, the way that each would prefer to access, interact with, and interrelate knowledge is also distinct. [...] Therefore, readers should be encouraged by the hypertext to jump around and even alter the text in order to make it more personally meaningful" [Jonassen 1986, p. 270]. But this freedom comes with a price: the need to make many control decisions and to constantly hold in memory one's place in the complex structure, in order to be able to return to the "highways" of the hypertext. This may in times cost the user heavily in terms of available mental resources: mental resources that would otherwise be available for learning the contents of the document, must now be allocated to dealing with control issues. This is as it should be, since control issues are always important in learning in general and in problem solving in particular [Schoenfeld 1985]; but, again, the question before us is how to optimize the allocation of mental resources between learning the material on the one hand, and the management of the learning process on the other hand.

Factors influencing the allocation of mental resources

The issues discussed in this section require much empirical research. Here we can only offer some tentative observations based on theoretical considerations and reflection on practice (our own and others').
There are two kinds of guidance which may be desirable for the user in order to facilitate the navigation of a complex hypertext structure. One, *global* guidance on the structure of the entire document and on suggested ways for traversing it. Two, *local* guidance on substructures – small, coherent and relatively independent clusters of modules in the document. The first kind is well known and is (to some degree) taken care of in the first few pages presented to the user. Here we will limit ourselves to dealing with the second kind.

We have identified in our experience one typical situation in which people have usually preferred to be guided sequentially rather than having to jump back and forth through the hypertext links. Here is an example taken from Microsoft Word 7 Help (abbreviated MSWH). Suppose one wishes to design a page in MS Word which includes the logo of one’s company and some additional information, such as regular and email addresses, phone and fax numbers, URL, etc. In other words, one needs to learn how to design a new *template* – a fixed-format page with “slots” for adding variable information. For this purpose MSWH is indeed helpful. After some selecting and clicking (in fact, Help/Microsoft Word Help Topics/Contents/Formatting/Setting Default Formatting with Templates) one gets to the templates “contents page”. Here are listed the actual 12 short help pages on the various aspects of templates, such as creating, editing, saving, etc. Now it is quite likely that one might want to get an overview of templates by quickly scanning the 12 short pages sequentially (this might typically take about 10-15 minutes). However, MSWH does not provide the user with this option (at least not as of Word 7). Rather, the user must skip back and forth between the individual help pages and the contents page.

The example of help on templates is typical of what we have called a *compact subdocument*, which is a cluster of modules satisfying the following three conditions:

- One) the cluster in itself forms a well-defined complete entity which is of independent interest.
- Two) it may be desirable to read the cluster in its entirety.
- Three) the total length of the text in the cluster’s modules is relatively short and can be reasonably read in one stretch.

These conditions are clearly relative: they express a relationship between the given document and a particular person at a particular time. That is, whether a particular cluster forms a compact subdocument or not may change from one person to another and even for the same person at different times. Still, some clusters are more obvious candidates than others.

Our main observation is that *when encountering a compact subdocument, users often prefer to read it sequentially*. We were first clued to this observation when we had noted our own relief during web surfing, upon discovering that 10 links to subsections of some document pointing to different locations on the same long page. Oh good, we’d say to ourselves, now we can simply read the whole thing from beginning to end, rather than skipping back and forth through the contents page. Indeed, when you come to think of it, being forced to go to the contents page is a bit of a nuisance if all you want to do is move on to the next page, and the nuisance turns to annoyance if you are forced to do it 12 times for one topic!

What this means in practice is that when designers of a hypertext document encounter a likely candidate for a compact substructure, they should offer the user a *choice* of reading the entire substructure sequentially, while of course retaining the standard option of clicking on the individual links. This choice should suggest itself clearly and naturally by an appropriate user-interface. We will discuss below some ways of actually implementing this idea and will add some more at the conference talk. Note that this is a typical example of what we have called meta-freedom, since the user is in effect choosing the degree of freedom (or, conversely, the degree of guidance) he or she wants. Note too that it is good enough that the designer can only *guess* at whether a particular cluster of modules would be a compact substructure for a “typical” user, since what the user gets is just an additional option (of following the cluster sequentially), which the user may freely ignore.
Implementing Meta-Freedom

We recall that a hypertext document is made up of "pages" (individual text files or other chunks of information) and links between them. It may happen that a particular page will contain several sections with their own headings, and will consequently be relatively long. For example, one often encounters a page consisting of 10 subsections, each taking up about one screen or less. The Setting Default Formatting with Template MSWH topic mentioned above could be such an example, had the designers chosen to implement it as one long page (they didn't). In such cases it is customary to start the page with a "contents" opening screen, containing the list of subsections headings as links. Such links, which point at different sections of the same page where they appear, are to be distinguished from "genuine" links, which point to different pages. However, these two kinds of links are usually represented by the same symbol (an icon or underlined phrase in a particular color), and are rarely distinguished so that the user could know in advance which is which.

In light of the discussion in the previous sections, it is suggested that the features of a subdocument be made explicit via a suitable interface design, such as:
- that the cluster in question has been explicitly designated a compact subdocument;
- that the user has a choice, in addition to the standard use of links, of perusing the subdocument sequentially, e.g., by scrolling (if it is in one long page) or by clicking on a "next" button;
- that some measure of the length of the subdocument is given (say, 5 sections, each one-screen long, or some similar measure).

Incidentally, and independently of the above recommendations, one may wonder whether it is advantageous to design a compact subdocument as one long page (as is often done), rather than making each module into a separate page. It seems to us that the logical structure of the document is represented more faithfully and clearly by the latter, but for technical reasons designers at present often prefer the former. One reason is that with present communication technology, clicking a link to a location within the same page may get a much faster response than clicking a genuine link.

Clearly, following these suggestions will give users the meta-freedom we have been talking about, since they would be able to determine whether they prefer to be totally guided by the designer of the document (following the subdocument sequentially), keep their total freedom of control (ignoring the linear order, using the buttons as they wish), or any combination thereof. They will also be given enough prior information to be able to make their meta-decision wisely.[2]

We conclude with a few thoughts on implementing the meta-freedom user-interface.
- Links to locations within the same page may be distinguished from genuine links, e.g., by using different colors for the underlined phrases.
- Individual buttons pointing to the subsections may be inscribed in a large super-button. Clicking on the super-button will bring up the subdocument as one long page. Clicking on a regular button leads to a specific item. Figure 1 demonstrates how the two options are provided: Clicking on the circumscribing ellipse give us the compact document entirely as one page. At the same time one can still choose to go to individual subsections by clicking on one of the small buttons.

[2] Since hypertext documents are constantly being updated (especially when they are on the Internet), editors should have the facility to automatically update this prior information when the document is changed. This is especially relevant to the third item on our list (the length of the page), but may apply to additional items that may be added to the list.
Compact subdocuments may be represented by a single sign (name or icon), just as computer scientists represent a subprocedure by its name. Clicking on the button may display its inner structure and the control choices as above.

In some of current software tools one may get information on an icon by merely pointing the mouse at it, or by clicking the right mouse button. Similarly, some of the initial information on a compact substructure can be so displayed.

**Appendix: What's is a link?** Since we have made such intensive use of the term *link*, it may be interesting to clarify just what *is* a link. We take as our starting point the definition given to a variable in computer science [e.g., Abelson and Sussman with Sussman 1996]: A variable is a binding between a word or a phrase (called the variable’s *name*) and an object (called the variable’s *value*). Similarly we may say that a link is a binding between *three* entities: a word or a phrase (the link’s *name*), a URL (the link’s *address*) and a hypermedia page (the link’s *value*). Or we may look at a link as a *double-layered variable*, since the URL is the value of the link’s name, and the page is the value of the URL. In other words, the link is like a double-decker hamburger, made of two variables sharing the middle layer: The upper-deck is the variable whose name is the link’s name and whose value is the link’s URL, and the lower-deck is the variable whose name is the URL and whose value is the link’s page. Here is an example to illustrate these terms: On Netscape’s home page there is a link called ASSISTANCE, whose URL is http://home.netscape.com/bbhelp/assist/index.html and whose value is the page containing assistance, customer service, etc.

Abstract: The population of South Africa represents a microcosm of the world. The music of various cultural groups and countries is heard daily. A typical South African style is being developed by the blending of these various styles. The Unit for Telematic Teaching and Learning and the Department of Music of the University of Pretoria have designed a music program on CD-Rom, Music in South Africa, to expose students in Music Education to the various styles. This paper will describe the purpose of this program, show how it was designed and briefly review a few highlights.

1 The Purpose of the Program Music in South Africa

The population of South Africa represents a microcosm of the world. The music of various cultural groups and countries is heard daily. A typical South African style is being developed by the blending of these various styles. An aim of the CD-ROM program Music in South Africa was to expose students in Music Education to the various styles.

Those charged with the teaching of music often do not have the resources, knowledge and skills to make Music Education relevant to pupils and students. Especially in the previously disadvantaged communities, this program can also be used for in-service (INSET) training to provide teachers with a wider background of musical concepts and styles. It can also be used for basic teacher training (PRESET) and music enrichment.

The University of Pretoria needs to position itself for the 21st century by employing more appropriate teaching models. These include the expansion of distance learning opportunities with technology, in particular computers, TV’s and satellites, that will form an integral part of these teaching models. These modern technologies can be used to provide teaching material to address backlogs in education. This program will provide students with the opportunity to work at their own pace and whenever it suits them. Little has been done in the area of music programs that focus on learning. This program aims to meet this need.

2 The Design Approach

The Quest Net Multimedia Authoring System was used as authoring tool. Using an on-screen design approach, an artist designed the backgrounds and colourful borders, the subject expert provided the content, while the instructional designer was responsible for the layout and structuring of the program. It was an interactive process in which the realization of the possibilities of the authoring system provided new ideas to
both subject expert and designer. The instructional design did not start with a full storyboard but evolved from a few basic ideas.

The product was taken to an outside authoring company and they estimated that they would use more than double the time to design the product. Although it was time-efficient to use an on-screen design approach, it had its own problems. The language editing was done at a late stage and changes to a whole screen had to be done. The subject expert is a full-time lecturer and was not assigned only to this project. She had to find extra time to compile the subject content which caused difficulty with the scheduling of the instructional design.

The University of Pretoria is committed to provide a flexible mode of learning to the student in which the physical contact time between lecturer and student is lessened. Multimedia on CD-ROM will be only one of various technologies that provide teaching and learning interventions. The Unit for Telematic Teaching and Learning realises that lecturers often do not know what the possibilities and limitations of multimedia are and that they find it very difficult to create a storyboard. To attain a better production rate it is envisaged that prototyping will frequently be done with an on-screen design approach but that the rest of the program will be out-sourced.

3 Highlights of the Program

The program is divided into four main sections: Elements of Music, Art Music, Popular Music and Folk Music. A shell-motif was used in the design because listening to various musical styles forms the basis of the program. The shell-motif was used on the first screen and all subsequent menu screens. The soft pink-brownish colour of the shell and the basic background made it compatible with many colours, borders and other design elements. After each main section the student can do a quiz for self-assessment purposes.

3.1 Elements of Music

In the first part of the program the student can learn about the common elements of music. The program uses short music excerpts to introduce the student to pitch, dynamics, duration and tone colour. It also deals with form, texture and style. The student needs to work through this section to understand the terminology and concepts used in the rest of the program. The following is an example of a menu screen in which the student
can choose to learn about the common elements of music. The ticks will only appear when the student has worked through that particular section. The student can listen to short excerpts of music to reinforce the various concepts that are discussed. The designers tried to chunk the material. The sections on meter in 3 and meter in 4 will only appear on the following screen after a More-button is clicked. The top left corner always indicates the main section that is dealt with to provide cognitive support to the student.

### 3.2 Art Music

#### 3.2.1 Western Art Music

The Baroque, Classical period, Romantic period and Twentieth Century are considered in this section. These musics are heard daily in South Africa and are therefore important in Music Education curricula. The designers aimed to make the visual layout of the screen complement the style of the music that can be heard. Different borders and visuals such as paintings and buildings of a specific period or style are used to reinforce the characteristics of the music style.
In each style or period an excerpt of music along with an animation of certain pertinent features is presented to allow the students to see what they are supposed to hear. On the following screen the instruments appear when they are heard in the sound example.

3.2.2 South African Art Music

This music is often a blend of styles which includes typical African characteristics such as irregular rhythms. An orchestral work about Shaka, who became king of the Zulus in 1815, is one of the music excerpts used to illustrate South African music.

3.2.3 Indian Art Music

This part of the program emphasises the fact that the character of Indian music is spiritual and that it does not blend easily with other music styles.
3.3 Popular Music

Popular music is the general term for modern commercialised music. In South Africa there is a rich variety of popular music and in this section of the program the South African style of popular music is discussed as well as Gospel music, the Afrikaans ‘Luisterlied’ and Township music. On the following screen the poem is animated while being sung.

3.4 Folk Music

Folk music is derived primarily from oral tradition and is passed from one generation to the next. African Folk, “Boeremusiek” and Cape Malay music are heard in this section of the program.
4 Summary

The on-screen design approach used in the development of the CD-ROM *Music in South Africa* stimulated the creativity of both the instructional designer and subject specialist and made it a rewarding project. Putting music technology together in a CD-ROM was not only a new experience for the University of Pretoria, but the beginning of a new research project. How this CD-ROM can be expanded, upgraded, evaluated and used in educational and enrichment programs, are aspects currently being explored further.

Abstract: A Web-based learning environment for elementary school students was created in 1996 with the sponsorship of the National Science Council of Taiwan. For the purposes of evaluation on courseware design and system usability analysis, a tracking system was integrated with the learning environment. The tracking system could monitor learning activities on the learning environment and record them in a database. In addition, the tracking system also could provide teachers the recorded information in the prospect of instructional management. This paper describes the design and applications of the tracking system.

1. Introduction

A Web-based learning environment was created for the study in 1996 under the sponsorship of the National Science Council of Taiwan. The learning environment consists of a courseware with on-line test service and a communication mechanism for users. The courseware is the most key component in the learning environment and it is associated with earth science curriculum in the sixth grade. For the purposes of evaluation on courseware design and learning system usability analysis, a tracking system is integrated with the learning environment.

The courseware was adopted as a required learning material by a sixth grade class of the Affiliated Elementary School of the National Tainan Teachers College in the spring semester of 1997. All the learning activities of the class on the courseware were recorded by the tracking system.

The study is focusing on the design of the tracking system and its application in evaluation on courseware design and system usability analysis based on the experimental data. However, due to the limit of length, this paper describes mainly the design and components of the tracking system.

2. The Importance of Tracking Systems for the Web Learning Environments

The Web and its renovating technologies provide an excellent distance learning environment for K-12 students. However, the fact that Web-based distance learning environment is lack of the capability in monitoring learning processes of students is creating a negative image for its widespread diffusion in the field of instruction. Without the function of monitoring the learning processes, courseware on the Web is unable to keep track of students' learning activities and teachers never have the chance to follow the learning paths of their students. Teachers and students are totally isolated in terms of learning processes under this circumstance. Furthermore, the quality and suitability of courseware are unknown when teachers are unable to monitor the learning activities of their students.

In addition, originally the Web provides nothing for system usability analysis [Bachiochi et al. 97]. Without users accesses information on the courseware, it is impossible for Web instructional designers to evaluate the
performance and quality of the learning systems [Newmarch 97].
The tracking system is the answer for both problems above.

3. The Solutions on Tracking Systems

In order to meet the needs of evaluation on courseware and system usability analysis in Web learning
environments, people have been searching for tracking systems since the Web was deployed in the field of
education. There are two types of solutions that have been adopted for evaluation of courseware and system
usability analysis.

3.1. The HTTP Server Log File with Analysis Tools

Every HTTP servers have their own events log files. The system log files are generated automatically. With
this solution, there are no further works needed to be done for instructional system designers in collecting users
accessing data except preparing log file analysis tools with existing application software or simple coding with
scripting languages such as Perl or VBScript [Jones & Jones 97]. However, the data in log files are not
accurate and the information inside are poor [Boalch 96]. This solution leads to a lot of problems in making
interpretation of learning activities on the Web.

3.2. The Tailor-made Tracking Systems

In order to overcome the problems of log file solution and acquire more meaningful information in terms of
evaluation of courseware and system usability analysis, it is necessary to design a tracking system specifically for
the system. The tracking system should be independent from HTTP server but has to be integrated with the
courseware. The only problem for this solution is the time consuming in design and implementation of the tracking
systems.

A tailor-made tracking system, the Web Courses Tracking System (WCTS), was created specifically for the
purpose of the study.

4. The WWW Aided Learning Environment and the Courseware for the Study

The WWW aided learning environment that the study created is composed of an online courseware, online
testing sessions, and a virtual classroom. All elements of the system are integrated into one user interface ---- MS
Explorer, one of the significant WWW browsers [Lin 97].

The online courseware addresses earth science in the sixth grade. The leading Web technologies, such as Java,
Microsoft ActiveX, and authoring systems related plug-ins, are employed to create dynamic multimedia HTML
pages. The online testing sessions take advantage of hypermedia features and provide instant feedback to the
students.

The primary role of virtual classroom in the WWW aided learning environment is to provide
communication services among students and teachers. The communication modes include one-to-one, one-to-
many, and many-to-many.

The learning environment was developed in the platform of Microsoft Windows NT. The development tools
consist of MS Access, MS Exchange Server, MS ActiveX Control Pad, MS Visual J++, MS Visual Basic, and
Macromedia Director with Shockwave, etc.

5. The Components and Functionality of WCTS

The WCTS is shown as [Fig. 1]. There are three key components in the WCTS.

5.1 The Tracking Frame

Every HTML files in the system consist of two frames. One is the courseware frame, with 100% scale that
carries the courseware materials. The other frame, the tracking frame, with 0% scale that holds the programming
code and WinSock TCP Client which are responsible for monitoring the learning activities and transferring the
data to WinSock TCP Server respectively.
5.2 The WinSock TCP Control
The control consists of two related services, server and client. The server is sitting on a networked machine and waiting for messages that are sent out from the client. Clients are located at every tracking frame in HTML files.

After receiving messages from clients, the server forwards the messages with ODBC toward the database.

5.3 The Database
The database has two roles in WCTS. It is responsible for storing messages that come from the tracking frame originally. The other role of the database is to retrieve and analyze the data inside the database with SQL language.

6. Evaluation of Courseware Design and System Usability Analysis
It is required for every user to identify himself/herself upon accessing the courseware. As soon as user login the system, WCTS starts to monitor and record his/her learning activities. The recorded information is categorized in terms of individual courseware page and user. The framework of the recorded information is shown as [Fig. 2]. The evaluation of courseware design and system usability analysis are the main themes of the study and they are conducted with the experimental data that are collected with WCTS [Shimada et al. 97] [Yan 96].

The Effect of Being Hypermedia Designers on Elementary School Students' Motivation and Learning of Design Knowledge

Min Liu

Abstract: Current educational theory and practice clearly show that project-based instruction has the potential to enhance learning. Preliminary findings on one type of project-based learning in which students take on the role of hypermedia designers support this claim. This study examined the effect of being hypermedia designers on fourth-graders' motivation and learning of design knowledge. The findings showed that engaging students in hypermedia authoring could enhance their motivation, and allowing students to be hypermedia designers could support the development of design knowledge and higher order thinking skills. The skills mostly affected in this study included planning, presentation, reflection, collaboration, task distribution, and time management.

1. Research Framework

Project-based learning, requiring students' active participation and engaging them in authentic problem investigations, is considered to have great potential to enhance students' motivation and learning [Blumenfeld, Soloway, Marx, Krajcik, Guzdial, & Palincsar 1991]. Technology can play an important role in facilitating project-based learning by enhancing students' interest and supporting information gathering and presentation [Blumenfeld, et. al. 1991]. Engaging students in hypermedia/multimedia design is one type of project-based learning which has shown some encouraging results in promoting higher order thinking skills.

Engaging learners as hypermedia designers is an instructional strategy that invites learners to become intellectual partners with the technology and provides them an opportunity of using the technology as a cognitive tool to extend their minds and to construct their own knowledge [Jonassen 1994], [Solomon, Perkins, & Globerson 1991]. Perkins [Perkins 1986] states that the process of design promotes learners' active pursuit and use of knowledge. As designers, learners are encouraged to be creative, to integrate new knowledge with their prior knowledge, and to pursue their own intended goals actively. Because designing hypermedia programs "taps a diverse set of skills" [Carver et al., p. 388 1992] and involves both the process and product, educators believe it can provide a concrete and meaningful context for developing higher order thinking skills.

Research on engaging learners as hypermedia designers has only appeared recently. Lehrer, Erickson, and Connell [Lehrer, Erickson, and Connell 1994] conducted a study in which ninth-graders created hypermedia presentations on American history for other students. They found that students' time on-task increased significantly over the course of successive design projects. In addition, the study showed that the design process helped students to internalize various design skills. Students reported increases in mental effort and involvement, interest, planning, collaboration and individualization. Supporting their findings, Beichner [Beichner 1994] found in his study that junior high school students were highly motivated and often spent extra time when working on producing a multimedia program. Spoehr's study [Spoehr 1994] showed that designing hypermedia programs could help students develop more complex knowledge representations and assist the development of their thinking skills. A study by Liu and Rutledge [Liu & Rutledge 1997] found that high school students showed a significant growth in their value of intrinsic goals, and hypermedia design helped them to acquire several critical design skills. Other studies have shown that seventh graders, both advanced and behaviorally/emotionally disordered, were motivated by creating multimedia projects...
The studies on learner-as-hypermedia/multimedia-designers suggest the following: 1) such a learning environment can have a positive impact on students' motivation toward learning; 2) such an environment encourages creativity and enhances the development of cognitive skills; and 3) high and middle school students learned design skills in addition to content and computer knowledge. While the preliminary findings in this area have shown some encouraging results, much is to be learned about designing and implementing such a learning environment effectively for different learners and curriculum needs.

2. Purpose Of The Study

Given the preliminary findings of the positive effects of the "learner as a hypermedia designer environment" on high and middle school students, we are interested in finding out if elementary school students can benefit from a similar learning environment, and, if so, what issues and factors need to be considered in designing such a learning environment. The research question for this study, therefore, was "What is the effect of being hypermedia designers on elementary school students' motivation and learning of design knowledge?"

3. Design Of The Study

3.1 Participants

The participants of this study were two intact fourth-grade classes (N=38) from an elementary school in a mid-size city in the southwestern United States. Seventy-nine percent of the student population were white, and twenty-one percent were minority. Thirteen percent (N=5) were identified as talented and gifted students (TAG). Twenty-four percent (N=9) were resource students who need additional academic help in various subject matters. Seventeen were female and twenty-one were male students.

3.2 The Hypermedia Learning Environment

The research study took place over two semesters, from November 1996 to April 1997. Both classes participated in this hypermedia authoring project as part of their daily 50-minute science class four days a week. The entire project consisted of three phases. During the first phase, which lasted approximately six weeks, students in both classes received the same instruction on the use of HyperStudio, an open-ended authoring system specially designed for children to create hypermedia programs with links, nodes, colors, text, graphics, animation, sound and video. The purpose of this phase was for students to acquire the technical skills and create a small HyperStudio stack with guidance.

In phase II of the project, which lasted approximately four and half weeks, students in one class worked in teams in a learner-as-designer environment, while students in the non-designer class worked independently. Both classes created HyperStudio stacks as part of a unit of study. In the non-designer class, the typical sequence for a day was for the teacher to spend about 15 minutes introducing the science content and then instruct students to create a card in their HyperStudio stacks on this topic. While students in the non-designer class made decisions individually about the content and organization of their stacks, students in the designer class worked in groups and made those decisions collaboratively. Because students in the designer class shared the responsibility for the creation of a group stack, individual students created fewer cards in the designer class than in the non-designer class. However, students in the designer class received instruction in the design process, including instruction on planning, division of responsibility, peer evaluation, and interface design principles. In a typical week, students spent about thirty percent of their time on of the were class-related activities, such as content teaching, design discussion, or group presentation, while about
seventy percent of the activities were group related and led by students, such as planning, research, task
distribution, and the creation of cards, stacks and multiple types of media. Collaboration within the group
was required and between the groups was strongly encouraged.

Phase III of the project was similar to phase II, with the exception that, for both groups, the support
from the teacher and researchers was faded.

3.3 Data Sources

Both quantitative (motivation scale, design questionnaire, task ranking, HyperStudio tests, and
analysis of student-created programs) and qualitative data (observations, response log entries, and interviews)
were collected. The triangulation of the multiple data sources provides a better picture of the learning
environment under study.

Harter's scale of intrinsic versus extrinsic orientation in the classroom was used [Harter 1980]. It is
30-item scale that measures five aspects of motivation: (1) preference for challenge vs. preference for easy
assignments; (2) curiosity/interest vs. pleasing the teacher/getting grades; (3) independent mastery vs.
dependence on the teacher; (4) independent judgment vs. reliance on the teacher's judgment; and (5) internal
criteria for success/failure vs. external criteria. This instrument was developed for use in grades three through
six, and the reliability index for the subscales range from .68 to .84 [Harter 1980]. It was given to both
classes at the beginning and at the end of the hypermedia project.

The design questionnaire was based on one developed by Lehrer and his colleagues to assess
learners' development of various higher order thinking skills needed in producing hypermedia projects
[Lehrer, et al., 1994]. This project questionnaire has been used in the research of learner-as-hypermedia-
designer with a reliability index of .97 [Carver et al. 1992], [Lehrer, Erickson, & Connell 1993], [Lehrer,
Erickson, & Connell 1993], [Liu, in press], [Liu & Rutledge 1997]. This self-report questionnaire was
adapted to include only statements directly linked to the project. The KR 20 for this modified version was
.82. Students in both classes completed the instrument at the end of the project.

In the task ranking questionnaire, students were given a list of eight tasks relevant to their project
development, and were asked to rank the tasks according to their relative importance. This instrument was a
simplified version, tailored to the fourth graders, of the task ranking evaluation used in a number of research
studies on the same topic [Lehrer et al. 1994], [Liu & Rutledge 1997], [Liu in press]. Students were given
this instrument at the end of the project.

Performance was assessed using the stacks created during phase III. These stacks were judged by
two external evaluators in terms of the product quality using a fourteen item survey, with each item scored on
a five-point scale. The total score for the survey was the composite score from the two raters, ranging from
28 (14 items X 1 minimum score for each item X 2 raters) to 140 (14 items X 5 maximum score for each item
X 2 raters). The development of this evaluation was based upon the literature on assessing interactive
multimedia/hypermedia programs [Fleming & Levie 1993], [Laurel 1993], [Mullet & Sano 1995]. It
addressed the application of four design principles: consistency, contrast, legibility and simplicity. The
intrarater reliability of all items for all the stacks was 88%.

Interviews were conducted with the teacher (at the mid-point of the project), the parents (during two
open houses), and the students (at the end of the project). Students selected for interviews were from both
classes and from various ability groups. Interview questions focused on perception of motivation and
comparison with other types of projects.

The teacher kept a journal detailing her observations of the classroom, and students were assigned
three response log entries at different times. Observations and response log entries focused on student
engagement, their perception of learning, and reflections on the design process.

3.4 Analysis

To understand if hypermedia design had an impact on the elementary school students' motivation,
five two-factor mixed ANOVAs were run with the grouping (designer vs. non-designer) as the between-
subjects independent variable and the data collection points (pre vs. post) as the repeated measure
independent variable. The dependent variable was the pre and post scores of each of the five measures in Harter’s motivation scale (challenge, curiosity, mastery, judgment, and criteria). Unpaired t-tests were conducted between the designer and non-designer groups on each of the five categories of the project design questionnaire (audience, presenting, planning, interest, mental effort, and collaboration). Students’ responses to the design task ranking were analyzed descriptively. An unpaired t-test between the designer and non-designer groups was conducted on students’ performance in creating their stacks.

The interview data and the response logs were analyzed using a two-level scheme following the guidelines by Miles and Huberman [Miles & Huberman 1994]. At the first level, codes were generated directly from the interviews and response logs through multiple passes of the data examination. At the second level, codes generated directly from the data were regrouped into more general categories. Patterns from the data were extracted and the relationships between the coded segments were compared and contrasted. With the research question as a guide, the data were then sorted into categories and sub-categories according to their common themes and shared relationships. The observation data were used to corroborate the findings from the interviews and response logs.

4. Results

4.1 Results from the Quantitative Data

For the motivation scale, the results of the two-factor mixed ANOVAs indicated that there was a significant two-way interaction between the grouping (designer vs. non-designer) and the data collection points (pre vs. post) for scores on judgment: \( F(1,35) = 5.3, p < .05 \) [see Tab. 1]. The designer group increased its score on judgment from pre to post whereas the non-designer group decreased its score slightly. That is, the difference between the pretest and posttest for the designer group was significantly greater than that for the non-designer group. The two groups, however, were not significantly different in scores of challenge, curiosity, mastery and criteria: \( F(1,35)_{\text{challenge}} = .02, p = .88 \); \( F(1,35)_{\text{curiosity}} = 1.02, p = .32 \); \( F(1,35)_{\text{mastery}} = 1.11, p = .30 \); \( F(1,35)_{\text{criteria}} = .02, p = .88 \) [see Tab. 1].

* = significant two-way interaction at \( p < .05 \)

Table 1: Mean and Standard Deviation (in Parenthesis) for the Motivation

For the design questionnaire, the unpaired-T tests showed that there were significant differences between the groups for the following categories: (1) planning: \( t(1,35) = 3.0, p < .01 \); (2) interest: \( t(1,35) = 2.8, p < .01 \); and (3) collaboration: \( t(1,35) = 2.2, p < .05 \) [See Tab. 2]. The average scores for planning and collaboration were significantly higher for the designer group than for the non-designer group. However, the non-designer group had significantly higher scores in the category of interest than those for the designer group. Such results showed that the students in the designer group had a better understanding of the importance of planning and collaboration, while students in the non-designer group showed more interest in
the project than the designer group. No significant differences were found between the groups for the categories of audience, presentation, and mental effort [see Tab. 2].
Table 2: Mean and Standard Deviation (in Parenthesis) for the Design Skills

In the task ranking measure, students from both classes were given a list of eight design tasks and were asked to rank their relative importance. Both the designer and non-designer groups ranked planning tasks as most important [see Tab. 3]. However, the two groups were different in ranking some of the other tasks. The designer group ranked the task of having "someone to try out the stack" as having greater importance than the non-designer group did. It ranked the tasks of "making the graphics very colorful," and "making animation" less important than the non-designer group did. Some of these differences between the two groups were statistically significant [see Tab. 3].

Planning and having others evaluate a product are more important steps for hypermedia design than making graphics colorful or making animation [Lehrer et al. 1994], [Liu & Rutledge 1997]. The results of the task ranking showed that the designer group had an overall better understanding of the design tasks and their relative importance than the non-designer group.

Table 3: Importance of the Design Tasks Ranked by the Students

Performance on the stacks created during phase III was assessed by two external evaluators with regard to the quality, the breadth, the depth and the use of the four design principles (consistency, contrast, legibility and simplicity). The unpaired t-test showed that there were significant differences between the designer and non-designer groups: t (1,19) = 2.6, p < .01 with the designer group having a mean of 95.2 and the non-designer group having a mean of 74.94. The higher the mean, the better the quality of the stacks. The designer group contributed 5 stacks (one from each of the 5 groups) and the non-designer group contributed 8 stacks. The results of the unpaired t-test showed that there were significant differences between the designer and non-designer groups: t (1,19) = 2.6, p < .01 with the designer group having a mean of 95.2 and the non-designer group having a mean of 74.94. The higher the mean, the better the quality of the stacks.
contributed 16 stacks (one from each student). The highest score for the designer group was 120 and the lowest score was 63, whereas the highest score for the non-designer group was 93 and the lowest score was 50. Eight of the 14 statements in the stack evaluation survey relate directly to the application of the four design principles, including "The text on the screen is very readable," and "The navigation buttons are laid out consistently on each card." The designer group did significantly better than the non-designer group when their stacks were evaluated using these eight statements: Mean_{designer} = 61, Mean_{non-designer} = 45.38, t(19) = 4.25, p < .01. These findings suggested that on the whole, the quality of the stacks produced by the designer group was superior to those produced by the non-designer group.

4.2 Results from the Qualitative Data

The interviews with the students and their entries in their response logs showed that both the designer and non-designer groups enjoyed the project and that they felt this high interest level impacted their level of learning. Parents seemed to agree that the project had motivated their children and made learning more fun. Their comments included "It really grabbed the kids' attention" and "K was so excited, motivated, and proud to have created and succeeded in this project." The teacher shared this view on students' interest, explaining that "They look forward to coming to the computer lab to continue their projects."

The interview data and response logs indicated that students in both classes learned design skills by participating in this project. Students in both groups mentioned that they learned the technical skills of how to scan pictures, make colorful backgrounds, and use clipart pictures to enhance their stacks. Additionally, several students in the designer group mentioned the value of collaboration: "I'm getting a learning experience working in groups and deciding what's best for the group." Students from both groups appeared to recognize the importance of planning, though responses from the designer group were more concrete than those by the non-designer group. For example, students in the designer group commented on the need for planning in order to ensure consistency and avoid redundancy. One parent of a student in the designer group summarized the feelings of many parents well: "What a wonderful application and assimilation of learned content as well as skills. Clearly, the computer skills are of great value, but it is really exciting to see the children apply development skills and make choices for format and presentation."

The teacher commented on how a few students who were identified as having difficulty in learning reacted to the different treatments, stating that in the beginning those in the non-designer group seemed to "accept more responsibility for their work as it is [an] individual [project]," while the low ability students in the designer class tended to depend on the stronger students in the group. However, during the course of the project, the low ability students in the designer group eventually took responsibility for their group's work with the help of their team members. In the end, "the needy students did more [for their stacks] in the designer group than those in the non-designer group because of the continual help from other members." while those low ability students in the non-designer group who did not ask for help and did not work hard accomplished little. In commenting about the gifted children, the teacher said that "They generally would do well whenever given the opportunity. This [the project] is a vehicle for them doing that." The gifted students in the designer group took initiative to help others in the groups and ensure that work was completed on time.

5. Discussion

Using HyperStudio as the students in the non-designer group did is a typical way of using hypermedia authoring in a classroom. Engaging students as hypermedia designers, on the other hand, extends hypermedia authoring by placing students in a designer position. Instead of merely learning the technical skills and creating a project, the designers need to consider other issues such as the needs of the audience, the distribution of work in a group, the management of time and resources, and the deadline. They need to implement steps such as planning, designing, evaluation, and discussion. The authenticity and complexity of the design tasks provide students a learning environment where they can develop higher order thinking skills and skills of high value to the work place. This study investigated the effect of being hypermedia designers
on elementary school students' motivation and learning of design knowledge, and found some interesting results.

The findings on motivation, as reflected in the Harter's motivation scale [Harter 1980], showed that there were no significant differences between the designer and non-designer groups on the categories of challenge, curiosity, mastery and criteria. That is, both groups were interested in the hypermedia project, a finding which was supported by the qualitative data in that comments from students in both groups, their parents, and the teacher showed that the students enjoyed doing the project and viewed as a good way to learn science as well as computer skills. This finding is consistent with the literature in showing that engaging students hypermedia authoring is motivational and promotes students' interest in learning [Beichner 1994], [McGrath et al. 1997], [Orey et al. 1997].

The designer group, however, outperformed the non-designer group on the category of judgment from pre to post, indicating that they felt more comfortable making independent judgments, rather than relying on the teacher's judgment, than their peers in the non-designer group. This suggests that the learner-as-designer environment may encourage the development of intrinsic motivation.

Both the Harter's motivation scale and the qualitative data showed that all students liked and enjoyed the project. Yet, the results on the project questionnaire showed that students in the non-designer group showed more interest than students in the designer group in the project. This gap between the two groups can possibly be explained by the frustrations experienced by the designer group, who had a greater variety of activities to handle, and who were responsible for planning and providing peer support. The peer pressure created by heterogeneous grouping, while beneficial, may also have added to the frustration. Finally, the designer group also had to transfer cards from one disk to another to create a group stack, a fact which became frustrating as file sizes grew and work was lost due to computer error.

Learning the science content was one of the objectives of the project. The two science tests (on plants and oceans) showed that students in both groups had significantly increased their knowledge on the subject matter (p < .01) from the pretest to the posttest. In addition to the science knowledge which the students would have gained by working on other types of projects, this project allowed the students to learn some important technical skills involved in hypermedia authoring.

For the designer group, students also learned skills such as planning, project management, reflection (getting feedback from the peers and the audience), and working in groups to achieve a common goal. The statistical analyses indicated that students who were hypermedia designers had a significantly better understanding of planning and collaboration than the non-designer group, and valued these tasks above those of a more mechanical nature, a finding which supports other research [Lehrer et al. 1994], [Liu in press], [Liu & Rutledge 1997]. As Carver and her colleagues pointed out [Carver et al. 1992], such skills are invaluable for students to learn, especially when they are young. It is obvious from the data that the students as well as their parents viewed the opportunity of learning both science and hypermedia design and authoring as not only important but also beneficial to their future.

6. Conclusion

In an effort to examine if being hypermedia designers can have an effect on elementary school students' motivation and learning of design knowledge, this study found that engaging students in hypermedia authoring can enhance students' motivation, and allowing students to be hypermedia designers can support the development of design knowledge and higher order thinking skills. The hypermedia design project allowed the students to grow at their own pace cognitively, affectively and socially. The findings of this study support other research on the same topic in showing the benefits of a learner-as-designer environment [Beichner 1994], [Erickson & Wilhelm 1996], [Lehrer et al. 1994], [Harel 1991], [Kafai 1996], [Liu in press], [Liu & Rutledge 1997], [McGrath et al. 1997], [Orey, Fan, Scott, Thuma, Robertshaw, Hogle, & Tzeng 1997], [Spoehr 1993]. At the same time, it calls for more research in replicating and extending the findings. Literature has clearly shown the benefits of engaging students as hypermedia/multimedia designers.

1The science tests are the ones the teacher had used in the science class last year and would give to students regardless of types of projects they were working on.
Designing such a learning environment is nevertheless a very challenging task. Continuous research on the topic can advance our understanding and help us to search for new ways to design such a learning environment effectively.

Design and Development of an Intelligent Simulation Training System for Process Control Operators

Richard K. Lowe, Education, Curtin University of Technology, Australia, R.Lowe@educ.curtin.edu.au

Thomas E. Nielsen, CBT Simulation Technology Pty. Ltd. Australia, thomas@sage.wt.com.au

Abstract: An interactive knowledge-based simulation has been developed for training process plant personnel to operate distributed control systems. It addresses generic skills by focusing on four basic control loops used by operators across various industries. At the heart of the simulation is a model representing process control expertise in terms of production rules. The tuition situates trainees in a simplified process control environment designed to foster a dynamic problem solving approach without cognitive overload. Instructional design challenges involved in training for dynamic tasks are discussed.

Introduction

This paper reports the development of a knowledge-based simulation system for training process control operators. The project utilises cognitive tutoring principles that are implemented by way of a research-based model of expert performance in the content domain. A number of complementary learning modules are used to support trainees' construction of a mental model of the fundamental control loops underlying effective process control operation. The staged simulation environment is designed to expose learners to the special challenges of dealing with a dynamic problem solving situation while at the same time carefully limiting the cognitive demands imposed. To appreciate the purpose of the process control training system reported in this paper, it is necessary to understand the type of setting for which it is designed. We will introduce the concept of process control by considering the example of an electric power plant. This example allows us to illustrate a typical setting and to characterise the performance demands faced by process control operators.

Process Control: an Example

Ensuring a continuous and well-regulated supply of electrical power to consumers 24 hours each day requires that the process of power generation is maintained within strict limits. In a steam-driven electric power plant, the generators that produce electricity are turned by pressurised steam flowing from jets onto turbine blades attached to the generators. To keep this type of power plant operating safely and properly, there needs to be careful control of:

- the temperature of the steam supplied to the turbines,
- the flow of steam leaving the jets that turns the turbines,
- the pressure of the steam as it leaves the jets,
- the level of water in the tanks supplying the steam boilers.

In modern power plants, these four process variables of temperature, flow, pressure and level are monitored continuously by electronic sensors installed at relevant parts of the plant. This sensing equipment is complemented by a range of electronically operated control devices which automatically perform functions such as changing the temperature, regulating the flow, varying the pressure and maintaining the water level. For each critical function, there are also alarms that will be triggered automatically when any one of the process variables goes outside its permitted range of values. The various components involved in keeping the plant operating properly (sensors, control devices, etc.) work together as an integrated whole known as a...
control system. Information gained from the monitoring of process variables by means of electronic sensors distributed around the power plant is fed back to the central control room. The operator in the control room views this status information which is displayed diagrammatically on computer screens. Alarm information is displayed in a similar way. Further, the control room operator can remotely adjust settings on the various control devices that alter the process variables out in the plant. The operator may take manual control to exert faster control or to override an alarm. This procedure of adjusting settings in response to monitoring and alarm information is carried out via dynamic interaction with the displayed graphic information. The type of control system described here is known as a Distributed Control System (DCS) because an operator working in the single location of the central control room is able to exercise control over many individual aspects of the process that are in reality widely distributed throughout the plant. Although the above example used a power generation process to illustrate the concept of a distributed control system, such systems are widespread across a diverse range of industries.

Overview of Process Control Training System (PCO_CBT)

The PCO_CBT training system was developed as an interactive simulation for delivery via personal computer in either stand-alone format or as a hands-on supplement to an instructor-led course. It was designed to develop generic skills in process control, rather than focusing on developing the specific skills needed for a particular industry. The training addresses four basic control loops that operators must typically master (temperature, flow, pressure and level). These are treated by means of interactive simulations that give trainees experience of working in a simplified process control environment in which the cognitive load is carefully limited to a manageable level while retaining the essential dynamic problem-solving approach required for such operations. The main modules comprising the training are Introduction, Preliminary Training, Job Oriented Simulation Training, and Reference. The instructional environment resembles the sort of control room context which a trainee might encounter if being given more conventional one-to-one training by an experienced process control operator. The approach used in the Job Oriented Simulation Training emulates the usual training situation in which inexperienced operators are trained by attempting to perform actual control tasks under the supervision of an experienced mentor. During training, the trainee’s knowledge and capacities are engaged and developed from the outset when they choose a job to do or an error condition to correct. The different jobs or error conditions trainees can choose range across various types of process variables and levels of complexity. [Figure 1] shows a typical display presented to the trainee during the Job Oriented Simulation Training. The learner’s task is to interpret the abstract representation of the control loops depicted (left hand side of the display), read the information provided in the faceplates (bottom right) and monitor the trend data as adjustments are made (top right). Expert advice and feedback is provided by way of an on-screen mentor (paralleling the situation that might exist with a supervisor in real life). Involvement of the mentor has been carefully designed to be context-sensitive so as to maximise correction of errors at the point of need while minimising possible disruptive effects. The mentor functions by having the knowledge of an expert process control operator encapsulated in “if-then” rules.

Process Control as a Dynamic Task

Process control operators, such as those working within DCS contexts, perform their duties in a highly dynamic task environment [Decourtis 1993, Wallach 1995]. As with other dynamic tasks such as driving a motor car [Aasman 1995], [Donges 1978] or controlling air-traffic [Lee, Anderson & Matessa 1995], process control requires operators to respond in real-time to a continually changing set of task conditions. Many of these changes in the nature of the task are due to alterations in process variables that occur independently of the operator or that are beyond the operator’s immediate control.

Rather than simply being fixed problems that can be dealt with by making a finite set of choices, dynamic tasks can be considered to be control problems [Brehmer & Allard 1987]. As such, these tasks are qualitatively different from the static problem solving situations that have been extensively studied by cognitive
psychologists in recent years. For example, in domains such as physics [Chi, Glaser & Rees 1982] and computer programming [Davies 1994], the nature of the overall problem is defined at the outset and does not change. A satisfactory outcome can be obtained if an appropriate set of steps is followed through to the solution. However, this is clearly not the case with process control.

The immediacy of the task demands in process control are such that there can be little or no time for deliberation on the part of the operator. As with driving a motor vehicle, skilled performance needs to be a largely automatic process that involves significant unconscious control of behaviour. The time imperative for continuous interactive adjustment to the system does not allow for lengthy decision-making processes or extensive introspection. Nevertheless, process control cannot be carried out effectively in a purely intuitive manner. The choices of actions made by a skilled operator in the control room from moment to moment must ultimately be related to their likely physical consequences within the plant itself. This suggests that skilled process control involves the operator constructing some type of mental representation of the situation depicted on the DCS displays and basing decision-making on that representation.

Further complicating factors involved in the learning of dynamic tasks such as process control arise from the inherent unpredictability of the situation the learner is dealing with. This means that it is typically impossible to do a look-ahead search, or to carry out extensive backtracking due to uncontrolled changes in the task environment. In addition, there are temporal characteristics of a dynamic skill that need to be considered, such as the time taken for changes to occur in the process environment and the time taken to complete tasks within the operating environment [see Brehmer 1990]. To perform process control effectively, the operator must take
proper account of these temporal aspects. Trainee operators therefore need to be given the opportunity of 
learning to handle these aspects during their instruction. These additional demands all increase the complexity 
of the task for which operators must be trained.

Expertise in DCS Operations

As with performance in other complex problem solving domains [see Lowe 1993], some aspects of the skills 
involved in process control are largely implicit and therefore unlikely to be revealed during an expert’s explicit 
explanation. However, carefully designed investigations have allowed researchers to infer many of the 
underlying cognitive structures and mental activities that underpin expert performance. The expertise exhibited 
by skilled operators in many fields is associated with their possession of extensive stores of domain-specific 
knowledge.

Expertise in DCS operation has been studied by [Nielsen & Kirsner 1994] and characterised in terms of its 
proactive nature (a response to the complex dynamic environment involved). From these investigations, a 
computer model has been developed which represents such expertise in terms of production rules (“if-then” 
condition-action combinations) and follows on from the extensive work of [Anderson 1993a] on this form of 
knowledge characterisation. This external modelling of DCS expertise has led to a proposal that skilled DCS 
operators may possess knowledge structures that allow them to model process control functions in a fashion 
somewhat analogous to the operation of the computer model. According to this proposal, these knowledge 
structures would include the mental equivalent of production rules and be the basis on which expert DCS 
operators constructed their highly flexible mental models of the system’s behaviour.

The main function of the DCS training system discussed in this paper is seen as being to help trainee process 
control operators develop the capacity to build suitable mental models of the situations they were required to 
handle. A similar approach has recently been used with some success to improve trainee meteorologists’ 
capacities to make weather map predictions [Lowe 1995]. A fundamental requirement for designing instruction 
based upon such approaches is for the design team to have a clear, explicit conception of the knowledge 
structures that underlie the model-building capacities of expert performers in the domain. However, this 
conceptualisation on its own deals only with the nature of the desired outcome of instruction. It does not give 
any guidance about what instructional processes are likely to be effective in promoting that outcome. We also 
need to consider the way in which characteristics of the learning situation itself may interact with the 
development of expertise.

Challenges for Training: Developing Expertise in Process Control

One approach to training DCS operators might be to use a straightforward simulation that closely resembles the 
actual situations which such operators would typically be expected to encounter. However, it can be seen from 
the discussion in earlier parts of this paper that this approach may be ineffective due to the undesirably high 
cognitive processing demands it would make on the learner [see Sweller, 1993]. Faced with a conventional 
simulation of this type, the learner’s response is likely to be primarily one of survival. That is, the actions taken 
would be a result of the learner’s attempts to cope with the immediate exigencies of the situation, rather than 
efforts directed towards the building of an expert-like knowledge representation.

Coping strategies such as the focusing of processing resources on some aspects of a task while paying less 
attention to other aspects are often adopted in situations of high task demand. This type of cognitive load-
sheddng would be a possibility if multimedia-based training in process control was to rely upon high demand 
real-time problem solving tasks. [Sweller 1988] has suggested that the cognitively-demanding nature of 
problem solving activity itself may mean that it is not the most efficient way to acquire expert knowledge 
representations.
The specific results from studies of process control operators in a German power plant [Wallach 1995], [Wallach & Tach 1994] appear to be consistent with the general concerns about cognitive load expressed by Sweller. Wallach has speculated that subjects who were given the dual tasks of learning and controlling the process achieved relatively poor results because of the effects of cognitive overload. If this was the case, it may be that DCS instruction would be more effective if, rather than being asked to cope with the demands of a full-blown control situation, learners were presented with a considerably scaled-down level of control demands. However, it would be important that the way in which the control demands were scaled down still required the operator to switch between the dual roles of (a) passively supervising an automated process and (b) actively manipulating process control variables in a direct fashion [see Reinartz & Reinartz 1989].

**Approach to Instructional Design**

At the heart of the instructional design of the DCS training materials described in this paper is a knowledge-based system that models the performance of an expert process control operator. While in certain respects some its features resemble those of traditional simulation training, it goes beyond the preoccupation with surface fidelity that characterises most such approaches. This is partly because it deals with an abstracted working environment in which the reality of the equipment out in the plant is replaced by highly simplified two-dimensional symbolic representations. However, it is also because of the incorporation of an explicit model of process control performance. In contrast to many other model-based approaches, this system does not attempt to model the cognitive processes of the trainee but rather is derived from cognitive modelling of expert performers. As a consequence, its function is to act as a powerful resource for monitoring trainee actions while providing context-sensitive feedback to guide the learning process in an efficient manner.

With respect to the practical design of intelligent tutoring systems, Anderson [Anderson 1993a], [Anderson 1993b] has enunciated general principles intended to support the implementation of cognitive engineering approaches in computer-based instruction. These principles can have implications for design decisions taken at the micro level (computer programming of the rule base) or the macro level (development of practical instructional strategies). The following list summarises these principles:

1. Represent student competence as a production set.
   *(The skill is decomposed into an accurate model).*
2. Communicate the goal structure underlying the problem solving.
   *(To be done through the interface as much as possible).*
3. Provide instruction in the problem solving context.
   *(Instruction is provided as each new set of production rules is introduced).*
4. Promote an abstract understanding of the problem solving knowledge.
   *(The conditions of the rules are sufficiently general to do this).*
5. Minimise working memory load.
   *(Do not present instruction while problem solving).*
6. Provide immediate feedback on errors.
   *(Cut down on time in error state).*
7. Adjust the grain size of instruction with learning.
   *(The grain size to reflect larger chunks built during problem solving).*
8. Facilitate successive approximations to the target skill.
   *(The tutor fills in some steps during early stages).*

Wherever possible, the design of the present project was carried out in accordance with these principles. In some cases (such as point 1), the principles are concerned with the characterisation of the knowledge structures that underlie the desired performance outcomes. In others (such as point 5), the principles address the demands of the instructional situation by considering ways in which the learning which ultimately leads to the performance outcomes can be facilitated. For the design situation described here, strict adherence to Anderson's principles was not always possible and sometimes not even desirable because of the special nature of expertise in process control (including its dynamic character and the need to support construction of a
coherent mental model). For example although representation of student competence as a production set certainly became the core of the design, it proved to be impractical to build in meaningful computer-based adjustments of the grain size of instruction with learning.

Conclusion

Instructional design typically involves some degree of optimisation in which competing demands arising from the nature of the content and the characteristics of learners must be reconciled. For the DCS operator training discussed in this paper, this reconciliation process was particularly challenging because of the complexity of the task involved, its dynamic character, and the abstract way in which the information involved is represented. The learner is dealing with what could be thought of as a moving target. However, developing the capacity to deal with this target effectively relies on the construction of knowledge structures that will permit the learner to generate and modify mental models of the depicted remote situation in order to take appropriate action. A major challenge to the developer of instruction in this area is the lack of a comprehensive theoretical framework to guide design activities. An important reason for this deficiency is that conventional approaches to instructional design are not able to handle the complex issues that arise in dynamic environments. In the project reported here, although we have taken a strongly theory-driven approach to the design of the instruction, it has been necessary to be quite eclectic in our approach. It may be that this is unavoidable in a domain such as DCS but the absence of coherent, principled approaches to guide the design of instruction for dynamic environments in general is a matter of some concern. In our future development of DCS operator training, we will be exploring possible approaches and design methodologies that can be used in this demanding area. It is anticipated that the innovative use of cognitive modelling based upon expert performers rather than trainees will contribute to more principled instructional design for dynamic environments in general and effective training in the specific context of distributed process control.

DEVELOPING AND FACILITATING A SELF-PACED TECHNICAL
CALCULUS COURSE ON & OFF CAMPUS

Pamela Lowry
Mathematics/Computer Science
Lawrence Technological University
Southfield, Michigan
U.S.A.
Lowry@LTU.edu

Abstract: Developing and facilitating a self-paced Technical Calculus course on and off campus is a learning experience. The course was first developed for Focus: Hope and is now being taught at Lawrence Technological University. This paper goes into details describing the course at both sites. It describes the structure of the course, the materials used, and a summary of my experiences. I have also described changes I have made to the course based on the needs of the students and how I envision this course in the future.

The Technical Calculus course described in this paper was developed in the summer of 1996 by me and Professor Barbara Chambers of the Northern Virginia Community College for Focus: Hope in Detroit, Michigan. Focus: Hope is a metropolitan Detroit civil rights and human rights organization. It was founded in 1968 following the 1967 Detroit riots by Eleanor Josaitis and Father William Cunningham. The goal of Focus: Hope from the very beginning has been to help build a strong community among people of diverse backgrounds through practical action to overcome racism, poverty, and injustice.

Focus: Hope began by distributing food to low income mothers with children and senior citizens. Over the years it has expanded tremendously to include the following:

1) Fast Track education program to provide basic math and reading classes along with short term job skills for inner city people who wish to work toward advancement or prepare for a longer course of study in Focus: Hope's Machinist Training Institute (MTI).
2) Machinist Training Institute provides State-licensed, fully accredited training in precision machining and metal working. Trainees gain comprehensive machining skills working from blueprints to a finished product.
3) Center for Advanced Technologies - The highest level of education and training is provided through the Center for Advanced Technologies which accepts graduates of MTI.

In the Manufacturing Technology Education provided by the Center for Advanced Technologies (CAT) the candidates (students) receive manufacturing training along with academic learning in an actual production setting. It is a federally funded project to educate it's candidates in advanced manufacturing engineering at world class levels. The candidates learn how to build, operate, maintain, and repair complex computer-integrated, flexible manufacturing equipment and systems. The typical candidate is 20 years old or older and comes from a disadvantaged background. They have progressed through the Fast Track and MTI programs to be eligible for CAT. They often are supporting families and receiving paychecks from Focus: Hope for the production work they perform on a full-time basis. The combination of working a production job and taking college level courses toward a degree is very rigorous and time consuming.

Upon entering the CAT, the candidates take a diagnostic math test which places them in one of 18 mathematics modules which are based on the Technical Mathematics 1 and Technical Mathematics 2 courses at Lawrence Technological University (LTU). Lawrence Technological University is an independent, co-educational, accredited university founded in 1932 in Southfield, Michigan. The University is composed of the Colleges of Architecture and Design, Arts and Sciences, Engineering, and Management.

Once the CAT candidates at Focus: Hope are placed in a math module they proceed on a self-paced basis until they are ready to take the module test. They must score 85% or higher on the test to proceed to the next
module. Once they have passed the final exams for Technical Mathematics 1 and 2 they can proceed to Technical Calculus. Prior to summer of 1996 Technical Calculus had not been developed into self-paced modules. I taught the course at Focus: Hope just like I would on LTU’s campus, as a lecture course. There was a need to develop this course as a self-paced course to also be consistent with Technical Mathematics 1 and 2. During the summer of 1996 Barbara Chambers and I developed eight self-paced modules that make up the Technical Calculus course.

STRUCTURE OF THE COURSE

The course is designed as an introduction to Calculus for Manufacturing Engineering Technology. This is a course in which the candidate (student) works at their own pace and should take no more than 15 weeks to complete. The course is made up of the following eight modules:

1) Limits and derivatives
2) More derivative rules
3) Applications of derivatives
4) Curve sketching
5) Derivative of trigonometric, logarithmic, and exponential functions
6) Integration
7) Applications of integration
8) Methods of integration

When the assignments in a unit are completed and understood, a unit test is taken. There is also a comprehensive final exam following completion of the eighth module. A unit test, on which a grade below 75% is scored, may optionally be retaken only once with the higher of the two scores counting toward the candidate’s average. The final exam may only be taken once. I spend approximately 2 hours twice a week at Focus: Hope either tutoring the candidates, administering exams, or conducting mini workshops with a few of the candidates. It is very important for the candidates to see that I am available and very willing to work with them. The semester grade is based 50% on unit tests and 50% on the final exam. The grading scale is:

<table>

MATERIALS FOR THE COURSE

The book we developed summarizes each module. It has an assignment sheet for each unit keyed to the textbook entitled Basic Technical Mathematics With Calculus by Allyn J. Washington 6th edition Addison Wesley Publishing. The units utilize video tapes which are basically lectures on demand, along with worksheets, and Calculus software. The software available at Focus: Hope is Calculus by Broderbund and
Calculus Connections. There are 20 video tapes available for the course, with each module requiring the student to view anywhere from 1 to 5 tapes. The use of a graphing calculator is also strongly encouraged.

**SUMMARY OF THE SELF-PACED TECHNICAL CALCULUS AT FOCUS: HOPE**

The first time I taught Technical Calculus at Focus: Hope was the Winter 1996 semester. The modules were not developed at that time so the class was a lecture course. I have been facilitating the self-paced Technical Calculus at Focus: Hope since the Summer semester 1996. If a candidate does not complete the course in 15 weeks they are given an I grade and given the opportunity to complete the course in the next 15 weeks. If after that time they do not complete the course, they receive an F grade and they have to register for the course at another time. There are many reasons that this can occur. Since all the candidates work at least 40 hours/week operating machinery at Focus: Hope to produce parts under contract with the Big Three Auto Makers, their jobs often interfere with the course. Production scheduling can vary from week to week to meet the customer's demands for parts. In other cases they may be overburdened with other courses they are taking that are not self-paced. They are strongly encouraged to register for the class again at their earliest convenience since the Mathematics is a basis for their other courses.

**SELF-PACED CALCULUS AT LAWRENCE TECHNOLOGICAL UNIVERSITY**

Technical Calculus has traditionally been taught at LTU using the lecture mode of delivery in the evening school. The evening school student typically works during the day and is trying to complete a degree at night. They are usually older than the typical freshman in college. They quite often are in their twenties, thirties or even older. I was encouraged to apply what I was doing at Focus: Hope to our LTU campus. As a result, during the winter semester 1997 school year, I facilitated a self-paced Technical Calculus class at Lawrence Technological University. We also offered a lecture course if the students did not want a self-paced course. At the beginning of the semester 16 students registered for the course. Two students withdrew from the class within 3 weeks because they did not like the concept of self-paced.

The materials used were basically the same as at Focus: Hope. They used the book Barbara and I developed, the textbook, and the video tapes were available for reference. There was no Calculus software available during the LTU course however. I gave the students a schedule approximately half way through the course describing where they should be in terms of the modules. They thought that was very helpful and I should have distributed this at the beginning of the course. I also distributed a questionnaire at the beginning and the end of the course. The questions were based on a scale from 1 to 5 with 1 indicating least and 5 indicating most. Some of the questions at the beginning of the course were:

1) How motivated are you to take a self-paced course?
2) How helpful do you think the video tapes will be?
3) How helpful do you think the self-paced book will be?
4) How disciplined do you think you are?
5) Do you think it will be helpful to have an Instructor in a classroom?
6) Do you think it will be helpful to progress at your own rate?

Their answers to these questions ranged between 2 and 5. At the end of the course the same questions were asked in the past tense. This time the answers were strictly 4's and 5's. I also asked the students if they now preferred a traditional or self-paced course. All but one answered self-paced. They liked the idea of the flexibility that is built into the course.
SUMMARY OF SELF-PACED CALCULUS AT LTU

After I facilitated the course for one semester at Lawrence Technological University I realized I needed to make some changes. The video tapes were a problem because the students could not check them out. I had more copies of the video tapes made so the students in the next course offering could check them out for a couple of days. The students this semester like this idea. I also did not think there was enough interaction among the students and myself. As a result, I have put more of an effort into interacting with the students this semester. They have my home phone number and I have their work and home numbers. I talk individually to each student at least once a week. The class is a 3 credit hour course, and I am available each week for 1 ½ hours in a classroom to answer questions and administer tests. There is also another instructor available another evening to tutor them. I feel the interaction with the students is essential but it is more time consuming on my part. The book that Barbara and I developed is also now available on a CD in preparation of offering this course on a distance learning basis. The students have been given the option of purchasing the book or using a copy of the CD to try for the semester. They need a browser to view the CD such as Netscape or Microsoft Explorer because the CD was developed in HTML in anticipation of being placed on the internet. I am also requiring the students to turn in the worksheets I provide them before they take a unit test so I can see what types of mistakes they are making if any. To incorporate this into the course I have changed the grading for the course. The 8 module exams count 55%, final exam 35%, and the worksheets count 10% of their grade. The students seem to feel very comfortable with this structure.

THE FUTURE OF THE SELF-PACED CALCULUS COURSE

The first point I feel very strong about is that a self-paced course is not for everyone. Some student definitely learn more effectively as a lecture. We all learn differently. I think we will continue to need to offer Technical Calculus as a lecture course for the time being in addition to the self-paced course. The CD will eventually be offered over the internet as an LTU course. The students should also be given the option of purchasing this in printed form as it is now. They should be given all the necessary information at the beginning of the course such as a syllabus, worksheets for the course, and a schedule of possible exam dates to keep them on target. The students should have access to my home number, work number and email address. This I believe has been successful this semester. They can either mail, fax, or email the completed worksheets to me to correct. The video tapes should be available on video tapes and CD. This will give the students complete flexibility at their site. The unit tests can be given via a proctor at a given site or sites designated. The exams can then be faxed to me to grade. A chat room can be set up so the students can interact with each other. I would still like to do a survey at the beginning and end of the course so I can constantly improve the course.

Next semester (Winter 1998) I will be advising a senior in a directed study course to make the CD more interactive by adding audio, animations, and video. Good educational software is active, not passive. Students ought to be doing something, not watching something. [Schank, 1993] At the end of the directed study course the CD will be a true multimedia product. According to the literature, the more senses you involve the more learning takes place. It is also very important to interact with each student. I would like to either travel to their sites at least once or schedule at least one video conferencing section. If they do not own equipment like Vtel, then possibly it could be rented. As we reach out via distance education to attract more non-traditional and place-bound students, we need to think of them as our students. [Sedlak & Cartwright, January/February 1997] Distance education is not a new phenomenon; it has been a mode of teaching and learning for countless individuals for at least the past one hundred years. [Moore & Kearsley, 1996] Imagine a nontraditional learner where learning can take place anytime, anywhere, and where the learner makes the choices. [Perrin, February 1995]
CONCLUSION

Distance education offers students more choices and increases access to higher education. Dooley believes that with the technology now available, education is entering the most creative period it has ever seen. There is definitely a need to provide distance educators with systematic guidelines for selecting instructional strategies. [Dooley, 1995] The purpose of distance education is to meet the diverse learning and scheduling needs of students. Interactivity is an important aspect of learning regardless of whether the class is being taught in the traditional lecture mode or as a self-paced course.

Montréal, (Québec), H2L 4L5, Canada.

Abstract: In an attempt to converge the visions of a Virtual Campus, several research teams at LICEF [1] developed a prototype. To formatively evaluate this prototype, consisting of 18 computer tools facilitating communication, information gathering, learning management and navigation, 15 students and 3 tutors were employed during 7 weeks. The goal was to identify the strengths and the weaknesses of this learning environment from a technological, a pedagogical and a methodological viewpoint.

This article reports the global results of this formative evaluation allowing for some guidelines to be expressed.

1. Introduction

Since 1992 the LICEF research centre is involved in designing, developing and experimenting a Virtual Campus (VC) which co-ordinates the activities and tools required in a tele-learning process. During the spring of 1997, a prototype was developed by an interdisciplinary research team [Paquette et al. 1993; Paquette et al 1996a, 1996b; Paquin and Bleicher 1996; Dufresne et al. 1997; Dufresne 1997; De la Teja 1997]. The prototype integrated the research from several domains: system architecture, telecommunication, instructional design, interface design, tutor intervention methods, collaborative learning, meta-cognition, learning management, terminology and linguistic discourse analysis. On the technical side, the prototype included:

- three types of telecommunication systems (ISDN, ADSL, cable-modem) to accommodate both real time communication (video/textual) and asynchronous communication (FTP, e-mail, computer conferencing).
- multiple electronic tools to facilitate production, peer communication, self-management, and information gathering

The formative evaluation of the Virtual Campus had a two-folded goal:
• the integration of research from all the members of the team;
• to identify the learners reasons for using and their attitudes towards the tools included in this model of the Virtual Campus.

2. Theoretical underpinnings

The underlying principles shaping, both the instructional and the technical development of the prototype, have its roots in a constructivist philosophy. The following points stand out as basic guidelines for the design:

- Active learning through exploration of the environment, the content and getting to know peers, that is, the learner takes on the main responsibility for the learning;

[1] L'informatique Cognitive et Environnement de Formation
- **Collaborative learning** encouraging negotiating and validating newly found knowledge with peers, tutors and experts, and consequently yielding a gradual construction of a personal representation of the content [Henri and Lundgren-Cayrol 1997; Lundgren-Cayrol 1996];
- **Tutor as a facilitator** of learning rather than a instructor [Hotte 1995];
- **Providing multiple perspectives of the content** to facilitate the acquisition, elaboration and evaluation of both the content and the learning process.

3. **Methods**

A learning situation was designed allowing to apply the "Learner Verification and Revision" method [De la Teja 1997; Weston 1988]. This method aims at the improvement of learning materials and tools, during the development phase, by identifying the flaws through an iterative trial and revision process with the learner as the main evaluator. The learners were asked to do "real tasks" admitting a variety of data gathering techniques.

3.1 **Participants**

Fifteen students in Management and/or Administration, with differing knowledge in computer use, various experiences in distance learning, and from two age categories, were employed to take on the role as the learner. The initial selection also catered to two research demands, that students had some interest in the course content, a basic knowledge of the IBM desktop environment and possessed essential word-processing skills. Three tutors were involved in the experiment, a subject-matter specialist, a moderator and a method's specialist. These tutors worked together as a team using a private asynchronous conference as their workspace. Further, the complexity of the learning environment demanded technological assistance in terms of telecommunication, hardware and software problems.

3.2 **Materials**

The prototype of the Virtual Campus included different ways in which the learners could proceed in the environment to acquire the course content. Three levels of navigation were designed:
- the Virtual Campus in form of a space station named Explora (Figure 1); Each node brings the learner to a set of tools;
- the course scenario designed as a Centre of Congress (Figure 2);
- the Knowledge Model and the Learning Scenario offering different perspectives of the learning content (Figure 3 and Figure 4).

![Figure 1. The interface to the Virtual Campus, Explora](image-url)

The tools supporting the environment operated in a Windows-97 environment and provided means of
- Navigating in the learning environment
- Communicating with peers
Producing academic work
Gathering, organising and structuring content information
Managing the learning [Ruelland and Bergeron 1995]

The learning scenario was designed around an undergraduate economics course, ECO 3004: Training and Economical Competitiveness [Tremblay 1997] divided into five modules: stating the problem, doing a literature search, sharing information, holding a multi-point video debate, participating in an asynchronous debate, and completing a take-home exam. These activities were available at the Centre of Congres.

The course modules took the graphical form of a map, linking modules in terms of precedence in time. These modules could be viewed from different perspectives, as an outline of the course with or without all the details of an event.

The Knowledge Model took the form of a conceptual map allowing the learner to explore the content from an expert's point of view. Another view of the content took the form of an outline from which the learner could explore the documentation (book chapters, articles and videos).
3.3 Instruments

Data were gathered through questionnaires, telephone interviews, video observations, think aloud protocols, automatic computer traces, academic productions, computer-conferencing messages, and informal discussions with the students.

3.4 Procedures

The course scenario revolved around a video debate that was prepared first on an individual basis, then in teams. Once the teams were ready, they held a debate using multi-point videoconferencing. The main points of the discussion were elaborated upon in an asynchronous computer conferencing debate. In all, the learning activities lasted 7 weeks. Subjects were geographically distributed in the Montreal area as well as two other cities.

Since the LRV method proposes that the evaluation is carried out in a situation as realistic as possible, the data gathering took place according to these three phases:

- Exploring the environment (privately and in teams). Data was gathered through videotaped training sessions, and an attitude questionnaire. To keep track of technical problems occurring in this initial phase, a log was held.
- Elaborating the content (alone/team/group). A log was held to keep track of the academic performance and participation in the collaborative activities by the transcript of the conferences. A second attitude questionnaire was administered.
- Evaluating the experience (group). Messages in the asynchronous conference and a videotaped face-to face debriefing session, that was held on the last day.

4. Results and recommendations

The formative evaluation of the prototype allowed the integration of efforts from different teams at LICEF as well as the development of an efficient and effective communication among teams. This translated into the harmonisation of terminology and in the sharing of a common vision of the Virtual Campus.

In terms of technical issues, overall findings reveal that participating students relied on synchronous communication when in need of technical help or for motivational purposes, but preferred asynchronous communication to learn content. Moreover, it became evident that in order to appropriately serve students and tutors at a distance, the technological expertise must be both varied (telecommunications, software, hardware) and distributed.
In terms of pedagogical issues, the time to explore the environment was underestimated and students felt slightly overwhelmed by the plethora of tools in the beginning of the experience, but reported 'at home' at the end. However, 86% of the students reported satisfied or very satisfied with the experience.

The development of an integrated prototype brought forth the problems that future research must face:
- Initial learning activities must be designed to use the technology in a purposeful manner; e.g., the note taking tool, Atelier FX [Desjardins et al. 1996], was very appreciated by the students, and which was the purpose of the first activity;
- From the tools designed to assist in learning management, only a few seemed to be useful in this situation.
- Multiple access to the content as well as to the learning activities are appropriate to cater to different learning styles;
- Tele-learning seems to benefit from different types of tutors, the three tutors were very appreciated by the students;
- A fine balance between the use of videoconferencing and asynchronous conferencing is necessary, since students preferred the asynchronous mode for learning content, but the synchronous mode for motivational purposes and technical help;
- Interface design for these types of learning environment appears to profit from metaphors.

A bigger sample and a longer learning period might shed more light on the purposefulness of the different tools proposed in the Virtual Campus prototype.

Detailed reports are being prepared by each one of the research members involved in the Virtual Campus project. The prototype is presently being revised and developed as a Web version.

Abstract:
Designing and implementing Educational Multimedia Systems (EMS) is hard; even when design methods may help in this task, most critical design decisions remain undocumented making reuse a difficult task.

In this paper we show how to use design patterns while building Educational Multimedia Applications. We first present the idea of design patterns and then discuss some simple though effective design patterns addressing different concerns in this kind of applications. Each one of them is exemplified with successful educational applications.

1. Introduction

In the past four years there has been a growing interest in hypermedia design techniques. The different problems an educational hypermedia author has to deal with are complex, since the combination of navigation through an intricate information space with the unstructured nature of multimedia data poses new challenges. There are some well-established notions of good hypermedia development, outlining three groups of design issues:

- The first group comprises the problem of organizing the information:
  - How do we organize the information space to let the user navigate following meaningful links established between information units, and let the users understand?
- The second group of design issues explores the organization of the interface:
  - Which objects the user will perceive and how these objects relate to the navigation objects?
  - How will the interface behave as the user exercises it?
- The third group of design issues has to do with implementation:
  - How these information units mapped into pages?
  - How are navigation operations and interface objects implemented?

Design Methodologies help the software designer to express an idea with an appropriate language, and the way it has to be implemented. Unfortunately, there is an important issue that no existing methodology addresses and that is: how to make good, effective designs.

This is the barrier that separates successful experienced hypermedia authors from the rest. Having reached a certain maturity in the process of designing hypermedia applications it was, until now, hard to talk about effective design solutions and convey experience to other people, mostly due to the lack of an abstraction mechanism.

Such a mechanism allows to express design strategies to face common design problems and to record design experience; it is a language to talk about how things must be designed rather than how they are written under any given methodology. If we are not capable of transmitting the experience gained through the years, how will we develop and enhance the next generation of Educational Multimedia Systems?

Though originated in architecture [Alexander77] design patterns are being increasingly used in software design [Gamma95]. Design patterns are a good means for recording design experience as they systematically name, explain and evaluate important and recurrent designs in software systems. They describe problems that
occur repeatedly, and describe the core of the solution to that problem, in such a way that we can use this solution many times in different contexts and applications. Looking at known uses of a particular pattern, we can see how successful designers solve recurrent problems.

In some cases, it is possible to give structure to simple patterns to develop a pattern language: a partially ordered set of related patterns that work together in the context of certain application domain. Design Patterns complement methodologies in that they address problems at a higher level of abstraction. Many design decisions that cannot be recorded through the uses of the primitives of a method can be described using patterns.

We next present a set of simple design patterns that address usual concerns in Educational Applications; though it is not our objective in this paper to show how they interact with each other, it will be clear from each example that they can be used together in a synergistic way.

2. Navigating through information

The patterns presented in this section, face common problems in the organization and access to the information. There is an underlying idea connecting the patterns presented here that stressed the importance of a clean separation between interface and. Some methodologies such as OOHDM [Schwabe96] propose an architectural model that follows this principle. Similar separations can be found in other methodologies such as RMM [Isakowitz95] and HDM [Garzotto93].

We next present some patterns discovered and used in the context of developing educational multimedia applications. We describe them using a single template describing the problem that originates the patterns, the motivation, the solution and an example in the context of Educational Multimedia Systems (EMS). This template allows expressing solutions in a "methodology-independent" way and so they can be used with different Hypermedia design methods, such as OOHDM, RMM or W3DT [Bichler97]. For each pattern we add a short comment explaining why it is relevant to EMS.

2.1 Navigational Context

**Problem:** How to organize the EMS navigational structure, providing guidelines, information and relationships that depend on the current state of navigation, in such a way that information can be better presented and comprehended?

**Motivation:** EIS usually involve dealing with collections (e.g. Concepts, Paintings, Cities, Persons, etc) These Collections may be explored in different ways, according to the task the user is performing. For example, we may want to explore Books of an author, Books on a certain period of time or literary movement, etc., and it is desirable to give the user different kinds of feed-back in different contexts, while allowing him to move easily from node to node.

Suppose for example that in an EMS about inventors and inventions, we reach Thomas A. Edison and then we arrive to the Light Bulb invention. However, we can also reach the Light Bulb while exploring inventions during a specific period of time, following a history of the most famous inventions, or while visiting another invention such as the "Fluorescent Light" and we follow the link to related inventions. It is clear that we will explore the same object under three different perspectives: as a Thomas A. Edison's invention, as an invention of the past century, and as an invention related to others such as the Fluorescent Lamp.

**Solution:** Decouple the navigational Objects from the context in which they are to be explored, and define objects' peculiarities as Decorators [Gamma95], that enrich the navigational interface when the object is visited in that context. Navigational contexts are composed of a set of Nodes (like Books or Inventions) and Context Links (links that connect objects in a context).

![Diagram of "Navigational Context" pattern and a working example](#)
Relevance to EMS: It is usual in EMS that the same concept may be reached from different "learning paths"; in each one of them we want to help the learner to explore other related concepts conforming with the actual context. The navigational context navigation pattern helps to group nodes in meaningful sets that can be easily explored. It also address the problem that arises when the same node belongs to more than a set by indicating that in each case the node must be decorated according to the context.

2.2 Information Factoring

Problem: How can we present information needed by the reader to understand a given topic/Information unit?

Motivation: This problem is of a particular interest in EMS. Many times, for example when introducing a new topic, it is necessary to refer to related concepts. The author has the possibility of adding links to the nodes of the referred concepts. But, if the reader is forced to navigate back and forth the original topic to read about complementary ones, the navigation overhead is high and the users’ focus desagregated through a number of nodes, instead of concentrating in one topic at time. Thus the effectiveness of having links with related information is reduced by the distraction penalty it imposes over the reader.

Solution: This problem has been devised in hypertext systems from the early days. The usual technique is to activate those nodes of related information inside the current node. The user sees this "in-place activation" as a pop-up window that generally can be easily dismissed with an escape keystroke. In this way, the reader does not have to navigate to other nodes avoiding the inherent context switch and cognitive overhead.

Known Uses: In the "The Way Things Works", complementary concepts are shown in this way in figure 3, where the concept of "energy" is mentioned in both topics, and a reference to a node containing its definition is given. Notice that the definition of energy is not a part of the topics but rather an independent node that is activated as a pop-up window. Also, the MS-Windows Help System [Win95], provides different ways of specifying anchors, depending whether the result of activating the anchor is navigation or in-place activation of the target node (these are called: jump-anchors and popup-anchors).

Related Pattern: Information on demand [Rossi 97], since additional information enriches the contents by activating other nodes in pop-up windows. The difference with Information On Demand relies in that information is not part of the current node, that is, it is not part of the node’s attributes and might be accessed from other ways, not only from the current node. The user activates simultaneously other nodes of information.

Relevance to EMS: This pattern address a common concern in EMS; how to provide background information to the reader without distracting his attention.

3. Organization of the interface

3.1 Information-Interaction Decoupling

Problem: How do you differentiate contents and various types of controls in the interface?

Motivation: A page of a complex application display different contents, and is related to many other pages, thus providing many anchors. Moreover, if the page supplies means of control activation other than
navigation (such as triggering some query), the user may experience cognitive overhead. It is well known that when too many anchors are provided in a text, the reader is distracted and cannot take profit of all of them.

Solution: Separate the input communication channels from the output channels, by grouping both sets separately. Allow the "input interaction group" to remain fixed while "the output group" reacts dynamically to the control activation. Within the output group, it is also convenient to differentiate the "substantive information" (i.e. content) from the "status information". This solution not only improves the perception of a node's interface, but also the efficiency of the implementation.

Example: in figure 3, all links to related information on the current topic are displayed on the left. The graphics/video relevant to the current topic is displayed in the middle. Notice there are no links in the text itself.

3.2 Behavioral Grouping

Problem: How to recognize the different types of controls in the interface so that the user can easily understand them?

Motivation: A problem we usually face when building the interface of a EIS is how to organize control Objects (such as anchors, buttons, etc.) to produce a meaningful interface. In a typical EIS there are different kinds of active interface objects: those that provide "general" navigation, such as "back" button, or anchors for returning to indexes, objects that provide navigation inside a context; objects that control the interface, etc. Even when applying Information-Interaction decoupling, there may be a lot of different kinds of control objects.

Solution: Group control interface objects according to their functionality in global, contextual, structural and application objects, and make each group to enhance comprehension.

Example: in figure 4, the first picture is taken from MindQ's CD-Rom "An introduction to Java Applets" groups the navigation controls at the left and the current topic playing controls at the bottom.
3.3 Behaviour Anticipation

Problem: How do you tell the user the effect or consequence of activating an interface object?

Motivation: Many times, when building an interface, it is necessary to combine different interface elements such as buttons, hotwords, media controls or even custom-designed controls. It is usual to find readers wondering what has happened after activating a control, and the exact consequence of the action performed.

Solution: Provide feedback about the effect of activating each interface element. Choose the kind of feedback to be non-ambiguous and complete: different cursor shapes, highlighting, small text-based explanations called "tool tips". Also, these elements can be combined with sound and animations. If we are using the behavioural Grouping interface pattern we can select different kinds of feedback according to the kind of behaviour provided; when the interface controls refer to a particular media such as animation, we could use a small status field for that family.

Example: In figure 5, there is an example from the Microsoft Atlas Encarta97. Each time the user positions the cursor over an interface element, a tool tip pops up with an explanation about the effect of activating the control.

![Figure Error! Unknown switch argument.](image)

Figure Error! Unknown switch argument.: Example of "Behaviour Anticipation".

3.4 Process Feed-Back

Problem: How do we keep the user informed about the status of the interaction in such a way that he knows what to expect?

Motivation: When the user interacts with a hypermedia application, it may happen that many options result in non-atomic operations, such as getting information from the database, loading an image, or contacting another machine (in the case of the web browsers). In these cases, the user may feel the system didn't receive the order or simple is not working fine. As the user loses his patience without any positive feedback from the system but a silent screen, he may start retrying the last action or even any other action no matter whether it is connected or not with the sole target of getting some response. At this point, the user may have already lost the orientation and the task to be performed has been left in a second place.

Solution: Provide a constant perceivable feedback about the status of the operation that is being carried out, indicating progress in the case of non-atomic operations. Analyze which operations are atomic and do not need to be tracked. For non-atomic operations, give information about the current status: beginning, progression and ending of the operation. The kind of feedback depends on what kind of operation is involved: network connection, file loading or database search.

Related Patterns: Both process-feedback and behaviour anticipation address a similar problem: giving prompt feedback to the user about the actions he is performing.

Known Uses: In Web Browsers like Netscape Navigator and MS-Explorer, process feedback is given through a status bar showing the state of the http connection. On many CDs, the feedback given to the user is to set the cursor to the OS busy-hourglass. However, there are others that explicitly implements such feed to the user, as the example shown below.

Example: In figure 6, we can see an example of "Process Feedback", from the "Programming Java Applets" CD. The slider bar tells the user about the amount of information that remains for a given topic, and the rolling knob tells that animation is taking place.
4. Conclusion

The process of designing and building educational hypermedia applications is far from being a simple task. There are several methodologies that already provide the necessary constructs and support for the different design tasks, though none the means to record the author experience and knowledge in the field.

We claim that through the use of patterns, authors are now able to identify common design problems and express solutions in a methodology-independent manner. Furthermore, now authors can talk about their designs with a common language and learn which were the ideas behind successful educational hypermedia systems.

In this paper we have presented some patterns we have found in different educational hypermedia systems on CD-ROMs and WWW. These patterns address important concerns in EMS and they can be used together to build complex but effective systems. Our aim is to define a pattern system containing a rich set of patterns dealing with most relevant issues in EMS.

It is our hope that, once a rich set of patterns is available, authors will be able to learn and work on multimedia systems at a higher levels of abstraction and with better results, since their work will be based on proven successful techniques.

Communications Technology and Video Production:
An Evolutionary Study of Their Effects
On a Distance Learning Program

Dr. William Lynch
Department of Educational Leadership
The George Washington University
United States of America
blynch@gwu.edu

Abstract: The purpose of this paper is to examine how the use of video has inspired and altered the implementation of teaching and learning in the delivery of a master's program offered in a distance learning format. In the process of this examination, technical issues concerning video production techniques, distribution, and utilization are also analyzed.

Introduction:

The Educational Technology Leadership program is a master's degree curriculum, which has been delivered entirely at a distance since 1989. Although the program was designed with distance education in mind, it has evolved substantially in form, substance, and philosophy since its inception. Challenged to utilize current distance learning delivery methods for academic and market reasons, options were continually evaluated in terms of accessibility, affordability, and curricular effectiveness. It appeared to be true, however, that as the technological applications evolved to accommodate market conditions, programmatic shifts also occurred. The current project explored the possibility that technical decisions, seemingly unrelated to curricular decision making, were, in fact, directly related to curricular changes.

Background of the Problem:

The Educational Technology Leadership program is aimed at adult students seeking career advancement or reorientation in the area of educational technologies for a wide array of professional settings. An examination of the student profiles reveals that they each bring a relatively unique set of backgrounds and expectations to the educational environment. The richness of this diversity is desirable, but it can also generate conflicting visions for the educational experience itself. It can also generate conflicting valuing for the instructional approach. Some students desire a straightforward 'give it to me and I'll learn it approach' while others want validation through extensive feedback, while still others enjoy the discovery oriented problem solving approach. One of the challenges confronting the program, therefore, is to provide an educational experience which meets a variety of learning styles and preferences, but does so in a way that is fundamentally oriented to a basic philosophy and theory of learning.

The ETL program basically pursues a constructivist approach to learning, utilizing a wide array of techniques to deliver the basic information and intellectual tools that can be used in building new understandings and meaning. Despite some general evidence to the contrary, the experience of the ETL staff is that the techniques of instruction do make a difference in how well this occurs. Over the years, improvements in the technical delivery of the program have led to improvements in learning. In other words, the conception and use of a particular technological form (e.g. video) can change the nature of the information that is delivered and the manner in which information is perceived and valued. Content is not all that matters, the style of instruction is also important.

During the history of the ETL program the role of educational video has changed progressively. In the early years, video was supplementary to computer use in the program, but as the technology, student audience, and style of instruction changed so did the role of video. As the role of video changed, the concept of learning became more flexible. In the ETL program's present configuration, computer based video in the form of web
based streaming video, digitized audio/video files, real time video conferencing, streaming animations and traditional video tape are each utilized in unique ways that shape as well as deliver the program content.

The ETL program was originally designed using multiple media for delivery. The basic media elements have always included video with audio (for demonstrations, interviews, illustrations), the bbs/Internet/web (for interaction), and print materials (for basic information and original source material). The ETL program staff has consistently viewed these media as different channels of information operating at different levels of effectiveness for variety of learners. The simplicity of the model and its appropriateness has been repeatedly challenged by several factors over time: 1) the student population’s skills and needs changed, 2) the available communications technology changed, and 3) an interest in a more streamlined efficient method of course production emerged. It is the position of this paper that changes in the instructional methodology of the ETL program can be directly understood as a function of the changes in students needs, available technology, and desired efficiency. This reality alone would not be significant were it not for the additional contention that by changing the technology to adapt to changing needs and possibilities, the program consistently reinvented itself in a systematic fashion. The following research question was pursued to determine if, in fact, the technology did have a substantiate impact on the conceptual development of the program from an instructional perspective.

The Question

Does technology used to deliver education at a distance affect the conceptual development of instruction for academic programs?

Methods

Although many technologies are utilized in the delivery and support of distance learning and the ETL program specifically, none was more pervasive or more strongly associated with this program that the various video technologies that have been implemented. For the purposes of this study, therefore, a study of the role of video was selected to determine what effects were present in the orientation of the students to the program materials.

The form and use of video in the ETL program was determined by analyzing video products utilized over the past eight years. This preliminary analysis resulted in four categories:

1) the technology used to deliver video resources,
2) the style of video production for each technological form,
3) the type of content delivered, and
4) curricular outcomes of each video form.

In each of these categories data was collected from the eight years of the program’s history. Instructors were interviewed and shown the outcome of the video analysis to validate the categories and conclusions drawn. In such cases, where there was disagreement by more than one subject, the conclusion was either withdrawn or corrected. Only instructors who had taught in the ETL program for more than 3 years were included in these interviews. As a result of the preliminary analysis, four categories emerged for comparison and presentation purposes. These categories and the results are described in the next section “Conceptions of Teaching with Video.”

Conceptions of Teaching with Video

For comparison purposes, characteristics of each of four historical phases of the program are summarized in four parts. Part one, “Students, Organization and Technology,” summarizes the general state of the program. Part two, “Video Concept,” describes the basic ideas guiding the use of video and its intended effects. Part three, “Production Techniques,” concerns the approaches taken to create video products consistent with the “video concept” and the general program parameters. Part four, “Outcomes,” reports the effects that specific approaches to video use had on students.
Phase I

Students, Organization and Technology

Starting in 1989, the ETL program was marketed exclusively to suburban Washington, DC. An ITFS transmitting system was used to send a line of sight signal to two large county school systems. The school systems in turn redistributed the signal on the education channel of their respective cable systems. The idea was to provide in-school and in-home access to educational programming for teachers from The George Washington University. This was the first National Capital area delivery of graduate education into student’s homes where it could viewed live and/or recorded it for later use. Transmission of the live classes lasted for two hours and included two-way audio connections for up to twenty-five phone callers. For the first year of the program students could opt to take the courses on-campus in the production studios.

Video Concept

The use of video in this initial context was conceived as the primary instructional vehicle. The basic content of classes was instructor led lecture, group exercises, and special content guest presenters. The instructors were responsible for the development of material and organization of classes. Video was viewed a powerful and almost exclusive replacement for the traditional class meeting, although the ETL program staff made a persistent effort to recognize telecast video as only one part of a three part system. In additional to telecast video, the ETL program also used a computer based electronic bulletin board system, and a printed materials sent by mail.

Production Techniques

Whiteboard graphics, props and printed materials, an overhead camera, and a three-camera production crew supported live production video. Computer generated text slides were integrated into the instruction through the use of video switcher and a scan converter. Instructors typically pre-planned the production with the director a week or even a few days ahead, arrived fifteen minutes before airtime, received make-up and a microphone. A director managed camera switching, while instructors taught to both the studio class and those at a distance simultaneously.

Outcomes

Skills developed by instructors included keeping the distance students feeling part of the class through realistic question and answer management. Live broadcasts with telephone call-ins provided opportunity for student interaction, personal attention, and fun. The camera movements, however, distracted students in the studio, and accommodations to the distance students; while distance students sometimes felt excluded when instructors spoke exclusively to the studio students. In addition, less than 10% of the distance students actually spoke during the live interaction (about the same for the studio students), the value of the totally live format was brought into question.

Phase II

Students, Organization and Technology

In 1992 international satellite and cable distribution of the video began in cooperation with Mind Extension University (now Jones Education Network: College Connection). The two-hour video format was retained, but live productions with real-time audio (telephone call-in) interaction were reduced to four per semester. The numbers of students enrolled increased dramatically; the audience was broadened to include educators other than schoolteachers. The on-campus studio audience was eliminated and the program became dedicated to distance education delivery.
**Video Concept**

The use of video in this second context was conceived as context setting, intellectually and emotionally motivational, and informational. Stylistically, the video followed either a news talk show format or a technology variety approach. Production standards were increased significantly including a professionally designed set and props.

**Production Techniques**

Production was accomplished through a team development model including television production staff, content experts (course instructor), and the program director. Production techniques were elaborated including the addition of pre-produced video segments including field shoots, text and graphic slides with some animations, software and hardware demonstrations, interviews, live games and simulations. Emphasis was placed on good lighting, lighting effects, frequent scene changes, semi-scripted events, three camera selection of shots including pans, zooms, and moving camera work. The primary goal was to achieve high quality instruction, but contextual motivations such as the training and values of the television staff, the standards of the distribution company, and the program staff’s interest in appearing more professional, led to an upward scaling of production values to approach commercial quality production outcomes.

**Outcomes**

High quality video productions had a strong appeal to those looking for video quality and added prestige to the program overall. Some students, however, complained that the high production value made the instructors feel more distant and less real. In addition, the production rigor, however, caused instructors to experience time / work overload and video productions became more expensive. Coordination of efforts consumed too much time and energy. The two hour production time frame was tyrannical often leading to production segments that were included simply because ‘five more minutes’ were needed. Production staff had greater control over the instructional product than the instructional staff during this time and small problems became big ones working against production deadlines. The project had begun to place too much emphasis on the quality of the production, following television production principles; rather than an emphasis on instruction, following instructional design principles. A more streamlined approach was needed.

**Phase III**

**Students, Organization and Technology**

In 1995 several changes were introduced to streamline production and improve the efficiency of information delivery. Live video was eliminated based on low usage, expense, and limited interactivity on the part of the students and the instructors. Consequently, prime time televised delivery was reduced and telecasts were moved to marginal viewing hours. In addition, video production was reduced to one hour segments. Since most students were either purchasing videotapes or recording off-air for delayed viewing, this did not have a serious impact on enrollments or student satisfaction. Audio interactivity was transformed into a greater emphasis on email interaction and asynchronous conferencing. Perhaps most dramatic was the shift to the World Wide Web and web pages as the primary focal point for course delivery, thus altering the significance, if not the role, of video.

**Video Concept**

Video was now conceived as a specialized information source. As more emphasis was placed on the development and utilization of the web as an analog for the classroom, video was re-conceptualized as a data source rather than a communications channel.
Production Techniques

Reducing two hours video “shows” to a one hour format forced a new strategy for production. One principle was to compress presentations to a more efficient communications format. An interview that would have formally taken twenty to thirty minutes would now be produced in a 10-15 minute segment. Chattiness and congeniality would be replaced by efficiency and focus. Demonstrations would be pre-produced, and often edited, segments were designed to show the highlights of software and hardware performance without the usual wait time of live productions. This strategy helped in circumstances where the instructor was not very interested in or suitable for TV teaching. In addition, classic materials such as interviews with policy makers, futurists, and educational philosophers were reedited from previous courses for reuse. In some cases, videos were produced as supplementary materials to pages and topics on the course web pages.

Outcomes

Placing less emphasis on the video as classroom analog created a subtle shift away from student identification with instructors and a sense of place which video tended to create, even if it was only in two dimensions. On the other hand, focus on the web site created a better integrated instructional experience where students moved seamlessly from one information source to another including interaction. The exception to the seamless transitions was tape-based videos. For example, when developing the web site, instructors tend to think less about the necessity and value of the video relying instead on the primacy of the web site and the greater flexibility for materials production that the web provides. Some students seem to think all the information should be in either the video or the website, but not in a combination of the two.

Phase IV

Students, Organization and Technology

Seeking to achieve the goal of seamless information channels on the web, experiments with digitized audio and video were executed using very brief segments (2-5 minutes). Content was drawn from previous classes plus new material acquired via digital tools. Team development involving multimedia and web developers provided an well-integrated design, but even small file sizes created wait times beyond acceptable levels. While some downloadable files continue to be used for specialized purposes, streaming audio and video has been pursued actively. These audio and video resources can not only be integrated seamlessly into the web based course design, but they provide access to virtually unlimited amounts of instructional and informational audio/video resources in either a pre-recorded or live format through a link on the website.

Video Concept

Video is now conceived as an information destination, a place, among other places, where students can go to experience multi-sensory learning synchronously or asynchronously. The role of video as a destination, a place, has begun to transform the analog of website as classroom to website as learning community. Perhaps this is a subtle distinction, but one which is highly significant, because in a learning community people meet other people in information rich environments, they interact with one another and with the information itself.

Production Techniques

Digital video should produced with reasonably high production values emphasizing lighting and sound quality. Traditional television production techniques often have negative results. Fast pans, zooms, special effects and other techniques which change the screen information quickly; work against sending a high quality signal over the web. Camera work should be simple and oriented to delivering important information through both audio and video. Temptations to pursue the fun, but frivolous should be discouraged. Also, since the digitization and compression processes lose information by their very nature, it is best to start with a high grade of video source material. Typically, this means utilizing Beta format videotape or at least Hi-8. At present, the size of the playback area of a computer screen is typically small. Wide shots reveal very little detail, so close-
ups or medium close shots work best. Emphasis should be on video production that conveys important information; even a single headshot can convey authority and credibility if it is the right head. Poor quality video, which doesn’t transmit well, actually reduces the information that students can obtain, by distracting their attention from the audio channel. Even more important than the technical camera issues is the goal of producing video that really matters. The concept of video as information destination, as opposed to information vehicle, frees the producer to create video of any appropriate length necessary to communicate the desired information. Couple this with the ability to index and contextualize the video and the educational experience is moved from a teacher-scripted experience to a student centered one.

Outcomes

While this is the most recent of the historical phases for the use of video in the ETL program, it is without question the most exciting. The current use of digital streaming video and audio, coupled with real-time video conferencing, animations and more traditional video tapes has created a well-spring of creativity on the part of instructors and students alike. For the first time students are not only engaging learning opportunities in an authentic collaborative style, they are engaging the materials in the style of researchers. Students are no longer simply consumers of knowledge, they are producers. Instructors are no longer simply providers of knowledge, they are validators. The distinction between students and instructors is blurring as they engage one another in learning communities. The shift to the idea of learning communities is just beginning; it is expensive in terms of support, and it is imperfect, but it is growing idea. To date, the biggest problem is providing everyone in the program access to the learning community. Those students with the fastest computers and fastest Internet connections encounter a system which works well, those with less able systems and connections are frustrated by erratic performance and information transfer loss. Since this was and continues to be a predictable characteristic of our current technological reality, the ETL program continues to support more traditional video sources such as tape. The program’s leading edge technologies are currently “added value.”

Conclusion

Studying the development of video resources and their implementation in the ETL program has provided a useful focal point to begin understanding the dynamics of program evolution. As a result of the study, it is clear that the format of the video, the delivery system, and the production techniques were altered by the dynamic needs of the students and the program designers; but in turn, these changes brought about conceptual changes in the instructional methods and goals of the program.

Whether this kind of dynamic affects other programs is unknown, as is the question as to whether other technologies had similar effects in the ETL program. What is valuable to understand is that communications tools do have the power to redefine our intentions and our behavior through their actual use. Even the most careful plans are likely to give rise to the creation of meaning and behavior well beyond the original intentions of their designers.

Abstract: Acadia University has completed year two of the Acadia Advantage initiative
which involved 1500 students and 170 Acadia faculty using IBM notebook computers in
the curriculum. By year 2000 all 4000 students at Acadia University will have notebook
computers and will be taking part in technology-enhanced courses. To assist faculty,
Acadia University developed a modular Automated Courseware Management
Environment (ACME) which allows an instructor to easily create online courseware. The
Online Testing Module (OTM) is one of the most successful modules, allowing faculty to
prepare web-based tests that include multiple choice, short answer, and essay questions
that incorporate formatted text, images, video, and audio. The module is template based
and users create tests that can be randomized, graded, and results posted both to the
students and instructor. Little or no computer experience is required to create a test. At
Acadia University the package has proven so successful that we routinely have 1000 plus
online tests taken and marked daily. Students using the testing package for tutorial
assessment have responded very favorably to the ease of access, and the ability to
monitor their own progress.

Introduction

There are many programs available for creating computer based testing, many of which allow users to create
tests that can be placed on the web. The complexity of the tests is usually proportional to the complexity of the
program used to create the test; simple multiple choice questions are easy to create using any number of
programs. More complex tests using various forms of multimedia (images, sounds, and video), and short answer
or essay questions, usually require expensive and difficult to master software packages. Adding the
functionality of randomization, access control, and the ability to edit on-the-fly can add enough complexity to a
package that it often requires the efforts of Instructional Designers to create the test or to work closely with the
instructor requiring the test.

The AITT (Acadia Institute for Teaching and Technology) undertook the development of ACME (Automated
Courseware Management Environment) in the summer of 1996. At the onset of development, instructors at
Acadia University were clear about the requirements of a web-based testing and tutorial component. Allowing
students to access databanks of tests for self-evaluation, and allowing instructors to view the results of these
self-evaluation tests was critical. The Online Testing Module (OTM) in ACME solved this problem for the
instructors by allowing them to easily create online tests that satisfied their immediate requirements. Every
component of the functionality of ACME is available through any Internet connection, allowing instructors to
prepare their courses from anywhere in the world.
Online Testing Module

OTM was designed as an enhancement to regular classroom courses, and not as a complete computer based training solution. At the onset of development the hardware and software of all users of the system was known, however a web browser is the only base requirement by both the instructor and student depending upon the type of multimedia used in the tests. Ongoing development is occurring due to constant feedback from the instructors using the system.

In the past, an instructor's first indication that a student was struggling in their course may have occurred only after the first midterm. Weekly tutorials and tests in OTM are providing instructors with the information they require to determine how well students are grasping the course information, and to allow early intervention when required.

In order to make use of web-based tests and tutorials instructors were insistent that OTM must allow them to create tests that went far beyond simple multiple choice questions, allowed the use of multimedia, were easy to create, and could provide instant feedback to the students. The online testing module, has been working for 4 semesters, and currently has hundreds of tests in the system. On October 15th, 1997, the Online Testing Module of ACME delivered, and marked 1309 individual tests in a 24 hour period.

Access Control and Security

Access to the ACME system is restricted to instructors and registered students by the use of usernames and passwords. Each individual with access to ACME has a profile on the system that indicates the courses they can edit as an instructor, or those that they can participate in if they are a student or guest. The administrator creates instructor profiles that link the individual with their course, and provide editing rights to that course. Student profiles are generated automatically from the university registrars' database. Guest profiles can also be created to allow individuals outside of the university to participate in a course. The instructor can also restrict access to individual test folders within a course.

Taking a Test

A student wishing to take a test simply authenticates into the ACME system, selects a course from their profile and goes into the OTM module by clicking the "TEST" button at the bottom of the course page (see figure 1).
From a student's perspective the OTM module has only one choice; select and take a test. The test presented to the student can be a combination of Short Answer, Multiple Choice and Long Answer questions (figure 2). After completing and submitting a test, students may be provided with instant feedback (if the instructor has enabled that option), with their grade and the answers to each question. The program grades multiple choice, true or false, and short answer questions. Long answer or essay questions are stored in a special marking folder to be graded later by the instructor.

![Figure 2: A student view of a test in OTM showing questions that include images, formatted text, audio and video.](image)

Creating and Editing a Test

Instructors must first create a folder, then put a test in that folder. Any number of folders and tests can be created. After creating a test, content must be added. The user-interface for creating and editing tests is shown in figure 3.

After creating a test, the basic test information can be changed. The name of the test, a time limit for the test, whether the answers are provided to the students when they complete the test, and whether the test can be
retaken are all in the control of the instructor. As a student could take a test from any location, passwords can be assigned to those tests that the instructor wants to give in-class. The student must then be in class to hear the password.

A current items window (figure 3) shows the number and type of questions in a test. Each type of question is shown by an abbreviation; MC, SA and LA representing Multiple Choice, Short Answer and Long Answer respectively. This window is empty if no questions have been added to the test. Individual questions can be edited or removed after selecting them in the Current Item window.

The number and type of questions added to the test determines the layout of a test. Section or title headings can be added anywhere throughout the test, and questions can be put inside random blocks. A random block allows a small number of questions to be randomly selected from a larger test bank when a test is chosen. Any number of random blocks can be added to a test, allowing for maximum test customization.

A full preview of all the questions in a test is available to the instructor, with the option to edit a question directly from that full preview. A student preview is provided also which differs from the full preview in that there is no option to edit each question. Also if the questions are randomized, the randomization will appear in the student preview.

Short answer, Multiple Choice and Long Answer Questions

Instructors create questions by completing a template (figure 4) for each question type, and can add a question anywhere within a pre-existing test.
The value of the question can be selected and the text of the question typed into the "Question Text" window. Short answer questions allow up to four possible answers. There is also an option to allow the answers to be case sensitive or case insensitive, or to have a variation in spelling. The selections of the possible answers and the case sensitivity determine how the ACME system will grade the question. Multiple choice and long answer questions are created in a similar manner, with the option of providing one or more correct answers in the multiple choice, and a comment to the student depending upon the answer they choose.

Formatting a Test

To add formatted text, images or other forms of multimedia such as sound and video to a test, an instructor clicks on an "Open Editor" button to open the AcmeScript editor. This semi-WYSIWYG editor was created to aid instructors in the formatting of their tests. The editor was written in JavaScript to be executed by the client. All forms of media, other than plain or formatted text, are located on a different web server to the one on which OTM resides. Links are made to these other media formats using the editor. Any media or file-type that can be supported by a browser plug-in will appear in-line in the test, other files will launch a helper application.

Test Management and Statistics

Instructors can view test statistics that are generated each time a student takes a test. The statistics include the number of times each student has taken a test, which students in a class have not taken a test (useful for large classes), and also statistics on each question. For multiple choice questions the statistics include the number of times the question was taken and how many times a student selected each answer. Short answer questions also include the number of times the question was answered, and the top five answers provided by students. This allows the instructor to quickly determine problem areas that the students may be having, or highlight poorly worded questions.

Tests are managed using the test management window (figure 5). The order of the tests and test folders can be changed by selecting the "ORDER" button, selecting a test by clicking on the radio button beside the test name, and then choosing to move the test up, down, to the top or bottom. Tests created in one course can easily be copied or exported to another course, at which time test information can be edited, and questions added or deleted.

![Figure 5: OTM test management window.](image_url)
Programming

Combining all of the features of OTM with a transaction-based World Wide Web (WWW) interface and an operating system-independent storage and execution mechanism has proven to be a less than trivial task.

The languages used for development of OTM, were PERL 5, HTML 3.2, and JavaScript 1.1. As PERL is implemented on the vast majority of operating systems, it makes a very suitable environment for implementing the required programs and libraries on the server side of the OTM system. Currently, ACME and OTM are running on Solaris 2.5.1, Solaris 2.6, SCO OpenServer 5, and Linux 2.x. We are also now working on a Windows NT, and a Windows 95 port.

JavaScript was chosen as the language for writing additional client-side functionality because it is the native language for programming Netscape Navigator. Netscape is currently the most popular WWW browser in use, and is available for the majority of operating systems, thus increasing the platform independence of the client. To provide even further client independence, we are making an effort to ensure all our client code is compatible with the ECMAScript specification.

To further increase portability, all files are stored as plain text. Initially attempts to use database formats such as dbm/gdbm or SQL databases were made, but each format was problematic. The dbm databases are not entirely independent of the operating system. When an operating system upgrade is performed, or when ACME data is moved from one operating system to another, dbm style databases tend to break, due to different versions of dbm libraries used. SQL databases were rejected because many organizations wishing to use ACME may not have somebody trained in the administration and use of such databases. However, all file access in OTM is done using a small file access library to allow it to use a database with minimal effort, and will eventually be an option in the configuration of ACME.

The tests themselves are stored using a rather simple mechanism. Each course has its own directory in OTM. Inside each course are directories representing each test folder created by the instructor. Inside each folder are files containing the information for each test and the results of students writing each test.

The automatic test generation and the automated marking are the most complex functions of OTM. The advanced testing features permitted by OTM, such as randomization, fuzzy matching, passwords, and time limits, add to this complexity. To handle these problems efficiently, lookup tables and small separate files rather than one large file have been used to reduce search times, and the processing times of critical sections.
Separating Structure and Content: 
Authoring Educational WEB Applications

Abstract: This paper describes a WWW server of a special architecture which clearly separates content and structure of educational materials. The server is based on so-called cluster concept. Clusters comprise a particular layout definition and a number of media objects (texts, still images, animations, etc.). A particular cluster is presented in a form predefined by its layout. There also exist a concept of cluster types which is essentially a definition of presentational aspects without any information content. The paper describes also a template-based authoring tool developed to support the approach.

1. Introduction

It is well recognised that authoring hypermedia documents is a very tedious and time consuming task. In this respect, we should clearly distinguish between a so-called "home page competition" where people implement a few fancy pages, and educational www sites containing hundreds of pages currently, and thousands in nearest future. There exist some specific features of educational WWW sites, which can be generically defined as a necessity to put reader's ability to construct a coherent mental representation of the information on the first place, even if some most fancy features of up-to-date hypermedia system are not used.

This situation was reflected in a number of www authoring guidelines which often recommend to use predefined layouts, one and the same heading styles, uniform notation for highlighted words and references, present still images and other media using an uniform techniques, etc.

Surprisingly, all the recommendations mentioned above are an inherent feature of so-called database systems. It results from a well-known meta-structuring concept which is a main feature of database technology. Conceptually, database management is based on the idea of separating a database structure from its contents. Quite simply, a database structure is a collection of static descriptions of entity classes and relationships between them. At this point, it is perhaps simplest to think of an entity class description
as a collection of attribute labels. Entity contents can then be thought of as the values that get associated with attribute labels, creating data objects. In other words, the distinction between structure and content is little more than the distinction made earlier between attribute label and attribute value.

This concept can be easily applied to hypermedia authoring via a concept of clusters which is presented in this paper.

2. Cluster

Cluster is a family of different media objects which constitute an actual multimedia document. Thus, for example, two HTML documents, a still image and a Java animation (see Fig.1) can be combined into such a cluster. It should be especially noted that each cluster has a layout template associated with it. The layout templates control appearing of cluster members on the screen. Thus, for example, a cluster mentioned above may have a layout prescribing the media objects appear as shown on the Figure 1.

![Figure 1: Assembling a resultant HTML Document](image)

Actually, the concept of a layout template is not new at all. The tags "Embed", "Frame", "Table", etc. often play role of such layout definition in a conventional HTML authoring. Please note that authors are aware about the fact that HTML as a successor of SGML is not a layout oriented language, we just refer to a current practice where the tags are used to roughly define appearance of the document. Essentially, HTML do not distinguish between actual content and such layout information.

We content that hypermedia authoring for educational applications can be considerably improved by introducing an additional meta-level of such authoring. Simply speaking, there should exist a convenient possibility for authoring just document layouts without putting an actual content into such layouts, and for producing multimedia documents simply by filling out predefined layouts.

In this case, we consider a hypermedia authoring as a two stage process where an experienced designer prepare a number of layouts first, and then actual content providers fill such layouts with ready to run media objects. Of course, there also exists a number of systems supporting a similar approach on a stand-alone basis. We concentrate on implementing a "real" meta-authoring via introducing concept of "cluster types" which is very similar to a database logical schema (i.e. to static descriptions of entity classes and relationships between them). Thus, an author working on a meta-level predefines a number of cluster types, content providers are allowed to contribute with their information by calling up a particular cluster which guides them through the whole process.

The cluster type descriptions and actual content are stored separately what provides a reasonable flexibility in altering layouts without changing content and vice versa (see Figure 1).

In a cluster, one can combine documents which should be presented to a user as one indivisible HTML document. Once a cluster is accessed, all its elements (members) are combined together as a new composite document. The cluster pools together many single media items and presents them as a single "multimedia document". Text and images can then be shown together along with the simultaneous play of an audio track. Thus pages can consist of small elements, separating an internal structure and content.

This authoring paradigm was especially developed for large educational organizations supporting catalogues of so-called reusable MM elements. Such elements can be developed by different authors,
using different authoring systems, at different time and then registered in the catalogue providing a necessary “background library” for teachers to assemble their courses quickly and without spending much efforts on graphical design.

As an example, suppose we have a repository of small MM elements (D1 – D6, in this particular case) which, of course, may be composite documents themselves. In order to prepare a new document, we are simply selecting four documents: D2, D3, D5 and D6 to concoct a new document. We form now a new document just by selecting the four documents in the cluster. This is very useful for many applications.

![Figure 2: Generating a new document in a cluster](image)

3. Authoring Documents

An especially designed Page Editor provide a convenient way for authoring pages (i.e. basic elements visualised on student screen as indivisible chunk of learning information) by means of reusing existing elements. It should be especially noted that the Page Editor is not designed as an alternative to any of existing HTML editors. It utilises a “template authoring paradigm” where existing HTML Editors can be seen as optional add-ons to provide basic elements. A final product is assembled of such basic elements via an advanced GUI.

The Page Editor works with a particular page template and page elements. The main way of authoring is filling the page template with existing page elements. Page elements are created with other editing systems. The following list of Page elements is currently considered for implementation:

- HTML Fragment;
- Still images (GIF and JPG formats)
- Movies (Mpeg and Vivo formats)
- Sound (AU, WAV and Vivo formats)
- Plain Text fragment (plain ASCII)
- MM Applet.

The Page Editor allows to combine the page elements into a valid HTML document by means of the following operations:

- drag and drop objects into a template cell,
- resize, delete and add a template cell,
- alter colours,
- edit content (HTML, texts and HMW format).

The Page Editor adds a value to textual page elements by means of:
Defining relative positions of page elements on the screen;
Assigning a type to template cells (ordered list, title, footnote, etc.);
Assigning a desired colour and font attributes to text fragments.

Thus, informally speaking, creating a particular page is a two-stage process: First, the author selects one of existing templates from a supplementary template library. Second, the author simply fills predefined cells with elements taken from the catalogue.

Technical Details: the Page Editor is available in two forms - as Java Applet and Java Application. As a Java Application the Editor allows to select Page elements from a local drive or from a Hyperwave server using unified "treeview" browser (see Figure 3). Using Hyperwave search facilities considerably simplifies localisation of such elements. The application allows to save the resultant page on a local drive or upload it to a Hyperwave Server. The Page Editor allows to edit existing pages residing on a Hyperwave server as well.

As a Java Applet the Editor has considerable limitations on using local drive. It allows to select Page elements from a Hyperwave server only. The applet allows to upload resultant file into a Hyperwave Server.

4. Alternative Clusters

Another important structuring facilities is the alternative cluster. In an alternative cluster, one can combine documents with the same or similar content but different appearances. For example, different explanations (text, audio, video) of documents in different languages, etc.

Clusters can be referred to or embedded as ordinary HTML documents or media objects. Only one of such cluster members is dynamically selected whenever the document is presented to a client. To select a cluster object, the system uses special information defining a particular user's profile or preferences.
It may also be the case that the same contents must be presented in different languages or that a certain media type must be mapped into another type because the former cannot be visualised by a particular hardware/software configuration or cannot be perceived by a particular user.

A multilingual document can consist of a cluster that comprises some language-independent objects and some language-dependent objects of the same document type. When the cluster is displayed, all the language-independent members are displayed and, depending on the language the user chooses, one of each type of the language-dependent document is displayed. Any document with more than one title is regarded as language-independent. For example, a picture may have one title in English and another in German. Or, one title could be in “lay” language and the other in an “expert” language.

![Figure 4: Only one cluster member gets selected](image)

Thus, alternative clusters can be seen as page elements similar to any other element (text, HTML, picture, animation, etc.). The page Editor provide a possibility to embed alternative clusters into page cells. When an alternative cluster is embedded into a template cell, it obtains new properties, i.e. a number of alternative media objects may be assigned to such single cell (see Figure 4).

4. Conclusion

The Web is fast evolving both in quality of services and quantity of available materials. Currently, many organisations are switching from small hand-crafted hypermedia applications to fully-fledged, very large hypermedia databases available via Intranets or the Internet. Obviously, authoring such hypermedia databases cannot be carried out by enthusiasts armed with a good taste and an HTML Editor. The need for new, “industrial” methods of hypermedia authoring already exists and will grow tremendously.

In this paper, we just roughly define one possible basis for such “authoring technology” – separating structure and content of hypermedia documents. We have developed a special authoring tool supporting this approach and will report our experience with this approach rather soon.
Learning of Basic Concepts in Informatics Using Collaborative Hypertext: Does Collaborative Hypertext Support Learning as a Whole?

Pekka Makkonen
University of Jyväskylä, Department of Computer Science and Information Systems, Finland.
E-mail pmakkone@jyu.fi

Abstract: Hypertext appears to be a powerful cognitive tool supporting knowledge construction. A study was conducted to determine whether or not collaborative hypertext affects learning outcomes in the learning of basic concepts in informatics. We organized two courses about the basics in informatics using collaborative hypertext and two courses without collaborative hypertext. We analyzed learning and in this paper we present results utilizing the tests of structural knowledge emphasizing learning as a whole. The study found that collaborative hypertext does not improve cognitive learning outcomes in our context. This reflects the need for traditional uncomputerized learning methods at the start of learning informatics or the need to concentrate on improving the truthfulness of a collaborative hypertext-based learning environment. The result confirms our previous results. However, the structural knowledge has been learned better than single concepts in the groups using collaborative hypertext. Thus, collaborative hypertext supports learning as a whole compared with learning single facts.

1. Introduction

Computational hardware and software have found their way into schools during the last decade. However, the use of these has suffered from a lack of educational perspective. [Hawkins 1993] stresses that computational technology has been brought into schools in the wrong manner. It has been made into a part of traditional teaching emphasizing relatively passive absorption of information.

The same kind of problems have affected computer supported collaborative learning systems. [Wan & Johnson 1994] argue that current systems focus on improving shared access to information, people and media. They emphasize that meaningful learning is often forgotten in regard to collaborative use of computers in education [Webb 1982].

One way to overcome these problems is to consider computers as cognitive tools, in other words, tools for knowledge construction. Meaningful learning is not simply information sharing but, more importantly, knowledge construction [Wan & Johnson 1994]. Generally, cognitive tools can facilitate cognitive processing and knowledge construction, hence they support a learning process [Jonassen 1992]. The use of a cognitive tool changes the role of a student into an active learner. However, hypertext and hypermedia have their own problems. They do not typically offer an explicit mechanism to help learners better interpret and assimilate information, the context surrounding its creation and use, or the perspectives on the information of the author or other learners. Simply improving information access without supporting learning leads directly to the problems of "information overload" and "lost-in hyperspace" [Wan & Johnson 1994]. The solution to these problems is understanding hypertext and hypermedia as a cognitive tool [Jonassen 1992].

2. Nature of Learning Basic Concepts

Since this study recognizes hypertext as a knowledge construction tool and learning as a knowledge construction process, we understand learning especially from the perspective of the constructivist view of learning...
According to it, an individual learns new concepts in relation to his/her prior knowledge [Risku 1996].

We often distinguish declarative and procedural forms of knowledge. Declarative knowledge represents cognizance or awareness of some object, event, or idea [Ryle 1949]. Declarative knowledge of ideas is often characterized as schemas [Rumelhart & Ortony 1977], which are ideational constructs that are defined by attributes that they inherit from other schemas. Procedural knowledge, on the other hand, describes how learners use or apply their declarative knowledge. [Ryle 1949] describes this type of knowledge as knowing how. An intermediate type of knowledge is structural knowledge, which mediates the translation of declarative into procedural knowledge and facilitates the application of procedural knowledge. Structural knowledge is the knowledge of how concepts within a domain (e.g. in informatics) are interrelated [Diekhoff 1983]. It describes how declarative knowledge is interconnected.

There are two kinds of learning concerning the basics in informatics. First, students must learn to understand the field of informatics and its basic concepts and facts. Second, students must learn to use computers and utilize instructions to facilitate the use of computers. These two goals emphasize the learning of both declarative and procedural forms of knowledge. Since both forms of knowledge are important, we argue that the structural form of knowledge is important. Structural knowledge enables learners to form the connections that they need to use scripts or complex schemas [Jonassen 1992].

For the basics in informatics it is typical that the basic concepts form structures and knowledge is in the structural form [Makkonen 1997a]. One way to understand why the basic concepts in informatics fall into the categories of both declarative and structural knowledge is a concept mapping technique [Novak & Gowin 1984] which facilitates a representation of meaningful relationships between concepts (for an example, see [Fig. 1]).

![Figure 1. Simplified concept map concerning information systems development.](image)

### 3. Hypercomposition and collaborative hypertext

Hypertext reflects a human's way of thinking and provides an opportunity to process information and interrelatedness between information cues [Bush 1945] [Jonassen 1993]. It can present a human's schemas concerning one event or idea. Thus, hypertext is useful as a cognitive tool. [Derry 1990] defines cognitive tools as both mental and computational devices that support, guide, and extend the thinking processes of their users. Collaborative hypertext permits hypercomposition and the benefits associated with it.

Hypertext can be called hypercomposition and hypercomposition supports instructional design in several ways [Lehrer 1993]. First, hypermedia-based composition involves the transformation of information into an n-dimension space, in contrast to the two-dimensional space of print. Second, because hypermedia composition involves multiple forms of media, students are confronted with decisions about the representational roles of each of the forms of media. Third, hypercomposition promotes a sense of authorship, if students are engaged in the production of a nontrivial product (a product that others are likely to use). Fourth, hypercomposition encourages the composer to be aware of the multiple voices of his or her composition because there is always more than one path through the hyperdocument. Last, on the social plane, hypertext focuses on the interactions of the authors.
[Rada 1991] has defined collaborative hypertext (grouptext) as "text that people create or access collaboratively". Grouptext systems can help groups create and access text in three phases:

1. The discussion phase occurs as people brainstorm and formulate plans as to how writing should proceed.
2. In the authoring phase, blocks of text are attached to a network of ideas and the network is traversed to generate a document.
3. The analog of reading in the collaborative sense is the making of notes by a group of people on a document. This annotative phase may also lead to a revised document as the annotators incorporate their comments into the original document.

Both hypercomposition and collaborative hypertext can be considered as cognitive tools, because they support knowledge construction. Cognitive tools support the constructivist view of learning because they actively engage learners in the creation of knowledge that reflects their comprehension and conception of information rather than focusing on the presentation of objective knowledge [Jonassen 1992]. This provides different opportunities for learning compared with traditional programmed instruction which is seen as the opposite of cognitive tools [Jonassen 1992] and usually emphasizes the passive role of a student.

We claim that hypercomposition can be used to organize knowledge structures, facilitating a more active role for the student. The basis for this as a learning tool in informatics is understanding concepts and facts which must be learned as structural knowledge. In the learning of informatics hypercomposition does not support learning that only facilitates knowledge construction. Additionally, the process where computers are used for hypercomposition helps students to learn basic concepts in informatics, because students encounter certain concepts in real life situations. To learn meaningfully, individuals must choose to relate new knowledge to relevant concepts and propositions they are already familiar with [Novak & Gowin 1984]. The concept of collaborative hypertext emphasizes knowledge construction. On the other hand, this concept stresses social interaction and we suggest that hypercomposition must occur collaboratively, because according to certain research interaction is the factor which has the greatest influence on learning [Harasim 1989] [Webb 1982]. In spite of the promise of hypercomposition and collaborative hypertext they can be more distracting than beneficial, since students must also concentrate on learning a tool itself [Hay et al. 1994].

4. Study Design

4.1 Experiment

We utilized collaborative hypertext as a cognitive tool. Our framework was constructed on the basis of Rada’s three phases of the use of collaborative hypertext as well as the idea of hypercomposition.

The themes of our course basic course in informatics are introduction (including the themes Meaning of Automatic Data Processing, Information Society and Problems Utilizing Computers), presentation of data in the PC environment, programs and programming, hardware technology, data communications, information systems development. Two courses organized for university students were based on collaborative hypertext (experimental groups). In order to compare learning based on collaborative hypertext with learning without it two other courses were organized for university students without collaborative hypertext (control groups) using uncomputerized teaching and learning methods. Thus, in the control groups we used contemporary learning methods, i.e., lectures, exercises based on the lectures and revision organized in a linear way as a typical university course based on programmed instruction. However, during the exercises the students were expected to work in collaborative groups as the students did in the experimental groups. All four courses lasted the same amount of time (36 hours in three weeks).

As a hypermedia software we used Toolbook which corresponds HyperCard for Macintosh computers in the Microsoft Windows environment.

4.2 Sample

Forty-six students, 32 females and 14 males, whose mean age was 24 years (range 20-42 years), participated in the experimental groups. 21 students participated in the first experimental group and 25 in the second. Thirty-nine
additional students, 30 females and 9 males, whose mean age was 23 years (range 20-39 years), were involved in
the control groups. 20 students participated in the first control group and 19 in the second. All students in all
groups studied informatics as a minor. All subjects were recruited using the announcements on the notice boards
of the university departments and were expected to attend the classes constantly during a selected course.

4.3 Measures and tests

We utilized the tests of structural knowledge to clarify learning outcomes and their quality, because they
reflected the quality of a student's knowledge structures. Additionally, the results of these tests complete our
previous results. In order to assess structural knowledge acquisition, we utilized two subscales of twenty questions
to measure different aspects of structural knowledge: a) semantic relationship, and b) analogies. All of the
structural knowledge test questions were developed to focus on relationships between important concepts. Based
on these tests we organized both the pre-treatment and the post-treatment contained 20 items in one test. For all
tests the items were selected separately.

Each semantic relationship treatment consisted of 20 multiple choice questions that required the students to
identify the nature of the relationships between two concepts. These relationships were be paraphrased from the
course material.

For example
Operating system...System software
a) is caused by
b) precedes
c) is part of
d) assists

Alternatives were produced based on the list of the most ordinary relationships between pairs of concepts
[Jonassen et al. 1993]. According to this list most concepts are related in one of the following ways: Has part/is
part of, has kind/is kind of, cause/is caused by, precedes/comes after, describes (defines)/is description (definition)
of, assists/is assisted by, has example/is example of, justifies (rationalizes)/is justified (rationalize) by, has
characteristic/is characteristic of, has opposite/is opposite of and models/is modeled by.

20 multiple choice questions of each test were given first for the laudatur level students of the information
systems. In the questions for the laudatur level students all alternatives from the list of most ordinary relationships
were presented. The purpose of this was to produce three different "wrong" alternatives for the tests both in the
experimental groups and the control groups. The first alternative or the "right" alternative was produced based on
the course material. Three other alternatives were produced based on the results of testing the laudatur level
students.

Each analogies test required the students to complete 20 analogies consisting of four concepts from the course
material. For example
Bit... Byte
RAM-memory...
 a) Central Processing Unit
 b) Processor
c) Field
d) Main storage

The alternatives were produced based on the course material. Two from three "wrong" alternatives were closely
related concepts of the "right" alternative. One from three "wrong" alternatives was selected randomly from all
concepts to learn.

5. Results

In our study we compared collaborative hypertext based learning (the experimental groups) and learning
without collaborative hypertext (the control groups). The dependent variables were learning the semantic
relationship and learning the analogies. Since the responses of the students agreed with the normal distribution, the T test was appropriate for this experiment.

The semantic relationship pre-treatment T test did not show significant difference between the experimental groups and the control groups (p=.161). The mean for the experimental groups was 9.11 and the mean for the control groups was 10.00.

The semantic relationship post-treatment T test did not show significant difference between the experimental groups and the control groups (p=.507). The mean of the experimental groups was 10.93 and the mean of the control groups was 11.05.

The analogy pre-treatment T test did not show significant difference between the experimental groups and the control groups (p=.387). The mean for the experimental groups was 7.96 and the mean for the control groups was 8.33.

The analogy post-treatment T test did not show significant difference between the experimental groups and the control groups (p=.631). The mean of the experimental groups was 10.33 and the mean of the control groups was 11.18.

6. Discussion

Our results show that a basic knowledge of informatics can be learned as easily as utilizing uncomputerized methods without exploiting collaborative hypertext. The finding is consistent with the threats mentioned in [Hypercomposition and collaborative hypertext]. However, the result is promising compared with our previous results in [Makkonen 1997a] where we found that the single facts can be learned more easily using the traditional learning. Thus, collaborative hypertext supports learning as a whole compared with learning single facts.

We lose the benefits mentioned in [Hypercomposition and collaborative hypertext], because much time is used to learn the tool itself. However, we claim that some people can utilize collaborative hypertext as a powerful learning tool. [Mayes 1992] claims concerning the use of cognitive tools generally, that they will always be more effective in the hands of an experienced user. The fact is that the students did not know what our cognitive tool or hypertext was at the beginning of the course. This may impair the results of learning, because students who are not experienced with computers must concentrate more on the skill of using the tool itself than experienced students.

The area of informatics and opportunities to create realistic learning environments may affect the power of hypertext to assist learning. [Kendall et al. 1996] have studied teaching system analysis using a hypertext environment called HyperCase which presents an organization realistically. Their findings showed that those using HyperCase performed as well or better on the examination questions than those using the standard approach. From the perspective of our study, if it had been possible to increase the feeling of reality, the result of this study would have been different. Additionally, our previous findings regarding the engagement to learning in our context support the need of improving truthfulness [Makkonen 1997b]. The study found that the use of collaborative hypertext affects both external and internal motivation equally in learning most themes of the course. Additionally, the development regarding the world wide web (WWW) may satisfy the need of the truthfulness. The possibility to make links may help learning, because links can be created meaningfully to any document on the WWW which will clarify an area to learn best.

Guidelines for the Design and Development of Computer-Mediated Collaborative Open Distance Learning Courseware

Vasilios Makrakis
Department of Education, University of Crete 74 100 Rethymnon, Crete, Greece
makrakis@fortezza.cc.ucr.gr

Abstract: Open and Distance Learning (ODL) substantiated by computers and computer networks and collaborative learning may provide an answer to the inefficiencies of the individualistic ODL which dominates present ODL systems. The successful integration of computer-supported collaborative learning in the development of ODL multimedia courseware necessitates an answer to the following two questions. First, under what conditions does collaborative computer-supported distance learning work? Second, how can we design multimedia distance courseware? This paper attempts to provide a set of guidelines for the design and development of computer-supported distance multimedia which reflect these two questions.

Introduction

Open and Distance Learning (ODL) has been witnessed an increased development, acceptance and recognition as an innovative and productive delivery mode of instruction and learning. However, most distance learning has taken place using an individualistic or self-study strategy, whereby the emphasis is placed on the distance and/or the learner, but not on the learning [Amundsen 1993]. The current widespread interest in the potential of collaborative or co-operative learning methods [e.g., Whipple 1987; Chung 1991; Mandl and Renkl 1992; Somervell 1993; Meloth and Deering 1994], on the one hand and of computer-supported conventional and distance learning [e.g., Nastasi and Clements 1993; Wild and Winniford 1993; Steeples et al.1994; Woodruff 1996], on the other hand, open up an interesting intersection. The concept of computer support implies the use of multimedia and computer networks as communication tools by learners and instructors to achieve certain teaching and learning goals and objectives [cf. Kaye 1991; McConnell 1991;1994; Riel and Harasim 1994]. The concept of collaborative learning is an umbrella term. Some people use the terms groups, co-operation and collaboration interchangeably. Others, try to see a slight but important difference. As pointed out in the editorial of the Journal of Computer Assisted Learning, «At a purely cognitive level, cooperation and collaboration may be quite similar but at an intentional and contextual level the processes seem to be distinct» [JCAL 1996, p.65]. Here, these terms will be used interchangeably. Group, co-operative or collaborative learning has been defined as learning that occurs through interaction with a peer group [Hiltz 1995], is based on learning principles relating to individuals within groups [Slavin 1995] and it involves the "active construction" of knowledge [Idrus 1993; McConnell 1994]. It has been researched and shown, that when collaborative learning is used appropriately, it improves student behaviour and attendance, increases liking of peers and of school, promotes positive interaction of learners in small groups [Lyman and Foyle 1990;1991]. It also improves student socio-cognitive achievement [Lyman and Foyle 1988; Mevarech and Kramarski 1992 Slavin 1995]. In a collaborative learning environment, both teachers and learners are active participants in the learning process, in which knowledge is not something that is merely transferred to students but rather something that emerges from active participation in the learning process. This view of collaborative learning is related to a constructivistic approach, which posits a view of knowledge as a construction based on previous knowledge or experiences, mental structures, and beliefs that continually evolve and do not exist independent of human experience. From a constructivist point of view, each learner actively constructs and reconstructs his or her understanding rather than receiving it from a more hierarchical and authoritative source such as a teacher or a textbook. The notion of the organism as "active" - not just responding to stimuli, or storing up information, is at the heart of collaborative and constructivistic conceptions of learning. Active learning is when the learner takes responsibility for what he or she wants to learn - making decisions about the "what" and the "how" [Bentley and Watts 1989; Bruner 1986]. Only in groups it is possible to envisage pupils talking about their work to any significant extent" [Eraut and Hoyles 1989]. Cooperative learning while doing group problem solving can improve students' team work, mutual
respect and better patterns of communication [Mittlefehldt 1991]. Successful implementation of cooperative or collaborative learning in a certain subject depends, to a great extent, on the climate of the classroom, which should be considered before longer cooperative activities are used [Lyman and Foyle 1991].

In a collaborative distance learning environment, the teacher's fundamental roles can be categorized into two categories: instructional roles and organizational roles. In the context of instructional roles, teachers act as reflective practitioners, as facilitators, and as scaffolders. While in terms of organizational roles, teachers act as resource, technology managers, and curriculum developers. Future teachers ought to analyze and reflect on (1) the pedagogical and curriculum means used to attain educational aims, (2) the underlying assumptions and consequences of pedagogical action, and (3) the moral implications of pedagogical actions and the structure of schooling [Liston and Zeichner 1987]. "When teachers themselves adopt a reflective attitude toward their teaching, actually questioning their own practices, then they engage in a process of rendering problematic or questionable those aspects of teaching generally taken for granted" [Smyth 1984 p. 60]. Implementing reflective inquiry based on critical theory is not a panacea to the problems faced in education [Ross and Hannay 1986]. In "critical reflection", the moral and ethical issues are considered along with the means and ends [Sparks-Langer et al. 1990]. The facilitating and scaffolding teacher's role is to have pupils regard each other as learning resources rather than as competitors and depend solely on the teacher as an instructor and leader. This does not imply that the teacher abandons all authority in the classroom. In fact, the teacher plays an important role as an information resource, as guide and as facilitator of the learning process.

In general, the strategic teacher's role in the "collaborative distance learning environment" is to provide a structured social environment in which students develop their capacity for self-regulation, cooperation, mutual respect and solidarity, critical and reflective thinking and engagement in the learning task to mention some.

The successful integration of computer-supported collaborative learning in the development of ODL multimedia courseware necessitates an answer to the following two questions. First, under what conditions does collaborative computer-supported distance learning work? Second, how can we design multimedia distance courseware? On the basis of the extended literature review outlined here and personal experience, a number of conditions and principles have been identified and appropriately modified to support the design and development of computer-supported collaborative ODL materials.

**Conditions for Effective Collaborative Learning**

- Students must see themselves as positively interdependent so that they take a personal responsibility for working to achieve learning goals;

- Instructors must be engaged in a facilitating, reflecting, and coaching role, teach the process skills necessary to work in groups and provide group rewards for engaging in cooperative interactions effectively. They must also specify instructional and collaborative learning objectives, usually in discussion with the learning groups.

- Introduce strategies that maximise student interaction and organise formal and informal testing to ascertain students' socio-cognitive progress.

- Identify which types of cooperative process are more effective than others and understand how students interact in a collaborative learning environment to advance their knowledge and skills.

- Ensure accessibility to the distance learning system and instructional material, stimulate the students' interest in the subject and their motivation to learn and respond to students' enquires and contributions.

- Plan before implement collaborative teaching, carefully explain the task, the goal structure and the learning activity and provide sufficient and meaningful feedback.
The effectiveness of collaborative distance teaching and learning is highly dependent on how well the technology involved can be used, in terms of operation, understanding of its potentiality, and of the teaching and learning techniques associated with that technology.

**Principles for Designing and Developing Computer-Mediated Collaborative ODL Courseware**

- Consider the "lost in hyperspace" problem by organising the instructional material in an appropriate way and structure, avoiding unnecessary breaking of topics, grouping small topics whenever possible, limiting the number of links, providing standard links whenever possible and avoiding special links that seem to be unpredictable.

- Courseware should include questions for discussion or response, rather than simply representing one way transmission of "knowledge".

- Include a table of contents, an alphabetical index of key topics, questions and assignments that enable students to present, analyse, discuss and synthesise problems or issues. Connect the course materials to current events or to students' experiences.

- Decide what, where and how to display items. Special consideration must be given to highlighting items, text legibility and the structure of the instructional material in a coherent pattern and sequence.

- Avoid hyperinteractivity and cognitive overload. Do not overload the user with meaningless animation, video, pictures, in terms of learning.

- Balance the needs of multimedia effects (graphics, text, sound, video, animation, color etc.) by taking into consideration the nature and the priorities of the topic, the preferences, characteristics, styles, age, knowledge and perceptions of users, the instructional goals and objectives, the context of learning, the previous research and the costs of various media.

- Include on-line and off-line collaborative interactions that allow students to present drafts of written assignments to one another, critique one another's drafts, and then revise the draft on the basis of suggestions and reactions from the other students (peer-group assessment). Students may be divided into teams to present opposing viewpoints or conflicting views or different aspects on same topics or issues, perhaps with some members of the ODL class acting as respondents and "judges".

- Provide opportunities to students by giving them responsibility for monitoring and making judgements about aspects of their own learning (self-assessment). Students, for example, may be guided to prepare a self-assessment schedule. This is a document that students prepare towards the end of a course in which they summarise their learning and make judgements about it.

- Define overall and specific instructional and learning objectives clearly and measurable for each unit and sub-unit of the courseware.

- Include one or more "seminar" type segments in the courseware and let students do more than simply read instructional material. In other words, turn students as equal partners in the ODL collaborative interaction by giving them space to add links between existing topics, add new topics and annotations.

**Concluding Remarks**

Research on the use of collaborative learning in distance education mediated through advanced computer and communications technologies is not extensive. Evidence suggests that collaborative learning when properly designed, developed and implemented, has the potential for contributing to socio-cognitive knowledge and skills. As pointed by Mevaresh and Light [1992], co-operative or collaborative computer
learning environments can function as a 'mirror for the mind' and thus, enable us to investigate the mechanisms underlying cognitive and social developments. Implementing computer-mediated collaborative ODL requires an understanding of the conditions that facilitate its operation and the principles for design and development of such learning interactions. To sum up, to deepen our understanding of designing, developing and implementing collaborative computer-mediated distance learning strategies, we are in need of innovative theories of teaching and learning. In this paper, a number of guidelines have been provided which stem from accumulated knowledge, personal experience from my teaching and research work in the field of new information technologies in education as well as my involvement in the project EONT (An Experiment in Open Distance Learning using New Technologies) which has been funded by the European Union [Papaspyrou et al. 1996; Makrakis et al. in press].

Automated Content Synthesis for Interactive Remote Instruction

K. Maly, C. M. Overstreet, A. González, M. L. Denbar, R. Cutaran, N. Karunaratne
Computer Science Department, Old Dominion University, Norfolk, VA 23529-0162 USA
Tel: 757-683-4545, Fax: 757-4900, E-mail: {maly,cmo}@cs.odu.edu

ABSTRACT: At Old Dominion University, we have built IRI, Interactive Remote Instruction, a computer-based system to support distance education. We have used IRI to teach several classes at sites up to 200 miles apart. In this paper we describe the extensions we are making to use IRI in both synchronous and asynchronous modes. We describe the architecture used to support recording of all class activities for future replay, and describe the interface which can be used to steer an IRI session.

1. Introduction

In higher education, distance learning is becoming key as more nontraditional students take courses. Two successful distance learning methods are TV-based and Web-based courses [Fox et al. 1995]. In the first method a course is transmitted to remote sites. In Webcourses, material is placed in a multimedia, hyper-linked format which students access through the Internet at any time. Many such courses allow students to interact with the system for progress assessment or to execute tools for acquiring skills. In their pure form the two approaches are on opposite ends of a synchrony scale. TV courses have added asynchronous capabilities by providing videotapes of a lecture that can be viewed at any time. However, tapes do not provide an index that enables students to navigate the material easily. Webcourses can provide excellent maps of their contents and are ideally suited for review at one's own pace and abilities. The disadvantage of Webcourses is the high cost to create a good one. It may take $100,000 and six months for a team of web experts, content providers, and graphics designers to put together a new course.

We propose a new approach intended to combine the best of the two methods. It is based on the concept of a virtual classroom where students at different locations have the same synchronous class experience. Each student uses a computer as his/her window into the classroom. Students use networked computers to communicate through video and audio and tool sharing. IRI (Interactive Remote Instruction), a system we have developed over the past few years, supports this approach. In this paper we describe how IRI can be used for both synchronous and asynchronous participation. Current IRI capabilities are described more fully in [Maly et al. 1997]. IRI records all audio and video, who speaks, whose video is shown and what tools are running when. The concept is simple: during a synchronous session, record all individual streams of actions with timing points. This information is synthesized and presented as a set of Web pages that can be used at a later time to review any portion of the lecture using the Web navigation pages as an index to all class activities.

Section 2 of this paper provides some background on technologies including a summary of IRI. In section 3 we describe the architecture of the recording and the replaying features of IRI followed by the design and implementation of the synthesized Web pages in section 4.

2. Tools and Environments

In this section we describe how the learning paradigm is shifting as a function of technological advances. Since ours is a technological research perspective we present a characterization based on technology and educational theories. First we summarize the relevant technologies, followed by a characterization of learning paradigms and then describe how various application level tools and environments support learning. The ideal paradigm we propose, and believe current technology can support, is one which scales well, is symmetric, allows for both asynchronous and synchronous use, has high perception quality, is highly interactive, does not require students to be collocated, allows learning tools to be shared, is cost effective, and can be used in groups or individually as appropriate for a set of learning objectives.
The tools we describe in this section are the technology tools and environments, which enable new learning paradigms. We categorize tools by which feature in a learning experience they support; for example, a video conferencing tool supports group interaction. An environment is a set of integrated tools, which provide support for most of the learning experience of a student.

Collaboration tools allow learning tools to be shared among class members in the sense that anyone can operate them. In the Unix arena an example is XTV [Wahab 1991], which allows the sharing of X programs. In the NT world, Netmeeting lets a group share win32 programs. These tools use TCP/IP and thus do not scale well and cannot handle large groups. No current tool allows the sharing of arbitrary learning tools across operating system platforms, but tools are being developed which will allow the sharing of specific tools across platforms. For instance, WEB-4M is a JAVA based tool, which allows the sharing of a white board and slide tool.

Video conferencing tools exists both over IP networks and ISDN based telephone networks. Vic and vat, a suite developed by van Jacobson, was developed for large audience as an asymmetric tool, i.e., for broadcasting to thousands with few sources. The tool is based on the Mbone and includes a whiteboard. SmartStation proprietary tool works over telephone networks with switched ISDN lines. It does not scale well and can become expensive because typically at least three ISDN lines (192K) are necessary for each participant to support an acceptable level of perception. None of the video conferencing tools support tool sharing.

Webtools are used to support Webcourses. At a basic level are the editors included with Netscape and Internet Explorer for creating multimedia web pages and groupware such as e-mail, chatrooms, newsgroups, and document managers. At an advanced level, Domino uses a secure webserver and provides a framework for writing applications that support group activities. Authoring tools help transform the educational content of a course into an interactive webcourse to the point that no specialists are needed. Other tools support the assessment part of the learning, for instance, QW (Oregon State University) allows teacher to create quizzes, administrates and grades the multiple-choice components. Web-based whiteboards and specialized presentation tools are common. C-browsing is a coordinated browser, which allows a group of participants to visit the same page on the Web together. Anyone in the group can click on a link and all participants can see the result.

Cross-platform tools are being developed for the two dominating platforms NT and Unix. The identification of Unix with academe and NT with home PCs is steadily eroding, hence the need to run a tool written for one platform on another platform. The best known tool for running X programs on a PC is Exceed which basically creates an X server under NT and allows any X program running on a Unix box to be displayed and manipulated on the PC running NT. Citrix provides the opposite: it runs on an NT server and any program running under NT can be displayed and manipulated by a Citrix client running on a Unix box. All of these tools, however work on a one-to-one basis. That is, it is impossible for a group of users on Unix boxes to see a tool running on a PC.

A successful environment is one where the end user has to perform few operations to operate the environment. TV based distance learning is a good example in this category. The student has only to go to a site and learn how to operate the audio button to ask a question. The entire system is run by technicians who ensure that the sending, receiving equipment and the cameras operate smoothly. The teacher does have to be trained in what can and cannot be presented in this medium and how to make effective use of cameras and audio channels. Similarly, environments have been created for Webcourses that integrate administration tools, content generation, and monitoring of students' progress; WEB-4M and the environment at Virginia Tech are good examples. CU-Seeme is an environment that combines video conferencing, whiteboard, e-mail, document sharing and other tools into one environment.

IRI is an environment which is being developed with the goals of the ideal paradigm described above. Currently, this environment solves the scaling problem for up to an order of 100 users while maintaining tool-sharing capabilities by the use of reliable multicasting, specifically, RMP. IP-multicast by itself does not support reliable transport that is essential when transferring data. IRI in its current state does not support true interoperability, i.e., a user can be at either an NT computer or a Unix box. X tools can be shared to any platform but not PC tools. Because of its use of multicasting it is totally symmetric. IRI supports both synchronous and asynchronous learning by recording live synchronous sessions in their totality (audio, video, and tool traffic) and automatically synthesizes the content to the asynchronous viewer.

3. Recording Architecture

In this section we briefly describe the components added to the IRI architecture to support recording and playback of IRI sessions. Two servers were added to the architecture: a Recording Server (RS) and a Playback Server. In general both resembles the Remote Instruction Server (RIS) described in [Wahab et al. 1996]. The architecture for recording in IRI is made up of a web-based interface, a session recording control (SessRec), a
recording process for each type of stream, such as audio, video, slide show tool, and a Reliable Multicast Protocol Server (RMPS), as shown in [Fig. 1].

A web-based interface allows the session leader to turn recording on or off at any time (for example during a class break). It establishes a TCP connection with SessRec and sends messages to control recording. The session recording control process is started like any other session control process of a RIS. Then it spawns the other recording components. As far as the rest of the IRI session is concerned, the recording server is a passive participant. SessRec does not bring up any interface, but waits for the connection of the web-based interface. In addition to the normal operation of an IRI session, SessRec stores the allocation of the media resources in a file, as the session progresses. The audio recording process joins the audio channels following the same protocol already implemented between session control and audio component of RIS. The major difference with the audio component of RIS is the redirection of the output to files rather than the audio device. In addition to audio streams that are stored in μ-law format, the audio recording process records timing information carried in audio packets to take into account silences and packet losses due to the unreliable multicasting.

The video recording process works like a video receiver process in RIS. However, instead of decompressing and displaying video streams on IRI windows, it stores them to a local disk using a video size of 320x240 pixels. There is no need for decompressing most of the video streams, but the presenter video (640x480 pixels) has to be decompressed, reduced, and then compressed again for storing. Like the audio recording process, this process also stores both the video stream and the necessary timing information to overcome gaps due to video frames losses. IRI has a number of specialized tools that were written especially for RIS. A modified version of each works in recording mode to store the important events associated to that tool. Later, during review, another version of this tool running in playback mode reads the events from a file and replays them accordingly to each tool operation. The Tool Sharing Engine (TSE) of IRI, based on the XTV system, allows sharing of X windows' applications collaboratively. The recording server runs a modified version of it, the tool-sharing engine-recording tool, to store the events related to any application running under this component.

3.1 Recording Files

Two layers of files are stored for each recorded media: a resource allocation layer and a data stream layer. The former is recorded by the session recording control process. It stores the users' names and times at which the resource was used. The latter layer of files stores the timing and data associated to each resource. One file keeps the timing information of the stream and pointers to the actual data that are saved in another file using standard formats, such as Sun μ-Law for audio files and GIF for slides. For example, in the case of audio, session recording control stores the time and names of those who have been granted an audio channel and those who release it as well. In addition, the audio recording process records the initial time of every recorded audio block.
and the offset where that block is stored within the data stream file. Thus, at review time a corresponding audio playback process can access the audio data and its timing to replay it as it was heard by the participants of the synchronous session. For video, we do not record individual user’s video streams (whose total is of the order of participants) but the windows’ videos seen by any participant (a total of 4 in the current IRI implementation). For each window’s video, a session recording process stores when and who took over that video resource (video allocation file for that window), and a video recording process stores the video data stream and its timing information. Slide show tool events and slides are recorded with a similar scheme to audio and video.

### 3.2 Playback Architecture

The architecture for playback in IRI is similar to the recording architecture. For every process in the recording architecture, there is a complementary process in the playback. While recording processes receive and write media streams to disk, playback processes read these streams from disk and send them to an IRI session. A web-based interface allows participants to see recorded IRI sessions and the resources that have been recorded for each person. Then users can select the streams to be played back. This interface connects to a session playback control process (SessRep) and sends messages to initiate, resume, or stop playback. The communication between the interface and SessRep is via TCP sockets.

Session playback control serves requests sent by the review interface, allocates and releases resources for streams being played back, and communicates to each playback process to start and stop their operation. A session control panel (see Section 4) is used to start the session playback control process (SessRep) just like any other session control process. Then SessRep spawns the other playback processes following the same protocol that session control uses. As far as the whole IRI session is concerned, SessRep is like another session control with an interface controlled by a review user. Like session recording control, SessRep does not bring up an interface, and it waits for messages from the web-based interface. SessRep displays labels and graphical indications for playback streams as opposed to live session streams.

The audio playback process operates like other IRI audio processes but reads recorded audio data. This greatly affects timing. While intra-stream synchronization during recording is controlled by a fixed sample rate of the audio input device, some mechanism needs to be provided for playback. The audio playback process inserts pauses to compensate the removal of silent periods and the loss of audio packets during recording. The video playback process works like a video sender of a normal IRI session, but instead of capturing video frames from a camera it reads them from a file and send them over the network. Like audio and video, there are other processes in charge of playback for each IRI multi-user tool, such as slide show tool, and a version of the tool-sharing engine tool for playing back the applications that run under this component, such as Netscape and emacs.

### 3.3 Recording Playback Synchronization

Timestamps are used for intra- and inter-stream synchronization. A data unit timestamp is the time in milliseconds since the IRI session begins. Video and audio streams are the most critical in terms of synchronization requirements. They carry timestamps, attached at the sender host to each application data unit (packets for audio frames for video). While video streams have a clear timestamp used for recording, it is not clear how to assign a timestamp to the audio stream coming out of the audio-mixing algorithm. Our approach uses the timestamp associated to the loudest audio stream being mixed. By doing this we keep synchronized the video/audio pair that has the attention of the participants.

In order to ensure that each RIS computes local timestamps from a common starting time for the class, we use the first leader's event sent reliably to synchronize the starting time of the class in every participant session. Another reason for a global synchronization is the need for a unique time line for resources allocation. Unlike video and audio streams, all other IRI resources set timestamps at the receiver, so we record what everyone sees as delivered by RMPS. Thereby, we need the recording server to be in sync with any possible audio or video stream generator (i.e., anybody).

Every playback process takes the local machine time and timing information associated to each data unit to synchronize the replaying of its stream; thus intra-stream synchronization is accomplished. Inter-stream synchronization is achieved by letting session playback control send a common playback starting time to all the processes involved. This way specific synchronization techniques are not required within dynamically changing playback processes set.
4. Implementation

In this section, we focus on the technical issues involved in building a Web-based interface to steer an IRI session in which we replay portions of previously recorded sessions. In the past we have used a Motif interface to steer an IRI session and to add resources needed for a session. Since we are in the process of developing a cross-platform implementation of IRI we decided to switch to a Web-based controller as a first step. First we discuss how we enable multiple users to steer and monitor a session securely and how we integrate their browsers with the IRI interface. In the second part, we present the content synthesis and presentation to the user for selecting arbitrary points of starting a replay.

4.1 Multiple-User Steering

IRI is based on reliable multicasting because of the number of students participating in a session. However, we expect only a few people, typically the teacher and an assistant, to be involved in the steering and monitoring process. Therefore, we can use normal, TCP/IP based, Web server-to-browser communication to coordinate the browsers of the controller group. The entire interface is a set of CGI scripts/programs, JAVA scripts and applets that access a protected directory on the server side and communicate with IRI through Unix sockets and with direct access to the IRI file tree. Each Web page presented to the user requires a proper authentication token that is only obtained by password authentication.

To start a session a teacher goes to the appropriate web page and authenticates herself. After specifying on subsequent pages the configuration for that session (machines to be used, servers, lesson plan) and the location and identities of specified controllers and monitors (defaults are available for all of these), she starts the session by sending a set of messages to the IRI process. We use the interface button for “class management” of IRI to connect to these browsers and make them active for all the controllers and monitors. Thus, at any time of the session, a teacher, for example, can bring the browser to the foreground and click on “start replay” and proceed from thereon as described below. Similarly, the monitor can bring up his Web page at any time and proceed to monitor the session using the pages provided.

4.2 Content Synthesis and Presentation

Assume that a group of students have started a session to review a previously recorded session. The group leader started the session on his PC in an office and has decided to steer the session himself on a machine in the IRI classroom that has no monitor. After logging on the machine, he uses regular IRI features to communicate with the other students. At some point he brings his control browser in the foreground and clicks “Activate replaying.” A cgi script will ask him to identify what session to replay and when that is specified, present him with a synopsis of that session through JAVA applets as shown in [Fig. 2]. The JAVA applet knows already what session is to be replayed and presents a list of participants who spoke or had their image present and at what times of the session. In addition the leader can select the level of abstraction the presentations should be given. The choices are class, presentation, and slides. The first one implies that the applet will only show from which classes the leader of the recorded session used presentations. In the second choice, the applet will present the times each different presentation was on the screen during the session. The example shown in [Fig. 2], the leader selected the third option and was given all the slides visited during the entire recorded session. The key is that each of these applets’ windows can be left on the screen and at any time the leader can click on any of the time intervals to start replay at a particular point of time. These windows provide the synopsis of the session in different forms and depending on how a person remembers best, she can choose whatever stream is most appropriate.

Once the leader clicks on a particular time interval, at a spot estimated, the applet computes from the two shown endpoints of the interval the time the user intended and sends a message to the replay IRI process. This one in turn, computes which IRI process was active at that time and sends messages to activate the appropriate processes (audio, video, or presentation tool). The replaying process selects a window on the IRI interface, tags it as being a recorded window, and plays as long as the next event happens, e.g., stream ends or next slide is shown.
5. Status and Future Work

At this point we have the first version of recording and replaying implemented and tested; it is not yet being used in an actual class environment because not all the features shown in [Fig. 2] are complete. At the next level we will use the same process for the remaining special IRI tools such as survey, exam, and coordinated browsing. The next major step will be to synthesize and abstract the recording of arbitrary X tools that were used in a session. Since we have no control over these tools, we will not be able to provide any summary information except screen images at selected time points. But even with these images as index to a time interval we have the problem of starting an X tool in the middle of its execution. We are investigating the concept of fast forward for the playing of X tools which will elide X commands which are not relevant after a certain time.

Abstract: We believe that complex documents can be better understood when the reader is able to choose a presentation style that suits the reader's task and situation. We have modified NCSA's WWW browser Mosaic so that it supports this type of user-centered presentation control. The primary change has been the addition of support for style sheets that specify the appearance of the HTML documents displayed by Mosaic. Our modified browser, called Multiple Presentation Mosaic or MPMosaic, supports a variety of presentation styles designed to address a wide range of user goals. Furthermore, it is capable of showing multiple presentations of the same document simultaneously. We conclude that the addition of style sheet support can add useful functionality to existing browsing and editing applications.

1. Introduction

We are interested in the presentation of information, i.e. how information can be displayed or played back on a computer. Specifically, we are interested in exploring the extent to which style sheet technology can be used to provide a variety of useful views of the same information. Our research is based on the premise that in order to understand a complex information artifact, that artifact must be presented in multiple ways and that sometimes it is very helpful to see multiple presentations simultaneously. Our focus is on providing multiple presentations of tree-structured documents, such as those represented by HTML [Raggett 97], SGML [ISO 86], or XML [Bray et al. 97]. This paper describes our work with Multiple Presentation Mosaic, a modified version of the NCSA Mosaic browser for the World Wide Web.

MPMosaic allows its users to control the appearance of the HTML documents it displays by choosing a presentation style. Presentation styles can vary in several different ways:

- Presentations of a document may vary in stylistic properties, such as font size or foreground color. One presentation might use the 12 point "Times" font while another uses 18 point "Helvetica."
- Presentations can differ in layout. For example, a journal article may be laid out in one column or two columns.
- Presentations can also differ in the content displayed. A presentation that provides a table of contents only displays the section headings of a document and omits the rest of the document. It is often useful to only display a particular element type, such as figures or images.

This work with MPMosaic grows out of a belief that readers will better understand complex documents when they are able to choose a presentation style that suits their varied tasks and situations. A user-centered presentation system provides the flexibility to meet the needs of different educational goals, different levels of intellectual abilities, and different physical abilities. Nearsighted and young readers may want to enlarge text. Color blind readers may want to adjust the colors used in a document. Researchers looking through many documents may want to limit their reading to abstracts and executive
summaries. Authors may find views of a document's outline and structure helpful for writing and editing that document.

There are two basic approaches to providing multiple presentations of the same document. The first approach is to hard-code presentation choices in the implementation language of a browser or editor. This works well if the range of presentations that are useful is known in advance. However, it places the responsibility for designing and implementing alternate presentations on the program's designers, who often lack the omniscience necessary to anticipate the diverse needs of users. Examples of this approach can be seen in CAD applications and in commercial word processing and graphics software.

We prefer a second approach based on style sheets. A style sheet is a specification of appearance for a collection of documents with similar structure. Style sheets may be written in a specification language, such as CSS [Wium, Bos 96], DSSSL [ISO 96], P [Quint et al. 95], or PSL [Munson 97], or may be defined using a GUI (as is common in commercial software). Unlike the hard-coded approach, the use of style sheets embodies a useful separation of concerns. An editor or browser that uses style sheets can be built around formatting services that have no knowledge about the way that a particular type of document should look. Instead, the editor/browser gets all of its appearance information from the specifications in the style sheet.

Style sheets provide a number of benefits. Adding or changing appearance styles does not require changes to the source code or recompilation of the application --- only the style sheets need to be changed. Style sheets are generally much simpler to write than application source code, because of their restricted domain. This makes it more likely that sophisticated end users will develop new styles and views of documents in order to obtain presentations they desire. Furthermore, the application's formatter is generally smaller and more generic, which makes it simpler to implement and easier to retarget for new classes of documents or new uses.

Applications differ in how they approach style sheets. The Microsoft Word word processing application embeds all style sheet information in individual documents, though it does provide a limited sharing mechanism called "templates." We believe that it is much more beneficial to keep style sheets separate from individual documents because this allows a user to apply any style sheet to any document at any time and to apply multiple style sheets simultaneously to the same document.

2. Multiple Presentation Mosaic

Multiple Presentation Mosaic (MPMosaic) is a version of the NCSA Mosaic 2.6 browser for the World Wide Web that has been modified to use the Proteus style sheet system. While NCSA Mosaic provides a single hard-coded view of an HTML document (with some options for adjusting font size), MPMosaic supports a wide range of presentation styles, many of which are quite different from the standard browser view of Web documents. We have written style sheets defining the following presentations.

- **Standard view.** This style sheet mimics Mosaic's hard-coded view and produces a presentation similar to other graphical browsers.
- **Tree-structured view.** This presentation shows the tree structure of a document. The markup tags of elements are shown and each tag is indented further than its parent's tag [Figure 1b].
- **Embedded tags view.** The markup tags are displayed in the formatted document [Figure 1c].
- **Links view.** Anchors and their destinations are shown. PSL, our style sheet language, allows us to add additional information like the text of an anchor's target to the presentation [Figure 1d].
- **Table of contents view.** Shows only the headings (the H1 through H6 elements).
- **Reduced size view.** All fonts and images are shown at half size.
- **Alternative view.** The document is shown as it would appear in an ASCII-only browser.
There are many other useful views. For example, we can write style sheets that only show the elements of a particular type, such as images or tables.

In MPMosaic, a style sheet controls the appearance of a document without altering the document itself. Through a file selection dialog box, users can select their own style sheets to control the appearance of a document regardless of the document's origin or authorship. MPMosaic also supports multiple presentations --- users can open multiple windows displaying the same document with each window using a different style sheet. Multiple presentations are synchronized: when a new document is selected (i.e. a link is followed), all views associated with that document are updated.

Multiple presentations can also be synchronized to display the same part of a document. The user can specify that a view is a display synchronization view: clicking on an element in that view automatically updates the other views of that document to display the same element. For example, clicking on a section heading in a “table of contents” view will scroll the other views to the corresponding section of the document.

Using display synchronization, MPMosaic can generate pseudo-frames that act like HTML frames [Raggett et al. 97]. A pseudo-frame is an alternate view of the document shown in the main view of the browser window. A pseudo-frame is displayed as a side bar in the window [see Figure 2]. When a user clicks on an item in the pseudo-frame, the main view is updated to display the same item. The contents of pseudo-frames are generated from style sheet specifications. Thus, pseudo-frames have two advantages:
authors do not need to write the cumbersome HTML markup for frames and readers can easily add frames to any document.

Figure 2. Pseudo-frames. MPMosaic is shown displaying the online version of this paper with an additional image. The pseudo-frame (the side bar) contains an outline of the document.

3. Proteus

Proteus [Graham et al. 92] is a portable style sheet system for documents in any medium. It is designed for use with tree-structured documents, such as those defined using SGML, but can also be used with list-structured documents. Style sheets for Proteus are written in the PSL language [Munson 95], which is a declarative, constraint-specification language.

Mosaic's formatter was not significantly altered when we added the Proteus library to Mosaic to make MPMosaic. Approximately 600 lines of C++ code were added to the 8000 line formatter in Mosaic. There were two major changes.

1. The internally representation of an HTML document was changed from a linked-list (in Mosaic) to a tree (in MPMosaic). This was done because Proteus requires the document to be represented as a tree. In addition, a tree data structure more accurately represents HTML documents (since HTML documents are tree structured), and it provides a more flexible representation for controlling presentation.

2. The values for style properties, such as font size and foreground color, are hard-coded values in Mosaic whereas in MPMosaic the formatter queries Proteus to retrieve these values from a specified style sheet.
4. Other Work

While commercial software has only recently adopted style sheet control, style sheet systems have existed in research for over 10 years. Amaya, which developed out of the Grief system, is perhaps the most prominent research application [Quint et al. 95]. Amaya has a different philosophy than MPMosaic and Proteus concerning style sheets; Amaya is author-oriented rather than user-oriented. In Amaya, all presentation views are described in a single style sheet for all users at an installation, and views require associated C functions. Thus, end users of Amaya in a multiple user environment are not free to add their own styles. Amaya provides partial support for CSS style sheets. However, Amaya embeds the style information in the document whereas MPMosaic does not alter the document.

In contrast to other systems, Proteus is an independent library that can be added to existing applications without much re-engineering. Our research has shown that interesting, non-trivial presentations can be created using style sheets. We conclude that the addition of style sheet support can add useful functionality to existing browsing and editing applications.

Our plans for MPMosaic are to continue to explore interesting presentations, to support multiple style sheets per view, and to use PSL’s fine-grained layout specification [Munson 95].

Abstract: We are living a new “Information Age”. The massive use of the new information and communications technologies is producing important changes in our society, with respect to the way we live, work and communicate. The paradigm of it is the already omnipresent Internet.

One of the university’s teaching objectives is to form the professionals for the future. The students, we have today in our classrooms will meet tomorrow the necessity of knowing and using these new instruments when they attain the labour market. At the same time, if used properly, these tools can help to innovate and improve the university teaching and learning process.

At the University of Girona, an interdisciplinary group has started the project to create an integrated platform where teachers can create and publish new dynamic and interactive teaching materials that make profound use of all the new possibilities offered by the information technologies. The platform will also be used by the students to access these materials in a decentralised way from anywhere on the Internet, and at the same time by the teachers to keep track of students’ utilisation. It also improves and facilitates communications between students and teachers, at all levels.

1. Introduction

Among all the services that Internet can offer, the World Wide Web [W3C] (WWW or simply “web”) provides an excellent platform for publishing and disseminating a wide variety of curriculum materials. These can go from textual resources that resemble traditional linear class notes, to highly dynamic and interactive non-linear materials, including multimedia resources (text, images, sound, video, animation sequences and interactive simulation applications). All these web-based materials can be available world-wide from the Internet.

The capacity of presenting multimedia information has made the web an effective tool for education. The interactive nature of this medium can enhance the teaching and learning process. It can be a fantastic tool for a constructive approach of this process, in which the educator and the learner are active agents in their respective progress. Moreover, it can be used as a mean to understand complex systems and ideas.

Internet based communications services such as electronic mail, news, Internet Relay Chat or videoconferencing tools, allow the collaboration between students and teachers. A student can communicate with its teachers and peers without the relative constraints of having to meet at specific places and times. Students can work on learning materials at own pace and discuss them with other people when they have questions, sharing experiences with others. They can learn individually but not alone; they can be physically separated but study together through computer networks.

2. The Project: the Teaching Support System

Based on the above argumentation an integrated platform is proposed. Basically, the objectives of the project are:

- Make possible for any teacher to create dynamic and interactive multimedia teaching materials, using the new standard information presentation techniques. These materials can be created from predefined templates by using imported resources made with any standard text, graphics, sound or video tool, or using specific tools such as web creators. The tools that enable this objective must be designed to be used by teachers without any previous computing knowledge.
- Enable teachers, students and authorised persons to access all resources in a decentralised manner, speaking both in terms of space and time, and with the benefits of the hypertext concept. Since all the materials are created around HTML and put on the web, they can be easily accessed from the web using any standard browser like Netscape or Internet Explorer, from anywhere and at any time. The information is structured in a non-linear basis, and therefore each student is able to access it according to his own learning patterns, needs

---

This work has been partially supported by the University of Girona [S-UdD97-197]
and initiative. Moreover, the use of associated technologies will make several types of multimedia and interactive units possible.

- Improve and facilitate communications and collaboration between students and teachers at all levels. The Internet gives services that facilitate the communication. The platform will make full use of these communication services in an integrated way with the materials.

- Provide an well-dimensioned environment to students in order to access the huge amount of resources available on the Internet, besides own local cites and incentive them to be active members of the net in all aspects, but also instructing them to make a wise and effective use of it.

- Give the training and advise university teachers will need in order to be able to construct didactic units for their courses, not only using the tool but making wise and effective use of courses and the Internet. Also, the collaboration between them for creating better materials is encouraged.

- This project doesn’t intend to substitute the traditional teaching in the class room, but to complement it.

In order to achieve these objectives, our platform need two different main modules. One of them is used by teachers to make the units, and the other one to make it possible for the students (and other people) to use these units. We will call them Units Creation Module (UCM) and Units Navigation Module (UNM) respectively.

The main function of the UCM module is the creation of the didactic units by teachers. But it is important to highlight that we are not only speaking of computer science teachers but all teachers. Therefore, the UCM must be easy to use and it must not require any programming skills nor a lot of new tools to learn. To achieve the last goal, the UCM will be able to make use of materials created using most common standard programs, like word processors, graphics packages, etc. Importing them into predefined templates, the UCM will generate the materials ready to publish. A lot of templates will be provided to adapt to many types of materials.

The complete implementation of the UCM module will be in a further phase of the project. On the first phase, a first version of the UNM module is designed and implemented. We use already existing standard tools (under a set of basic guidelines) to make the first test units to evaluate and tune the UNM. The current performance of these standard tools have partially covered the initial objectives for the ACM module.

The UNM module is the tool used to access the materials which are created by using the UCM module. Being the units created using HTML, it could seem that using an standard HTTP client and server would be sufficient, but our project goes beyond what is achievable using the standard browser controls and common HTTP server features.

The functions of the UNM module and its utilisation are shown in the following section, the variations of the initial proposal [INET96] are also presented.

3. Navigator module description

The materials offered to the users will be structured around “units”. A unit would be a lesson about some topic.

To access the units, the user needs a standard WWW browser supporting JavaScript and Java. After connecting to the starting URL [WA0], the user get a login dialogue, where the user have to identify himself by entering a login and a password. Without completing this process, the user will not be authorised to use the materials.

This login procedure shown above has two major purposes:

1. Be able to identify single users in order to keep track of them when using the units, and customise it for each of them if needed. Also, prevent unauthorised users to access the materials.
2. Be able to distinguish users categories with different privileges. The units can behave differently according to the privileges of the user. Some user categories may have access to features others will not.

Related to the above points, there are four user categories: Supervisor, Teachers, Students and Guests. The Supervisor acts as the system manager and, therefore, has total control over the UNM. He is responsible for assigning a login and password to the users, install units and keep the system running correctly. Teachers have full access to all the materials, including control and supervision features. Students will be able to fully navigate the units contents and make use of all features that the teachers prepared for them, but not the control or supervision functions. Finally, guests will have limited access to some of the units contents according to the teachers’ criteria. A login and password is assigned to teachers and students by the system manager, while guest users will only have to enter “guest” as login name.

It is interesting to record, the whole process that all users carried out. All sessions corresponding to an user are added to a log-file. The units which this user has visited in this session are booked. Therefore, at the beginning of each session the user can examine its previous work.

Figure 1 shows the aspect of the main screen that the users will face after login to the system and selecting one of the available units. Note that it is only a suggestion, and the final aspect may differ or even be user-customisable, but we will use it to describe all the functions.
Figure 1: Main Navigator Screen

This screen has two main elements: the header and the body. In the header, is the information about the unit used (course, author, name of the page, etc...) and the buttons. These buttons give additional features to complement the basic unit contents shown in the body window, and to enhance the navigation process. The body window is where the basic contents of the unit is displayed. All the menus and toolbars from the standard browser could be disabled, so all the navigation functionality is done by using these buttons.

Initially, the body was designed as a central window rounded by several buttons. The functionality of the buttons was focused on the navigation and the interactivity between users and teacher. Each button will add a different complementary function to the basic unit contents. The buttons on the left are associated to general functions (for all content pages and even for all the units), and the ones on the right are for specific functions (the author can decide if they are active or not, depending on the content page or unit being used. Note that some of the buttons may behave differently (or even be inactive) for some user types.

During the implementation of the test bed, to experiment with the first didactic unit, the navigation module was tuned. Training with eleven users in the class room, the drawbacks of this first scheme were detected and corrected. Moreover, new features and a new distribution of the buttons were proposed. This modification process is also presented in the following section.

The major modifications have been carried out on the main presentation screen for navigating. The necessity to include more text and graphic information leads to augment the visualisation area. Therefore, from a buttons-rounded central area we changed to a single header, to identify the user, the unit and the essential buttons to activate the remainder functionality.

Each button is briefly described hereafter:

- **(Button “Navigation”)** First, we have the navigation buttons. Besides the common “back” and “forward” features found with all browsers, we have “previous”, “next” and “up” buttons that will make possible to navigate the unit following a hierarchical order predefined by the creator of the unit.

- **(Button “Information”)** It will give information related to how the tool works, how the buttons work, etc. This is the always useful poping-up HELP window we can find in most applications. It will also include guidelines and advice to make a good use of the tool.

- **(Button “More information”)** In this case, new knowledge about the current lesson can be achieved by the user. This is the extension and consolidation of the knowledge about the unit which the user is into.

- **(Button “Bibliography”)** It shows the bibliography of the unit and links to related documents on the web. Although bibliography could have been integrated with the whole unit, we have considered that it would be useful to have it easily accessible. When a student clicks the button he will get a new window with the recommended bibliography (including books and Internet resources as well). But teachers will have additional functionality to modify the bibliography on-
line, in a similar way as the FAQ function.

(Button “Questions”) This button presents the student with complementary questions to help him know if he has learned the basic concepts explained in the unit, and make a self-evaluation. It also will give access to a set of complementary activities proposed by the teacher, like tests, exercises, concept associations, etc. The student will get automatic feedback. So he will be able to know automatically if the answers he gives are correct or not. Teachers will be able to consult students’ answers over time, and get various reports like “the most incorrectly answered question” and the likes.

These activities are created using the UCM, and consist of a set of predefined activities. For instance, to create a test teachers will be asked for a set of information like the title of the test, the number of questions, the number of options for each question, the text of the questions and the options, the score, etc. From that input, the UCM module will generate all the necessary items in order to put the test on the server and make it work and available to the students. The same procedure will be used for all other activities available.

(Button “Tools”) A set of tools are accessible to the user through this module. Utilities to seek information into the unit are provided. This information can be used by the user in the future.

(Button “Map of Contents”) This button shows the user a complete tree of the unit being used, showing all pages and how they are linked. This tree will be based on the directory tree function we can find in Windows 95 Explorer, with similar capabilities. It will be possible to “fast jump” to any page of the unit by clicking on it on the tree. Moreover, this tree will inform the user about which pages have already been visited by him (and how many times, how much time he has spent there, etc.), and which ones not. It also will help the students to make a better idea of the layout of the unit and to easily locate important pages or nodes. This is a useful feature because hyperlinked documents are not lineal and therefore it is very easy to get “lost in cyberspace”, or forget to visit a whole set of pages only because some link has not been followed. The teachers will be able to look not only at their own tree but at the particular tree of each student, and then warn them about any contents they may be missed.

Using that tree function it will be possible for the user to see and modify the printing order of the unit, or select a subset of pages to print.

(Button “Note book”) This opens an external text editor where users will be able to take notes about the unit they are using. The objective is to give the “piece of paper and pencil” to the users who surely will need to take notes according as they study the unit. It is basically an external editor, and as with the dictionaries above, it can be either a local one or a Java applet downloaded from the server.

(Button “Print”) This one is meant to solve one of the most important inconveniences people using the web are facing: how to print a whole site, or a set of pages. Browser’s printing capabilities make possible to print only one page at a time (the page that is being viewed). So if anyone wants to print a set of pages he must go and download one after another and print them separately. Trying to print a whole hypertext document can be a nightmare. With the printing tool we are able to print all the pages of a unit, following a predefined order stated by the unit creator. Moreover, with the use of the “tree” function it is possible to print only a set of pages, or even change the printing order.

(Button “Progress information”) Teachers will have another button that will give them access to the reports window. From there, teachers will be able to ask for a set of reports about student activity. For instance, they will be able to know all the information about any student activity, know which pages are the most and less visited, to know which question in the test is the most incorrectly answered, etc. Also, students could optionally have access to this button to get reports about their own progress.
(Button “Communications”) The communication among users and between the unit’s authors and users is allowed.

(Button “Synchronous communication”). This function requires communication parts to be on-line at the same time. When a user clicks this button, he is transported to an space where he is able to meet other people using the unit at the same moment, so being able to start a text-based conversation, debate, etc... It’s meant to be a sort of IRC, complemented with shared blackboard, but again very simplified and with much more control by the teacher. In the future, it will be enhanced to support not only textual communication, but audio and video, thus becoming a videoconferencing tool. Using this function we can get benefits equivalent to the study in group, but without the need of people being in the same place. Virtual classrooms can be also possible.

When clicking this button, a new window will open and will put the user in the “General” conversation area. Here he will find other people and start some conversation, or he will be able to locate other conversation areas already created. The objective is to transform the General area in a meeting-point. From the general area, users will be able to join other specific topic areas, or create their own area for the topic they are interested in. Many other functionalities as connected users lists, area and users managing, etc., will also be present. Some control functions will only be available to teachers.

(Button “Teacher’s mail”) This button gives access to the Frequently Asked Questions (FAQ) document creator. Using some of the communications functions described later on, the students will be able to ask questions to the teacher, and this one will be able to answer them. Over time, some questions will be repeated over and over again. So, if the teacher thinks it is recommendable doing it, he will include both question and the corresponding answer into a database where other students will be able to consult it. Over time, the database becomes a very valuable document to help students for better understanding the unit contents, and the teacher finds most common questions already answered, thus saving time.

When clicking on this button, a new window appears. The students are confronted with a database consulting tool, while teachers have editing capabilities. The editing capabilities are usually restricted to a small set of teachers, or even only one of them. The FAQ documents are maintained this way just because we think that they are updated much more frequently than the unit pages.

(Button “News”) It opens an space for asynchronous communications, where students and teachers are able to debate about any aspect of the unit being used. Note that asynchronous communication can take place without needing that communicating parts be on-line at the same time. This is an integrated “e-mail” and “news” feature, but controllable by the teacher. It communication also possible by using only the web and without having to have an e-mail standard account.

Clicking on this button a new window is opened. Students are able to read (and organise) their private mail, or read the messages sent to public addresses associated to any topic related to the contents of the unit. He is also able to send private e-mail to other students or teachers, or post public messages to the public addresses. All the messages are stored on the server. This scheme gives the functionality of both e-mail and news services, but with less complexity. Users will not need to have e-mail account nor e-mail and news clients, and will not need to configure anything. Teachers will be able to create public addresses and organise them, and will have total control over the whole tool.

This button makes it possible for students to ask questions privately to the teacher, without having to do it during the class, leading to better time saving and helping timid students to participate. Also, the use of the public addresses enables the creation of asynchronous debates. Teachers can promote the use of this functionality to incentive collaboration among students.
4. Conclusions and future work

This inter-disciplinary work is developed from both the first experimental unit and the users estimation, which will allow us to modify and improve the initial design. Moreover, this is a work in progress. The members of the project positively appreciate the inter-disciplinary environment to carry out the different components of the project: UCM, UNM and units contents. From initially different points of view about the matter, a more global vision that enhances the task of all members is achieved.

Note that this is a dynamic work. The design and implementation for future units also allow us to modify and evaluate the current proposal. This sort of work leads us to a true interactive platform that improves the communication between users and teachers, which is a major goal of the project. The current URL of the project is: http://eia.udg.es/-usd.

Abstract: Open Distance Learning is an emerging paradigm where students, teachers, and equipment may be at different geographic locations. The WWW provides an excellent platform for publishing and disseminating a wide variety of curriculum materials. To evaluate the impact of these materials on the teaching and learning process, user identification and tracking is needed. Current HTML clients and HTTP servers are limited in these aspects. In this paper, a solution is described based on an educational web environment. This proposal uses a server program, called Custom Server, that processes HTML pages before they are sent to the client and inserts user identification within hypertext links.

The Custom server takes also the following responsibilities: user identification and validation, HTML-document customisation, database maintenance, translation of database information into reports, control of private working documents, asynchronous and synchronous communications, and other similar capabilities.

1. Introduction

The World Wide Web [1] (WWW or simply “web”) is an Internet service that provides an excellent platform for publishing and disseminating a wide variety of curriculum materials. The web is an effective tool for education because of its capacity of presenting multimedia information. Also, the interactive nature of this medium can enhance the teaching and learning process. It can be used as a means to understand complex systems and ideas. It is also a fantastic tool for a constructive approach of this process, in which the educator and the learner are active agents in their respective progress.

Internet communications services such as electronic mail (e-mail), news, Internet Relay Chat (IRC) [2] or videoconferencing tools, facilitate the communication and make the collaboration between students and teachers possible. Individual students can communicate with their teachers and peers without the constraints of having to meet at specific places and times. Students can work on learning materials at own pace and discuss when they have questions, thus sharing experiences with others. They can learn individually but not alone; they can be physically separated but study together through computer networks.

To effectively make use of these materials and evaluate their impact on the teaching and learning processes, user identification and tracking capabilities are needed. Every user must be perfectly identified, and every step he makes must be stored into a database. This database must include for each user which documents have been retrieved, how many times, how much time has been spent within, which have not been visited yet, the responses to proposed tests or exercises, etc. Based on this information the system must generate reports to provide a feedback, to both teachers and students. This information will no doubt help to improve the teaching-learning process.

As we will see further on, current standard Hypertext Transfer Protocol (HTTP) clients [3] (browsers [4]) and servers [5] and HyperText Markup Language (HTML) [6] are limited in user identification and tracking capabilities. The aim of this paper is to provide a possible solution to the user tracking and identification problem within an educational web environment. The presented solution uses a Common Gateway Interface (CGI) [7] program that processes HTML pages before they are actually sent to the client. The CGI program encodes user identification within hypertext links, enabling the server to identify users from modified links passed back from the client. In this way, it provides tracking across a series of HTTP requests while it offers a way to overcome the stateless nature of HTTP sessions without changing the underlying nature of the protocol.

2. The Teaching Support System Project. Objectives

An interdisciplinary group, at the University of Girona, has started the Teaching Support System project [8] and [9]. The main objective of this project is to create an integrated set of tools where teachers can create and publish new dynamic and interactive teaching materials that make good use of all the new possibilities offered by the information technologies and the Internet. The tools are also used by the students to access these materials in a decentralised way.
from anywhere on the Internet, and at the same time by the teachers to keep track of students use. It also improves the communication between students and teachers.

Several objectives of the teaching support system project can be identified. A major goal is to allow teachers to create dynamic and interactive multimedia teaching materials (from now on, "units"), using the new standard information presentation techniques (HTML, Java [10], javascript [11], complemented with Common Gateway Interface programs (CGIs), Server Side Includes (SSI) [12], etc.). The tools are designed to be used by teachers with any level of computing knowledge.

Teachers, students and authorised persons access to the available resources in a decentralised way, speaking both in terms of space and time, and with the benefits of the hypertext concept. The information is structured in a non-linear basis, and therefore each student is capable to access it according to its own learning patterns, needs and initiative. The communication and collaboration between students and teachers is enhanced. The Internet gives us several services that facilitate this communication. The platform must make full use of communications in an integrated way with the materials.

However, this project does not intend to substitute the traditional teaching in classroom, but to complement it. In order to achieve these objectives, our approach has two different main modules. One of them is used by the teachers to make the units, and the other one makes it possible for the students (and other people) to use these units. We call them Units Creation Module (UCM) and Units Navigation Module (UNM) respectively.

The main function of the UCM is the creation of the didactic units by the teachers. But it is important to highlight that we are not only speaking of computer science teachers but all teachers. So the UCM must be easy to use, and it must not require any programming skills nor a lot of new tools to learn. To achieve this last goal, the UCM can make use of materials created using most common standard programs, like word processors, graphics packages, etc. Importing them into predefined templates, the UCM generates the units ready to publish. A complete set of templates is provided to adapt to many types of needs.

The implementation of the UCM module is postponed to a second phase of the project, although some parts are already being developed. In the first phase, we design and implement a first version of the UNM module, and we mainly use already existing standard tools (under a set of basic guidelines) to make the first test units to evaluate and fine tune the UNM. After the UNM is evaluated and validated, the final design and implementation will be made. Then, the UCM module will be designed and implemented.

3. The user tracking and identification problem

The UNM module is the tool used to access the units created using the UCM module. But many of the UCM functionalities require a perfect identification of every single person accessing the system, and must be able to completely track each action this person is performance. For instance, the UNM needs to perfectly know who is accessing which document at any moment, or the answer he gives to any exercise. It would also be interesting to keep some kind of "state" about the user's navigation through the materials, for instance, to enable users to start any new session where they left their previous session. Some of those UNM functionalities that require user tracking and identification are:

Personal Working Space. By clicking a single button, users have access to a personal document with editing capabilities. The objective is to give to the users the "piece of paper and pencil" they certainly need to take notes according as they study the unit. The editor can be either a local one or a Java applet downloaded from the server. In the first case, users are responsible for their documents (name, location, saving it, etc.), while in the second one, the document resides on the server machine, and thus, is automatically loaded and saved when starting or exiting the working space tool.

The Navigation Tree. This tool shows the complete structure of a unit (all their pages, and how are they linked). It makes it possible to "fast jump" to any page of the unit by clicking on the tree. Moreover, this tree informs the user about which pages he has already visited (and how many times, how much time he has spent there, etc.). The Navigation Tree is a useful feature that helps to solve the main hypertext inconvenient: hyperlinked documents are not lineal and therefore it is very easy to "get lost", or forget to visit a whole set of pages only because some link has not been followed.

Complementary Activities, Tests and Exercises. The units can contain complementary activities proposed by the teacher: multiple choice exercises, concept associations, etc. are classical examples. The student gets automatic feedback, being able to immediately know if the answers he gives are correct or not. These activities are created using the UCM, and consist of a set of predefined activities.

Reports. At any moment users can get reports about how the unit is being used. Teachers can ask for a set of reports about the student activity. For instance, teachers will be able to know all the information about any student activity. Also, students can get reports about their own progress. A complete set of activity reports is available.
All these functions, and obviously asynchronous-synchronous communications, have to be implemented with users identification. But current HTTP protocol is very limited with respect to this topic. Therefore, some of the features needed for the UNM are difficult (or impossible), when standard browsers and servers are used. It can be said that the HTTP is an stateless protocol, that is, every request to the server is treated independently, thus a request has no information of previous related requests. In particular, two consecutive accesses made by some students are not related at all from the server point of view. Moreover, a web browser user does not need to identify itself in order to navigate the web, since an HTTP request carries no information about the user, so the server cannot track users.

Therefore, to add identification and tracking capabilities to the basic HTTP client-server scheme is necessary to make all the above functions possible. Moreover, a major design objective is the UNM portability; that is server and platform are independent, and accessible by standard web browsers. We considered some previous possible solutions which are briefly described in the following:

**Using the standard log files generated by the server.** When a user selects an HTML page link, the browser requests some contents from the HTTP server, (see Figure 1). The server gets and sends the HTML document to the browser. The server keeps several logs for each transfer, but these logs keep only track of content items requested (pages, images, etc.), time, date, the client machine name and IP address. As with most popular operating systems, the use is not identified onto the machine, and the browser does not send any user identification on requests; different users on the same machine generate identical entries into the log file. In this case, whenever different students use the same machine, to keep track of each different student activity is impossible (see Table 1). The server logs only register accesses from the computer, but it is unable to know if they are from a single user or not, and even who is making the requests.

<table>

</tr>
</tbody>
</table>

**Table 1**: standard log file contents

Some entries from a standard log file are showed in the Table 1. Each line represents a request made to the HTTP server. The information shown is relating to the client machine (for instance pcl.udg.es), date, time, the type of request (usually GET), the URL requested (for instance /-usd/Icons/logo.gif). Note that it is impossible to know if requests made from pcl.udg.es (a computers room machine) at 18:00 and 18:15 are from the same user or not. Since standard logs do not save the information that is needed, and they are not a valid solution under our design strategy.

**Modify an existent HTTP server in order to adapt it to the tracking and identification needs.** Most of standard servers have some Application Programmers Interface (API) that would enable to carry out tracking and identification functions. However, the applications produced for a specific server API are rarely usable by a different server. Moreover, APIs link the application code into the server core, hence, a bug in one API-based application can corrupt other applications or the server, or some malicious application could steal security information from the server. Furthermore, APIs are tied to the internal architecture of a particular server, hence, changes on the server also imply changes on the API, and consequently to the applications which are using the API. In [13] a solution based on APIs is proposed, the client is modified, therefore, similar problems are found. This solution was definitely against our design objectives.

**Using Cookies** [14]. Netscape proposed Cookies as a mechanism to enable the server side of an HTTP connection to store and retrieve information on the client side; this task is usually carried out by a CGI process. When returning an HTTP object, the server may also send some state information to the client, this state can be stored. The state information includes the range of URLs for which the state is valid. Hence, any future HTTP request made by the client within this range will include the state information, and thus will be passed back to the server. This allows to carry out an identification information within the HTTP requests. Common practice would suggest using these cookies to carry out state and identification information. We discarded it because cookies are not a standard feature, and need non-standard extensions for clients and servers [12]. Moreover, with most common operating systems and current browsers, cookies on a particular client browser are shared by all users who are using the browser, consequently leading to security and identification problems. Cookies can also be easily disabled, copied, modified or erased. Finally, cookies are stored in the client machine, thus the users, who use different computers to log into the system, finish with different state information on each of these computers. For instance, if a user logged in the system using a different client machine would appear in the system as “new” user, since his previous history is ignored. The method to prevent that problem is storing the state information on the server, cookies cannot serve this purpose.

**Using standard HTML forms** [15]. The forms can contain user identification or any needed state information within hidden variables. The HTML pages that include these forms would be generated dynamically on the server by
CGI programs. When the user pushes the submit button on his browser, these variables are sent back to the server, a
CGI could process the information within the hidden variables, and then generate new forms with the new state
information into the hidden variables. All served pages should be based around an HTML form, and users should
submit them every time they use the application, this is the major limitation of this method. This approach constrains
the format of the pages beyond an acceptable limit, as using normal HTML pages would be impossible.

Client-server application using Java. It would also be possible to build a custom client-server application using the
Java language. In this case, the user downloads the client from a standard browser; from now on the transfer is
carried out using a custom protocol which is designed to support full user identification and tracking. The main
drawback is that Java applications are still very slow and resource-consuming at the present.

In [16] a solution is proposed. The major drawback is that a special dedicated client viewer is needed, which must
be downloaded and installed by the users before they can start the educational process.

4. The Adopted solution: description of the Custom Server

To overcome the drawbacks of those proposals, while standard browsers and HTTP servers can be used, we
propose the utilisation of a CGI compliant program running on the server machine called Custom Server (CS). This
approach uses any standard HTML browser running on the local (client) machine and any standard HTTP server
running on the remote (server) machine, which support CGIs (see Figure 2). The contents (i.e. the pages including
images and Java applets) is written in the HTML format, therefore, any standard editing tool can be used.

The CS is placed between the standard HTTP server and the contents. Consequently, the requested HTML
documents are not directly provided by the HTTP server. The information is adequately conformed by the CS by
inserting user identification within hypertext links, and redirecting them again to the CS.

In general, the modification of URLs pointing to local HTML files is needed. Note that not all local URLs need to
be transformed; most images (and other contents items like Java applets, etc.) do not need to be tracked, hence their
URLs are not modified. Therefore, the HTTP server must also be able to access the contents without passing through
the CS.

The contents is stored as HTML pages with “normal” links, and the CS is responsible for the customisation of
these pages before they are served according to each user, meanwhile storing information about his navigation steps.
Each single page request passes through the CS, thus the CS is able to have a entire control on the accesses
mechanism. Any necessary information can be computed, stored and then retrieved at any time.

To store all of this state information about users, the CS maintains a database that overcomes the lacking of default
log system which is offered by the Standard HTTP Server. This database includes not only the accessed pages and
from which remote machine, but also the information needed to track the user navigation, i.e. which users log into the
system, what materials he has accessed, how many times, how much time he spent on it, the responses to proposed
tests or exercises, the last pages accessed, etc.

The creation of HTML reports containing the information stored into the database is an important function of the
CS. Several reports that users and teachers may need can be easily implemented from this database. Finally, the CS is
responsible for another UNM functionality, that is: FAQ accessing and FAQ maintenance, control of working
documents, asynchronous and synchronous communications, etc. All of these functions are implemented in the CS.
4.1 The identification process

At the moment of starting the connection, by opening the entry URL [17] using any browser, the user is faced with a login dialogue where, by entering login and the password, he is identified. Without completing this process, the user will not be authorised to use the units on the teaching support system.

The above login procedure has three main purposes: a) to prevent unauthorised users to access the units, b) to be able to identify single users in order to keep track of them when using the units, and customise the context if needed, and c) to be able to distinguish between user categories. The units can behave differently according to the privileges of the user. Some user categories may have access to features others would not.

Related to the third purpose, there are four user categories: Supervisor, Teachers, Students and Guests. The Supervisor acts as the system manager, therefore he has the entire control over the UNM functions. He is also the responsible for assigning login and password to new users, install the units and keep the system running. The teachers have full access to the units, and they can control and supervise their own ones. The students can fully navigate contents of the units and make use of all features that the teacher have prepared for them; but they only can control and supervise their own personal information. Finally, guests have limited access to some units contents, according to the teachers' criteria.

The description of how the identification process is implemented, is explained by an example in the following. First, a user has just entered the login (Enrique) and password (K3db21) on the initial identification page, that is made in a HTML form. By clicking the submit button, the following URL is requested to the remote HTTP server:

When the HTTP server gets this request, the Custom Server CGI program (CS.CGI) is invoked. Three parameters (after the “?” and separated by “&” chars) are passed to the CGI on the URL. The first parameter (“Function=ID”) informs the Custom Server about an identification request. The second parameter identifies the user requesting the page, and the third parameter is the name of the page requested.

4.2 Inserting user identification within hypertext links

The CS must check this login and password in the database. If this is correct, the CS gets the default root page from the contents. Before passing the page to the HTTP server, which will serve it to the browser, the local URLs are customised as is shown in the following. Suppose the starting (root) page contains the following HTML expression:

\(<A \text{HREF= } "subject1.html" \text{ >SUBJECT 1</A}>\)

then the CS explores the HTML source to locate such a local URL, which is transformed to:

\(<A \text{HREF= } "http://eia.udg.es/~usd/CS.CGI? Function=PR& User=Enrique& URL=subject1.html" \text{ >SUBJECT 1</A}>\)

The served page has the modified URL containing the user identification. After some time the user may click on that link, then a new request is passed to the Custom Server. In this case, the value of the function parameter is “PR”, that is a page request, the second parameter identifies the user requesting the page, and the third parameter is the name of the page requested.

The CS gets the desired page (subject1.html) from the contents pool, and customises this page in the same manner as before. Subsequently, the CS passes the modified page to the server which actually delivers it to the browser. The CS also reflects on the database that this user is getting this page, and any other needed information.

To simplify this presentation, aspects as parameters encryption to avoid security problems, or questions related to more complex URLs, are omitted. In the current implementation, parameters passed to the CGI are encrypted. URLs contain security information to avoid URL copying and pasting into other browsers that could lead to several problems. The encryption algorithm contains time-out information, hence URLs expire after a reasonable amount of time. It also contains information about the client machine. Consequently, copying URLs from one browser to another on a different machine, the mechanism does not work as desired. Finally, a “request-sequence” information is also used, hence, copying the URL to another browser on the same machine will also fail, preventing the user from “parallel navigation” which could confuse Custom Server.

4.3 Database management and HTML Report documents

By the user identification, the Custom Server can maintain a database that overcomes the stateless nature of the HTTP protocol. The database consists of a set of log files, similar to the standard HTTP-server log files, but also storing the complementary user information. Mainly, a general log file where users login and logout are stored; but
another particular log file associated with each user is also maintained. In this case, the requested pages and the time spent are saved.

The contents of general log file (Table 2), and user Enrique’s log file (Table 3) are described in the following.

<table>
<thead>
<tr>
<th>Date</th>
<th>Time</th>
<th>Action and Username</th>
<th>Client Machine</th>
</tr>
</thead>
</table>

Table 2: Custom log file contents

<table>
<thead>
<tr>
<th>Requested HTML-document</th>
<th>time spent in seconds</th>
</tr>
</thead>
<tbody>
<tr>
<td>*Unidad: LES XARXES DE COMUNICACIONS I LA INFORMATICA</td>
<td></td>
</tr>
<tr>
<td>teleinfo/index.html</td>
<td>9 (00:00:09)</td>
</tr>
<tr>
<td>teleinfo@percusions/comunicacio.html</td>
<td>227 (00:03:47)</td>
</tr>
<tr>
<td>teleinfo/index.html</td>
<td>330 (00:05:30)</td>
</tr>
</tbody>
</table>

Table 3: One session tracking information.

The Custom Server analyses these files and translates the information into HTML reports. By consulting these reports, both teachers and students may be able to evaluate how the materials are being used, and to improve the teaching-learning process. In [12] a similar solution is proposed for similar objectives. But, since all state variables are embedded into the URL, the state cannot be preserved between different sessions at the application level.

5. CONCLUSIONS AND FUTURE WORK

In this paper, a solution to the user tracking and identification upon an educational web environment is proposed. This approach is implemented into a wide project that needs to keep complete track of users who access to a set of contents published on the net. This approach is relatively easy to implement, it also gives enough flexibility and it is compatible with any standard HTML web browsers and HTTP servers.

This is a work in progress, consequently, some parts are still being implemented. Therefore, some above aspects may change in the future, new functionality may be added, like new reports, according to the suggestions of the actual users. The adopted solution gives sufficient flexibility to adapt the platform to future needs.

Abstract: It is very important task for a student to compare problems in exercises. To design the learning support system which assists novices to compare two problems, it is necessary to define a problem representation and control the comparisons by using the representation. In this paper, we described a method to compare between two problems based on the U-behavior which is a representation for simple recursive programs and we described facilities of comparing between problems which are (a) generating explanation of differences and similarities between two problems, (b) searching problems for comparisons, and (c) generating exercises of grouping problems. And we have also described implementation of a learning support system which helps a student to compare between two problems. Finally, we described an experimental evaluation of the facilities.

1. Introduction

Novices can't solve a problem no matter how similar problem they have solved. One reason is that they understand a solving depends on the problem. They don't understand it as a strategy can be used for many problems. In this case, it is very important to provide them with not only instructions about each problem but also with instructions regarding similarities and differences between problems.

In educational situations, comparing problems is very popular. Polya made a representation for comparing problems [Polya 54], and Hirashima proposed a model of mechanical problems based on the process of problem solving [Hirashima 94]. In this paper, we designed functions for guiding novices in understanding similarities and differences between two problems in learning recursive programming by using a description of program behavior. Our system aims to help students, who have learned a programming language, to learn a behavior of recursive programs. And it also provides with a programming exercise. The functions we designed are required by such a system.

Most studies of programming instructional systems assist novices to solve a problem [Timothy 92][Ueno 94][Itoh 94]. They implicitly deal with comparing problems. We have already proposed a description of a recursive program behavior and a solution for novices to write recursive programs. We called them U-behavior and U-solution. And we confirmed the effectiveness of the U-solution in an experiment which compared it with a programming textbook.

Programming instruction requires an explanation about specifications and about behaviors of programs. But recursive programming is very difficult for novice programmers to understand a behavior of a recursive program. One reason is that there are differences between the order of statements and the order of the execution of those statements. In this paper, we discuss an instructional system which assists novices in understanding and designing the behavior of recursive programs.

We have already proposed a representation of behavior of simple recursive programs [Matsuda 95]. The U-behavior is representation for recursive algorithm and The U-solution is a procedure for novices to make simple recursive programs with the U-behavior. In this paper, we described a method of comparing between two problems based on the U-behavior and facilities of comparing between problems which are (a) generating explanations of differences and similarities between two problems, (b) searching a problem for novices in order to compare problems, and (c) generating exercises of grouping problems. The system goal is that novices understand the U-solution. We have also described implementation of a learning support system which helps a novice to compare between two problems. Finally, we described an experimental evaluation of the facilities.
2. A representation for recursive programs

This section discusses the U-behavior and the U-solution which help novices understand and design a simple recursive program.

2.1. U-solution

A number of simple programs (or program specifications) have a common structure; we have derived the common structure from some programs to use the structure as a template. To describe the recursive algorithm, we have identified 4 components of the simple recursive program. We currently deal with simple recursive programs which include one recursive call, and one terminating condition for recursion. For example, Figure 1 is the U-behavior of the factorial program. Factorial is the product of all the positive integers from 1 to a given number.

The first component is the statements which are above the recursive call are repeatedly executed. In this case, the subtraction is repeatedly executed (Figure 1(1)). We call it Pre-recursion sub-procedure. The second component is condition to terminate the recursive call. This condition must be placed before the recursive call. In this case, the terminating condition is that the input data is equal to zero (Figure 1(2)). We call it Terminating Condition. The third component is the initialization of return value when the recursive call terminates. In this case, the initialization is to set output data one (Figure 1(3)). We call it Return Value Initialization. The last component is the statements which are after the recursive call are repeatedly executed (Figure 1(4)). In this case, the multiplication process is repeatedly executed. We call it Post-recursion sub-procedure.

2.2. The U-solution

The U-solution has following three steps:

1. Novices fill in parts in the U-template to complete the U-behavior from a program specification.
2. Novices check the U-behavior. (They can use the algorithm visualization tool(Figure 3).)
3. Novices fill in parts in the program template to complete the recursive program from the U-behavior.

The U-template consists of four blanks. Novices can fill in four parts in the U-template to write the U-behavior. Currently we prepare the U-templates and parts for Prolog and C.

3. Facilities of comparing two problems

We described the system which assists the novice programmer to learn recursive programming. Especially, we described the facilities of providing novices with the differences and similarities. We realized the learning support system with the U-behavior. The U-behavior is a representation for recursive programming problems.

3.1 Representation for the differences and similarities between problems

We used the U-behavior as a representation of a problem. The U-behavior consists of four parts. The similarities are represented with parts which are common in two U-behaviors and the differences are represented with parts which are different in two U-behaviors.

Figure 2 shows an example of representing similarities and differences between the append program and the reverse program.
verse program. Append program is to connect two input lists and Reverse program is to reverse the order of the input list. The similarities of these U-behaviors are to eliminate the first element in the first input list until the list becomes the empty list, then keep the second list, and to combine the element with the output list. The difference of these U-behaviors is the time of combining the element with a list. The append program combines the element at Post-recursion Sub-procedure. The reverse program combines the element at Pre-recursion Sub-procedure. These similarities and differences between two U-behaviors can be represented with parts of U-behavior.

3.2 Facilities to compare problems

We designed the facilities to compare problems based on the U-behavior. The facilities are (1) generating explanations about differences and similarities between two problems, (2) searching problems for comparisons, and (3) generating exercises of grouping problems.

3.2.1 Facilities to generate explanations about differences and similarities

The basic facilities in the exercise to support comparing problems is generating explanations about differences and similarities of problems. Our system automatically provides text and animations for explanation. The text and animations are generated by parts of the U-behavior.

First, we described the method to generate a text for explanation. The system generates a text to combine a text of a program specification and a text of a U-behavior part which is written by expert (programming teacher). To combine two text, the system uses a text template. Text for similarities is combined the text template with text of parts which are the same in the two U-behaviors. Text for differences is combined the text template with text of parts which are the different part in the two U-behaviors.

Figure 2 (C) shows the example of the representation for similarities and differences between the append program and the reverse program. To generate a text, the system combines a template with text of these parts. Text of a U-behavior for the append program is "The 1st Input List was eliminated the first element by a element until it was the empty list. The 2nd Input List was not changed. When recursive process terminated, the Output List was initialized the 2nd Input List. The Output List was added the element as new 1st element from the lst Input List." The underline shows text for parts of the U-behavior. Text of a U-behavior for the reverse program is "The 1st Input List was eliminated the first element by a element until it was the empty list. The 2nd Input List was added the element as new 1st element from the lst Input List. When recursive process terminated, the Output List was initialized the 2nd Input List." Text for differences between them is "The 1st Input List was eliminated the first element by a element until it was the empty list. When recursive process terminated, the Output List was initialized the 2nd Input List." Text for differ-

![Diagram](attachment:image.png)
ences between them is "In the append program: at the Pre-recursion Sub-procedure, the 2nd_Input_List was not changed, and at the Post-recursion Sub-procedure, the Output_List was added the element as new 1st element from the 1st_Input_List. In the reverse program: at the Pre-recursion Sub-procedure, the 2nd_Input_List was added the element as new 1st element from the 1st_Input_List, and at the Post-recursion Sub-procedure, the Output_List was not changed." Furthermore, the system provides text of program specifications which is written by experts in order to explain the references between the U-behavior and a program specification. A specification of the append program is "The Output_List is made to connect the 1st_Input_List and the 2nd_Input_List." And a specification of the reverse program is "The Output_List is made to reverse the order of the 1st_Input_List, and connect the list and the 2nd_Input_List."

Next, we described the method to explain with animation of the U-behavior. The U-behavior is representation for the behavior of recursive program. Then, Animation is very effective representation for novices to understand the U-behavior. Figure 3 show the example of explaining with animation of the U-behavior. In Figure 3, the downward movement of The 1st_Input_List represents the process of eliminating the first element form the 1st_Input_List. Hence, the 1st_Input_List divided in two lists, the first element moved the right, the rest of the list moved downward. In the append program, the first element of the 1st_Input_List which moved the right is added to the Output_List by the glove icon. In the reverse program, the first element of the 1st_Input_List which moved the right is added to the 2nd_Input_List by the glove icon. Therefore, the difference of the location for the glove icon shows the time when the first element was added to the list. And these animations specified the difference of the order of the Output_List. The effectiveness of these explanation based on the U-behavior specifies the U-behavior as the representation for problem to compare problems. We described it in section 4.

3.2.2 The facility to search a problem

Our system has two searching conditions which are divided by the contents of explanation.

(A-1) Explanations for parts of the U-behavior

The system selects a problems Ps in order to explain the role and behavior of the U-behavior parts b through comparing with the problem Po. In this case, the condition to find the problem Ps is that the problem Ps has the part b and the problem Ps has more same parts which are included in the problem Po than any other problems.

(A-2) Explanations for types of U-behavior parts

The system selects a problem Ps in order to explain the role of the type t of parts through comparing with the problem Po. In this case, the condition to find the problem Ps is that the problem Ps has a different part in type t from the

</table>

problem Po and the problem Ps has more same parts which are included in the problem Po except the type t than any other problems.

And the system has two situations which divided by the problems for searching.

**B-1 Searching a problem for example**

The system searches problems which novices solved. In this case, the problem which are found was provided novices as an example.

**B-2 Searching a problem which novices should solve as next problem**

The system searches problems which novices didn't solve. In this case, the problem which are found was provided novices as next problem.

The system searches for all problems which satisfy the condition. If the result of searching is two more problems, we need the condition for conflict resolution. The condition in our system is that the problem has more parts which are experienced many times in exercises than any other problems in different parts between the problems. To find a problem which satisfy this condition, we use the evaluation value which shows how many times a novice used a part of the U-behavior in his/her exercise. Table 1 shows the evaluation value by experienced times. When the same part between two problems, the value is the highest 1. When the different part between two problems, the value is in the rage of 0<v<1, and when the part is the first time in exercise for a novice, the value v is 0.

We specified an example of explanation for part II of Return Value Initialization by comparing the append program. The system searches for a experienced problem. Hence, this example is (A-1)(B-1). In this example, a novice solved problems shown Table 2. First, the system retrieved problems which includes the part II are the last, the append and the append_del program. Next, searches the program which has more same parts from the reverse program. In this case, the append program was retrieved as an example problem.

3.3.3 The facilities to generate the grouping problem

To help novices understanding the U-behavior, it is very important to learn the similarities and differences between two problems. Our system provides novices with the grouping problem. In grouping problem, the system provides novices with the figure of grouping programs, and novices put a given program into appropriate group. When novices put a program into groups, they must consider the similarities and differences between a given program and programs in groups. We can expect novices to learn the role of parts and the type of parts through solving the problem.

To generate the grouping problem, the system select a program at random and make a figure of grouping problem with the rest of the program. Next, the system decide the order of the type of parts. For novices can group programs any order of the type, the system decide the order at random. And programs which have the same parts at the first type in the order belong to a group.

4. An Experimental evaluation

To evaluate the method to generate an explanation based on the U-behavior, we held an experiment. In our experi-
Virtual Reality Hypermedia Design Frameworks for Science Instruction

Abstract: This paper develops a framework to categorize virtual reality applications in science education. Examined are the implications of VR in science instruction, components to integrate VR into hypermedia presentations, and considerations when utilizing VR in classroom settings. The framework explores methodologies for the processing, collection, examination, classification and presentation of multimedia information within hyperlinked virtual reality environments. The analysis is intended to help assess whether children can use VR to supplement their traditional education and learn concepts in science.

1. Introduction

This study conceptualizes a research framework to aid software design and development for virtual reality computer applications for instruction in the sciences. The framework will provide methodologies for the processing, collection, examination, classification and presentation of multimedia information within hyperlinked virtual reality environments. Referenced are traditional teaching and virtual reality instruction. The analysis will also provide a framework to help assess whether children can use VR to supplement their traditional education and learn concepts in science. The framework will thereby help justify VR instruction as a viable supplement for standard teaching methods in science.

2. Virtual Reality Environments

Virtual Reality (VR) is a new way to use computers. It offers the possibility of becoming immersed in, and interacting with, a computer-based environment that engages visual, auditory, and tactile perceptions. It features a "high-end interface" that involves real time simulations and interactions through multiple sensory channels [Mikropoulis 1996]. Virtual reality is currently in the very early stages of development, but has the potential to be a highly effective method for training people who learn and remember best by doing. The two most popular environments are immersive VR and VRML.

2.1 Immersive Virtual Reality

Virtual Reality is currently used to describe an extensive gamut of technologies. Within the genre are semantic and technical breakdowns--including virtual reality, artificial reality, and cyberspace [Helsel 1992]. Herein, we will specifically focus on the technology of virtual reality and its commonly associated characteristics. From a technological standpoint, virtual reality may be defined as a form of human-computer interface characterized by an environmental simulation controlled in part by the user [Springer 1991]. Virtual reality typically features hardware and software that furnish a sense of: (a) inclusion or immersion, (b) navigation, and (c) manipulation [Mikropoulis 1996]. In a comprehensive implementation, a virtual reality...
configuration consists of a head-mounted display, a data-glove, and a tracking device. The viewer wears the head-mounted display that contains sensors to track the position of three-dimensional coordinates of the head as it moves. The data-glove provides hands-on interaction within the virtual world by registering finger and hand gestures using fiber-optic cables that act as sensors to detect the flexing of fingers. Electromagnetic sensors then report the positions of the goggles and glove. The computer calculates what the artificial world looks like from those angles, draws it in 3-D, and shows it on the LCD screens mounted in the headset in front of the user's eyes.

2.2 Virtual Reality Modeling Language (VRML)

Simpler VR implementations mimic the immersion effect and VR hardware to enable user navigation through a 3D world simulated on a 2D computer screen. Navigational and interactive capabilities are essentially the same, albeit the sense of immersion is partial. Still, for instructional applications the designs and objectives are essentially the same. Limited immersion VR is currently being popularized in non-immersive arcade-style computer games, and in advances with the VRML computer language for creating VR on the World Wide Web. Technically, VRML is a universal description language designed to support 3-dimensional environments on the WWW—complete with multi-participant interaction, and real-time user defined simulation [Ames, Nadeau & Moreland 1996]. As such, it provides a WWW-based VR user-interface to online media. VRML is used to create virtual reality environments (worlds), which are networked through the Internet, and reside as an application or functionality atop the WWW. These environments are fully compatible with the hypermedia linkages characteristic of Web interactions. VRML specifies all aspects of virtual world display, interaction and internetworking.

The technology consists of a language specification and a software browser—which is generally integrated into other Web browsers to form a comprehensive utility. In perspective, HTML describes documents and their layout in two-dimensional space, while VRML describes three-dimensional environments and their interactive capabilities [Maule 1997]. The specification provides for worlds with multiple levels of detail, dependent on the chosen rendering resolution of the user, and the display capabilities of the browser. As a graphics composition language, it enables a structured display to be composed on the screen from a number of items, each of which may be local or remote. Elements may be identified by their network, local, or URL addresses. If properly cached, operations are quite rapid since screen refreshes only invoke a reissuance of the specifications—which the machine would draw using its internal capabilities (as opposed to downloading images). [Note that this is similar to Postscript wherein a description language alleviates the need for the loading of bitmaps, with the output devices than able to process and represent the data to the ability of that particular system.]

VRML 1.0 adopted the Open Inventor file format from Silicon Graphics (SGI) for its ability to support complete descriptions of 3D scenes with polygonal rendered objects, lighting, materials, ambient properties, and realism effects. Extensions to support networking were added and became the basis for VRML. The VRML file format was then released into the public domain. As such, VRML is not an extension to HTML, but is compatible with HTML, and in typical applications both HTML and VRML will exist. Generally, VRML requires more finely tuned network optimizations than HTML, is composed of many more inline objects, and involves many more servers than typical HTML documents. The VRML 1.0 specification enables the creation of virtual worlds with interactive behavior via objects with hyperlinks to other worlds, HTML documents, or other valid MIME types. When the user selects an object with a hyperlink, the appropriate MIME viewer or display routine is launched. Similarly, when the user selects a link to a VRML document from within a correctly configured WWW browser, a VRML viewer is launched or routine activated. Thus, VRML viewers are designed to be integrated into standard WWW browsing as a means for navigating and visualizing the Web. Evolving versions of VRML, and compatible software developed by independent programmers, support animation, motion physics, and real-time multiplayer interaction.

The Moving Worlds standard, developed by Silicon Graphics, with important contributions from Sony Research and Mitra, became the VRML 2.0 specification in March of 1996. Moving Worlds is an event- or message-passing system dependent on a scripting language, such as Java or JavaScript. Because Moving Worlds is simply a file format, other languages can also be used. It uses a platform-neutral open architecture and file format to support the 3D animation, behaviors, and interactivity. VRML 2.0 also accommodates
dynamic object behaviors, multiuser interaction, and multimedia components such as animation, sound, and streaming video. In operation, VRML 2.0 navigation within the virtual spaces is through a mouse, trackball and/or joystick. Control keys can be used to provide more advanced navigation. When encountering an interactive object the cursor changes to a hand symbol to provide the user with the capability to grab the object. Joysticks provide additional tilt and turn controls. A SeekTool is to enable quick and easy movement toward a selected target. Of course, the display and interactive capabilities depend on the hardware and software components available to the user. The better the equipment, the better the graphics and interactivity.

3. VR Science Instructional Designs

Science has been defined as a way of “knowing”—a derivative of the Latin scientia, meaning "to know, or having knowledge." One acquires knowledge through various intellectual activities concerned with the physical world and its phenomenon." Even more essential than knowing about the physical world is the curiosity, the urge to discover, and the need to know that motivates students to pursue knowledge and seek truth. Science education is thereby discovery learning, the teaching of meta-reasoning, with emphasis on the intuitive perspective. Selected topics generally reflect fundamental problems, and fundamental concepts in biology, physics, chemistry and earth science. VR may ultimately be the most natural artificial interface to discovery learning.

3.1 Science Instruction

Many nations are at a crisis stage in science education. Students are graduating from high school with limited knowledge in science, and little understanding of the application of science in the real world. In the U.S., the science abilities of elementary and secondary students has been declining for several decades [ETS 1988]. Internationally, in a survey of 17 countries, the United States was ranked near the bottom in achievement in science and math [IAEEA 1988]. Many believe this inexperience with science may have negative impacts on society. Nations are either directly or indirectly impacted by the astuteness of their citizens in science. Modern societies demand technically literate, informed, involved and proactive citizens. Organizations are dependent on workers for their ability to understand scientific concepts. Without an educated public, politicians and voters will make their decisions based on ignorance, or an unhealthy reliance on others to make their decisions for them. In the U.S., the National Commission on Excellence in Education argues that a scientifically literate public is essential for the United States to remain economically competitive in the world market [NCEE 1984].

A major problem faced in science education results from the way science is taught through rote learning and memorization. In many instructional settings, students acquire only "facts" rather than "tools" for problem solving. They do not experience the kinds of problems that make information relevant and useful, so they do not understand the value of this information [Bransford, Sherwood, Hasselbring, Kinzer & Williams 1990]. Thus, many students consider that science is boring, irrelevant, or a fragmented collection of knowledge. VR technology may help.

3.2 VR and Science

Educators are slowly becoming exposed to the theories and ideas of constructivist philosophy, which emphasizes building children's own categories of thought about the world and encouraging students to construct their own knowledge. "Virtual worlds" are constructive environments in which participants can create, manipulate and edit any form of digital information. Objects, processes and programmed inhabitants of the "virtual worlds" are elements for active problem solving. Thus, virtual reality programming can be used to facilitate an awareness of problems and encourage the personal seeking of solutions. Students can develop important science-process skills rather than just rote learning. Virtual reality curricula may engage students experientially in scientific investigation and application. Students may participate in responsive
environments in which they become engaged in full body-mind kinesthetic learning. Studies have shown that students and users are able to benefit when given the capability to shape their personal learning environments [Maule 1991]. Ideally, such learning may combine cognitive, affective, and psychomotor skills as students pursue their own learning strategies [Walser 1990].

Investigations into the potential of virtual reality to enhance children's learning of science may have far-reaching consequences. VR instructional designs can provide structures to help ascertain whether or not critical multimedia variables in virtual reality programming are effective in the learning and teaching of specific science concepts. Through this testing and analysis, important information design variables appropriate for virtual reality programming may be documented. Collectively, these variables, consisting of information designs, systems and processes, will provide critical insight into the potential for multimedia virtual reality programming to improve children's achievement, interest and motivation in science.

4.0 VR Hypermedia Component Integration Frameworks

There is certainly no substitute for actually performing scientific experiments in real world and laboratory settings. Of course, the time, money, technology and expertise for real world science is rarely available, especially at an elementary school level. Students generally experience textbook explanations and examples. The increasing availability of computers and the Internet in elementary school classrooms means that VR and VRML resources may be a viable supplement to traditional textbook instruction. They may experience science more safely, in less time, and with less expense than field or laboratory work.

4.1 VR and Classroom Integration

Virtual reality systems will provide a less formal experience than a true laboratory or field trip, but they may be equally fun, and certainly more "realistic" than mere pictures in a textbook when considering the wealth of experiences that may be generated. As learners begin to work, study and communicate in virtual environments, whether singularly or collectively (through computer networks), they learn not only the subject matter, but new ways of thinking and structuring information [Maule 1992, 1993]. The customization and interactivity may permit users to shape their interpersonal and collaborative electronic experiences. Stand-alone and networked virtual reality technologies thereby offer the potential to not only change the way students learn, but also the way teachers teach and interact with technology [Wolsey 1996].

4.2 VR and Learning Objectives

In the past, the costs of virtual reality technology limited use to specialized fields of research and study—such as those found in higher education and corporate and military training. Today, VR technology is finding its place in public elementary schools. The learning objectives of VR are becoming adopted by school systems and standardized [Pantelidis 1996]. In one of the first research studies on K-12 virtual reality applications, Sherman and Judkins [Sherman & Judkins 1992] studied virtual reality in educational curricula for five groups of children, aged 9 to 15. The children were able to design and create virtual worlds of their own. Although technical assistance came from the HITLab at the University of Washington, initial predications actually underestimated the children's ability to understand and assimilate the virtual reality technology. Children worked cooperatively and collaboratively. Moreover, they were highly motivated. Children completed the project, plus, they learned programming, networking and design. The technology had a short learning curve, and children could easily retrace their steps. This was a very successful educational program for both teachers and students.

4.3 VR and Hypermedia Components
Studies have not fully researched information designs for virtual interaction, nor the interplay among highly complex media variables. Studies of media interactivity within programmed environments have generally isolated and tested simple, controllable variables [Maule 1991]. Virtual reality presents highly complex interactions. While complex authoring environments have been tested for their impact on learning and perception [Maule, Gregg & Petry 1991], the impact of complex multimedia within virtual environments, and issues stemming from information designs for complex multimedia learning systems, have not been adequately addressed [Maule 1994]. Frameworks are needed to structure variables to help determine the overall effectiveness of the virtual reality instructional experiences.

Previous studies have drawn insight from working applications of VR in education [Pantelidis 1994]. From the integration of traditional instructional objectives, and VR capabilities, primary content design initiatives may be drawn to address the integration of the media components—including the graphic, video, audio, and animation elements, and the linkages between the media. Linkages, and the arrangement of media, then become the design framework for the instructional objectives. For purposes of analysis, the following schema has been developed to represent primary media and instructional design variables for science instruction in hyperlinked virtual reality:

- **VR Collection Variables**: psychomotor skills (explore, navigate, look, manipulate)
- **VR Examination Variables**: cognitive skills (assess, determine, calculate)
- **VR Classification Variables**: spatial skills (arrange, sort, structure, inference)
- **VR Processing Variables**: affective skills (interact, feel, associate, participate)
- **VR Presentation Variables**: interactive skills (links, relationships, associations)

The VR evaluation variables would then determine the degree to which the above schema accurately convey the needed information and deliver the appropriate learning experience. Secondary assessment would address the effectiveness of pertinent information design and multimedia interaction variables. The virtual reality programs may use hypermedia branching to customize and target both advanced and disadvantaged students. For example, it may be relatively easy to develop applications for above average students because they may have an easier time comprehending the subject matter. It is more difficult to develop a program for the average learner or uninitiated learner who may have difficulty concentrating. Multiple testing formats may determine if motivation has increased for each level of interaction, for each individual student, and for each class of student. Knowledge retention may be tested cumulatively with each interaction.

### 5. Conclusions

In anticipation of the widespread availability of virtual reality technology, frameworks are needed to help structure VR and hypermedia designs to enhance the experience of children learning science. Secondary issues would involve the effectiveness of the virtual reality teaching process, supporting VR information design issues, and the interactions of complex media variables which may not be available in traditional teaching. Hopefully, VR instructional designs will demonstrate that the knowledge acquired from interactive, virtual reality experiences will enable children to retain knowledge and appreciate the importance of science. This will occur as children “live” the experience. Moreover, different levels of learning may be programmed into the environments. Further frameworks can be developed to help structure the branching necessary to provide different levels of science to different levels of students.

On Two Aspects of Improving Web-Based Training

Hermann Maurer
Graz University of Technology, IICM, Schießstattgasse 4a, A-8010 Graz, Austria
hmaurer@iicm.edu

Abstract: In this paper we discuss two ideas that might help to improve teaching in certain situations, and could also provide better means for information transfer between persons in general. The first aspect is centered around proposing to use the "Tamagotchi craze" for teaching purposes, the second deals with new ways of unobtrusively collecting data on the subjective satisfaction of persons with information and teaching material offered on the Web.

1. Harnessing the Tamagotchi Craze

The Tamagotchi craze that started in 1997 has driven many kids, teachers and parents to the brink of desperation. An estimated 20 million Tamagotchis or clones thereof were sold within one year, resulting in hundred millions of hours spent on keeping the virtual beings happy. It is the aim of the first part of this paper to propose to harness the appeal of caring for such virtual beings for teaching and training purposes: rather than taking care of Tamagotchis by "feeding", "cleaning" and "entertaining" them we propose to implement what we call VR-Friends (virtual friends) that differ in three crucial ways from traditional Tamagotchis: (i) they are kept happy if their owners answer questions correctly; (ii) they are implemented in software, not hardware and (iii) they live on the Web, in WWW servers. In a way, VR-Friends can be considered to be special types of Avatars [Damer 1998] (as often mentioned in connection with VR games), or intelligent agents ([Riecken 1994], [Maes 1994]).

Psychologists have not been able yet to fathom the real reason why Tamagotchis have been successful in such an unprecedented way. But no matter what the explanation is, it seems worthwhile to exploit what are seen as major reasons for the success for the education of primary and secondary school children.

1.1 Introduction

VR-Friends are implemented as programs that run on WWW servers and can be accessed by ordinary Web browsers from e.g. Netscape or Microsoft. They come in various behavioral and knowledge domain classes in the sense that they act as instructional agents for different ages and subject matters. Their success as "teachers" is assumed to come from the fact that they are seen as live beings that thrive only if continually "fed" with correct answers to questions they keep asking. I.e. VR-Friends want to "learn" and in doing so - it is actually their owners that learn!

In what follows we present the basic ideas of how such VR-Friends will work. We do this in three subsections. In section 1.2 we describe a typical scenario. In section 1.3 we explain the main implementational aspects. And in section 1.4 we argue why VR-Friends have indeed a chance to be successful yet why they may fail, and what practical use and further developments might look like.

1.2 A Typical Scenario

So far, twelve year old Mark has shown very little interest in learning basic geographical facts: Although the importance of factual knowledge and rote memorizing has been much challenged by educationalists over the last few decades there is still a wide-spread feeling that some basic facts have to be stored inside our brain (rather than on easily accessible storage devices) as basis for "associative" and "intuitive" thinking.

*) An earlier version of this paper has appeared in the Journal of Universal Computer Science 3, 10, (1997), 1126-1132.
To improve Mark's performance and following a counselor's recommendation, the geography teacher has activated an appropriate (i.e. certain level of geography) VR-Friend on the school's Web server. Mark has chosen the name Nick and certain features (like a special T-shirt and trousers) for his VR-Friend Nick when first logging in. Now, whenever Mark logs in on the school server for whatever activities the first thing Mark sees is Nick. Nick's appearance, his attitude, and what he says (yes, Nick might be able to talk in certain situations) depends on Mark's past performance and on how much Mark has "cared for" Nick. Sometimes Nick will be smiling, "Hey, great you are looking me up again", or may be sulky or even tearful ("You are really neglecting me"). Overall, if Nick is treated well he stays healthy, becomes more and more friendly, will show Mark a cartoon, a joke, or tell him some tidbits (e.g. pointing him to an interesting URL on the Web, see section 1.3); otherwise, Nick will look more and more sick, he will sit in a sad posture (potentially in a not so good-looking neighborhood) and, if seriously "neglected" will actually die. On the other hand, if Mark learns well (treats Nick well), Nick will eventually congratulate Mark and tell him that he has to move on, but will stay in contact with him: and Nick will once in a while (with a decreasing tendency) briefly show up when Mark logs in, tell him some tidbits, and disappear again. Note that Mark may have a growing number of VR-Friends that way, that entertain Mark a bit here and there as he does other Web stuff.

The actual heart of the conversation between Mark and Nick (who was after all created to teach some geographic facts) consists of questions asked by Nick that have to be answered by Mark. (Mark can exit "no time right now" any time he wants). A typical "geography" VR-friend may help the student (Mark) to learn about the location of cities, countries, etc. on the globe. Questions that Nick might ask are "show me the location of xxx" (where xxx is a city, a country, a mountain, etc.) Mark's reaction is to click at the right place on the globe or map shown. The system is very patient: if Mark clicks on Antarctica when asked for the location of Vienna, the system (NOT Nick) will explain that this is Antarctica, some facts about it, and will show the real location of Vienna and information on it and Austria. However, the system records the information ("Vienna, totally wrong") in such case. A second totally wrong answer to Vienna's location would give a somewhat more stern reply to Mark, and the system would record again ("Vienna, totally wrong"). A third complete failure of Mark would result in the system storing ("just fooling around"), etc. Thus, the system basically records for each session between Mark and Nick five numbers (a,b,c,d,t). Here a is the number of correct answers, b the number of totally wrong answers, c the number of approximately correct answers, d the number of times Mark just seems to have been fooling around; t is the point of time when the session takes place. The "development" of Nick depends on how often and lengthy sessions between Mark and Nick take place; it is up to the teacher to set parameters like: "at least one session with 10 questions every second school day and all questions answered correctly twice within a total of three months".

Above is clearly just one typical scenario. Other questions (requiring e.g. text input or such) are of course conceivable. Finally, Nick has always some surprises "up his sleeve": like instead of VR-Nick appearing, Mark finds a sign "Out right now. Back in 2 minutes", or finds some other VR-Friend, etc.

The main point is that although Nick forces Mark to learn (unless Mark accepts that Nick deteriorates rather than prospers) this learning is fun and full of surprises.

1.3 The Implementation

The main idea of the implementation is to have two completely separate modules called development and learning.

The learning module is clearly domain dependent, i.e. differs from subject to subject and takes the age of the learner into account. However, learning modules are created readily with teaching wizards: the most simple form of a teaching wizard just helps preparing problems as follows: each problem consists of a question and possibly a picture (image), and the answer is a click in a certain position, where a click is recorded as "correct", "close" or "wrong" dependent on how far from the current position the clock occurs. Note that the system will keep track of "close" or "wrong" answers to be able to decide if a student is seriously trying or just fooling around. Other teaching wizards that e.g. allow textual answers can also be used.

The main point is that the teaching module communicates to the development module only five numbers (a,b,c,d,t) as explained in section 1. The reaction of the VR-Friend as carried out by the development module only depends on the sequence of "answer-quintuples"(a,b,c,d,t) obtained. To keep the system simple there is no substantive data-flow from the development module to the teaching module.

Depending on the answer-quintuples the state of the VR-Friend (and hence its appearance and utterances) within the development module are changing. A random element makes sure that the VR-Friend behaves somewhat unpredictably. A number of VR-Friends (age, looks, clothing, ...) with certain developmental paths...
can be built into the system, so new subject domains do not necessitate changes or additions of the development module, although tools to introduce new VR-Friends may well be provided in the future.

The development module and its functionality is clearly very much open ended. On a first and primitive level for each "state" of the VR-Friend one of a number of facial expressions, gestures, background images and utterances are combined in a random fashion. This leads to a fairly complex "behavior" at moderate development cost.

It remains to mention that both teachers and students can set certain environmental parameters as mentioned in passing: the teachers can define time intervals that are "acceptable", students will choose sex, name and age of their VR-Friends.

It is clear that a good part of the success of the VR-Friend scenario will depend on the quality of the implementation of the development model.

In a first experiment, we have implemented a close approximation of a Tamagotchi in software [Kernbauer]. This implementation was based on DINO [Freismuth et al. 1997], hence was called Dinogotchi. While it did show the viability of the approach as such the solution cannot be deemed sufficiently appealing to promise success.

Clearly other ways to implement the VR-Friend are necessary. One obvious idea is to use avatars [Damer 1998]. Another one is to use synthetic actors, like the famous Marilyn Monroe model that is continuously being improved by the group around Nadia Magnenat-Thalmann in Geneva [Magnenat-Thalmann and Thalmann 1994]. Indeed, much work in the area of synthetic actors [Trappel and Petta 1997] could be used for VR-Friend implementation.

For simplicity's sake we are opting for a simpler model in our first real implementation: each VR-Friend will be in one of 50 "happiness" - states (static pictures obtained by morphing a number of photographs of a real person) and - to avoid boredom - will appear with a background picture selected at random from a database of some 10,000 geographical pictures whose copyright was obtained for another project. Although not ideal, we believe this is a first viable approach that can be later enhanced by more and more "intelligence".

1.4 Other Issues

The most burning issue is certainly if VR-Friends will be interesting enough to indeed motivate students to learn. There are strong arguments both pro and con, and only experiments can answer this question.

On the one hand, Tamagotchis have been amazingly successful, and VR-Friends are similar in a number of important ways: once "born" they cannot be "stopped" but either develop well (if treated well) or else they visibly deteriorate, even to the extent that they die. On the other hand, while Tamagotchis are "omnipresent" and keep reminding users of their existence by beeping at appropriate or less appropriate times, VR-Friends only show up when a user logs into the correct server, typically the main server of a school or school-district.

There is another crucial issue. Kids who love to play and love to learn all kinds of irrelevant information seem to loose interest in games once they realize that they are actually learning useful information (!). It has been theorized that the association "learning is work, work is unpleasant" (a product it seems of our less than optimal school systems) is sufficiently strong to turn kids off. A typical case supporting above arguments is the huge success of the "Space Quest" adventure games vs. the meager sales of the "Goldrush" adventures game, all by Sierra: all have the same interface and the same kind of story: users have to help the hero to discover certain facts: Those facts are "useless" in "Space Quest" but contain real historic information in "Goldrush". It is vexing to see that sales of Space Quest have been hundred-fold better than those of Goldrush!

However, there have been some educational games that have been successful (like the classic arithmetic learning game "How the West was won" or the geography/history games "Where in the world (where in history) is Carmen San Diego"). Thus, the final verdict whether playing cannot be combined with teaching is still out!

There is also another, rather opposite issue that can only be settled experimentally: can it happen that kids get attached to their VR-friends to an extent that their departure, let alone death, will cause serious emotional turmoil? Note that even Tamagotchis have turned out to be fairly addictive: What will a more human-like, reality-like VR-Friend do? Whatever the answer is it is clear that VR-Friends programs have to make sure that users will not develop guilt feelings, e.g. when a VR-Friend gets sick or dies since its owner was sick, on vacations, or such.

The most interesting aspects of VR-Friends is the fact that they are on the Web. We leave a detailed discussion of the implications of this for the future. But observe that VR-Friends can potentially communicate, compete, or temporarily be taken care of by "Baby-sitters" via the Web. Note further that VR-Friends can use and point out relevant information (i.e. URL's) on the Web, lead to discussion forums, on-line chats between owners of similar VR-Friends, etc. Indeed the dialogue of users and their VR-Friends may lead to questions
posed by other VR-Friends to other users. It should be clear that the complex interaction of VR-Friends will have
to be based on what has been learnt and developed in the area of intelligence agents as mentioned earlier.

The notion of Web-based VR-Friends used for educational applications opens a new and potentially very
powerful way to communicate factual knowledge - and maybe even more. Experiments will have to demonstrate
the viability of the approach. At the time of writing no polished version of VR-Friends software exists, but we
expect to have one ready by the end of 1998.

Note also that successful implementations of VR-Friends will be much eased by using powerful Web-servers
such as Hyperwave [Maurer 1996], [Maurer 1997].

2. Unobtrusively Collecting Data on Web-Based Material

When offering educational material on the Web it is of crucial importance to obtain feedback on
effectiveness and user satisfaction. In this section we focus on one sub-aspect, obtaining data on subjective user
satisfaction. We discuss "traditional" techniques, none of which has worked well in the past. We then present
novel techniques that we believe could provide effective tools desperately needed to assure continuous quality
improvement of Web based training material.

2.1 Classical Ways to Collect Satisfaction Data

There are three main classical ways to collect data on user satisfaction with educational material available on
the Web: (a) the use of questionnaires; (b) evaluation of log files; (c) explicit user observation.

The problem with questionnaires is that there is much user resistance to filling them out carefully, thus
creating lots of statistical "noise". Even "willing" students are often at a loss of how to answer questions
properly that refer to material that was worked through some time back.

The second approach, the evaluation of log files is problematic for two reasons: the HTTP protocol used on
the Web is "stateless", i.e. it is not possible to record the "trail" of users but only how often each page has been
hit. Using more sophisticated techniques such as session oriented protocols, or simulating them by using
"cookies" or "session keys" as is done e.g. in Hyperwave ([Maurer 1996], [Maurer 1997]) it is possible to keep
more detailed records of usage of educational material. However, such detailed records have already been kept in
non-Web based systems as early as in Plato [Bitzer 1976], but have rarely been terribly helpful. It seems that
efforts to extract interesting information from a huge mass of log files have never been entirely successful. The
third approach, hidden or overt user-observation has been used quite successfully but is very labor and cost
intensive.

Thus, it should be clear that new techniques to judge subjective users satisfaction are needed for use on the
Web which is becoming a major tool of teacher-student communication and course administration. We propose
three such techniques in the next section.

2.2 Novel Ways to Judge Subjective User Satisfaction

The first alternative we suggest to use instead of questionnaires is the use "questionnairelets", Q-lets for short. Such a Q-let consists of a single question that can be answered within a few seconds. Q-lets are presented
to users in a random fashion but never more than a few per session. As little bonus for answering a question an
optional cartoon or joke is shown to encourage answering the Q-let. Cartoons or jokes shown must be chosen so
as not to disrupt the flow of learning. Note that an option "skip question" is presented, i.e. the answering of Q-
lets is not enforced. However, clicking at the Q-let "skip" button will often be the same amount of work as
clicking at one of the choices (e.g. radio buttons) offered in the Q-let.

Observe that users in a Q-let environment do not even need to fill out a complete questionnaire in total, yet
may actually answer the same Q-let more than once. Different answers will thus be a good indication of the
(un)reliability of user answers. Users can be "anonymously identified" across session boundaries in the sense of
[Flinn and Maurer 1995], i.e. users have (self-chosen) names and passwords, so that a detailed record can be kept
for each "anonymous" user, yet the system does not know the real identity of any of the names chosen.
Experimentation on the distribution and frequency of Q-lets used will have to be carried out.
An alternative to Q-lets (or an additional feature) is a so-called "Feedback Button". When clicked at, a form appears where users can click at any of the presented checkboxes to voice their opinion about the current "page" presented, or even about a certain part or aspect of it.

We feel that collecting individual answers at points where they are relevant is both less bothersome for the user, and leads to more reliable results at the same time.

The second alternative to evaluate subjective user satisfaction comes from the approach used in GENTLE [Maurer and Dietinger 1997] to questions posed by students: at any point while working through some material students can "ask a question" by inserting a question mark anywhere on the screen. This action triggers the sending of an appropriate message to a certain user group (i.e. tutors), who will answer the question (synchronously or asynchronously) at which point the question mark turns into an exclamation mark; also, the answer is mailed to the person having asked the question, and other users seeing an exclamation mark can retrieve the "question/answer" dialogue that occurred earlier by just clicking at the exclamation mark.

By evaluating pages with such question marks and exclamation mark much valuable feedback can be collected. In first experiments it was observed that questions were not only asked when material was badly explained but actually even more frequently when the material interested the users to the extent that they wished further explanations!

The third alternative is called "sensitive button". After all, each "page" of courseware or some Web information usually leads to one of a number of further pages by clicking at some navigational button. Users are informed that the position where they click the button will be seen as the expression of an opinion concerning the current "page" at issue. There are many alternatives. However, to be specific, here is one scenario: clicking at a button on the left could mean "I don't like this page", while clicking on the middle of the button may mean "my feelings are neutral" and clicking on the right "I like this page". Clearly many alternatives are possible and need careful testing.

We feel that sensitive buttons (although they will generate some statistical noise) will work well after some initial period (during which the user may be asked "do you really mean xyz?"): some "click" to navigate is necessary anyway, so users "may as well" signal their level of satisfaction.

Abstract: Throughout Australia, audiographic conferencing is widely used as an instructional medium to link schools in rural and remote areas with urban schools which have curriculum and teaching expertise in particular subject areas. This technology involves a two-way audio link via telephone, and a computer link up via modem. The computer acts as a shared visual link between teacher and students. Several schools may simultaneously link up with a “host” school which delivers instruction.

The physical absence of the teacher from the classroom often results in forms of teaching which are didactic and asymmetric, with the teacher striving to control all elements of “the invisible classroom”. The present research was an in-depth investigation of telematics classrooms in Western Australia, with a deliberate focus on changing the teaching-learning environment in order to develop higher order thinking skills in learners.

The creation of conditions for higher order thinking was orchestrated through an action research approach entailing successive interventions in the learning environment by teachers as they conducted lessons. Each stage in the process was monitored and analysed with a focus on fostering students’ thinking processes through dialogue.

The framework adopted for analysis investigates types of talk which are indicative of higher order thinking skills. Results indicate that students’ capacity to display higher order thinking increased as a result of changes in pedagogy, in particular, the scaffolding role of the teacher.

Introduction

The use of interactive communications technologies in education is becoming more widespread as learners can now access courses at a distance or learn via networked communications. Many classrooms and open learning environments depend on a range of technologies, from computers to electronic whiteboards, e-mail, video and audio components as part of the educational process. While new technologies are much in evidence, in themselves they have not transformed pedagogies, and the communicative, socially oriented nature of learning is still intact [Laurillard, 1995].

Throughout Australia, audiographic technology is used to reach students at a distance. This technology can be defined as: electronically based equipment and the processes and strategies used to enable interactive teaching and learning between two or more geographically remote locations. In audiographics teaching there is a physical and geographic separation of students and teacher, and student participants are distributed over several sites rather than physically present in the same classroom. Three forms of technology enable the interactive link to be set up and maintained: telephone, computer and fax machines. The telephone provides a two-way audio link and the computer is used to share visuals and graphics. The screen can provide a number of interactive supports for learning, including:

- immediate feedback to students when used as a blackboard;
- visual stimulation;
- a flexible, editable page;
- shared reading and writing; and
- a record of written work that can be shared and printed.
When computers to two or more sites are linked, teachers and students have views of the same information on the computer screen, and an audio link is used to establish and maintain dialogue. The development of effective communicative and listening skills is therefore essential to both teachers and students participating in telematics lessons. The audio and visual qualities of telematics environments are conducive to communication and verbal reasoning skills, as dialogue and a high level of interaction are required to sustain the teaching-learning relationship.

**A Focus on Learning or on Technology?**

Discussion of how to support learning in technology supported environments where spoken language mediates the interaction between teacher and students is still widely debated [Kozma, 1994; Jonassen, Campbell & Davidson, 1994]. Two distinct approaches to the question of how learning is best achieved are now emerging. One of these approaches called the “cognitive tool” approach [Jonassen & Reeves, 1996; Lajoie & Derry, 1993] indicates that if technology is reconceptualised as a “mindtool” and an “intellectual partner” [Salomon, Perkins & Globerson, 1991] then learners will develop higher order cognitive processes. Jonassen & Reeves [1996] believe that the capacity of technology to transform learning and support higher order cognition lies rests on its power to enable learners to become designers of their own knowledge, and that media will enable the expression and representation of knowledge. At the heart of this approach is the constructivist approach to learning, where the individual discovers, invents and creates knowledge from available resources.

The second perspective, upon which the empirical research in this paper is based, regards learners and the teaching-learning process as paramount, and in this perspective the technology becomes part of the social fabric of learning. This perspective is based on sociocultural theory, which regards cognitive development as culturally based, and a social rather than individual process [e.g., Wertsch & Toma, 1995]. Based on a socio-cultural paradigm, a pedagogy for learning in technology supported environments would recognise that technologies are educational resources and mediational devices, but cannot replace the interpersonal and social dynamic of learning.

**Language and Learning**

The perspective adopted in this research can be described as socio-cognitive developmental theory based on Vygotsky’s [1978] approach to learning in social environments. Otherwise known as cultural psychology [Crook, 1991], its main orientation and central tenet is a concern for the interpersonal processes in development. For Vygotsky [1978], language and thought come together and are combined as a cognitive tool for human development, and children undergo profound changes in their understanding by engaging in joint understanding and conversation with other people. Talk and spoken language are central to this view of learning which has been extended and applied by researchers in a wide range of disciplines [Bruner, 1984; Moll, 1990; Nastasi & Clements, 1993; Pea, 1993; Chang-Wells & Wells, 1993].

Another important facet of Vygotskian theory is that instruction is but one form of social interaction, and is not a one-way activity but a partnership, or form of collaboration requiring active involvement by all participants. Through participation in social practices children learn how to construct ideas [Rogoff, 1990], and learn the norms that guide thinking in different subject areas [Richmond & Striley, 1996; Pontecorvo, 1990]. Higher order thinking according to this definition involves the explicit statement of reasons, with justification and citation of evidence for views held [e.g., Resnick, 1987; Weisstein, 1993]. Applying this conception of learning to the technology supported classrooms of the study meant recognising that language plays a vital role in sustaining learning and thinking and that learning involves socially organised activity where the teacher supports learning by orchestrating social experiences for learners through which they can engage in communicating, reasoning and argumentation.

**Aims of the Study**

Studies have found that a great deal of teacher talk occurs in telematics environments, sometimes to the detriment of student initiative and opportunities to question [Oliver & McLoughlin, 1997]. Overall, the interactions and learning activities that have been observed to occur in these environments are usually low level exchanges and expository talk, with teachers displaying a didactic and controlling pedagogy. In response to curriculum requirements that students achieve higher order thinking outcomes, it was imperative to change
the pattern of teaching and learning that have characterised such classrooms in Western Australia [Oliver & Reeves, 1994; McLoughlin & Oliver, 1995].

This study was conducted with a group of teachers using telematics in subjects where the curriculum specified that students develop higher order thinking skills, in the form of generic competencies such as information handling, problem solving, analysis and synthesis skills, and critical evaluation. An action research partnership was planned between the teachers and the researchers in order to develop an understanding of higher order thinking could be fostered and enable teachers to plan for thinking in their own classrooms. The study was based on actual teaching encounters and events over the duration of one academic year, and traced the evolving skills of the students at expressing ideas, reasoning, explaining and engaging in collaborative discourse.

Method

The participants in this study were five teachers in different subject areas, Mathematics, Science, English, Italian and Social Studies. Each teacher taught a small class of students, and the students were distributed across several distant sites. All students participating in the study were in the first year at secondary school and aged between 12.5 and 13.5 years. The study focussed on two important aspects of teaching for higher order thinking, teacher planning for higher order thinking, though specification of lesson formats and teaching strategies that would support these outcomes, and the adoption of pedagogies that would facilitate the development and maintenance of higher order thinking and students' awareness of their own thinking.

Teachers utilised the curriculum guidelines to develop programs to meet the needs of their students, while exploiting the technology to achieve an appropriate level of communication and create a context where higher levels of cognition could flourish. The research involved both naturalistic observation of classrooms and diagnosis of teachers' pedagogies and students' learning processes.

Research Phases

The research was conducted in three phases.

Phase 1: During this stage classes were simply observed and teacher and student behaviours were monitored and recorded on videotaped. Two hours of classroom teaching were videotaped for each subject. Lessons were then fully transcribed to include activities, technology use and interactions of students. At the end of this ten week phase, the nature of each classroom environment was analysed and teachers were able to consider the appropriateness of strategies they had employed.

Phase 2: In collaboration with the researchers, a training session was planned to enable teachers to develop strategies and language protocols in their classrooms which would substantially improve students' independent thinking skills. Teachers were then videotaped and interviewed for 2 lessons during another term of 10 weeks as they sought to implement their changed teaching practices and foster more occurrences of higher order thinking.

Phase 3: Teachers were shown the outcomes of their changed practices and caused to reflect on their achievement of increased higher order thinking and how this could be further enhanced. Once again, two lessons of each teacher were videotaped during a third term of teaching in order to explore the nature of the teaching and learning environments.

Instrumentation for Analysis of Data

A classroom observation instrument that served as an indicator of teacher pedagogy and to provide descriptors of the teaching and learning environment. A number of approaches have been proposed for analysing interactions in classrooms and learning environments, such as discourse analysis, systematic observation and coding schemes [McLoughlin & Oliver, 1995]. Discourse analysis of communicative interactions was chosen for the present study because of its potential to provide a multilevel understanding of the learning process. A framework of seven forms of interaction and discourse was chosen for the present study because of its potential
to provide a multi-level understanding of the learning process. Table 1 presents an overview of the categories used to code teacher-student talk.

For analysis of talk, the categories of non-task, procedural and expository talk were used, as these were reciprocated by students when teacher initiated the dialogue. The other major category of student talk was higher order thinking, which was coded according to whether higher order thinking was evident in the data. Four dimensions of higher order thinking were identified through language indicators of reasoning [Perkins, 1997] where students cited evidence for views held, demonstrated inquiry and reflective skills and interpreted concepts throughout the lesson.

Table 1. A framework for investigating interactions in classrooms

<table>
<thead>
<tr>
<th>Type of Interaction</th>
<th>Description</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non task talk</td>
<td>participants engaging in social or administrative talk not relevant to the learning task</td>
<td>T: Hello Vicky how are you? S: Very well thank you. T: good. So how was your homework?</td>
</tr>
<tr>
<td>procedural</td>
<td>teacher/student dialogue involving information exchange on course requirements or homework and procedures</td>
<td>S: Teacher can you tell me how many pages you want us to write? T: I'm looking for about 2 pages in total. S: Can we do more?</td>
</tr>
<tr>
<td>expository</td>
<td>student or teacher demonstrating knowledge or skill in response to a direct request from another.</td>
<td>T: Can any one tell me word for ice-cream in Italian? S: Is it gelato? T: Fantastic</td>
</tr>
<tr>
<td>feedback</td>
<td>teacher using student responses to give feedback, praise or reinforcement</td>
<td>T: This is how we place our fingers to play the note A. Can you play for me Mandy? S: plays the note on her recorder T: That was good but you have to blow a bit harder</td>
</tr>
<tr>
<td>cognitive support</td>
<td>teacher providing constructive feedback to a student response causing the student to reflect and to consider an alternative perspective/realty.</td>
<td>T: Can you tell me what you think was the main reason for his actions? S: He was angry and wanted to get even. T: But was that all? What about his wish to improve his position and standing? S: I suppose but he did but I thought that he would done it differently.</td>
</tr>
<tr>
<td>control</td>
<td>teacher issuing a directive or instruction to students that would limit interpretation of the task</td>
<td>T: OK everybody, write &quot;speech &quot; in your graphic outline of culture.</td>
</tr>
<tr>
<td>reconstruction</td>
<td>teacher repeats the student’s response, but changes the wording so that it is more correct</td>
<td>T: So why are trees useful to us? S: They are home for animals T: Yes, good. They are the natural habitat for animals.</td>
</tr>

</table>

Classroom Observations in Phase 1

The initial observations of teachers working in classrooms showed that much of the talk that occurred was expository, procedural and control based. Didactic patterns were evident in the data, where teachers asked the questions and students responded with short factual answers. Descriptive statistics on each of the categories are displayed in Table 2.

Table 2: Mean percentages of teacher talk by category in phase 1
Table 2 illustrates that much of the teacher talk that occurred in the observation phase was to do with non-task, or procedural matters, such as management, roll call, disciplinary issues and homework. The proportion of teacher talk that related to cognitive support and development of conceptual understanding was relatively low, with the maximum being 22% in the Mathematics classes.

Initial observations of the classrooms in phase 1 of the study also revealed that students had:

- dependent roles in the dialogue where they responded but did not initiate;
- limited opportunities to talk and practice skills, and engage in social talk;
- lack of meaningful activities to enable them to express personal views, opinions and engage in informal reasoning about their own educational experiences.

**Phase 2**

To overcome these limitations, teachers and researchers planned to develop strategies to assist their students to become independent thinkers and develop rational forms of talk in the classroom. All teachers made the decision to:

- be explicit in stating the goals and objective of each lesson;
- develop a lesson plan for each lesson stating student thinking outcomes;
- build into the lesson opportunities for students to respond to classroom experiences and reflect on these;
- encourage learners to judge the purpose and effect of their own learning, and make personal statements about their classroom experiences.

Teachers were encouraged to adopt a variety of strategies based on modelling, scaffolding and encouragement of analysis, questioning and critical thinking. Instructional approaches were based on the provision of supportive social contexts for learning. Videotaping of lessons continued during the second semester, following the intervention.

The principal changes that occurred from phase 1 to phase 2 phase were that:

- there was an increase in cognitive support for students across all subject areas;
- the proportion of feedback also increased;
- the amount of non-task talk and procedural talk decreased.

The types of teacher talk which decreased were those related to non-task or routine, and management issues [Table 3].

Phase 3

Following the intervention changes were observed to occur in the pattern of teacher talk and student talk.

In phase 3 the pattern of pedagogic support was that teachers continued to support thinking skills in students by offering a range of scaffolds, such as asking reflective questions, encouraging discussion, promoting reflection, and asking questions which enabled students to reflect and elaborate on their own thinking processes.

Table 4 shows the mean percentage changes in teacher talk from phase 2 to phase 3, when teachers were implementing their process-based strategies for higher order thinking.

The data clearly showed that for teachers, the proportion of cognitive talk devoted to supporting thinking and reasoning improved from phase 1 of the study and remained reasonably stable for the two terms following the training program. Student talk also showed increases in higher order thinking from phase 1 to phase 3 [Figure 1].
The changes in the quality of teacher pedagogy and student and talk following the training session confirmed our belief that telematics environments could be designed to foster higher order thinking as a pedagogical goal and provide a supportive context for learner engagement.

Teachers created the social conditions in the classroom conducive to thinking and expression of ideas, so that students could become independent thinkers. In particular, the role of scaffolding was shown to be of great importance, and this was reflected not only in teacher pedagogy but also in learners’ increased capacity to demonstrate thinking at higher levels.

Abstract: The paper describes a redevelopment of a successful Veterinary Bacteriology and Mycology multimedia project at The University of Melbourne into a Web-based format. The design of the initial project is described, together with learning benefits that short-term evaluations revealed. The positive benefits were not sustained in the long term, as this was a once-off experience for students. Several needs and opportunities emerged:

- We sought a more adaptable model which veterinary (and other) colleagues could use in their own discipline areas, so that the overall nature of the student experience was changed.
- An international consortium of over 30 veterinary bacteriology and mycology teachers was formed in January 1996.
- We wanted to respond to, and take advantage of, new communication and information technologies (CIT) being packaged together in a Web environment.

These needs have led to the VetSource project, which uses the Creator engine. The evaluation during the first year of this Web-based project is described.

Original Veterinary Bacteriology and Mycology (VBM) Project

The Veterinary Bacteriology and Mycology (VBM) project at The University of Melbourne was begun in the early 1990s. It set out to use computer technology to overcome some of the current problems of subject presentation and integration in overcrowded veterinary curricula. It involved the development of interactive, multimedia databases of veterinary curriculum materials, linked to a revised set of educational objectives, a range of other learning situations and more appropriate assessment procedures. The expanded set of learning objectives required students to acquire information management and problem solving skills, as well as understanding bacterial and fungal diseases of animals. The development of group learning skills and communication skills were also explicitly built into the course. The curriculum rationale is explained in detail in [Whithear, Browning, Brightling & McNaught 1994]. In this computer-based, case study learning system (CB CS LS), 24 lectures, 40 hours of laboratory sessions and course notes were replaced by:

- few formal lectures;
- course material in multimedia databases;
- case studies with associated quizzes, 6 of which were intensive laboratory exercises (10%);
- short essays (20%);
- seminar (5%);
- literature review (15%); and
• ‘open computer’ examination (50%) (assessment percentages in brackets).

This has been well evaluated with findings like the following [McNaught, Whithear & Browning 1994]:
• Students took more responsibility for their own learning. They were expected to acquire new information from a variety of sources, including primary sources, and to develop skills to control their own information using a computer.
• There was no requirement to memorise by rote. Learning was predominantly contextual, using simulated, problem-based case studies.
• Higher order cognitive skills were sought and demonstrated in the presentation of seminars and essays, and in the ‘open computer’ examination answers.
• More opportunity was provided, and emphasis placed, on collaborative learning.
• More opportunity was provided for students to develop written and oral communication skills.
• Continuous monitoring and feedback (both quantitative and qualitative) of student progress was provided.
• Increased awareness of, and interest in, the subject and improved practical skills were demonstrated in this class compared with previous experiences with classes taught in the conventional manner.
• Students acquired familiarity and skills with computers and computer networks.

These students were followed through into their clinical years. A focus group interview with clinical teachers and some individual interviews with students were conducted. The teachers did not think the students were noticeably better at clinical diagnosis than in previous cohorts, or knew more microbiology. Several of the teachers had looked at the VBM material and valued its intentions and design. However, they felt that this approach was not integrated into the whole veterinary course in a way which would make any real differences. It was an isolated experience. These views were echoed in students’ comments; one recalled the VBM experience as “a fond memory”. So, the evidence the project team has is that these initial positive shifts were not sustained by students in their work in later years in clinical settings. This is hardly surprising; one eight-week experience is unlikely to alter students for long when other subjects encourage information reproduction. We wanted a more adaptable model which veterinary (and other) colleagues could use in their own discipline areas to encourage a genuine change in the nature of veterinary students’ experience.

The Emergence of Creator

The emergence of new communication and information technologies (CIT) being packaged together in a Web environment has resulted in a much higher profile being given to the use of CIT in T&L within Australian universities. There is also a growing international awareness of the potential of Web-based technologies to facilitate the development of long distance collaborative projects. Both of these factors have resulted in an international consortium of over 30 veterinary scientists working with a team of software engineers from Melbourne Information Technologies Australia (Melbourne IT)—the commercial Information Technology subsidiary of The University of Melbourne—to develop a Web application which satisfies the requirements of the VBM project as well as other courses. This Web environment is called Creator, and is a course management and authoring system that is designed to combine the flexibility to satisfy the academic needs of different disciplines with a University-wide interface consistency for staff and student users alike. It provides a unique generic authoring tool and integrated platform for the communication of education over a network, either internet or intranet.

It has become trite to say, but is still true, that the role of the educator is undergoing a transition from that of the ‘sage on the stage to the guide on the side’. Being a repository of expert knowledge is no longer enough to be accepted into the hallowed halls of pedagogues. The online world of the Internet can provide a wealth of information; the important skill now is to manage and synthesise it all. Many are struggling with the transition from an industrial to an information society. On the other hand, many are embracing the opportunities provided by new technological innovation [Reeves & Reeves 1997].

With the convergence between database and internet technologies we are seeing the rise of education as a consumer item in a general sense. Something to be packaged neatly into modules ready to be taken away,
unwrapped and ‘consumed’ at leisure. Coupled with this is the changing nature of educational delivery via the Internet, a delivery mechanism by virtue of bandwidth limitations, demanding that information be provided in snapshots or manageable chunks to enable acceptable delivery times online.

These forces combine to ensure that any semester course created or converted to online delivery will consist of many individual elements. Management of large sets of data has typically been handled by databases. They are purpose-built to store large amounts of data. The Internet is an excellent mechanism for serving up information via browsers. In the past twelve months there have been rapid developments in the convergence between database and internet technologies to the point now where new middle layers of functionality are being developed to potentially revolutionise the delivery and management of online educational material.

Once the question of getting course material on the Internet has been addressed, and the decision has been made to follow a digital direction, the issue then becomes one of how much time and resources are available to ensure delivery. This is where integrated authoring environments come into play. For small-scale teaching with only a few students and limited resources, the creation of ordinary HTML (HyperText Markup Language) files is quite appropriate [Hart 1996]. As a site grows with the accumulation of text, graphics and videos along with the incorporation of CGI scripts or Java applets to ensure some degree of interactivity, the site begins to require more and more basic management to ensure that the ever-growing number of individual files are organised in a coherent way.

An integrated environment based on active server page technology, such as Creator, allows for resources to be stored in a database and then served-up ‘on the fly’, as they are needed. In this way, the same resources can be shared among many users. Of more importance to the authoring academic is the ability to collaborate with other academics via the Internet to assemble resources into learning activities.

The potential for online authoring in a virtual university environment is immense, particularly where the issue of Intellectual Property is addressed by allowing individually created learning objects, such as text, graphics, quizzes, Shockwave objects and so on, to be ‘stamped’ as created by a particular individual. Creator allows for these ‘learning objects’ to be authored into a sequence of case studies, tutorials or lectures for delivery to students.

A summary of Creator’s features are:

- Text, images, animations, video, audio and other media objects are stored in a database for fast retrieval on the fly and efficient management.
- Teachers can create different reference works from the same data, or can provide different views of the same work to individual students.
- Objects cut and pasted into the resource palette can be re-used in other work.
- Easy-to-use authoring tools are provided for teachers to create learning objects containing interactive multimedia components.
- Collaboration between teachers is managed through a set of editorial tools.
- Outputs from quiz and other assessment objects are stored in the database for reporting purposes.
- News groups on particular subjects supporting synchronous and asynchronous group discussion can be easily created.
- Threaded discussions to simplify tracking of multiple email messages are included.
- Chat sessions, video/audioconferencing are enabled using MicroSoft NetMeeting.
- The results from simple or complex searches can be added to individual Resource Palettes for later inclusion in Library and Learning objects.
- Intelligent agents provide a variety of unique, powerful search features.
- Includes a dictionary helper for inserting lengthy names into the search field.
- Tracking of student performance at a subject and course level is provided, including the time a student spends on each activity.
- A wide variety of graphical and text-based reports of assessment results, student activity, etc. are available to teachers and administrators.
Development of the VetSource Materials

An international consortium of veterinary bacteriology and mycology teachers using problem-based learning and interactive multimedia was formed in January 1996. The educational mission of the consortium is to improve the quality of veterinary bacteriology and mycology teaching by facilitating adoption of problem-based learning systems that incorporate innovative use of interactive multimedia. This is to be achieved through an integrated system that electronically links the learning (problem-based) process with multimedia information sources. In other words, it uses the educational concepts that have been practised over the past five years for teaching veterinary bacteriology and mycology at The University of Melbourne. However, there will be two important differences. The first is that the teaching materials are being delivered via the World Wide Web using the Creator platform being developed by Melbourne IT. The second major difference is that the combined specialist talents of the teachers involved will be available to the consortium as a group. The most tangible immediate benefit of this will be the production of an international, multimedia textbook on the subject that is accessible to consortium members and their students via the Web. An editorial board has been formed to oversee the content and educational quality of the electronic text. In addition, it is expected that consortium members will share case studies and other materials. However, it should be emphasised that other than for the text content, the ways in which the materials are used will be up to the discretion of individual teachers. Flexibility of learning modes has been built into the system. As a pilot, two chapters and accompanying case studies were produced to allow members of the consortium to comment on issues such as content and style. At this initial stage the information content is the focus; a focus on communications will follow.

The first two chapters of the Veterinary Bacteriology and Mycology book in the Library were:
- Campylobacter, Helicobacter, and other curved Gram negative rods
- Mycoplasma—Class Mollicutes

There is also a Dictionary of Veterinary Bacteriology.

The first two case studies are:
- Puppy diarrhea case (John Prescott), and
- Air sac disease (Kevin Whithear)

‘Air sac disease’ is an original VBM case study which has been translated to the Web environment. While the ‘story line’ of the linear unfolding of a case study is still apparent, students can access any place in the case study. It is hoped that the ‘authenticity’ of the original case study about problems in a 28 day old broiler flock still remains with additional flexibility and functionality. The material appears as a menu:
1. Quiz about some important biological properties of the organism involved
2. Quiz about culture of fastidious pathogens.
3. Identifying a bacterial species belonging to a genus with unusual properties
4. Quiz about some biological consequences of unusual properties of the causal organism
5. Quiz on possible role of parent to progeny transmission in this case
6. Identifying an important secondary pathogen
7. Pathogenesis of the disease
8. Controlling the infection
9. Feedback

‘Puppy diarrhea case’ is a new case study designed for the Web environment. It was designed with the intent of getting veterinary students to understand some of the complexities of the problems that they will be faced with in their work, including highly charged contexts in which high value placed on an entity (here an unborn child) can significantly distort perceptions of risk. The case was designed to help students identify possible issues involved in a problem, then to use the search function of VetSource to identify an agent(s) of possible significance. As the Library element of VetSource is developed then other agents will be added to the list. As the case progresses, the students continue to search the relevant part of the text to increase their understanding of the sources of this infection, and of the relative risks of different sources. The underlying aim is to get the
student to understand the sources of this infection, the type of disease that it causes, as well as how to analyse a problem which they might not see initially as within the field of veterinary medicine. They are led to engage with the material by their need to know and by the intriguing nature of the problem, rather than because some professor tells them this is important. It is also part of the concept behind VetSource that they need to find out about how to find and use information, and therefore need familiarity with a text that they can learn to know and trust. Like 'Air sac disease', the case study appears as a listed menu.

1. Quiz about case
2. Search on words: pregnant, diarrhea, young dog
3. Choose what to do next.
4. Choosing the correct laboratory sample
5. Choosing an antibiotic
6. Choosing a photograph
7. Quiz about sources
8. Put a list in order of importance
9. Feedback

Student Response to these Initial VetSource Materials

The first author interviewed five students in September 1997. In most cases she watched them open VetSource for the first time and then came back a few times to see how they were progressing.

- All found it easy to get going. This is very encouraging, especially as there were glitches with using Netscape 2 instead of Netscape 3.
- Indeed, students were unfazed by the prototype 'bugs' and navigation issues that would have greatly concerned students a few years ago. Here are a few examples of these initial problems. They are mentioned because students' ability to deal with them and record them for our benefit represents a stage where formative evaluation has reached a much more sophisticated level than in previous years.
  - We had problems with the 'back' Netscape button.
  - It was not clear that the vertical buttons ‘Learning’, ‘Library’, ‘Discuss’ and ‘Search’ are ABOUT buttons and that access is by the menu bar at the top. It doesn’t take long to figure out but it is not elegant.
  - The buttons on the menu bar always take you to the beginning of the ‘Learning’, ‘Library’, etc. section. This means that if you are in the middle of a Learning module and decide to go to the Library, you then get sent back to the start of the Learning section again.
- All of the students liked the speed of access.
- The layout of the Library material was considered great. In particular the expandable thumbnail images were appreciated. Three students commented favourably on the number of images and the juxtapositioning of the images and text.
- All of the students like having only short sections of text. One called it a ‘leaner and meaner’ approach. One suggested the possibility of ‘more info’ as a possible button. This point does raise questions for Web designers to consider. How much is this a real change in student learning styles? Is this a visual age? How much are we concerned because of our own text-based education? How can we decide on a useful balance point?
- All commented that they liked the brief introduction to the case studies. Of course, this evaluation was done near the end of the academic year where, as one student commented, the students are tired of extended stories. It is planned to try one case study with a longer introduction and one with a brief introduction with some students in 1998.
- All liked being able to move around the Learning modules easily. They acknowledged the need for better graphic design, rather than a list of numbers, but didn’t think it a big deal. One student actually began to discuss the design for a map of a case study which could be implemented with mapping software currently available.
- All liked the idea of explanations to both right and wrong answers.
The level of discussion with students was high. For example, the idea of different types of question formats was discussed with two students; they were very receptive to the idea of variety and made suggestions about possible formats. As stated above, many students are now sophisticated computer and Web users and we may be under-using these students as potential ideas sources in educational design.

Staff wanted more of an immersion feel for each Learning module—the sense that students were in a clinical laboratory was much less pronounced than in the original VBM. Staff are concerned by this. The students didn't seem to feel this; they were too interested in the advantages described above. However, the 'feel' (flatness?) of a Web environment is an item we think we should keep this on the agenda.

Student response to the initial VetSource materials is very encouraging. There is clearly a great deal of developmental work still to do but the results appear to be worth the effort.

Emerging Veterinary Projects

Several other staff in the Faculty of Veterinary Science at The University of Melbourne have decided to use Creator as a vehicle for development and we have a sense of growing momentum towards a veterinary online curriculum—not yet an avalanche but a really significant change. These projects are:

- Redeveloping an existing Basic program for a PC called 'Sick Moo' which aims at assisting students to develop a clear procedure to use in examining cows. The focus is on facilitating clinical examinations and diagnosis. While the current software is well-designed from an educational point of view, in that students enter their ideas about clinical procedures as free text and so are not influenced by choosing from a list, a separate set of audiovisual equipment is needed for its use. A Web version will be more elegant, will allow for more data to be accessed and will facilitate future extensions to the project.

- Regional anatomy of the dog. This is a new project aimed at enhancing students' attitudes to veterinary anatomy and maybe how this might affects their approaches to learning.

- Clinical pathology. This will focus on providing another experience for students in viewing pathological slides so that their ability to use slides diagnostically is enhanced.

- Mammary gland and respiratory tract streams. The focus here is on vertical and horizontal integration of material. This will be designed as a series of problem-based activities linked to information sources which students can use across several years of their studies.

- Continuing education for practising vets on mastitis. The potential for developing short modules aimed at exploring topical material in an interactive way brings another dimension to veterinary education.

Evaluation plans are being developed for these new projects as well as further work with the microbiology materials. We believe we are entering a new phase of the use of CIT in T&L. We can use all what we have learnt about designing for stand-alone multimedia environments in these new integrated online learning environments. It is a new phase but not a new slate.

The Impact of Information Technology on Practices and Policy in Higher Education

Carmel McNaught
Educational Program Improvement Group, RMIT University
Melbourne, Australia
carmel.mcnaught@rmit.edu.au

Abstract: Are computers just another tool for teaching? Nice images, lots of memory, but nothing fundamentally new? Or have we entered a 'new age' in our ability to explore and represent knowledge, to present knowledge to our students, and to design systems of education for delivery of this knowledge to large numbers of students? These are not simple questions to answer. This paper will explore some of the characteristics of information technology. In particular, information technology raises epistemological questions which are explored. Some implications of the characteristics of information technology for university policy and planning will be discussed.

Characteristics of Information Technology

By appreciating the metaphorical power of the computer as well as its technical capabilities, ... the computer is more than merely a sum of its component parts. It has become an 'object-to-think-with'—stimulating thought and providing a new medium of expression.

[McQuillan 1994], p. 650, using [Turkle 1984]

There is no doubt that computers have transformed the working and living conditions of many people. Four of these transforming characteristics are:

- access and retrieval of large amounts of information,
- representation of information in a wide variety of ways,
- information access geographically widespread, and
- rapid communication.

However, much of the current debate centres around the logistics and economics of technological advances—the what?, when? and how? type questions. There are also fundamental epistemological questions which need to be explored—why? and towards what future? What is needed is an overview of how changes in the nature and structure of higher education are interdependent with changes in technology. Some of these interrelationships are shown in [Fig. 1]. Higher education is a highly dynamic and rapidly changing situation, and staff development and training needs become of paramount importance in university policy and planning. [Fig. 1] portrays many areas which need exploration and debate. This paper will focus on exploring some of the epistemological questions raised by information technology and discuss some implications for university policy and planning.

Epistemological Implications

As we represent data in new ways, do we ask new types of questions? There are some indications that this is occurring. As we share our ideas in new ways and in new time frames, do our thinking patterns change? We need to consider what epistemological shifts that may be facilitated by current technologies. Some of these are:

- from object-focussed to process-oriented views of knowledge,
- from individual ownership of knowledge to a community ownership of knowledge,
- from a transmissive to a transformative view of student learning,
- to an increasing legitimation of collaborative processes,
- towards a public process of peer refereeing.

995
towards a greater focus on associational thinking over linear thinking, and
towards the use of visualisations as both research and teaching strategies.

<table>
<thead>
<tr>
<th>Traditional view</th>
<th>New tendency</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Knowledge as an object (printed, storable) (closure is possible)</td>
<td>Knowledge as conversation (consensus, process) (closure is difficult)</td>
<td>This is not to say that knowledge was only viewed in an objective framework before the advent of computers, but rather that the fluidity of knowledge exchange using computer technology is beginning to challenge an objective paradigm in new ways. I have only recently begun citing email discussion groups and Web sites. The shift in my own thinking and academic practices has been marked. The 'authority' of the words on the screen has added another resource to my literature searching. Note that this is an enrichment of my knowledge base, not a replacement of one resource by another, and brings new criteria into my assessment of the value of ideas and strategies I read about onscreen. I have a sense of being more critical, less reliant on the authority of other reviewers. This places new responsibilities on academics—both in their own scholarly work and in relation to the academic training they provide for their students.</td>
</tr>
<tr>
<td>2. Knowledge identified with individual 'experts' (e.g. theories are labelled as Freudian, Darwinian, etc.)</td>
<td>Knowledge identified with community (e.g. public email discussions)</td>
<td>This table was originally posted on the AAHESGIT (American Association for Higher Education Special Group on Information Technology) listserv and opened to public debate. Many of the comments I am including have been stimulated by that open, quite rapid, international debate.</td>
</tr>
<tr>
<td>3. Teaching as conveying knowledge</td>
<td>Teaching as getting students engaged in the knowledge-development process</td>
<td>Interactive multimedia has enabled the construction of resources for students to use in constructing their own understandings. Computers offer more dynamic opportunities for using visual media to represent both concrete and highly abstract entities and relate these representations. A good example is use of multiple representations by [Thomason, Cumming &amp; Zangari 1994] in their statistics multimedia package where students can manipulate and construct their own distributions and visually solve statistics problems in several distribution playgrounds. The emphasis is on personally held constructs and not on formula-driven solutions.</td>
</tr>
<tr>
<td>4. Professional collaboration still difficult in some fields</td>
<td>Collaboration seen as how knowledge is developed and therefore legitimate</td>
<td>Collaboration is now much easier at both national and international levels. Sharing of large data files on a global basis is now relatively easy, making genuinely collaborative work across continents and cultures a reality. In Australia collaborative grants between universities which are thousands of kilometres apart are actively encouraged by several funding agencies and the use of email and computer conferencing are normal professional practices.</td>
</tr>
<tr>
<td>5. Publications are refereed before distribution</td>
<td>Publications may be refereed ex-post facto</td>
<td>Some Web sites now clearly distinguish more finished papers from works in progress. An example is the Australian Committee for the Advancement of University Teaching (CAUT) Humanities and Social Sciences site called [ultiBASE] where active debate is encouraged on posted papers.</td>
</tr>
<tr>
<td>Traditional view</td>
<td>New tendency</td>
<td>Comments</td>
</tr>
<tr>
<td>------------------</td>
<td>--------------</td>
<td>----------</td>
</tr>
<tr>
<td>6. Linear favoured over associational thinking</td>
<td>Associational thinking gains credence</td>
<td>The advent of hypertext media, both in instructional interactive multimedia and in hypertext essays on the Web illustrates this well. [Beaumont &amp; Brusilovsky 1995] and [Ecklund 1995] discuss the relationship between cognitive structures, instructional design and learning outcomes; they argue that people learn by constructing several links between concepts, personal records of events and formal theories. Hypertext media are therefore likely to facilitate learning. [Kozma 1991] describes the critical capability of the computer to proceduralise and relate the relationships between symbols in mental models. One powerful tool that has evolved is concept mapping software that is used in variety of ways, e.g. [Gaines &amp; Shaw]. Many Web sites are still very linear in design and therefore underutilise the potential of the medium; a good example of a hypertext essay on the Web is on the Open Learning Technology Corporation [OLTC] site.</td>
</tr>
<tr>
<td>7. Classroom and the real world seem separate</td>
<td>Classroom connected to off-campus world</td>
<td>Open learning now applies to both on- and off-campus courses. Email and electronic conferencing (both desk-top and room-based) technologies have reduced 'the tyranny of distance' considerably [Ring &amp; Watson 1994]; [Goddard 1995]. Many large IMM projects are being converted to Web delivery. The technology for this exists; large resources (video, animations) can be on a local CD-ROM but the interactive elements can be Web-based. Substantial projects, e.g. ChemCAL, 70 hours of introductory chemistry [McTigue et al. 1995] are currently being reworked in this way.</td>
</tr>
<tr>
<td>8. Visualisation a ‘frill’ in some fields</td>
<td>Visualisation as a knowledge path</td>
<td>The supremacy of text is changing. There is an increasing awareness that students are becoming more visually literate and that the ways in which they learn from visual material may be changing, e.g. [McNaught, McTigue &amp; Tregloan 1996]. Computers afford opportunities for dynamic use of visual material. For example, visual search engines on the Web are being produced, e.g. [Apple Computers] Hotsauce project which should allow more flexibility in our explorations of the loosely structured world of the Web; one can literally look around for information, rather than searching with pre-determined key words. This is done using the mouse to move into a specific domain of knowledge and then down through layers to reach specific Web sites.</td>
</tr>
<tr>
<td>9. Experimental methods limited to certain fields</td>
<td>Simulation used as a means to explore knowledge in many fields</td>
<td>Data mining using genetic algorithms or neural networks is now being used to rapidly sift enormous amounts of data relatively rapidly, looking for new patterns and relationships. These techniques are used in a wide range of disciplines from business to astronomy [Kiernan 1994]; [Matthews 1996].</td>
</tr>
</tbody>
</table>

Table 1: Epistemological shifts that are facilitated by current technologies (after [Batson 1995])
[Batson 1995] lists nine dichotomies in an attempt to map the epistemological shifts that are facilitated by current technologies. As with all attempts to dichotomise issues, Batson's framework should not be taken as implying that all approaches on the left no longer have value and should be replaced by the approaches shown on the right. It does, however, provide a framework where new approaches can be seen as presenting fresh opportunities in higher education. The discussion is contained in [Tab. 1].

### Some Implications for University Policy and Planning

My own interest is in the use of information technology in teaching and learning, though the distinction between research and educational uses of computers is not at all clearcut. One of the benefits that competition between universities for student markets is that the educational design of new courses is getting more serious attention and real effort is going into the conceptualisation of interactions between teacher and students. [Laurillard 1993] describes a teaching and learning model containing the four aspects of discussion, interaction, adaptation and reflection. She argues that the use of multimedia can enhance the teaching-learning process effectively by facilitating 'conversations' between students, teachers and instructional material. Many innovative curriculum projects in higher education involve stand-alone interactive multimedia modules. Others involve open learning modules using network delivery. There are also other curriculum strategies which can enhance student learning such as email discussion groups, online help processes, students producing their own multimedia presentations, and computer databases used for cooperative learning projects. Certainly the quality of some of these innovations is not high but there are enough examples now of projects [Wills & Mc Naught 1996] where improved student learning has been demonstrated for us to feel that the investment may indeed pay off! These pedagogical questions are not just for individual teachers to consider; there are larger policy questions for universities to consider.

[Laurillard 1996] examined the balance of student study activities in a UK university. She mapped the distribution of student learning activities by type of activity and nature of the process, using four categories—attending (21 hours), practising (10 hours), discussing (1 hour) and articulating (8 hours). This data was taken from an engineering department in a campus-based university where the main activities were lectures, use of audiovisual materials, tutorials, problem practice sessions, private reading and completing assignments. There were several differences found in other departments and in another university but the general pattern was usually the same, with attending being by far the commonest activity:

Laurillard then describes how the use of information technology could be used to redistribute student learning time in a different way, so as to achieve a more effective balance between active and passive modes of learning. She describes this as follows:

'Ve can add computer-assisted learning (CAL, to represent any form of computer-based teaching program), audio-graphics (to represent synchronous conferencing), computer-mediated conferencing (CMC, as the asynchronous form of conferencing), and interactive computer-marked assignments (ICMA) to cover those aspects of assessment that can be handled adequately by a program. The same total student study time can then be redistributed over a wider range of teaching methods, resulting in a more balanced distribution across the key types of learning activity, as shown again in the final totals for each line.'

The final totals could then be attending (14 hours), practising (13 hours), discussing (4 hour) and articulating (9 hours). The technology infrastructure in a university can be organised to maximise the potential for more active student learning.

This piece of research can be embedded into a theoretical framework where we can view university policy making as an evolutionary scenario or a revolutionary scenario [Alley 1996]. Evolutionary changes are essentially 'more of the same', an adaptation of new technologies and conditions into existing frameworks; revolutionary changes work towards the development of new models of communication and accountability. The differences between evolutionary OR revolutionary scenarios can be considered for a range of policy issues, including:

- hardware choices—fixed networks OR dial-up phone lines
- media support—video OR Web, email, chat
- instructional design support—distributing traditional teaching OR inventing new learning
- funding arrangements—State/Institution special funds (not base funds) OR Institution base funds
The location for student activity—user comes fixed, prescheduled classes OR site is with user in flexible mode

- curriculum assessment—retains classroom groups idea OR based on individual needs and career pathways
- institutional quality assurance—productivity for provider OR quality for clients (staff and students)

There are congruences or patterns which exist between epistemological and policy perspectives. The consequence of these patterns for the design of on-campus and open learning systems of education is that there are now a much greater number of options which are available for course design and delivery. It is hoped that the university of the future will use this flexibility to create a variety of pathways for students to follow. This may relate to the ways in which students mix on-campus and distance courses, to flexibility in the design of individual courses, to changes in assessment options and to altered relationships between the work place and university education. A time of intense exploration lies ahead. Let us not set our universities in electronic concrete that locks us into modes of delivery that are too specialised and inflexible. Rather let us keep to a vision of global sharing of knowledge and systems in a manner that allows the needs of individuals learners and communities to be met.

Abstract: This paper reports the results of applying metrics to hypermedia authoring under the SHAPE research project. The aim of SHAPE is to help authors develop high quality large hypermedia applications for education. The quality characteristics considered are the reusability of information, the maintainability of applications and the authoring effort.

Although a number of metrics for hypertext systems have been proposed, we believe that many of the measures proposed in the past lack the necessary mathematical and/or empirical justification.

The metrics proposed in this paper have been developed using the Goal-Question-Metric approach, and adhere to the representational theory of measurement. We describe the development of the metrics and the results of a quantitative empirical study which compares two different hypermedia authoring systems.

1 Introduction

Even with a very clearly stated theory, there have been plenty of examples of software development projects whose budgets and schedules overrun. Software engineers have tried to address such problems by continually looking for new techniques and tools to improve process and product, but without corresponding empirical evaluation [Fenton & Pfleeger, 96].

Measurement can be used to [Basili et al., 94]:

i) Support project planning.
ii) Determine the strengths and weaknesses of the current processes and products.
iii) Provide a rationale for adopting/refining techniques.
iv) Evaluate the quality of specific processes and products.
v) Assess the progress of a project during its course.
vi) Take corrective action based on this assessment.
vii) Evaluate the impact of such action.

The representational theory of measurement seeks to formalise our intuitions about the way measurement works. That is, data obtained as measures should represent attributes of the entities
observed, and manipulation of the data should preserve relationships observed among the entities [Fenton & Pfleeger, 96].

In the hypertext field we can identify similarities with software engineering: for a long time there has been little interest in any sort of evaluation to prove the usefulness of a method or tool. Thus, the community can be accused of ‘advocacy research’ [Fenton et al., 94], [Glass, 94].

There have been proposals for hypertext metrics, developed in an ad-hoc fashion, expressing measures in an ambiguous manner and therefore limiting their use. Many measures proposed in the literature therefore lack the necessary mathematical or empirical justification.

At the University of Southampton we have developed metrics for hypermedia authoring under the SHAPE research project [Mendes & Hall, 97a], [Mendes & Hall, 97b]. The aim of SHAPE is to aid authors in the development of high quality large hypermedia applications for education.

In applying scientific method to the definition of metrics, we base the principles of our work on a framework for software measurement proposed by Fenton et al. [Fenton & Pfleeger, 96], and on the guidelines from the DESMET project [Kitchenham, 96], [Kitchenham, 93].

In Section 2, we present a survey of hypertext metrics already proposed and in Section 3 we compare those proposals and offer further discussion. In Section 4 we present the research project SHAPE and describe how we have developed metrics applied to hypermedia authoring. Finally, in Section 5 we give conclusions and comments on future work.

2 Hypertext Metrics

The application of metrics to hypermedia has stimulated considerable interest [Botafogo et al., 92], [Rivlin et al., 94], [Garzotto et al., 94], [Garzotto et al., 95], [Hatzimanikatis et al., 95], [Yamada et al., 95] but their utility is still questionable since there has been little corresponding empirical validation.

Botafogo et al. [Botafogo et al., 1992] proposed the stratum and compactness metrics, both calculated by considering only the structure of the hyperdocument. The compactness metric indicates the connectedness of the hypertext and the stratum metric indicates to what degree the hypertext is organised so that some nodes must be read before the others.

The work from Garzotto et al. [Garzotto et al., 1994] provides a framework for design-oriented hypermedia evaluation, using both a set of design objects, based on HDM [Garzotto et al., 91], [Garzotto et al., 93], and a set of fine-grained attributes of these objects that can impact on hypermedia usability. No internal attributes were proposed as measures since they assumed that finer grained attributes could be obtained by combining the three categories (consistency, self-evidence and predictability) with the three classes of design constituents (structure, behaviour, and presentation) and with the two levels of design (in-the-large and in-the-small), producing eighteen finer-grained attributes in total.

Yamada et al. [Yamada et al., 95] propose three metrics: i) an interface shallowness metric (ISM), ii) a downward compactness metric (DCM), and iii) a downward navigability metric (DNM). The ISM represents the heaviness of the cognitive load on users. The DCM measures the compactness of links from the root and the DNM metric measures hypermedia navigability. This assumes that an easily navigable hypermedia system (1) has a shallow interface layer from the root to the nodes (light cognitive load) and (2) is compact from the root (that is, it is structurally simple to reach the nodes from the root).

Hatzimanikatis et al. [Hatzimanikatis et al., 95] define a hyperdocument quality model using the Factor-Criteria-Metric model [McCall et al., 77]. The factors considered are readability and maintainability, which they decompose into: size, path complexity, tree impurity, modularity, node complexity, coherence, complexity of node contents and simplicity. They define metrics for path
complexity, tree impurity, modularity and individual node complexity. Their definitions are, respectively: the number of different paths or cycles that can be found in a hypertext graph; the extent to which a graph deviates from being a tree; whether modules are self-contained and independent; the complexity that a single node imposes on the overall hypertext structure.

[Tab. 1] compares the four proposed hypertext metrics considering the four questions that should be asked when validating a measure [Briand et al., 97]:

1) Is the measure adequately capturing the attribute it purports to measure (i.e., construct validity)?
2) Is the attribute itself well-defined based on an explicit empirical model (i.e., empirical relational system)?
3) Is there any empirical evidence supporting the underlying hypotheses of the empirical model?
4) Is the measure useful from a practical perspective?

'X' means that the characteristic has been fulfilled by the proposal.

Table 1 - Comparison of the proposals

The metrics proposed by Botafogo et al. have been used in some experiments [Adams & Jr, 97], [Calvi & DeBra, 97], but they were neither based on an empirical relation nor proved to be useful by empirical evaluation. According to Calvi & DeBra “while these methods are able to find link structures which are likely to be unusable, they cannot guarantee that link structures having all suggested values for different metrics will actually belong to highly usable hyperdocuments”. Hatzimanikatis et al. did not define any empirical relationships for their metrics. They were unable to present precise limits or ranges for acceptable values of the metrics proposed because they believe that acceptable values can vary according to the application, the authoring tools used and the production environment. Empirical evidence would help to provide baselines for these metrics.

3 Metrics applied to SHAPE

3.1 The SHAPE project

Southampton Hypermedia Authoring Paradigm for Education (SHAPE) [Mendes & Hall, 97a] is a research project being carried out at the University of Southampton. The aim of SHAPE is to help authors in the development of high quality large hypermedia applications for education. The quality characteristics we consider are reusability of information, maintainability of applications and authoring effort.

Instead of defining improvements to be applied to an authoring tool and later verifying if they are adequate, we decided to use a more consistent and systematic approach: to apply metrics in order to identify how adequate an authoring tool is for the maintainability of applications, information reuse in applications and the level of authoring effort required.

We have chosen to compare Microcosm [Davis et al., 92] to the Web [Berners-Lee et al., 94] because the two systems propose different and opposite ways of representing and managing links, and this
seems to have a big influence on authoring [Hill et al., 95]. Microcosm is an open environment, characterised by the separation of link structures from the information being linked [Hill et al., 95]. The WWW, on the other hand, provides a simple point-to-point linking model based upon embedded links.

The principles of the metrics we have developed [Mendes, 97] are based on the goal-based framework for software measurement proposed by Fenton et al. [Fenton & Pfleeger, 96], and on the guidelines from the DESMET project [Kitchenham, 96], [Kitchenham, 93]. Both have been extensively used in experiments in the software engineering field [Harrison et al., 95], [Daly, 96], [Briand et al., 96], [Briand et al., 97], [Briand et al., 97], [Basili & Rombach, 88], [Basili et al., 94], [MacDonell, 91].

We have planned two evaluations within SHAPE. The first was a quantitative evaluation and the second is quantitative and qualitative evaluation. In Section 3.2, we describe and present the results of the first evaluation.

3.2 Design of the First Evaluation

For the first evaluation the stated hypothesis was:

H1 - Microcosm applications are more maintainable and their information more reusable than applications built using a standard WWW environment.

3.2.1 The Method

The survey involved the use of questionnaires that were completed by either Microcosm or Web developers.

A survey offers the following advantages [Kitchenham, 96]: i) reaches a lot of users; ii) makes use of existing experience; iii) makes use of standard statistical analysis techniques; and iv) confirms that an effect generalises to many projects/organisations.

Both questionnaires had three sections: reusability, maintainability and experience. The reusability section was defined using knowledge from three distinct domains: software metrics, hypermedia and software reusability. The maintainability section was also defined using the knowledge from three domains: software metrics, hypermedia and software maintainability. The experience section was defined using knowledge from software engineering and hypermedia domains. More information about the questionnaires and the evaluations within SHAPE can be found in [Mendes, 97]. In order to prepare the maintainability and the reusability sections we had to consider common tasks accomplished by authors in the development of hypermedia applications for education.

Before sending the questionnaires to both Microcosm and Web authors we carried out a pilot study [Preece et al., 94] where the questionnaires were answered by a group of five people with previous experience in the development of hypermedia applications for education, using either Microcosm or the Web. They gave us feedback concerning: i) Ambiguous questions; ii) Unusual tasks; iii) Definitions in the appendix; and iv) Number of questions.

3.2.2 The Results

The survey results were analysed using standard statistical techniques. To determine whether the two sets of questionnaires (from Microcosm and Web authors) were from different populations we used the Kruskal-Wallis one-way analysis of variance, with a level of significance of 5% and 10%. To identify the correlation between the independent and dependent variables we used Gamma as a measure of correlation, with a level of significance of 10%.
The applications developed by both the Web authors and the Microcosm authors shared similar compactness, stratum, size, connectivity and structure of the applications. This was also confirmed using statistical tests. No statistically significant differences were found. Both groups shared similar experiences and levels of involvement in the development of the applications. This was confirmed statistically.

We measured time and level of difficulty using a questionnaire with 15 tasks. For each of these tasks, authors were asked: i) the level of difficulty to accomplish the task, on a scale from 1 (very easy) to 5 (very difficult) and ii) the time it would take, in minutes, using 10 different intervals given. Thirteen tasks were based on usual activities concerning maintenance and reuse. As we did not want to bias the evaluation, only two questions were developed where the tasks involved might be more effectively accomplished using generic or local links. These were questions 12 and 13 respectively. The tasks are described below:

1) Finding dangling links within a document that has five links to other documents.
2) Deleting a document, that has five links to other documents, without leaving dangling links.
3) Adding a new paragraph to the beginning of a text document, that has five links to other documents, keeping the links intact.
4) Modifying the source anchor of a link.
5) Modifying the destination of a link.
6) Deleting a link.
7) Checking for dangling links caused by the deletion of a document that had two links.
8) Link ten terms to descriptions defined in a glossary.
9) Copy five documents (each with two links to other documents) to another application, keeping all the links already defined.
10) Finding if a document is part of an island.
11) Moving five documents (each with five links) from one directory to another, keeping their links valid.
12) Moving five documents (each with five links) from machine A to machine B, keeping their links valid, where both machines have the same operating system.
13) Checking for islands caused by the deletion of five links.
14) Linking a word that occurs in five documents (once in each) to a destination document.
15) Copying a document that has two links within your application, keeping all the links already defined.

When comparing tasks involving point-to-point links in both Microcosm and the Web we found that in 33% of the answers the medians for the level of difficulty were lower for Microcosm than for the Web and in 46% of the answers the time was shorter. In 46% of the answers the time spent in both Microcosm and the Web was the same. But Web authors needed to use an auxiliary set of tools in order to accomplish the tasks in a reasonable time and with a low level of difficulty. This was not necessary using Microcosm.

Even with 7 answers where the level of difficulty was higher for Microcosm than for the Web there was no corresponding increase in the time spent to accomplish the tasks. As Microcosm is an open hypermedia system, the author has to edit the linkbase many times in order to maintain links. This task can be considered more difficult than changing links on the Web, but, as shown by the data, there was no overhead on the time spent.

When comparing tasks involving point-to-point links in both Microcosm and the Web we also found 8 answers with a statistically significant difference. Four showed advantages for The Web and four showed advantages for Microcosm. The medians for tasks involving Microcosm point-to-point links, Web point-to-point links and the corresponding level of significance are presented in [Tab. 2]:

<table>
<thead>
<tr>
<th>Question</th>
<th>Attribute</th>
<th>Median point-to-point Microcosm</th>
<th>Median point-to-point Web</th>
<th>Level Significance</th>
</tr>
</thead>
<tbody>
<tr>
<td>02</td>
<td>Time</td>
<td>1</td>
<td>2.5</td>
<td>0.04*</td>
</tr>
<tr>
<td>05</td>
<td>Difficulty</td>
<td>2</td>
<td>1</td>
<td>0.00*</td>
</tr>
</tbody>
</table>
Questions 5, 6, 14 and 15 represent simple tasks, but for Microcosm authors involve the editing of the linkbase in order to update the information about the links. We understand that this was the reason for a higher level of difficulty using Microcosm. But, even with a higher level of difficulty, no statistically significant differences were found when comparing the time involved in the same tasks. Questions 2 and 8 showed a statistically significant difference in the time spent in accomplishing the tasks. The time was higher using The Web. Questions 12 and 13 also showed a statistically significant difference in the level of difficulty spent in accomplishing the tasks. Again the level of difficulty was higher using the Web. Questions 12 and 13 would be easily accomplished (in Microcosm) using generic links for the former question and local links for the latter question. Here we can see that when the applications require the definition of links to be valid within the whole application or within a particular document, the use of point-to-point links on the Web increases either the time involved or the level of difficulty in accomplishing the task.

For the independent variables number of documents, compactness, stratum and experience we found significant Z values for questions 9, 14 and 15. The results are presented in [Tab. 3]:

<table>
<thead>
<tr>
<th>Questions</th>
<th>Application size</th>
<th>Compactness</th>
<th>Stratum</th>
<th>Experience</th>
</tr>
</thead>
<tbody>
<tr>
<td>09 Time</td>
<td>1.85*</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Difficulty</td>
<td>2.04*</td>
<td></td>
<td></td>
</tr>
<tr>
<td>14 Difficulty</td>
<td>1.67*</td>
<td>2.06*</td>
<td>2.31*</td>
<td></td>
</tr>
<tr>
<td>15 Difficulty</td>
<td></td>
<td></td>
<td>1.98*</td>
<td></td>
</tr>
</tbody>
</table>

* A Z critical of 1.64, denoting that the result is statistically significant at the 10% level

Table 3 - Significant association between independent and dependent variables

We found values of Gamma higher than 0.50 not only for the four independent variables presented in table 7, but also for the number of links and the structure of the application. Values for Gamma equal or higher than 0.50 show that there exists an association between the variables compared, but without corresponding statistically significant Z values we cannot generalise the results.

We are carrying out further evaluation, using large hypermedia applications, in order to determine whether or not the metrics proposed can be applied to measure the maintainability and reusability of hypermedia applications.

4 Conclusions

Hypertext metrics have been developed in an ad-hoc way, expressing measures in an ambiguous manner and limiting their application. For example, there are many different decisions that have to be made when defining a usability measure or maintainability measure. These decisions have to be made with respect to the goal of the measure and by defining an empirical model based on hypotheses. Unfortunately, many measures proposed in the literature do not have the motivation behind these decisions documented, making it difficult to understand the underlying assumptions of the measure.
The principles of the metrics we have developed are based on the framework for software measurement proposed by Fenton et al. [Fenton & Pfleeger, 96], and on the guidelines from the DESMET project [Kitchenham, 96], [Kitchenham, 93].

We carried out quantitative evaluations aimed at comparing both Microcosm and the Web concerning the reusability of information and the maintainability of the applications. The data collected showed strong evidence that the link representation, link type, highlighting of anchors, structure of the application and the author's experience can strongly influence the maintainability of the application and the reusability of information. We also found some evidence that the number of documents, compactness and stratum can also influence the maintainability of the application and the reusability of information.

The next evaluation will be both quantitative and qualitative and its aim will be to measure the authoring effort involved in the development of a hypermedia application using both Microcosm and the Web.

Are We Really Doing Students a Favour? - A Study of the Use of an Electronic Study Guide in Distance Education.

Dr John Messing
School of Information Studies, Charles Sturt University
Wagga Wagga, NSW, Australia
jmessing@csu.edu.au

Abstract: The climate of increasing demand for higher education places, serious discussion of global strategies for the delivery of courses and an extensive body of relevant literature are notable for the dearth of discussion about the effect of the use of electronic materials from a student perspective. Research which was focused on the definition of a set of features that might make electronic books a more desirable alternative to printed ones for distance education students, collected and interpreted data about the way that distance education students used various features of an electronic study guide. Analysis of the results indicated that there are serious misconceptions in the literature about how acceptable such products really are. The major issues are not simply ones of how sophisticated the electronic book might be but ones of minimising the inconvenience to the learner. Many more learning features need to be provided than is generally thought necessary, to compensate for the restrictions that an electronic medium places on the learner.

The higher education system in Australia and indeed many other parts of the world, is changing. The demand for more higher education places is growing as a result of community expectations and the effect of such things as the need for retraining [Zastrocky 1996]. Offering education in the distance mode is one of the key expansion areas for higher education. International competition and the marketing of education courses globally are already established trends [Ayad 1996]. For organisations that have a successful history in ’Distance Education’ (DE) as well as those who are only just embarking on such ventures, the choice of most appropriate delivery medium is one of the critical factors in their success. Many already anticipate using electronic means such as the World Wide Web (WWW), CDROM etc. as a distribution mechanism. Pressures for change have been building for some time as successive governments cut budgets while Australian society expects progressively more and more of its school leavers to aspire to post secondary education.

Teaching is a labour intensive task. No university can afford the luxury of Socratic dialogue for any but the most rare of students. Providing guidance, assessment and feedback for the vast majority is a goal that is difficult to achieve in a climate of increasing student:staff ratios and decreasing per capita grants. Administrators and policy makers sometimes use economic rationalist terms such as ’economies of scale' or 'cost effective' practices. There are many such as the vice-chancellor of the Open University in the United Kingdom, Sir John Daniel, [Daniel 1996] who believe that the future of higher education is inexorably tied to the implementation of strategies based on the use of new and emerging information technologies.

DE or 'Open Learning' as it is sometimes referred to, is one of the methods by which the high cost of face to face teaching may be reduced. There are serious doubts about the intrinsic value of some of the traditional face to face methods such as the lecture, that most
The appropriate use of technology is a significant component in such ventures. Computer technology has been used in education for many years but what is surprising, is the relatively superficial effect that it has had. From almost the very beginning, computers were seen as an important tool to be used in the educational process. Society was promised [Suppes 1968] the ultimate in individualised instruction, an infinitely patient tutor, a system which would revolutionise both the educational processes at schools and in the home. [Bork 1980] claimed that: "By the year 2000 the major way of learning at all levels, and in almost all subject areas will be through the interactive use of computers." (p53)

The Australian National Teaching Development Projects since 1994 bear witness to the same sort of confidence that Bork expressed nearly two decades ago but also highlight the difficulty of extremely high production costs. Such high costs are unacceptable in the current funding climate unless they can be spread over a large student load or produce significantly higher learning outcomes. The widespread adoption of the Internet and the WWW by academic as well as business and private interests around the world has led to suggestions that this is the means by which cost effectiveness may be achieved. While the concept of the 'virtual university' is most definitely an item on the higher education agenda, questions about the mission of such a university [Gilbert 1996] and the impact of working in one [Taylor 1996] are only just beginning to be raised. However, little appears to be written from the perspective of the learner.

Charles Sturt University (CSU) is one of the major providers of DE in Australia with over 24,000 students, three quarters of whom, study in the DE mode. The Technology Strategy Report [Rebbechi & Barnard 1994] mapped out a comprehensive set of alternatives for the development of technology used in the teaching and administration of CSU students. One of its key recommendations involved the conversion of as many as 1200 subjects from print into electronic form by the year 2000. This was seen as an ambitious and probably unrealistic target but it did indicate a support for the use of electronic teaching at the strategic planning level within CSU. There was general agreement that some method of automatic conversion would need to be used for a large percentage of these subjects and that this would not provide the opportunity for substantial enhancements.

Fundamental to this decision to move to electronic format for teaching materials was the belief that in doing so, students would not be disadvantaged and indeed the provision of 'added value' features would actually make this method of delivery more attractive to students. The adding of value is the attribute about which, least quantitative data is available. The notion of just what the value is, that is being added, is different from the student's, academic's and organisation's point of view. Quite clearly, the organisation might see value in the reduction of the cost of printing or the perception of 'With-it-ness' [Taylor 1996]. Academics might see value in the reduction of lead times from existing levels associated with a production model dominated by the publishing process. Students however, would not necessarily be aware of this type of added value or even see this as having much to do with the quality of their learning experiences in a course.
For students there may be added value in just having the learning materials in electronic format. Such a scheme could be achieved with minimal extra effort requiring just a simple translation of existing DE materials that are already largely in electronic format as word processor files, into a suitable format for user viewing. This type of translation is already commonplace in the publishing industry with the use of Standardised General Markup Language (SGML) or commercial programs like Adobe Acrobat.

This would facilitate access to the content in a way which allows them to manipulate, extract, reorganise and customise the learning materials to suit their own needs and preferences. Catering for individual differences and learning styles has been a long standing goal of education. Being able to make margin notes which do not limit one to the width of the margin, using copy and paste to export some sections to another electronic document or import sections from another source are examples of value that is added by virtue of having the materials in an accessible electronic form.

Electronic copies of learning materials are usually much more compact than bulky printed ones, are less bulky to carry around and easily duplicated. This would allow students to have multiple copies of their materials at different locations such as at home and work. Taking study materials on a plane would add very little to the weight of the baggage and in that respect encourage portability.

Whether these are sufficient to have students perceive an increase in quality is open to question but this represents only the minimal set of possible advantages that may accrue from a move to electronic format. Since cost of printing determines such things as page limits for learning materials, the number of colours used in the typography, diagrams and other graphics, these could be easily enhanced with very little increase in cost, both in terms of money and time. The use of colour to enhance presentation and information content is well documented [Macaulay 1995]. This would be an obvious example of added value from the student's perspective.

The provision of more valued added items would require additional effort which would reduce the cost effectiveness from the organisation's perspective but if it enhances the learning process and results in higher success rates, better client satisfaction and ultimately an increase in prestige for the course, the academics or the university, then such increases may be justified. Among the value added features that could fall into this category are ones such as the better integration of resources. Providing structural features such as hotlinks, multiple views, expansion boxes, content maps, free text searching etc. to give the student more sophisticated tools with which to use the basic materials would require a significant effort on the part of the producers of these materials. Allowing students to make their own links is in the opinion of [Jonassen 1993], a vital step in constructivist use of such learning materials. Links to WWW resources are an obvious extension to this type of value adding.

[Laurillard 1985], argues that the full benefit of computer based materials does not come with just the student's control over the sequence of content and learning strategy. It requires the provision of highly interactive simulations which are designed to help the student acquire the requisite knowledge by means of a goal oriented manipulation of the information in the domain. Such features are extremely expensive to provide and serve as the upper limit of what could conceivably be achieved in the process of adding value to existing materials.

Determination of the amount of advantage or disadvantage that results from the provision of electronic learning materials is difficult. Even considering only the student's perspective there are many variations which affect the ability to make accurate judgements. Objective
measures such as differences in the amount of time required to deal with same amount of content need to be analysed in the light of various factors in the students' background that could affect this. Allowances also need to be made for additional 'overhead time' such as how long it takes between the arrival of the materials and when they are actually installed and functional. Simple cost benefit analyses need to take account of the real cost to the student of such practices including hardware, software, consumables (paper, ink and possibly telecommunications costs) not just the obvious ones of production time and cost of distribution. Even so, there will be many subjective factors such as the amount of inconvenience that it may cause or the amount of enthusiasm that it engenders, that will be impossible to accurately quantify.

Computer programming is a subject that requires a significant amount of integration of relatively easy to produce resources (program code as text, problems, flowchart diagrams, pseudocode) with the basic explanations of the concepts. Since most of these resources already existed in electronic form by virtue of their nature, the conversion of an introductory programming subject's learning materials into electronic format using a minimalist approach outlined above was a good choice to establish a benchmark for levels of acceptance of this style of delivery of DE materials. Programming was also an ideal choice because the nature of the subject required students to undertake significant amounts of interactive exercises with computers, eliminating one of the potential variables, the need to use a computer and also minimising the effect of some others such as computer anxiety. Programming students are more likely to be adopters of the technology than other students.

A substantial body of literature is available that deals with a range of theoretical issues surrounding the design and implementation of hypermedia based learning materials. Most of it however, discusses these from the perspective of the designer rather than the end user and makes assumptions about student reactions. Empirical studies of users' behaviour are usually focused on specific features that are often investigated over a short period of time and in controlled laboratory situations. This study [Messing 1997] was carried out for the duration of a full semester for five consecutive semesters.

The goals of the study were to collect and interpret data about the way that students used various features of an electronic study guide in the context of a distance education setting and to uncover any relationships that affected the desirability of this as a means of delivering educational materials. Data were collected using computer logging procedures within the study materials which recorded every action along with time based data. Surveys were used before the start of the subject to determine the level of experience with computers and computer based learning materials. Surveys and interviews after the teaching period were used to gather data about student reactions.

The analysis of the survey data using the 3G approach proposed by [Collis 1991] proved to be an appropriate technique for evaluating electronic books. The '3G factors' may be loosely translated as:

Gewin - a meaningful gain in relation to the goals of the project i.e. some level of performance or achievement
Gemak - a payoff in making the life of the participant somewhat easier
Genot - a measure of the pleasure or satisfaction derived from the project

Two variations of the standard 3G approach were used. Positive and negative aspects were quantified separately and plotted and the whole group was divided into four categories based on their disposition to using the technology as well as inclination to make strong or weak comments.
The 3G vector diagram agreed very well with the theoretical prediction for the use of electronic books in a school setting without a teacher support focus as suggested by Collis. One could argue that such a setting is not dissimilar to a distance education environment. The results in [Fig. 1] graphically illustrated the dichotomy that was evident in other aspects of the analysis. The positive aspects indicated a measure of achievement and satisfaction that students derived from using the electronic study guide while the negative components reflected the fact that there were some significant costs associated with using it.

The gemak (payoff) vector appeared to represent the factor which needs to be addressed most urgently. The negative components were a measure of the obstacles that students had to overcome in using an electronic format which still largely restricted portability. Rather than making life easier, the use of the electronic study guide actually caused significant inconvenience. The results for the pleasure vector indicated that in general, the students in this study were, as suggested, adopters of the technology. As [Bates 1997] observed of other distance education students, they were prepared to overcome significant hurdles and still retain a commitment to technology-based education.

The analysis of the usage data revealed that even though a number of significant features were added to the electronic book to make it a supposedly attractive alternative to the printed version, these were not sufficient to prevent most students from preferring the printed one. Electronic format places many restrictions on distance education students due largely to its lack of portability. It forces changes in the way that students study which are not really taken into account in the cost/benefit analysis that the providers of this material undertake. For example, one student semi-jokingly replied that "I used to read in bed at night but the 14 inch monitor got too heavy for my arms!".

Such restrictions are even more pronounced when this is coupled with tighter requirements such as having to connect via a telephone line. Not only does this cause disruption to family organisation and routine but it can cause considerable acrimony on the part of the student who may feel that the additional social pressure is not really being balanced by exceptionally good learning material. It may seem like a good move from the academic and organisational perspective to supply students with their learning materials over the Internet, but unless these materials justify the expense and inconvenience to the student, they will not be well received. The indications from this study are that the perceived benefits need to be much higher than the typical level currently available.

1018
In listing the supposed benefits, one must be careful not to confuse perceived benefits from the designer's projection of the learning process with the reality. The way that features of electronic learning materials affect student learning may not be what was originally expected. For example, being able to easily execute program code in the examples was considered a highly positive aspect of providing an electronic study guide for this group of students. Data revealed that there were a number of unanticipated factors that partly explain why the usage was actually quite low. Some students who initially made moderate or extensive use abandoned the technique for a very sound educational reason. While the process made it relatively quick to demonstrate program code in action, it by-passed the act of typing code into the compiler. During such an act, there would normally be a great deal of incidental learning of the structure and syntax of Pascal programs as well as how to operate their compiler. These students reported feeling that they derived better learning experiences by actually typing the code themselves.

The majority of students in the study could be characterised as having both highly positive opinions on the use of electronic format as well as highly negative ones. They could see the educational value of many of the features that were provided but the practical restrictions of having to use a computer for most of the time were dominant. They, in common with most DE students [Roberts 1984], use their learning materials in a diverse collection of situations, on the train to work, at work during lunch breaks, in planes, at airports, waiting in the car for a child at football training, in bed at night and many more. Not all of these situations are conducive for interactions with a computer.

Electronic learning materials may well meet the various objectives that their academic creators have for themselves or their organisation but in the end, the test is whether the learners share these positive views. The implication from this study is that the break even point where learners prefer to use the electronic materials because of added value features and despite the greater restrictions, is much higher than one would expect. The following student comment provided an accurate summation of the general attitude:

"It exposed us to the way all distance education is likely to be delivered in the not too distant future and it showed us what learning from course notes provided only in electronic form is really like - which wasn't as easy as I thought it would be - there is something about learning and reading from paper which is so much easier than doing it from a screen. I had originally thought that I would really enjoy studying from a computer screen - but I really didn't, although it was an effective way of providing a lot of interconnected information."

Abstract: Due to the increasing need of educational tools for the Portuguese language learning by foreign people and also by the great community of lusophone countries spread around the world, emerges the Simmpatico Project which tries to fulfill that gap using the possibilities created by the new Information Technologies. This paper describes technical and educational issues related with the development of this project.

1. Introduction

The decision to construct a multimedia tool for the teaching of Portuguese as a foreign language is linked to the importance which this language has assumed in the world today, both in terms of numbers of speakers, and of its distribution over all the continents. Having been worked on for more than a thousand years, permanently enriched by the contributions of the multiple variants of Europe, America, Africa and Asia, the Portuguese language, spoken by more than 150 million people, as a mother tongue, second language or official language, is part of the universal heritage.

"Portuguese is a living element in political, economic, cultural and scientific exchange between the peoples of Africa, Asia, America and Oceania. It is therefore a matter of placing the Portuguese language in the position it deserves to occupy in international affairs, in a world where its contribution – on account of the wealth and diversity of cultures which it vehiculates – can reinforce international Cupertino between nations." [OSPINA 1985]

The structure of the course, conceived primarily for the teaching of Portuguese as a foreign language, permits, however, with some alterations, its use in support of the teaching of Portuguese in the lusophone African countries (countries where Portuguese is the official language) and even in the teaching of Portuguese as a mother tongue (being able to facilitate and stimulate teaching through appropriate, interactive use of the techniques of hypertext).

2. Package Organisation

2.1 Linguistic Approach

The target population for this course is young people and adults who have acquired several types of competence through the learning of their mother tongue and probably through the learning of one or more
foreign languages (or a second language) – linguistic competence, metalinguistic competence, narrative/discursive/textual competence, pragmatic competence (communicative / metacommunicative).

There exist, however, significant individual differences in relation to linguistic knowledge, which are linked to a great number of interdependent factors: aptitude, motivation, memory, attitude towards target language, time given to learning, quantity and type of input in the target language, socio-economic, educational, and affective factors, knowledge of the mother tongue and other languages.

These differences will cause significant variation in the speed and effectiveness with which the learners are capable of creating and putting to work a control mechanism, i.e. the way in which they will retrieve the appropriate knowledge from several separate knowledge’s (modular structure), causing the posterior integration of these several knowledge’s. The objective of this course is to facilitate the installation and development of these retrieval procedures, in such a way as to make them progressively more automated [McLaughlin & Rossman & McLeod 1983].

The non-reflective acquisition of knowledge is not, however, incompatible with the process of becoming aware of the way in which the learner solves his/her learning difficulties. This course therefore presents (relatively brief) descriptions of the levels of language functioning – phonological/phonetic, morphological and morphosyntactic – which we consider indispensable for the construction of representations of the linguistic structure of Portuguese.

In this way, we appeal to the metalinguistic capacity of the user (conscious representation of the properties of the various utterances) and to the capacity/possibility of transferring prior linguistic knowledge (especially lexical knowledge, which is normally neglected in favour of syntactic orthodoxy) to the resolution of problems (especially in comprehension tasks) [E.Kellerman 1977] [E.Kellerman 1978a] [E.Kellerman 1978b] [Kellerman & Sharwood 1986] [Ringborn 1987] [Miranda 1996]. The grammar is presented explicitly in order to help the learner to explicit (gain awareness of) the way in which he/she understood and interiorized the workings of utterances – through multiple choice exercises using paraphrases, rules, judgements of acceptability/grammaticality.

2.1.1. Methodological Organisation

The course consists in a set of teaching modules divided into three levels: Level 1 (real beginners); Level 2 (post-elementary); Level 3 (pragmatic/cultural). With Level 1, the learner should be able to recognise and produce isolated words and simple sentences (at a relatively slow speed of oral discourse), being able to communicate with native speakers on matters of daily routine, obtaining essential information, understanding and producing simple (and essentially written) instructions. With Level 2, the learner should be able to participate in verbal interaction with native speakers, understanding and expressing opinions on topics (which go beyond themselves and their personal sphere), at a speed of oral discourse which is progressively closer to intercommunication between native speakers. With Level 3, the learner should have acquired sufficient autonomy in Portuguese, to be able to understand authentic documents (written – literary texts and non-literary texts covering sociocultural and oral aspects – songs and media documents, talk-shows, news, interviews).

The course is conceived as a “journey”, a path through the several “scenes of daily life”, and attempts to cover a wide range of interests: tourism/travel, business/shopping, food, sport, etc. Each one of these levels is made up of a particular number (not necessarily the same number) of thematic units approached in specific situational contexts [Casteleiro et al. 1988].

The situations of communication are organised in successively smaller units (exchanges and speech acts), made explicit through utterances whose difficulty depends on the level in which they are situated. The themes and situations of communication are repeated in the first two levels, helping the learner to transfer and reuse the various “knowledge’s” and motivating him/her to construct (or make more complex) some situations. This can either be done by introducing variations in the extra-linguistic parameters and reconstructing the web of discourse accordingly, or by modifying the semantic-pragmatic structure of the to fit new communicative intentions.

Example:

Level 1 – Topic: Tourism/Travel Situation: In the hotel/reception. A couple are looking for accommodation; they ask for information - Dialogue on video, possibility of visualising the text by means of subtitles corresponding to each utterance, or even the whole text of the dialogue. Slow discursive speed (non-native)
Level 2 – Same topic, same situation.
- The text of the interaction which took place at level 1 is repeated, but the dialogue becomes more and more complex, the verbal exchanges are in greater number and the discursive speed is closer to the "native mode".
- From this situation, two new situations are created which do not exist at level 1, one for oral production (telephone conversation) and one for written production (the female character writes a postcard, in the hotel bedroom).

Some of the elements of this situation can be transferred (re-used) to another situation (in the same thematic unit or in different thematic units).

The course comprises:
- Various exercise types, according to the capacities which are being developed in each step: exercises which are more focused on the structure of the language, paraphrase/lexical expansion exercises (reduction and integration), confrontation exercises and text/discourse production, the written transcription of oral register, the reconstruction of texts/according to a framework of discourse types.
- Explanatory and systematic tables of grammatical elements and their functioning (using a grammatical metalanguage which can be easily understood by the majority of users).
- Assessment exercises, with the respective answer keys or suggestions (appropriacy).
- A Portuguese/French/English dictionary, based on Basic Portuguese [Port. Fund. 1984].

2.2. Hypermedia Structure

Our program structure tries to cope with a correct integration of day to day communication dialogues with, up-to-date hypermedia concepts into an intuitive, and interactive, human-machine interface. The multiple communication dialogues originated various digital video records in a coherent sequence, organised in 3 learning levels. Text labelling is synchronised with each video and translates ongoing dialogues. Both video hot-spots and text labelling have hypermedia connections to other information structures as depicted in [Fig. 1]. These different hypermedia elements contents have a relation with culture, nature, local/national tourism, geography, etc, producing an integrated environment to understand the local/national socio-cultural signature as a whole.

Figure 1: Hypermedia relations.

2.2.1 Interface/Icon study

The interface project took into account the program's usability, interactivity and its various options. The interface icons try to translate common day to day situations using intuitive symbols within a creative perspective. The next figures, [Fig. 2] and [Fig. 3] represent some of our interface proposals.
3. Technical Aspects

As in any multimedia application it was defined a target machine with a set of minimum requirements to play the SIMMPATICO multimedia piece: IBM-PC or compatible; MS Windows 95 or above; 16 MB of RAM; 4X CD-ROM drive; 16 bits sound card; Graphic Card with a minimum of 256 colours at a resolution of 800x600; MPEG-1 enabled hardware or software decoding capacity.

These requirements are the result of a constant optimisation process during the development phase, with the purpose, that even a common and simple multimedia machine can run the application. As a consequence of this, a wider range of potential users is reached by our project.

The development of the application is being done on a well known multimedia authoring tool - Authorware. This program has long been the leading tool for computer-based training and interactive learning.

With the developing of a multimedia application, there are various types of media to produce, process and finally integrate in a main program. Each type of media as is own characteristics, and production cycles.

Sound - Every sound was originally recorded in studio, and afterwards digitised with the aid of a professional sound card at a 22,050 kHz, 16 Bits and Mono quality. By doing this, a quality sound is obtained and the associated files are in a very acceptable size (Data flow of 43KB/s). After that, every sound file was processed with the use of the Animator SoundLab, namely the tools for noise removal and sound equalisation. In the end, the sounds obtained were of excellent quality and with a reduced file dimension.

Image - The multimedia application makes use of original artwork and also of photos, icons and vectorial drawings contained in popular clipart CD-ROM’s. The original artwork was digitised in a Umax PowerLook 2000. All this material was then processed and manipulated using the Photoshop and some of its plugin filters from Kai’s Power Tools. The final images were limited to the maximum resolution of 800x600 with a colour depth of 256 colours and were saved in DIB graphic format. This type of graphic format is one of many with direct integration in Authorware. In the end all images were reduced to a common 256 colour palette with the purpose of avoiding strange colour shifts in systems with only 256 colours.

Computer-Generated Animation and Images - Certain concepts and ideas that could not be easily explained, with real videos or images, were created in virtual animations or graphics. All this was made possible, thanks to the use of modern 3D Graphic Packages like 3D MAX, which can create still or animated images. All the animations were produced in the FLIC format which is directly integrated in Authorware. The still images were first generated in the popular BMP format and later converted to the already referred DIB.
format. With all animations and images great efforts were made in the creation of a global palette, to avoid the

Video - This was the most challenging and difficult media to produce, process and integrate, because of the huge quantity of data involved. Initially the decision of delivering the final videos in the so popular AVI format terms of storing it in a single CD-ROM. So a different approach was followed, the compression of the videos in the MPEG-1 format. The use of this compression method gave a significantly reduction in the video file sizes,

Pentium 120MHz and 48MB of RAM. The video production chain was the following:
1. Recording the scenes and scripts on studio or on location, using U-MATIC SP equipment. The actors were recruited among the members of the University Theatre Company with a special care for the actor's the sound recorded during the video shoots, because any noise could interfere with the comprehension of the dialogues.
2. Analog Editing with the purpose of cleaning the raw video footage's from the major part of unwanted to reduce the amount of data to be processed in the next steps.
3. Digitalisation process was made with the parameters referred in [Tab. 1]. Special care was taken with the video sound tracks, to ensure a maximum purity of sound in the dialogues.
4. Digital Editing on Premiere. The original captured files were here edited and assembled in AVI video user. The most significant parameters of the AVI's files are in the [Tab. 1].
5. Video Sound Tracks Processing on Animator SoundLab. Due to the high sound gain in the Miro card and some noises generated during the precedent steps, every video file had to be processed in respect to its sound of 50% on the sound volume level and afterwards a digital filtration with a band-pass filter to remove unwanted noise.

Codification in MPEG-1 format on a MPEG Encoder. As a mean to reduce the large amount of video a MPEG-1 compression of the AVI's was made. The size of the video files was reduced has the [Tab. 1] indicates, while maintaining a good image and sound quality level.

4. Conclusion and Future Work

The dialogues corresponding to the various situations of communication (Levels 1 and 2) have already been recorded, and the descriptive/explanatory tables of the several grammatical topics and the dictionary are nearing completion. The next tasks will be the completion of the exercise banks and the selection and digitalisation of the documents to be used at Level 3.

Given that this is a research project, we believe that tracing mechanisms should be included to enable the system to be perfected, while at the same time permitting self-assessment to take place. These mechanisms will
further permit the elicitation of feedback which will be important for the evaluation of our strategy of “back to lexico-grammar” or of “lexico-grammar refresh”.

The first prototype will be tested with foreign students who frequent Portuguese university courses (Erasmus/Socrates programme) and the International Summer Course (July 1998).

One of the important goals in the SIMMPATICO project is to develop an “on-line” version of the final application. For this purpose we used the Shockwave technology, with which anyone can easily convert and transform a regular desktop multimedia application to a web-based multimedia application. This technology picks a desktop multimedia piece and creates a compressed runtime version of it, that will play across Intranets or over the Internet using the networking services of a simple HTTP client.

The major drawback in this technology is the fact that Shockwave doesn’t support streaming audio and video over a network. So as a consequence we have to limit in great extent the audio and video contents of the “on-line” application in comparison to the desktop version. If this problem isn’t serious over a fast Intranet, it becomes a great burden to the overall performance and joy of use when the application is delivered over the slower Internet. The potential user has to wait until the video and audio parts are downloaded before he can start using the application, so if there is a great amount of video and audio information on the piece, the starting delay time could be very frustrating, leading him even, to not explore the application at all.

In conclusion great cares have to be taken, to create a low-bandwidth demanding application with less or smaller video and audio files. Also in the graphical interface some changes have to be made to make a lighter piece as possible, that is, a application that will play nicely and smoothly even over the Internet.

The Notion of Functionality in the Faculty Use of E-mail for Instruction

Dr. Ananda Mitra
Dept. of Communication, Wake Forest University, Box 7347 Reynolda, Winston-Salem, NC 27109
Tel: 1-336-758-5134, Fax: 1-336-758-4691, E-mail: ananda@wfu.edu

Abstract: The notion of functionality is described as the way in which users perceive the usefulness of a computer. This paper demonstrates that the faculty use of E-mail for the purposes of instruction are related to the way in which they perceive its functionality with the faculty with a positive pre-disposition profile tending to use it more.

1. Introduction

Much of the existing research on e-mail and education makes an implicit assumption that teachers, students and other members of educational institutions indeed use e-mail for their teaching, learning and administrative activities. It is also assumed that since Computer Based Communication Technologies (CBCT) are becoming increasingly available to members of educational institutions, there is little reason to doubt the universality of e-mail use. However, I argue that this assumption of universal use needs to be verified on a case by case basis, particularly because the widespread computerization of universities is providing the e-mail option to a heterogeneous group of faculty and students. This larger group could include people with minimal computer skills or a specific predisposition toward computers, and they could represent groups who have not volunteered to be included in courses where the use of computers plays a significant pedagogic role. Here the distinction between use and acceptance becomes especially critical. While it might have been accepted that e-mail is part of the emerging pedagogic system, the actual use of e-mail is perhaps lagging behind. This paper first attempts to discover the extent of faculty use of e-mail for communicating with students within the environment of a small Southeastern private liberal arts institution where the barriers to CBCT usage have been largely removed through a collaboration with a major information technology provider.

One set of attitudes that can impact the use of technology is the notion of "expectation," and ways in which a desire to use or not use a technological tool is related to expectations associated with that tool. Jackson summarizes this by saying:

The social elements are the expectations of what the artifact will or can do. They act to conscribe or enlist the artifact in the accomplishments of some particular purpose or task…Expectations buffer our perceptions of the material elements (Jackson, 1997, p.256).

These expectations fall into the category of social elements of the use of technology that can influence the material elements of technology use.

The author makes these claims on the basis of an extensive review of the existing research on CBCT, and then develops a framework to categorize the research into broad areas of emphasis based both on the social and material elements of CBCT. My purpose is to elaborate on the notion of expectations by hypothesizing that people with different expectations for technology would have different levels of technology use. However, the notion of expectation itself is differentiated into several components to reflect the social elements that can implicite the use of technology.

Following from Jackson, I argue that the first component of expectation is related to what can be called the functionality of technology. Functionality refers to the "ability of an artifact to be used to accomplish a social task (Jackson, 1997, p.255).” It is likely that low- and high-level users could exhibit differences in expectations about the ability of technology to improve the current pedagogical process. If indeed a technology is considered functional it is then necessary to assess whether the faculty perceive themselves using the technology. In other words, the faculty may accept the functionality of technology, but might not anticipate their personal use of it.

Based on the concept of functionality, it is now possible to present a preliminary research question that address the relationship between functionality and use:
Is there a difference in the levels of faculty e-mail use for teaching based on differences in expectations about the functionality of technology in instruction?

2. Method

The data used in this study comes from the first year of a five-year longitudinal study that began when the university implemented the computerization initiative that provided new students and all faculty with a standardized laptop computer. The overall goal of the study is to assess the effects of the implementation on different university constituencies. The study includes annual surveys of all enrolled students, incoming first-year students, alumni, and faculty. The faculty survey was distributed by campus mail to all full- and part-time faculty of the university. Two mailings of the questionnaire were conducted, separated by a period of three weeks.

The questionnaire was sent to all faculty members. A response rate of 50% produced a total of 154 responses from the faculty. The respondents consisted of 71% men and 29% women, with 49% of the faculty claiming, “anthropology, business and accounting, communication, economics, education, history, politics, psychology and sociology” as their major academic discipline. Of the remaining 51%, nearly half belonged to the arts (e.g., art, classical languages, religion, romance languages and theater) and the rest claimed the sciences (e.g., biology, chemistry, mathematics, computer science, and physics) as their major discipline. In terms of length of employment, 17% claimed that they had taught for less than three years at the university, 9% claimed to have been teaching at the university for four to six years, 23% for 6 to 10 years, and 51% for more than 10 years. Nearly 86% of the respondents were either tenured or on a tenure track while 14% were assistant professors; 31% were associate professors and 43% were full professors.

The research question was answered by dividing the respondents into two groups based on high (responses 3 or 4) and low (responses 1 or 2) scores on the functionality scale and then computing the differences in mean usage of e-mail with students. Statistical tests of significance were conducted with the use of independent sample t-tests assuming equality of variance of the two groups.

3. Results

First, the extent of e-mail use by faculty to communicate with students for teaching-related activities was estimated. The mean response to this item was 2.0 (SD = 1.2) on a four-point scale where “1” represented no use and “4” represented frequent use, with 56.3% of the faculty respondents indicating that they have never used e-mail to communicate with students about teaching-related activities, 9.3% indicating that they use e-mail with students infrequently, 15.2% indicating frequent use of e-mail with students, and 19.2% indicating that they very frequently use e-mail with students. These findings support the assumption that not all faculty members use e-mail with students even though both the faculty members and the students have easy access to e-mail. As shown in Table 1, this trend is also reflected in the frequency of e-mail use with on- and off-campus colleagues.

<table>
<thead>

These results lead to the research question, which focused on the differences in use of e-mail to communicate with students between faculty members who had high and low expectations about the functionality of technology in instruction. There were significant differences in the use of e-mail with
students, with faculty with a positive expectation reporting a mean use of 2.1 (SD = 1.0) and faculty with a negative expectation reporting a mean use of 1.6 (SD = 1.3). These means were significantly different at the 0.05 level (p = 0.023).

4. Discussion

4.1 Expectations

The preliminary results suggest that the use of e-mail is not necessarily universal, particularly when considered within the context of campus-wide implementation of CBCTs.

Indeed, it is the perceived expectations about the functionality of technology that is related to the use of technology. In this case, the expectations about the functionality of technology with respect to instruction are moderately related to the extent of use of e-mail technology for the specific purpose of communicating with students. The faculty members who perceive that technology will positively impact the general process of instruction tend to be more frequent users of e-mail for communicating with students.

Faculty who perceive that technology plays a positive functional role in improving the instructional process are also the ones who feel that e-mail can function as an effective and appropriate communication tool for interacting with students. As the results indicate, such perceived positive attributes and expectations are related to the extent of e-mail usage. Faculty members who have a more positive opinion about the “promise” of technology tend to use it more. From this perspective, the use of e-mail is related to the way in which the technology is perceived, and not on its availability or material efficiencies of speed, ease of use, etc. These results illustrate that use is related to a very fundamental perception about what technology’s promises, and how the faculty perceives the ability of technology to deliver on its promise. Needless to say, the expectations about technology’s promise are also related to the specific aspects of academic life that technology is most expected to enhance.

In summary, those who are not hopeful about how they perceive “the promise of technology,” tend to use it less. Technology as a material artefact is expected to serve a series of functions in its particular application. As discovered in the focus group discussions with faculty and students, both groups anticipated that the computerization at the university would have certain specific effects. To be sure, some sections of the population were far more skeptical about the expectations, and it is precisely the nature of such expectations that appear to be related to the extent of use of the technology. As demonstrated in the results of this study, these expectations reflect a variety of components of technology and the expectations are, in turn, related to each other.

4.2 Usage

The results also suggest that heavier users of technology tend to use the computer for a variety of applications. Like the earlier studies, this study also demonstrated that faculty who would use the computer for e-mail with colleagues would use e-mail with students as well. Similarly, non-users tend not to use e-mail with either colleagues or students. There is certainly an element of customary work pattern that is related to computer use, where the usage level is related to the existing “habit” of computer use. If faculty members use computers for exchanging e-mail with colleagues there is a likelihood that they would also use computers for interacting with students.

The significance of this finding lies in being able to promote the use of computers to communicate with students. This encouragement can take several shapes. Earlier it was suggested that forced compliance would be a way to encourage use (see, e.g., Kerr and Hiltz, 1982). However, other studies seem to reject that assumption, as Komsy (1991) suggests that requiring people to participate in an established electronic mail system “will not be the most important determinant of usage.” It is perhaps easier to demonstrate the value of e-mail in communicating with peers, and if that can be encouraged and facilitated for the faculty, there is a likelihood that the users would also apply the technology to communicating with students. No doubt, usage is related to attitudes and expectations, but if e-mail is perceived as the accepted and customary form of communication it is likely that faculty will use the technology to communicate with students.
4.3 User and Non-User Profiles

Finally, these results suggest that there are a set of attitudinal and behavioral criteria that are related to usage trends, particularly with respect to faculty use of e-mail to communicate with students. Use of computers is certainly not guaranteed, and institutions adopting wide-scale computerization can expect to have non-users of the CMC technology. This begs the question: who are potential users of electronic mail CMC technology? This question can be approached by developing tentative profiles of faculty users and non-users of e-mail for communicating with students. The descriptors of the user and non-user groups are composed of a series of attitudes and demographic attributes. The attitudes include the general attitude toward the use of computers, the specific feelings about the computerization initiative at the university, and the attitudes toward the application of computers in teaching. The demographic attributes include age, gender, and position in the university, as well as computer-related attributes such as self-reported computer skill level and experience with computers. The profiles are thus based on a set of attitudinal items and some demographic and technographic characteristics.

The data suggests that there are two preliminary profiles of the users and non-users of electronic mail with students. The younger faculty who have been exposed to computers early in their academic career tend to be users of electronic mail for communicating with students. The older faculty, with less exposure to computers, have lower confidence with computers and are less likely to use electronic mail with students. Similarly, faculty members who have a positive predisposition toward the introduction of computers in education would be more willing to communicate with students using electronic mail as compared to faculty who are less hopeful about the promise of technology. Finally, faculty members who are in the habit of using computers for other tasks are also more likely to use electronic mail to communicate with students (see Table 2).

5. Conclusion

The results from this study illustrate that the availability of technology does not necessarily suggest its use. The potential user must see a clear advantage to the use of the technology to use it. In the case of communication technologies, these results suggest that these advantages are related to the communication functionality of the technology. This finding adds another dimension to the possible reasons for use or non-use of technology. The results supplement findings that, for instance, confirm the importance of determining factors such as communication apprehension, computer anxiety, or writing apprehension. While varying levels of communication apprehension, writing apprehension and computer anxiety can have an impact on the desire to use CMC, these results suggest that attitudes toward the functionality of technology can also play an important role.

The results also indicate that faculty use of e-mail with students is also related to the use of other technologies and certain components of the demographic attributes of the population. Given the significance of the differences between usage patterns and demographic attributes, it is thus possible to develop preliminary profiles of the user and the non-user. Such profiles can have great utility in assessing the potential user and non-user. Particularly when higher education is challenged with the need to incorporate CBCTs within its pedagogic style, it is certainly useful to consider such profiles. This would allow managers of higher education to anticipate the locus of support from the users of technology. Moreover, by examining the profiles, particularly with respect to usage patterns and attitudes, it could be possible to develop plans of action that can encourage the non-users to become more active users of CBCTs.

Finally, this study is methodologically different from most of the other research because of the survey design adopted in the study. Instead of creating an “artificial” experimental condition to assess the impact of a particular technology, this study used an approach where it was possible to assess the conditions of a particular academic environment within which significant improvements in computer availability were about to happen. This provided a more “natural” environment where the spectrum of use could be observed without having to assume that all the participants of the study are users. Indeed, the fact that a significant portion of the faculty claim not to use e-mail challenges the emerging assumptions of the technology-education partnership where availability is considered an incentive for use. It is implicitly assumed that since the technology is being made available it will be used, as suggested by Oblinger and Rush in saying:

The advent of the learning revolution is facilitated by the availability of a reliable and ubiquitous network infrastructure as well as access to computers, at any place and any time (Oblinger and Rush, 1997, p. 16).

However, the results from this study suggest that while availability of technology might make it easier for the existing users to continue using the technology, it might not be enough to convert traditional non-users to users. That change could call for more far-reaching alterations in the attitudes toward the functionality of computers.

A Knowledge-Based Teaching System for SQL

Antonija Mitrovic
Computer Science Department, University of Canterbury
Private Bag 4800, Christchurch, New Zealand
tanja@cosc.canterbury.ac.nz

Abstract: The paper presents SQL-Tutor, an intelligent teaching system for SQL programming. SQL-Tutor is designed as a guided discovery learning environment and supports problem solving, conceptual and meta-learning. The system uses Constraint-Based Modelling to form models of its students. We present design issues by focusing on the system's architecture. Student modelling and the generation of pedagogical actions are discussed in the light of tailoring instructions towards a particular student.

1 Introduction

Structured Query Language (SQL) is the dominant database language today, containing data and view definition statements, as well as data manipulation statements. Although SQL is a simple and highly structured language, students have many difficulties learning it. This paper presents SQL-Tutor, an Intelligent Teaching System (ITS) that helps students in overcoming these difficulties. SQL-Tutor is designed as a practice environment; it supposes that students have previously been exposed to the concepts of database management in lectures. Therefore, the system is not a substitute for the conventional style of education, but a complement to it. The system currently covers only the SELECT statement of SQL, but the same approach could be used with other SQL statements. This focus on the SELECT statement does not reduce the importance of the system, because queries cause most misconceptions for students. Moreover, many of the concepts covered by SELECT are directly relevant to other SQL statements and other relational database languages in general.

The paper examines the problems of learning SQL firstly, and then presents the architecture of the system in [Overview of SQL-Tutor] and examines the system's components in the following three sections. The directions for future research and conclusions are reached in the last section.

2 Difficulties with Learning SQL

Students experience many problems when learning SQL. Some errors come from the burden of having to memorize database schemas; incorrect solutions may contain incorrect table or attribute names. Other errors come from misconceptions in the student's understanding of the elements of SQL and the relational data model in general. Some of the concepts students find particularly difficult to grasp are grouping and restricting. Join conditions and the difference between aggregate and scalar functions are another two common sources of confusion. Other researchers report the same student misconceptions [Kearns et al. 1997].

SQL is usually taught in classrooms, by solving problems on the blackboard, complemented by lab exercises. However, students find that it is not easy to learn SQL directly by working with a RDBMS, because error messages are limited to the syntax only. [Fig. 1] illustrates a situation in which a student is required to specify a SELECT statement with five clauses, as shown in the correct solution. When the student enters an incorrect solution, typically the error message generated by a RDBMS (Ingres in this case) will not be of much help. The RDBMS can only complain about the syntactic error. The same figure illustrates the kind of messages the student would usually be offered only one message at a time, as governed by the pedagogical rules. Here we show all possible messages for illustration.

[1] Note that the student would usually be offered only one message at a time, as governed by the pedagogical rules. Here we show all possible messages for illustration.
student may obtain from the system. SQL-Tutor can generate messages about semantic errors as well; in this case, the student specified two tables in the FROM clause, when only one of them (MOVIE) is really needed.

Example 1: For each director, list the director's number and the total number of awards won by comedies he/she directed if that number is greater than 1.

Correct solution:

```sql
SELECT DIRECTOR, SUM(AAWON)
FROM MOVIE
WHERE TYPE='comedy'
GROUP BY DIRECTOR
HAVING SUM(AAWON)>1
```

Student's solution:

```sql
SELECT DIRECTOR, SUM(AAWON)
FROM DIRECTOR JOIN MOVIE
ON DIRECTOR=DIRECTOR.NUMBER
WHERE TYPE='comedy'
```

**SQL-Tutor:**
- You do not need all the tables you specified in FROM!
- You need to specify the GROUP BY clause! The problem requires summary information.
- Specify the HAVING clause as well! Not all groups produced by the GROUP BY clause are relevant in this problem.
- If there are aggregate functions in the SELECT clause, and the GROUP BY clause is empty, then SELECT must consists of aggregate functions only.

**INGRES:** E_USOB63 line 1, The columns in the SELECT clause must be contained in the GROUP BY clause.

**3 Overview of SQL-Tutor**

SQL-Tutor is a knowledge-based system that supports students in learning SQL. As in the case with other ITSs, SQL-Tutor tailors instructional sessions to the needs, knowledge, learning abilities and general characteristics of its students. SQL-Tutor is based on guided discovery, one of the teaching styles commonly found in ITSs. Guided discovery is based on the idea that students should be given opportunities to discover things themselves, rather than being told about them. There are psychological studies [Anderson 1993] which show that students learn better from discovery than from direct instruction and that such knowledge is retained for longer than when learning by being told. Of course, unrestricted exploration is not advisable, especially for novices, as students may waste too much time wandering. The solution is found in providing guidance, in form of solicited or unsolicited hints from the system.

The system is designed as a problem-solving environment and as such is not intended to replace classroom instruction, but to complement it. We assume that students are already familiar with the database theory and fundamentals of SQL. Students work on their own as much as possible and the system intervenes when the student is stuck or asks for help. In such a way, students maintain a feeling of control.

SQL-Tutor is implemented in Allegro Common Lisp [Allegro 1996] on SUN workstations and PC compatibles (see [Mitrovic 1997] for more details). The components of the system (illustrated in [Fig. 2]) are the interface, a pedagogical module that determines the timing and content of pedagogical actions, and a student modeller (CBM), that analyzes student answers. There is no domain module, as usual in ITSs that can solve problems given to students. There are two reasons for not having a domain module. Firstly, database queries are given in a natural language; however, the current state-of-the-art in Natural Language Processing (NLP) is still far from being able of handling various problems present in such queries, such as references and synonyms. There is a possibility to avoid NLP: the text of the problem may be represented not in its natural-language form, but in a form that could be the product of NLP, as done in [Anderson et al. 1995]. However, it is hard not to build parts of the solution into such a representation. Furthermore, even if we overlook the NLP problem, the knowledge
required to write SQL queries is very fuzzy and it would be very difficult to develop a problem solver in this area.

Nevertheless, an ITS must be able to evaluate student answers. SQL-Tutor does that by comparing student solutions to the correct ones. That is the reason for SQL-Tutor to require ideal solutions to problems. In order to be able to check the correctness of the student's solution, SQL-Tutor uses domain knowledge represented in the form of constraints, described in more detail in [Student Modeller].

The system contains definitions of several databases, implemented on the RDBMS used in the lab. New databases can easily be added to SQL-Tutor, by supplying the same SQL files used to create the database in the RDBMS. SQL-Tutor also contains a set of problems for specified databases and the ideal solutions to them.

![Architecture of SQL-Tutor](image)

**Figure 2: Architecture of SQL-Tutor**

At the beginning of a session, SQL-Tutor selects a problem for the student to work on. When the student enters a solution, the pedagogical module (PM) sends it to the student modeller, which analyzes the solution, identifies mistakes (if there are any) and updates the student model appropriately. On the basis of the student model, PM generates an appropriate pedagogical action (i.e. feedback). When the current problem is solved, or the student requires a new problem to work on, PM selects an appropriate problem on the basis of the student model. The following subsections discuss the individual components in more detail.

### 4 Interface

The interface of SQL-Tutor, illustrated in [Fig. 3], has been designed with several pedagogical guidelines in mind. Generally, interfaces for ITSs should be robust, flexible, easy to use and understand. An interface is a mediating device; hence it must provide information about the system itself. At the same time, ITS interfaces are problem-solving environments and therefore should be similar to real environments, support the reification of goal structure and reduce the working-memory load of students.

The interface of SQL-Tutor reduces the memory load by displaying the database schema and the text of a problem, by providing the basic structure of the query and also by providing explanations of the elements of SQL. The main window of SQL-Tutor is divided into three areas, which are always visible to the student. The upper part of the window displays the text of the problem being solved and the student can always remind him/herself easily of the elements requested in the query. The middle part contains the clauses of the SQL SELECT statement, thus visualizing the goal structure. Students need not remember the exact keywords used and the relative order of clauses. The lowest part displays the schema of the currently chosen database. The visualization of a schema is very important; all database users are painfully aware of the constant need to remember table and attribute names and the corresponding semantics as well. SQL-Tutor users can get the descriptions of databases, tables or attributes, as well as the descriptions of SQL constructs. The motivation here is to remove from the student some of the cognitive load required for checking the low-level syntax and to enable the student to focus on higher-level, query definition problems. SQL-Tutor supports the reification of the
Student Modeller

A student modeller develops an understanding of the student's state of mind that can be used to generate instructional actions tailored to the particular student. The task of building a student model is extremely difficult and laborious, due to huge search spaces involved and the small amount of information to start from. Several researchers have pointed to the inherent intractability of the task [Holt et al. 1994, Ohlsson 1994, Self 1990]. If the goal is to model student's knowledge completely and precisely, student modelling is bound to be intractable. However, a student model can be useful although it is not complete and accurate [Ohlsson 1994, Self 1994, Stern et al. 1996]. Even simple and constrained modelling is sufficient for instruction purposes, and this claim is supported by findings that human teachers also use very loose models of their learners, and yet are highly effective in what they do [Holt et al. 1994, Self 1994]. SQL-Tutor uses Constraint-Based Modelling (CBM) [Ohlsson 1994] to form models of its students.

CBM reduces the complexity of student modelling by focusing on faults only. Domain knowledge is represented in the form of state constraints, where a constraint defines a set of equivalent problem states. An equivalence class triggers the same instructional action; hence the states in an equivalence class are pedagogically equivalent. The assumption here is that there can be no correct solution of a problem that traverses a problem state, which violates the fundamental ideas, or concepts of the domain. A violated constraint signals the error, which comes from incomplete and incorrect knowledge.

A state constraint is an ordered pair \((Cr, Cs)\), where \(Cr\) is the relevance condition and \(Cs\) is the satisfaction condition. \(Cr\) is used to identify problem states, in which \(Cr\) is relevant, while \(Cs\) identifies the class of relevant states in which \(Cs\) is satisfied. Each constraint specifies the property of the domain, which is shared by all correct paths. In other words, if \(Cr\) is satisfied in a problem state, in order for that problem state to be a correct one, it must also satisfy \(Cs\). Conditions may be any logical formulas, hence may consist of various tests on the problem state.

There are several advantages of CBM over other approaches. It does not require a runnable domain module and is computationally very simple, because student modelling is reduced to pattern matching. Conditions are combinations of patterns, and can therefore be represented in compiled forms, such as RETE networks [Forgy 1982]. Student modelling is very fast then: in the first step all relevance patterns are matched against the problem.
state. In the second step, the satisfaction components of constraints whose relevance conditions match the problem state are matched. If a satisfaction pattern matches the state, the constraint is satisfied, and the ITS is not to take any action; in the opposite case, the constraint is violated. The student model thus consists of all violated constraints. Furthermore, CBM does not require extensive studies of student's bugs, and is not sensitive to the radical strategy variability phenomenon. [Ohlsson 1994]. The approach is also neutral with respect to the pedagogy, since different pedagogical actions (immediate or delayed ones) may be generated on the basis of the model.

SQL-Tutor models students by looking at the student's solution and by comparing the student's solution to the ideal one. The constraint base of SQL-Tutor currently consists of 352 constraints, which are acquired by analyzing the domain knowledge [Elmasri & Navathe 1994, Pratt 1990] and from a comparative analysis of correct and incorrect student solutions. Each constraint has a unique number, and contains the relevance and satisfaction patterns. Additionally, there is a constraint description, and the name of the clause of the SELECT statement the constraint refers to. Relevance and satisfaction patterns can be any logical formulas, consisting of any number of conditions. Some conditions match parts of the student's solution to presupposed patterns or the ideal solution; other conditions are LISP functions.

It is well known that knowledge acquisition is a very slow, time-consuming and labour-intensive process. Anderson [1995] reports 10 or more hours necessary for induction of a production rule. When interviewing domain experts in order to acquire knowledge for expert systems, usually 2 to 5 production rules equivalents are identified per day. The time spent on identification, implementation and testing of SQL-Tutor's constraints averages at 1.3 hours per production, which is significantly shorter than times above. This may be the consequence of the same person serving as the domain expert and knowledge engineer (and the system developer, at that matter), but may also illustrate the appropriateness of the chosen formalism.

SQL-Tutor models students by looking at the student's solution and by comparing the student's solution to the ideal one. The constraint base of SQL-Tutor currently consists of 352 constraints, which are acquired by analyzing the domain knowledge [Elmasri & Navathe 1994, Pratt 1990] and from a comparative analysis of correct and incorrect student solutions. Each constraint has a unique number, and contains the relevance and satisfaction patterns. Additionally, there is a constraint description, and the name of the clause of the SELECT statement the constraint refers to. Relevance and satisfaction patterns can be any logical formulas, consisting of any number of conditions. Some conditions match parts of the student's solution to presupposed patterns or the ideal solution; other conditions are LISP functions.

A student model in SQL-Tutor contains general information about the student, history of previously solved problems and information about the usage of constraints, as demonstrated in the solutions produced by the student. For each constraint, SQL-Tutor stores information about how many times it was found relevant for ideal solutions, how many times it was actually used by the student and how many times it was used correctly. This information is stored in terms of three indicators (relevant, used and correct), used by PM for selecting new problems as explained in [Pedagogical Module], and updated by the student modeller.

6 Pedagogical Module

Pedagogical module is the heart of the system; it selects problems to be given to students and generates appropriate instructional actions according to the student model. In SQL-Tutor, instruction can be individualized by generating feedback dynamically and selecting problems.

The level of feedback determines how much information is provided to the student. Currently, there are five levels of feedback in SQL-Tutor: positive/negative feedback, error flag, hint, partial solution and complete solution. At the lowest level (positive/negative feedback), the message simply informs the student whether the solution is correct or not and, in the later case, how many errors there are. An error flag message informs the student about the clause in which the error occurred [Fig. 3]. A hint-type message gives more information about the type of error. Here, the student is given a general description of the error. This description is directly taken from the definition of constraint. Partial solution feedback displays the correct content of the clause in question, while the complete solution simply displays the correct solution of the current problem.

It was stated earlier that a student's solution may violate several constraints at the same time (as in [Fig. 1], where 5 constraints were violated simultaneously). In such cases, SQL-Tutor examines the violated constraints and selects one, which is likely to be a genuine misconception. That is, SQL-Tutor selects the constraint with the maximum difference between the used and correct indicators. The rationale here is the student has made the same error several times, and therefore instruction must start with that constraint. Currently, the student is told the total number of violated constraint, but the error messages only deal with one constraint at the time. This decision is based on our intuition that it would be much easier for the student to deal with errors one at a time.

Problems are also selected on the basis of a student model. SQL-Tutor examines the student model and selects a problem for constraints that the student is not sure about (i.e., the one with maximal used-correct). Another

---

\[\text{footnote}{2}{In case that there are several massages in various clauses, the pedagogical module will select one of them to start with.}\]
possibility for the problem to be posed to the student is a problem that requires the use of a constraint that has not been used by the student so far.

SQL-Tutor also allows the student to select the problem on his/her own. Such an approach introduces randomness in the coverage of constraints, which can mean that the student in practising the use of some known constraint or even introducing new ones. Admittedly, such problem selection strategies are very simple and we are currently developing more sophisticated strategies.

7 Conclusions

SQL-Tutor is an intelligent teaching system, based on learning-by-doing. It supports three kinds of learning: conceptual, problem solving and meta-learning. The student can learn about concepts and elements of SQL. SQL-Tutor is a problem-solving environment which supports acquisition of domain knowledge in a declarative form (i.e. constraints) and strengthening of this knowledge in practice. The system provides assistance in problem solving and arguments against incorrect actions. Finally, SQL-Tutor encourages meta-learning by supporting self-explanation on the basis of error messages and correct solutions given to the student.

The system has been shown to a number of database teachers, and all were very supportive and expressed great enthusiasm for using it in their own courses. The first evaluation study is scheduled for early April 1998. We expect that a hands-on approach will encourage most students to experiment more fully and acquire a more in-depth understanding of SQL.

There are many possibilities for extending this research. The evaluation study will provide the data for completing the constraint base, and tuning the interface. A more sophisticated way of selecting new problems is the current focus of our research, as well as the development of a set of pedagogical rules that would govern the selection of appropriate amount of help for each student. We also plan to connect the system to a RDBMS, in order to allow students to view the results of their queries, once they are completed successfully. Porting the system to Web is another of planned tasks. There are many related areas in the database world, such as relational algebra and calculus, data modelling or normalization, which could serve as domains for other small instructional tools and be connected with SQL-Tutor into a “database exploration world”.

A Tutoring Wizard Guiding Tutorial Work in the Virtual University

Silke Mittrach, Gunter Schlageter
University of Hagen, Feithstr. 140, D-58085 Hagen, Germany
E-mail: silke.mittrach@fernuni-hagen.de, gunter.schlageter@fernuni-hagen.de

Abstract: The Virtual University is a netbased learning environment developed at the University of Hagen. Complex teaching activities based on totally new concepts integrating netbased communication and cooperation facilities take place in the Virtual University. Our experiences show that there is a threshold especially for tutors of non computer science fields to use the new technologies for tutoring activities. The problem is: they have to arrange completely new organizational processes and they have to manage the new technology. In order to ease the tutor's work we are developing a netbased tutoring concept that supports tutors considering both aspects: organizational and technical support. We demonstrate our concept of a netbased tutoring wizard as a model for the management of virtual seminars.

1. Introduction

As life-long learning is getting more and more essential in professional life, distance teaching is getting more attention and has started to play an increasingly important role in all modern societies. It's core features are that it offers timely and locally independent studies, and that it supports on-demand learning as required today. Obviously, time to be spent at the university campus has to be kept at a minimum. A project team at the University of Hagen has developed a concept for a virtual university, implemented a prototype and tested it with students:

The Virtual University [Buhrmann et al. 1996] of the FernUniversität Hagen is a virtual university system that integrates all functions of a university into a complete, homogeneous, extensible and cost-effective system with an easy to use and intuitive user-interface. The main menu of the Virtual University [Fig. 1] offers the functions: education - for participation in courses, seminars, practical trainings and exercises, news - a campus wide blackboard containing all sorts of up-to-date information relevant to the users of the Virtual University, office - the component including administrative functions, research - offering access to all research-related activities in the university, cafeteria - a forum for social contacts between students, library - offering access to both traditional and digital libraries, information - a menu containing general information about the university, and shop - offering all material that can be purchased from the university.

Figure 1: Home page of the Virtual University, http://vu.fernuni-hagen.de

The Virtual University supports totally new forms of learning like distributed working groups, seminars and practical trainings etc. Unfortunately, too many approaches focus on electronic delivery of learning material.
("online-university") - indeed, this is only a very small part of the overall concept of the Virtual University in Hagen. The major breakthrough comes from the integration of various media and communication and cooperation support via networks. In this environment the users learn an important element of today's industrial world: to cooperate in distributed processes and to manage and organize this kind of cooperation.

Of course, the impact of the Virtual University is not only restricted to students, but to all university users and user groups respectively tutors, authors, secretaries etc. Each user must learn to work and manage his job within the Virtual University system. Therefore user-interfaces fitting the individual user-groups' requirements must be developed.

Due to the fact that totally new forms of learning are executable in the Virtual University, particularly the tutors' work - organizing and managing teaching activities - changes. At the same time the integration of tutors is an important fact for the acceptance of our system: the more (teaching) activities we offer in the Virtual University, the more students will accept the system. As a reason, one important aspect of our future work is the development of tutoring interfaces.

In the following chapters we compare the tutors' work in traditional distance teaching environments with his tasks in netbased environments. The virtual seminar serves as an example for the comparison of tutoring tasks. Then we present our ideas for netbased tutoring support, again the seminar serves as an example. Of course, the tutoring concept is universal, extendable to other learning forms like practicals, exercises, courses etc.

2. Traditional and Netbased Tutoring - Concepts and Problems

All tutoring activities in a traditional distance teaching university must be well thought out, they have to be initiated a long time in advance; spontaneous reaction is nearly impossible. Most information is printed and sent to the students via mail. Personal communication is restricted to the phases of presence at the university; furthermore, communication between students and tutors is realized by mail or telephone, communication between students takes place rarely.

To give a practical impression of the tutors' activities in traditional learning environments, let us briefly describe the organization of a typical conventional seminar at the University of Hagen [Berkel et al. 1997]:

At first the tutors announce the seminar in the 'info', a booklet published every four weeks and sent to all 55,000 students of the University of Hagen. The students enroll by sending a postcard to the tutors. The tutors decide which student is allowed to participate and send a confirmation or cancellation to the students. Each confirmed student gets a specific topic he has to elaborate as his seminar contribution via mail. A written list of literature is added to help the student with searching for relevant literature. After two months, the student sends the written structure of his contribution to the tutors. They review the structure and send their comments and hints back to him. The student elaborates a written version of his contribution and a set of slides. During the elaboration phase, the student may contact the tutors via mail or telephone. Two weeks before final presentation, the students send the final version of their written contributions to the tutors. The presentation of all contributions takes place within two days at the university in Hagen. After the students' presentation, the actual topic is discussed between all students and the tutors. The students get the corrected and commented written version of their contribution back from the tutors. A booklet containing the corrected contributions is published for all participants of the seminar.

To summarize the problems of traditional tutoring:
- tutors publish mostly written announcements and information to very early dates (detailed seminar information must be fixed seven months in advance),
- tutors have rare contact to students (mostly in written form, but it is very tedious and normally restricted to only two discussion partners),
- there is nearly no possibility to react on students' remarks during the current semester (e.g. correct a mistake in the course material),
- tutors have to clearly define the problems for the students (e.g. no participation of the students in the selection of topics),
- hardly cooperation / arrangement between students to deal with overlaps concerning their topics.
Netbased tutoring can reduce most of the above mentioned problems in distance tutoring, but some other
difficulties - especially for the tutors - arise. We examined them on the basis of the virtual seminar, an example
for distance tutoring via networks [Berkel et al. 1997]. The seminar was carried out in the winter of 1996/97
with students from the faculty computer science. All (traditional) seminar activities described above were
carried out over the internet. Therefore, various internet services - asynchronous components like email, news,
ftp and www and synchronous components like chat, audio- and videoconferencing - were mixed in different
combinations for specific seminar activities. The used internet services were integrated into the Virtual Univer-
sity user interface, based on the www. Students could initiate all activities by mouseclick (search for adequate
communication partners, participate in a seminar videoconference or read the seminar newsgroup) from the
seminar web pages.

We noticed that most negative aspects of traditional distance tutoring could be reduced in the netbased learning
environment as described for the virtual seminar: spontaneous reaction on students' remarks was possible,
various communication offers between students and tutors and students themselves were available, tutors could
leave problems to the students to decide or they could help amongst themselves via network based
communication. The tutors merely played the role of moderators who coordinated various messages, comments,
remarks and hints of the students and organized and published them to the other participants. Therefore, in
contrast to traditional seminars the tutors needed to have advanced technological knowledge about the internet
and the usage of internet tools in order to generate the seminar web pages and to support the students with
technical hints and tips, establish communication offers and integrate them in an easy-to-use way for the
students.

To summarize the results: there are two elementary new tasks for tutors (apart from the effort for achieving a
rudimentary knowledge and experience in the use of internet tools):

- the organization, technical arrangement and presentation of information produced during the far more
dynamic process of netbased teaching activities and
- the moderation and management of students' collaboration.

Both aspects must be regarded in further developments of the Virtual University. In this paper, we focus on the
first aspect. Therefore, we develop a concept of netbased tutoring - a tutoring wizard - supporting tutors in
arranging the technical frame for their work. Our approach will be presented in detail in the following chapter.

3. Concept of a Netbased Tutoring Wizard

Netbased tutoring as described in the previous paragraph includes various - sometimes quite technical -
activities. In contrast to traditional tutoring activities, most of the netbased tasks can be supported
electronically. Our idea is to develop a tutoring wizard, that simplifies the process of creating and managing
webbased tutoring activities:

The tutoring wizard is an application that offers an easy-to-use interface to the tutor. It supports standardized
organizational frames for the tutor's work and helps him to collect, organize and presentate the necessary
information without having much knowledge of the underlying technologies. The wizard automatically creates
and manages webbased information and reminds the tutor of forthcoming dates and tasks and delivers
information automatically to responsible persons.

A scenario clarifies our idea: The tutors Berkel and Lenzen shall organize a seminar. The first task they have to
deal with is the seminar announcement. They start the tutoring wizard, authentify themselves and select
'seminar' as the tutoring activity to support. Now they have to fill in the course number, the title of the
seminar and the names of the responsible tutors. Furthermore they specify the kind of communication offers
they would like to integrate into their presentation. The wizard now initiates all server based activities like
creating a seminar directory on the web server, installation of communicational offers (e.g. sending a mail to
the web administrator) etc. Now the announcement text must be filled in. Therefore, the tutors fill in all
relevant information in the textfields of the step-by-step presented dialog boxes. With the inserted text the
wizard generates on the basis of a seminar template a web based seminar presentation including all necessary
web pages (e.g content and navigation pages). The tutors chose the 'Publish'-command in order to publish the
information on the web server. For the moment, they leave the program. If any reaction of the tutors is required
(e.g. the tutors specified a discussion which is announced for the next days) the wizard mails a message to the
tutors reminding them of publishing further infos.
The scenario shows some characteristic functionalities that are expected of a tutoring wizard:

**Templates for webbased tutoring:** The wizard includes various templates for the diverse tutoring activities. The templates generate frames for complex web pages based on elementary components: e.g. header and footer pages, navigation functionality, frame construction etc. Changing the elementary component header page means that the header page changes in all web pages of the current tutoring web.

**Automatic generation of web pages on the basis of the tutors’ information filled in dialog boxes:** The users need not to know anything about the techniques to process material in suitable formats: the wizard automatically generates the information the tutor fills in the textfields of the wizards’ dialog boxes into suitable formats, e.g. directly as HTML web pages or as database input which is generated later to appropriate formats. The advantage is: The user needs not to know HTML or any other web presentation language. Furthermore, information can be integrated in various web pages – e.g. the title of the seminar is the header of each seminar web page - the tutor must fill it in only once, the wizard automatically copies it to various locations.

**Support of publishing and changing information on the web server:** A publishing assistant helps the tutor to publish the seminar presentation on the Virtual University web server. The assistant can be activated by clicking a simple ‘Publish to Web’-button. It includes the address and the parameters for publishing, the tutors do not need to start a completely new (ftp) program.

**Task management:** The wizard gathers all further to do’s in a task list, that shows what kind of action is requested and at which time it is requested. The tasks might be weightened (showing the priority of the task) either by the system on the basis of definitely required information or by the tutor’s subjective estimation.

**Notification mechanism:** Time fixed tasks can be related to a notification mechanism that reminds the responsible tutor of the task. Notification might be implemented via mailing mechanisms.

**Support of tutor groups:** Suggesting tutors often work in small groups, the wizard should support group oriented tutoring. Therefore specific functionalities like the management of tasks depending on the tutor’s identity, gradual access restrictions etc. must be considered.

**Integration of workflow aspects:** For tasks depending on subtasks, a task workflow can be described. It automatically generates the following to do’s and reminds the responsible tutors of the next steps to do.

Some further requirements derive from the Virtual University platform. They comprise aspects like: an easy-to-use interface, multi-platform compatibility, compatibility to existing software and the ability to expand the system with further software packages, services and protocols.

4. Implementation of a Tutoring Wizard Prototype

A first rudimentary prototype is implemented on the basis of Microsoft FrontPage. FrontPage is a web publishing and administration tool, that supports templates and wizards. It does not fulfill the requirement of multi-platform compatibility, but to begin with the work we can suggest that tutoring activities are done on PC’s. Furthermore, the tutors can work on their web presentations individually by using the FrontPage tool. In any cases, the FrontPage interface [Microsoft 1997] enables us to rapidly develop a specialised tutoring wizard showing our ideas described above.

The templates implemented in FrontPage build up the basic structure of web based seminar presentations: a frame structure subdeviding the screen into navigation and content pages, and a number of pages containing the diverse seminar information (announcement / introduction, content / themes, organization, lectures, communication / discussion). Furthermore, additional pages like glossaries, guest books, literature tips and blank pages can be included. A description and a preview of the templates is shown to the tutor in the preview window [Fig. 2].

1041
Dialog boxes are implemented to support the user in collecting the tutoring information. On the basis of earlier chosen templates the given information is integrated into the seminar presentation. This functionality is realized by self-implemented FrontPage wizards, independent executable programs written in Microsoft Visual Basic that collect input from the user in a series of dialog boxes, then place OLE automation calls to drive FrontPage by ‘remote control’ to create new web pages.

The seminar wizard asks the tutor step-by-step about the structure and the design of the seminar information and about the information itself; e.g. in the first step the tutor has to decide on the frame structure (navigation menu left side or at the bottom), afterwards he selects the required pages for his presentation [Fig. 3], then he fills in the seminar title and a short description and so on.

After filling in the information a ‘seminar presentation’ (in FrontPage called FrontPage Web) is created by remote control. The user can see the result and work on it with the FrontPage program [Fig. 4]. At the same time, a task list will be generated. The FrontPage web publishing functionality supports the publication of the created web on the basis of the WebPost API, an API for publishing information to web servers.
5. Summary and Prospects

In this paper we present the tutors' role in a distance teaching environment. Tutors in virtual environments have to manage technical processes, therefore they need a basic technical knowledge. The tutors' work is changing with regard to organizational (completely new courses) and tutorial aspects (tutor as a moderator). The paper shows our concept of a tutoring environment supporting tutors with regards to organizational aspects of their work.

A first prototype is implemented on the basis of FrontPage, a web administration and creation tool that supports some of the basically required functions. Primarily, further implementations shall demonstrate our ideas, e.g. the FrontPage task list will be extended with mailing functionalities, and experiences with users must show the suitability of our approach. Aspects like group support and workflow integration must be concepted in detail. Later on, aspects like the dynamic generation of information will lead us to (re)implement the system in combination with the VU databases: information will not be any longer managed in static HTML pages, but generated dynamically just-in-time and on-demand. Therefore, the seminar information will be saved in VU databases.

Abstract: We describe the Interactive Course Map, and discuss some of the rationale behind its design. This multimedia map provides a meta-learning environment, designed for use in distance education, and is intended to provide undergraduate students of a maths and computing course at the Open University with both an overview of the course structure, and also an introduction to the mixed media resources employed in its presentation. Formative user testing is described and its findings reported. We suggest that a meta-learning environment, such as this map, helps students take control of their learning experience by clarifying relationships between resources and learning goals, and by helping the student stay oriented and pace their study as the course proceeds.

Introduction

When forecasting the learning situation of the future, we envision students working with a wide array of on-line tools—ranging from standard productivity tools and communication software, to specialised learning environments tailored to particular curricular needs. In this scenario, learners are not only trying to master the subject or domain content, they must also cope with: (1) mastering a potentially complex assortment of software tools, and (2) developing new study habits to make effective use of these tools. A challenge for learners in such a situation is effectively ‘managing the media mix’ to achieve their educational objectives [Laurillard 1995]. Recent empirical studies indicate that many learners, particularly those who are inexperienced with computer technologies, feel overwhelmed when faced with this new way of learning [Sumner and Taylor 1998].

We are investigating how interactive course maps and study guides can help students successfully manage potentially complex mixes of new technologies to enhance their learning process. In effect, we are trying to create meta-learning environments; i.e., environments to help beginning scholars ‘learn how to learn’ with new media. Here, we describe the Interactive Course Map we have created for a new first-level course on object-oriented computing, and discuss some of the rationale behind its design.

Setting: A First-year Computing Course

Since the late 1960’s, The Open University (OU) has been providing mixed media, distance education courses combining printed texts, television, video, audio, and home-laboratory kits. Materials are centrally produced to an academically high standard, and presented in an open learning style that is accessible to people with no previous academic qualifications. The specific setting for this work was the design and development of a new first-year undergraduate introductory computing course called “Computing: An Object-oriented Approach” being developed in the Maths and Computing Faculty here at the OU. Such introductory courses at the OU often have 3000 to 5000 students enrolled during a given presentation. Table 1 shows the resources that were created for this course, a more detailed discussion can be found in [Woodman and Holland 1996]. What is striking about this table is the multitude and diversity of learning environments used to support a rich, year-long course.

The Interactive Course Map

As shown in Table 1, the M206 course involves a fairly complex mix of media. The challenge which the multimedia Interactive Course Map aims to address is to give the student an overview of the whole course structure, and to introduce the mixed media resources required while studying. It also introduces the computer
tools the student will be using. The map needs to present a complex situation as simple and manageable. It should help the student to feel that they are in charge of the situation, and that they need not feel overwhelmed by the pile of course materials arriving through the post.

Electronic Glossary  
World Wide Web Site  
Computer Conferencing  
Email  
Personal Productivity Tools

Table 1 Course resources.

We began by analysing the proposed course structure and resources. We identified three key strands of information: study time in weeks, a guide to block structure, and study resources. It was particularly valuable to look at the relationships between the three strands of information to be presented in the map, and from this build a visual representation [Figure 1].

Figure 1 The Course Map. The course content area (right half of picture) reflects the course's block structure and provides information about what students need to do each study week. The course resources area (bottom left) provides a high-level overview of how each resource is used in the course. The tour area (top left) is used to provide students with advice about how to study and how to use the Map.

The map is composed of three main areas reflecting these strands: the course content area, the course resources area, and the tour area. The course content area consists of seven large buttons, corresponding to the block structure of the course. The course resources area lists all the resources used in the course. As the mouse cursor moves over items in the resources list or the big block buttons, these items are highlighted, giving visual feedback to indicate that they are pressable. The box in the tour area is used to display a narrator's head with headlines supporting the audio narrative. Each of the three areas will be described in more detail below.

**The Course Content Area**

This area has been designed to give the student an overview of the teaching blocks and to help the student in the organisation and pacing of their own work. The time line through the course study drives the main pathway through the information. This time is also reflected in the print materials which are presented in a large reference binder, with dividers for each week of study. The week dividers each carry the colour of the block to which they
belong, thus linking study weeks to blocks of study. Consistency of colour coding is carried across to the use of colours for the Block Buttons in the multimedia map.

Pressing the Block 1 button at the top level brings up the two panes shown in Figure 2. Each block area is structured into two panes — the block overview pane (on right) and the weekly resource pane (lower left). The block overview pane shows how each study week is composed of one or more chapters. Clicking on any chapter title will bring up a third level pane containing a brief chapter description.

</table>

**Figure 2** The Contents of Block 1. Each block area is structured into two panes — the block overview pane (on right) and the weekly resource pane (lower left). The block overview pane shows how each study week is composed of one or more chapters. The left side of the weekly resource pane shows what learning resources are used in any given study week. The right side (not shown, under the block pane) discusses how the resources will be used to meet specific learning objectives.

The weekly resource pane shows what learning resources are used in any given study week and what resources comprise each chapter. As shown in Figure 2, Chapter 1 consists of a printed text, a Smalltalk LearningBook, and a chapter web page. Clicking on a study week heading brings up that week’s weekly resource pane. This mechanism enables students to get a quick overview of the amount and the type of work they’ll need to do for any given week.

Our second objective was to provide bridging support to help students make connections between learning goals and more detailed activities. This objective is supported by the interplay between the block pane and the weekly resources pane. These two panes are layered, clicking on one brings it to the front and overlays part of the other pane. The chapter descriptions available from the block pane focus on learning goals. The left side of the resources pane shows what tools and resources are used to achieve the learning goals. Clicking on the resource pane brings it to the front and makes the right side visible, which describes how the resources will be used to meet specific learning objectives. If the resource being discussed is a television programme or an interactive multimedia title, then previews or demonstrations are available on the right hand side of the week resource pane.

The colours and fonts used in the Map match those used in the printed text and the course web site. Thus, where possible, resources used in the course have a familiar and consistent ‘M206 look’, regardless of the media. By using a familiar look and following a simple and straightforward layout, we hoped to make the Map seem friendly, fun, and relatively intuitive to use. The colours used for the pane borders match the colours used to identify the different blocks (e.g., the light blue is always used for Block 1 and the deep red for Block 7). The colours are not only pleasant, they also reinforce a sense of orientation. These design decisions reflect Shneiderman’s [Shneiderman 1992] findings about the use of colour:

- Recognise the power of colour as a coding technique.
- Be consistent in colour coding.
- Design a display in monochromatic form, using spacing and arrangement for organisation, and then judiciously add colour where it will help the operator.
The basic structure of the map, with these two overlapping panes, is very simple yet powerful. We believe that simplification where possible is entirely appropriate in designing educational multimedia such as this. In 'The Psychology of Everyday Things', Donald Norman describes his "...fundamental principle of designing for people: (1) provide a good conceptual model and (2) make things visible" (page 13, [Norman 1988]). Though Tufte's [Tufte 1990] starting point is specifically graphic presentation of complex statistical data, his conclusions can be applied more generally to visual presentation of information, i.e., "The operating moral premise of information design should be that our readers are alert and caring; they may be busy, eager to get on with it, but they are not stupid. Clarity and simplicity are completely opposite simple-mindedness. Disrespect for the audience will leak through, damaging communication."

The Course Resources Area

The aims of this area are twofold. One aim is to provide an overview of how a particular resource will be used in the course. Another aim is to provide students with global advice about how to study with the resource for this particular course. For instance, the course team has developed a special version of the LearningWorks™ environment for the Smalltalk language. This environment organises work into computer-based modules called LearningBooks that contain exercises, learning worlds, and programming tools. Figure 3 shows the course resource area for the Smalltalk LearningBooks.: this pane is obtained by clicking on Smalltalk in the resource list at the top level. Notice how the area does not describe Smalltalk in general, this is what the course is about! Instead, it focuses on describing the LearningBook structure and how one might study using this structure.

Figure 3 The Smalltalk pane in the Course Resources Area. This pane shows the structure of the Smalltalk LearningBooks. As the mouse cursor rolls over each of the miniature screens, it is highlighted, and an overview of its purpose appears at the bottom of the pane. The arrows illustrate one idealised work flow using the LearningBooks.

The Tour Area

We have outlined the structure of the map and the ways in which it can be navigated. Now we return to the goal of bridging between resources and course content. We wanted not only to facilitate the linking of different media with different learning experiences, but to also provide a guided experience which would take learners through the map, and show how to use it through a process of self disclosure (DiGiano and Eisenberg 1995). We combined this notion of self-disclosure with Plowman's notion of narrative guidance and the use of an 'explicador' [Plowman 1996].

She describes Bunuel's account at the turn of the century of people called explicadors who used to stand in front of the cinema screen interpreting for the audience the revolutionary new form of the moving picture. This was necessary because audiences had not yet built up a grammar of interpretation to allow them to understand filmic devices indicating passage of time, change of location, intensity of focus and so on. Plowman adapts this role to
multimedia, arguing that users have similar difficulties in acquiring an appropriate grammar, or literacy, in the new media, so explicadors are needed to help in the process.

In the map, the explicador(s) take learners on tours of the map. There is a general Course Tour and a Block 1 Tour. Students can obtain print-outs of the audio scripts if they wish (this is important for supporting hearing impaired students). The Course Tour introduces the overall structure of the course, but most importantly, students are shown each of the various media and given advice about how to use that medium to maximum benefit. The Block 1 Tour steps through the different activities in each of the first four study weeks, discussing how the computer-based learning tools will be used in the different activities. The Block 1 Tour also emphasises the need to get organised and get the software installed.

The explicador in the Map is not a full-motion video head. Such a representation be a drain on the computational resources available, thereby slowing the tour down We also felt it was unnecessary. The particular form of the explicador is adapted from KMi Stadium [Eisenstadt and Scott 1998] and is a low-band width format which conveys a small amount of information when attention is focused on the explicador, but otherwise stays very much in the background. We used members of the course team as explicadors (as opposed to famous celebrities or cartoons) since, from our experiences with television, we know that students enjoy seeing programmes which feature course team members because they like putting faces to names.

Next Steps: Improving the Map

The Map obviously needs testing to ascertain whether or not it actually meets its design goals. We use two types of testing: formative testing, which feeds into the current round of development and is conducted intensively with small numbers of people; and summative evaluation which is based upon students' experiences with the map during the first year of the course's life.

We have completed the first round of formative testing [Sumner, Taylor et al. 1997]. Six volunteers, all drawn from a pool of people who would typically register for such a course, were asked to do two tasks. Each task consisted of taking a tour first and then use the map to answer three questions. Each participant was then asked questions about the tours, the map layout and structure. Each session took approximately 1.5 - 2.0 hours.

All participants were very enthusiastic and positive about the overall look and feel of the map, and had few problems navigating, seeming easily to find the things we set them to look for. We were most anxious about the tours, because there was a strong chance that people might find them irritating, and of no use whatsoever. However, all participants described the tours as 'helpful' in the following specific ways: for taking them through the structure of the course phase by phase, for introducing the media and for showing them how to use the map itself. All participants said they would probably listen to all, or parts, of the tours several times. The drawbacks, however, were that the tours, as written, tended to cover too much, too fast. Most people were comfortable with the general content and level of description offered, but wanted more time to assimilate what they had just heard. To address these shortcomings, we have re-written and simplified the scripts to eliminate detail, and we have synchronised the audio track and the text more clearly to help prevent cognitive overload.

As a result of using the Map (with tours), 5 out of 6 participants were able to clearly articulate the structure of the course and the rather complex structure that ‘chapters’ might have (e.g. printed text, electronic learning books, web pages and television programmes). Additionally, everyone was able to articulate the general role of major resources in the course; i.e., that conferencing was for communicating with other students and tutors, whilst the web was a resource area for getting updates to course materials. We regard this as a measure of success.

As a final part of the testing, we asked people to select descriptors (e.g., boring, technical, approachable, interesting, hard, fun, etc.) from a stack of cards that best described the course as they perceived it after using the Map. Most participants claimed that the organisation of the Map and the tours made the course look well-organised, interesting, and approachable, yet challenging due to the subject matter. Several participants who stated that the course looked approachable noted that they would normally not have the confidence to take such a technically challenging courses. A few felt it even looked fun! In our view, the map clearly made a large contribution to people's overall positive perceptions of the course.

Obviously, testing involving such small numbers can only tell us a certain amount. As a next step, we will engage in summative testing to track the Map's usage during the course's presentation. The key point for us is not so much to ascertain whether students CAN use the map (which is the main focus of formative evaluation), but DO they use it? We may find that we still do not have quite the right level of description to provide the bridging function between media and content in actual practice. Students may respond that the map was a good idea, but it just didn’t quite work.
Conclusions

In summary, many students can feel overwhelmed when facing a new way of working and learning. We hypothesised that meta-learning environments could alleviate this problem by helping students take control of their learning process, making clear the relationships between resources and learning goals, and helping students stay oriented as the course proceeds. We have built an initial version of such an environment: The M206 Interactive Course Map and our experiences with the map so far are very promising.

So what next? Do meta-learning environments only fulfil a short-term need? With increased exposure to tools, environments and media, will students develop the kinds of skills and literacies that eliminate the need for meta-learning environments? We don’t think so. In both the short and long-term, the need for meta-learning environments will not disappear. We accept, as a fundamental principle, that learners need support from their teachers, no matter how sophisticated their materials are, or how elaborate the learning environment is. This support may be provided in a variety of ways, and need not always be from the human teacher to the learner on a one-to-one, face-to-face basis. But we can – and do – confidently assert that students will always need help!

Acknowledgements

The map would not be exist without the hard work and generous support of the M206 Course Team (in Maths and Computing) and the production team at the BBC/Open University Production Centre. We also wish to thank Chris McKillop for her assistance with the formative evaluations.

An Object-Oriented Architecture for a Web-based CAI System

E-mail: naka@isl.ntt.co.jp

Abstract: This paper describes an object-oriented design and implementation of a Web-based CAI system. The goal of this design is to provide a flexible CAI/ITS framework with full extendibility and reusability as well as to exploit WWW-based software technologies such as JAVA, ASP, or various plug-ins for customizing the behavior and appearance of the material. Courseware objects are defined to implement ITS courseware consisting of tree-structured material objects and the learning target objects associated to the material objects. Each material object has the method to invoke the tutoring strategy thus the strategy is easily customized or replaced by the class inheritance. The page object, the leaf level object of the material tree, is associated with the URL pointing to either the normal multimedia data or the exercise script consisting of server-side script like ASP. The page object communicates with the exercise script to dynamically generate the interactive exercise. An example of courseware consisting of an interactive simulation is implemented by making use of the exercise script. The proposed object-oriented design has the potential to be extended for constructing the framework of distributed courseware object.

1. Introduction

As the World-Wide Web becomes more and more important, there have been a lot of researches or projects on the WWW-based CAI/ITS systems[6, 5, 1, 11]. We have been working on a ITS on the Web called CALAT[8, 9, 10].

CALAT, as well as the other WWW-based CAI/ITS systems, is based on the conventional CAI system or ITS shell on the standalone computer. The system consists of CAI logic on the WWW server and GUI on the WWW client. It uses http for the multimedia data communication between the server and the client. In this sense the WWW framework is used just as a multimedia communication platform. Although CALAT allows multimedia data on the other WWW server to be incorporated as the static courseware pages, the characteristics of the WWW as a distributed media platform is not fully exploited. In addition, the current WWW-based system based on the conventional CAI system inherits the problem of the conventional system that it is often very difficult to modify, improve or extend the functionality or behavior of the system. As pointed out in [3], this is due to the design in which the module structure directly reflects the basic ITS functional components, namely tutoring engine, student model, courseware scenario, courseware pages and GUI. This structure makes it very hard to make even a slight function improvement, since the modification can not localized in one module but it causes every module to be affected. This means that it is difficult to modify tutoring strategy as well as to implement smart courseware pages/GUI by making use of new WWW-based software technologies like JAVA, ASP, or various interactive plug-in programs.

To overcome these problem, an object-oriented architecture is employed to design new version of CALAT. Courseware objects are defined to implement ITS courseware consisting of tree-structured material objects and the learning target objects associated to the material objects. Each material object has the method to invoke the tutoring strategy thus the strategy is easily customized or replaced by the class inheritance. The page object, the leaf level object of the material tree, is associated with the URL pointing to either the normal multimedia data or the exercise script consisting of server-side script like ASP. The page object communicates with the exercise script to dynamically generate the interactive exercise with variety of multimedia and GUI plug-in components. An example of courseware consisting of an interactive simulation is implemented by making use of the exercise script. This direction leads to the distributed ITS or distributed courseware on the WWW recently discussed[2,
This paper is organized as follows. The next section discusses the requirements and issues to be considered in the new design. Then the current object-oriented design is described in the third section. Application of the design to a particular courseware is presented in the following section. The concluding section discusses the potential of the proposed design to be extended for constructing the framework of distributed courseware object.

2. Design Issues

The current WWW-based ITS, including CALAT, are usually implemented based on the conventional ITS shell as their kernel. Common ITS shell consists of the modules directly reflects the basic ITS functional components, namely tutoring engine, student model, courseware scenario, courseware pages and GUI. This module structure is quite intuitive and naive but even careful implementation based on this structure tends to lack the flexibility for additional improvement and customization[3].

This is because there are very complex dependencies and references between each modules. For example, to add a new parameter in the student model requires the new method in the tutoring engine to calculate and interpret the parameter, the new behavior description in the courseware scenario to utilize the parameter, and so on. From the software engineering point of view, numerous dependencies between modules means the poor module design.

With this module structure, it is very difficult to incorporate the new WWW-based technology like JAVA, ASP, or various interactive plug-in programs for courseware pages or GUI customization because the existing pages or GUI module has the strong dependencies to the other modules. The concept of distributed tutoring systems aiming at high reusability of the intelligent tutoring resources[8, 2, 7] is also incompatible with this module structure in which the highly dependent modules form the closed courseware world.

3. Implementation

The new object-oriented ITS platform is designed to overcome the design issues discussed in the previous section. The design is intended to provide a increased flexibility for modification or improvement in the tutoring strategy as well as to provide a generic interface to utilize the new WWW-based technology for implementing easy-to-customize courseware pages. Extension to the distributed tutoring environment is also in the scope of the new design.

3.1 Courseware objects

As mentioned in the previous section, it is very important to minimize the dependencies and references between the system modules to achieve a high flexibility. Concept of the courseware object is introduced for this purpose. Main classes of the courseware object are shown in Figure 1:

- Tree-structured material objects. Objects of this class forms the usual tree structure of the text such as chapter, section, subsection, ..., and text page. These objects have their own method invoking the tutoring strategy, and the pointers to their upper and lower level objects. The page object, the leaf level object of the tree, in addition has the pointer to the corresponding physical courseware page represented as the URL, the method returning the available ITS command, the methods corresponding to these commands, and the method controlling the GUI.

- Learning target objects. This class is introduced to implement the learning target based ITS. Target objects are associated to the material objects. State of the target object reflects the learner's state concerning the learning target, which is referred and updated by the associated material objects.

Tree structure is employed with several reasons:

1. Each subtree of the courseware can have its own tutoring strategy. This means that courseware
chapters or sections with various tutoring strategies can be combined to compose a courseware. For example, it is possible to built the courseware such as: the first chapter has no ITS strategy, the second chapter has the overlay strategy, and one section in the second chapter has the exercise based on buggy model. It is rather easy to improve or specialize a tutoring strategy to be suitable for a certain chapter without affecting the strategies of the other chapters in a courseware.

2. It is natural to build a large tree-structured courseware from the chunks of courseware subtrees each associated with its own leaning targets. This is well-suited for the reuse of the tutoring resource.

**Figure 2: Exercise object and exercise script**
3. From the practical point of view, tree-structured courseware material is valuable even without ITS functionality. There already exist a lot of tree structured courseware material which can be a starting point of ITS courseware.

3.2 Exercise object and exercise script

Among the tree-structured material objects, exercise object has several special characteristics because of its interactive function between learner. In addition to the method and data of the usual page object, it has the method for question initialization, error analysis, hint generation, and so on. There is also a method to judge if the learner mastered the learning target associated to the exercise. The behavior of the exercise page can be thus customized by modifying these methods. Similar to the usual page object, the exercise object has the URL entry pointing to the physical WWW page. This URL can not only point to a usual multimedia page but invoke a server-side script such as CGI, ASP, or Java Servlet which can dynamically generate the physical exercise page. This server-side script is called "exercise script" (Figure 2). The exercise object passes the exercise script parameters such as learner name, courseware name, learning targets, etc. The physical exercise page generated by the exercise script send to the exercise object the information reflecting the learners response for the presented questions. The exercise object analyzes the learners response and determines if the exercise script should be invoked again or the control should be returned to the upper level material objects. This structure has significant advantage compared with the usual dynamic HTML page generation/modification employed in the other WWW-based CAI systems. The other system has a HTML page with special syntax extension[6, 11] or the HTML template with special keyword embedded[10]. These syntax or keywords are interpreted by the system to generate the actual exercise page sent to the client. This schema has several drawbacks:

- Lack of reusability. The HTML page with these special syntax or keyword has no interoperability with other system.
- Lack of extendibility. It is very hard to enhance the capability of dynamic page generation without introducing very powerful language processing module into the CAI system.

In contrast to these drawbacks, the proposed exercise script scheme does not need special HTML syntax but utilizes commonly used server-side scripting system. It means that the script itself can be reused from any tutoring system as long as the invoking URL is identical. Moreover, these server-side script is based on the complete programming language like Java Script, Visual Basic, or Java, making it

![Diagram](image-url)  
**Figure 3: Message passing between objects**
possible to perform virtually any type of processing for exercise page generation. It is also possible to
generate HTML page including client-side script, Java applet, or interactive multimedia plug-ins. Of
course the courseware authors can choose favorable script language for them.

3.3 Event driven kernel and message passing between objects

Runtime control of the tree-structured material objects are taken care of by the small event-driven
kernel(Figure 3). This kernel receives the event from the learner such as "press NEXT button" and send
it as the command to the "current page" object which corresponds to the physical page presented to the
learner at that time.
The current page object receiving the learner's command tries to process it. For example, when "HINT" com-mand is sent to the exercise object, the object presents the appropriate hint by itself since it "knows"
the hints related to its questions.
On the other hand, when "NEXT PAGE" command is received, the current page object passes it to the
upper level material object such as section object since the page object does not know how to deal with
the command. This is because it is the responsibility of the section object to invoke the tutoring strategy
which selects most suitable next page object among the section pages by taking into account of the
student model. The selected page object will be the next "current page" object. If the section object has
no page to be selected, it again passes the "NEXT PAGE" command to its upper level section object, and
so on.
This bottom-up control scheme, in which the object of each level processes the command it can deal
with or otherwise it passes the command to the upper level, simplifies the dependencies between
material objects maximizing the modularity of the design.

4. Courseware Example

Simple courseware example[4] has been developed exploiting the features of the proposed architecture.
The courseware deals with the fax equipment which also functions as normal telephone and photo copy
machine. The courseware consists of a section object, explanation page objects and exercise objects
under the section object, and learning target objects corresponding to the operational steps for the fax,
telephone and photo copy mode (Figure 4). The exercise page objects are associated with the exercise script which invokes the interactive simulation of the fax equipment. The simulation program itself is implemented with Java script and Macromedia Flash running on the client. The target function mode to be learned is selected by the parameter passed from the exercise page object to the simulation program via the exercise script. The simulation program stores the learners operation steps, compares the steps with the correct operation, and returns the result to the exercise object. The exercise object judges if the learner masters the learning target corresponding to each operation step, and pass control to its upper level section object. Then the section object invokes the tutoring strategy to determine the next page presented to the learner taking into account of the status of the learning target.

This courseware example demonstrates the flexibility of the exercise object and exercise script which makes it possible to take advantage of the server-side script and the multimedia plug-in. The example also indicates that the tree-structured material objects increases the modularity so that each object having active method can be modified independently to some extent.

5. Conclusion

An object-oriented design and implementation of a Web-based CAI system has been described. Tree-structured material objects have been introduced to allow teaching strategy customization whose affect is localized to the relevant module. The exercise script is proposed to to exploit WWW-based software technologies such as JAVA, ASP, or various plug-ins. Sample courseware has been implemented to demonstrates the effectiveness of the proposed architecture. The sample courseware in this demonstration is too small to completely justify the proposed design. Further trial is required to develop more larger courseware consisting of various tutoring strategy to evaluate the effectiveness and limitation of the proposed architecture.

It seems that the proposed architecture could be naturally extended to the distributed courseware object framework. Exercise script could be regarded as a primitive distributed tutoring resource which is possible to be reused from several coursewares. The bottom-up control scheme, minimizing the interaction between the objects, could be adopted in the distributed environment. Further investigation towards this direction could lead the distributed tutoring resource environment.

Abstract: This study evaluated student attitudes on Compressed Video Instruction (CVI). Of particular interest were questions related to instructor concerns, student attitudes, and course improvement. One hundred and nine students responded to the survey and indicated that CVI does not necessarily improve instruction, but that convenience in travel time is a strong factor in their positive evaluation of CVI. Recommendations include the use of cooperative groups, a mix of lecture and discussion, and the use of “portfolio assessment” as part of the course grade. Implications of this study include (1) survey results on several items, (2) a review of student and faculty attitudes and concerns in establishing a CVI facility, (3) data for schools making decisions to use CVI, and (4) a contribution to a growing body of research on the use of emerging technology in classrooms.

1. Introduction

The purpose of this study was to examine the reactions and adaptability of faculty and students to a new teaching format, Compressed Video Instruction (CVI). CVI transmits in real-time, lectures and interactive discussions to several locations simultaneously where students can respond to questions by pressing buttons which activate video cameras that enable all sites to see and hear the response on site-located TV screens.

2. Equipment

Jacksonville State University (JSU) first implemented CVI in its Distance Learning program for the 1997 Spring semester by offering four graduate courses on a Compressed Video Network that served four different locations, Guntersville, Gadsden, and Oxford, as well as the Jacksonville State University (JSU) campus site.

The CVI equipment is as follows: ITU-T standards supported: H.221, H.230, H.242, H.261, H.281, H.320, G.711, G.722, G.728, and HDLC - based proprietary. The characteristics of the system includes VTEL, Teleconferencing System (January, 1997), PC based, document stand, three monitors, three cameras, wireless, lavaliere and push-to-talk microphones, Internet access, thirty frames-per-second, node on LAN/WAN, University supported T1 connections to all remote sites (BellSouth provider), and multipoint control unit (4 - 20 ports), to operate sites at 512 Kbps.

The system capabilities include audio and video conferencing, data sharing, slide sharing, document sharing, multimedia at all sites, CD-ROM, VCR, Laserdisk player, real, opaque, and transparent materials (Elmo), and computer generated or stored images (PowerPoint). The Compressed Video options included: BRI ISDN BRI = 64 kb per channel, two 64 kb channels = 128 kb, three BRI’s = 384 kb, PRI ISDN 23 (64 kb) channels + data channel (64 kb) = 1.544 Mb which may be used to provide 128 Kb to 1.544 Mb T1, 1.544 Mb, unused bandwidth which can be utilized for the Internet.

In sum, each off-campus site has two large video/TV units: one to see the instructor (or overheads, PowerPoint presentations, videos, campus site students (etc.) –controlled by the instructor), and the other to see other sites. The on-campus site has three large video/TV units, two in front for the students to see the instructor and other sites, and one in back for the instructor to see the other sites so all students would view the instructor facing
forward.

3. Method

3.1 Participants

Of the 119 graduate students enrolled in the Spring courses, 109 responded to the questionnaire. Gender representation was 34% male and 66% female. Ethnic representation was 14% Afro-American, 2% American Indian, 82% Caucasian, 2% “other.” Most participants were at distant sites (89%).

3.2 Measures and Procedures

To evaluate the attitudes and effectiveness of CVI, a 42 item questionnaire was developed (see Table 1). A wide variety of questions were used to explore several aspects of CVI, e.g., preferences for instruction as well as the CVI experience. For all participants, this was their first exposure to CVI.

4. Results and Discussion

4.1 Instructor Concerns

Since the instructor is unable to physically be present at the sites, there is concern that inappropriate talking may occur. For the question, “The noise level at my location was _____ distracting.”, 64% indicated that it was “not distracting,” 23% responded “mildly distracting,” and 0% responded that it was “very distracting.” This was surprising because occasionally a student would indicate that there was some off task talking during instruction.

As to the students’ ability to “stay on task,” 92% responded that they “usually” and “always” were able to stay on task. As to the question of exams, most respondents didn’t know if there would be cheating (44%), however, various examination attempts have not been successful, resulting in the student’s coming on campus for a more closely monitored testing environment.

Another instructor concern was the teacher “spontaneity” with student interactions. Because of the slight delay time and reticence of most students to be on TV, some felt the spontaneity was diminished (26%), some thought it was enhanced (16%), but most thought it was about the same (58%).

4.2 Student Attitudes

The results indicated neither overwhelming praise nor condemnation of the new CVI format. On one question, for example, 13% of the students thought the quality of instruction was “better,” 11% thought the quality of instruction “worse,” but the majority of students, 76%, perceived the quality of instruction as “about the same.” With most students indicating a preference for discussion oriented classes (70%) over lecture oriented classes (30%), little negative effect was indicated over instructor concerns on pacing, instructor contact, effect on student participation (etc.). One of the selling points, convenience of travel and location, was validated with 76% indicating it as a major benefit for using the CVI format. The “bottom-line” question for the students was, “Will you take a future course by compressed video?” An overwhelming 85% indicated that they would take another CVI course, and 50% gave a high rating to CVI.

4.3 Course Improvements

It appears that at least half of the students (52%) would have wanted the instructor to rotate between sites for more personal contact. They also preferred a lecture and discussion format (74%), and felt that CVI is best suited for both a lecture and discussion format (65%). They also prefer a cooperative classroom climate (51%) over a competitive climate (2%), but with a close second preference for a mixed cooperative/competitive climate (47%).

4.4 Conclusion
The results of the survey suggest that although CVI does not necessarily improve instruction, the convenience of having various site locations is highly valued by the students. The data, as well as communication with instructors, also recommends using cooperative group-work projects during class time to foster student interactions. As student involvement increases and affiliation needs are met through the group work, a good mix of lecture and discussion is achieved. The work-sheet projects also provide material for "portfolio assessment" used in grading. For some students who require more monitoring in off-site centers, the use of an "end of class quiz" helps with on-task motivation as well as ensuring full class time attendance. (See Table 1 below for further response information.)

4.5 Survey and Results

Table 1: Anonymous Compressed Video Course Survey (N = 109)

Please respond to the following questions by either circling your preferred answer or marking it on a ScanTron sheet (if provided).

1. The compressed video equipment (microphone, audio, image, document camera, etc.) was
   a. reliable most of the time. 90%
   b. reliable some of the time. 10%
   c. unreliable 0%

2. Do you prefer that the instructor rotate between sites during the semester, allowing for more personal contact?
   a. yes, definitely 52%
   b. undecided 12%
   c. no, its not necessary 36%

3. Did you contact your instructor during the semester through the use of
   a. telephone 36%
   b. e-mail 2%
   c. neither because I didn't need to contact the instructor. 62%

4. The site manager was friendly & cooperative.
   a. Yes 100%
   b. No 0%

5. The site manager was knowledgeable and well trained.
   a. Yes 100%
   b. No 0%

6. The noise level (students visiting, etc.) at my location was ...
   a. very distracting 0%
   b. mildly distracting 23%
   c. not distracting 64%
   d. N/A (instructor's site) 10%

7. In class I was able to stay on task ...
   a. always 42%
   b. usually 50%
   c. moderately 8%
   d. rarely 0%

8. In my opinion, the compressed video format is best suited for
   a. lectures 32%
   b. discussions 4%
   c. both lecture and discussion 65%

9. Will you take a future course by compressed video?
   a. Yes 68%
   b. No 0%
   c. Maybe 16%
   d. Yes, but only if no other option is available 17%

The compressed video format is ___ than the format of "regular" classes" on ...
10. a. better 15%
    b. about the same 70%
    c. worse 15% ... organization of the class.
11. a. better 12%
    b. about the same 48%
    c. worse 40% ... student/instructor interaction.
12. a. better 13%
    b. about the same 76%
    c. worse 11% ... quality of instruction.
13. a. better 76%
    b. about the same 20%
    c. worse 05% ... convenience.
14. a. better 16%
    b. about the same 59%
    c. worse 25% ... sharing of documents.
15. a. better 19%
    b. about the same 72%
    c. worse 09% ... pacing of class.
16. a. better 36%
    b. about the same 54%
    c. worse 11% ... use of a variety of media.
17. I prefer classes that are more oriented towards ...
a. student centered/group work 17%
b. mixed student/teacher & group work/lectures 56%
c. teacher centered/lectures 27%

18. I prefer classes that are more...
a. discussion oriented 70% b. lecture oriented 30%

19. I prefer classes that are based more on ______ learning styles.
a. cooperative 51% b. mixed cooperative/competitive 47% c. competitive 2%

Compressed Video classes ...
20. have a ______ effect on instructor contact with students during class.
a. positive 25% b. neutral (neither positive or negative) 47% c negative 28%

21. have a _____ effect on organization of materials during class
a. positive 30% b. neutral (neither positive or negative) 53% c negative 17%

22. have a _____ effect on student response or participation
a. positive 29% b. neutral (neither positive or negative) 48% c negative 24%

23. Overall, I would rate the compressed video format as an instructional medium
a. high 50% b. medium 42% c. low 9%

I am taking this telecourse because ...
24. it fits best with my work schedule. a. Yes 85% b. No 15%
25. it fits best with my family responsibilities. a. Yes 78% b. No 22%
26. it helps with current transportation limitations. a. Yes 82% b. No 18%
27. it was not offered at any other time this semester. a. Yes 43% b. No 57%

I found out about the JSU telecourse through a
28. friend. a. Yes 22% b. No 78%
29. parent or relative. a. Yes 03% b. No 97%
30. JSU faculty/staff. a. Yes 63% b. No 37%
31. brochure, schedule, pamphlet. a. Yes 43% b. No 57%
32. newspaper ad, or article. a. Yes 03% b. No 97%
33. radio, or TV announce. a. Yes 01% b. No 99%

34. Within the compressed video format, I prefer to be at
a. the instructor's site 30% b. a distant site. 14% c. either site (doesn't matter). 56%

35. I think graduate teaching is best served with a ______ format.
a. lecture 17% b. discussion 9% c. both lecture and discussion 74%

36. Exams in a distant site would probably be more susceptible to cheating.
a. yes 20% b. no 36% c. I don't know. 44%

37. With the compressed video format, my "learning" (concept acquisition, not grade) was
a. higher 11% b. about the same 79% c. lower 9%

38. With the compressed video format, teacher "spontaneity" with student interactions was ...
a. enhanced 16% b. about the same 58% c. diminished 26%

39. I was at ...
a. the instructor's site 11% b. a distant site 89%

40. I am a ...
a. male 34% b. female 66%
41. My ethnic origin is
   a. Afro-American 14%
   b. American Indian 2%
   c. Caucasian 82%
   d. Hispanic 0%
   e. Other 2%

42. My age is...
   a. 20-30 21%
   b. 31-40 36%
   c. 41-50 34%
   d. 51-60 8%
   e. 61-70 0%

m.l.nelson@larc.nasa.gov

Kurt Maly, Stewart N. T. Shen
Old Dominion University, Computer Science Department, Norfolk, VA 23529, USA
{maly, shen}@cs.odu.edu

Abstract: We describe NCSTRL+, a unified, canonical digital library for educational and scientific and technical information (STI). NCSTRL+ is based on the Networked Computer Science Technical Report Library (NCSTRL), a World Wide Web (WWW) accessible digital library (DL) that provides access to over 100 university departments and laboratories. NCSTRL+ implements two new technologies: cluster functionality and publishing "buckets". We have extended the Dienst protocol, the protocol underlying NCSTRL, to provide the ability to "cluster" independent collections into a logically centralized digital library based upon subject category classification, type of organization, and genres of material. The concept of "buckets" provides a mechanism for publishing and managing logically linked entities with multiple data formats. The NCSTRL+ prototype DL contains the holdings of NCSTRL and the NASA Technical Report Server (NTRS). The prototype demonstrates the feasibility of publishing into a multi-cluster DL, searching across clusters, and storing and presenting buckets of information.

1. Introduction

Digital libraries (DLs) are an important research topic in many educational and scientific communities and have already become integral part of education at all levels. We have learned of many instances where undergraduate and graduate engineering courses are now supplemented with NASA research results that were previously difficult to obtain. DLs have allowed resource limited colleges and universities access to a wealth of research in a variety of disciplines. However access to these DLs is not as easy users would like. Digital library projects are partitioned by both the discipline they serve (computer science, aeronautics, physics, etc.) and by the format of their holdings (technical reports, video, software, etc.). A recent survey found over 10 existing or recent different World Wide Web (WWW) oriented digital library projects spanning over 5 different disciplines [Esler & Nelson 1998]. In short, each educational and scientific community is hand crafting their own digital library infrastructure.

There are two significant problems with current digital libraries. First, interdisciplinary research and education are difficult because the collective knowledge of each discipline is stored in incompatible DLs that are known only to the specialists in the subject. The second significant problem is that although technical information as well as educational materials created consists of manuscripts, software, datasets, etc., the manuscript receives the majority of attention, and the other components are often discarded [Sobieszczanski -Sobieski 1994].

Old Dominion University and NASA Langley Research Center have established NCSTRL+ to address both of these problems. NCSTRL+ is based on the Networked Computer Science Technical Report Library (NCSTRL) [Davis et al. 1995], which is a highly successful digital library offering access to over 100 university departments and laboratory since 1994, and is implemented using the Dienst protocol [Lagoze et al. 1995]. At the development stage, NCSTRL+ will initially include selected holdings from the NASA Technical Report Server (NTRS) [Nelson et al. 1995] and NCSTRL, providing clusters of collections along the dimension of disciplines such as aeronautics, space science, mathematics, computer science, and physics, as well as clusters along the dimension of publishing organization and genre, such as
project reports, journal articles, theses, etc. NCSTRIL+ holdings will be published in buckets [Nelson et al. 1997], an object-oriented construct for creating and managing collections of logically related information units as a single object. A bucket can contain both different data syntax (PostScript, PDF, Word, etc.) and different data semantics (manuscripts, data files, images, software, etc.)

2. Background

NCSTRIL+ has a long lineage. In 1992, the ARPA-funded CS-TR project began [Kahn 1995] as did the Langley Technical Report Server (LTRS) [Nelson et al. 1994]. In 1993, the Wide Area Technical Report Server (WATERS) [Maly et al. 1994] shared a code base with LTRS. In 1994, LTRS launched the NTRS, and the CS-TR and WATERS projects formed the basis for the current NCSTRIL. In 1997, NTRS and NCSTRIL formed the basis for NCSTRIL+. We chose to implement NCSTRIL+ using Dienst instead of other digital library protocols such as TRSkit [Nelson & Esler, 1997] because of Dienst's success in several years of production in NCSTRIL. Dienst appears to be the most scalable, flexible, and extensible of digital library systems we surveyed [Esler & Nelson 1998]. Dienst also serves as the basis for other digital library projects, including: the Electronic Thesis and Dissertation Project [Fox et al. 1996], the University of Virginia undergraduate engineering thesis project [UVa SEAS 1997] and the ACM SIGIR conference proceedings project (which requires ACM authentication) [ACM 1997].

Our buckets are similar in concept to the "digital objects" first proposed in [Kahn & Wilensky 1995]. It is important to note that many services have had "proto-buckets" in operation for some time. However, they provide only different formats of a single manuscript, or may support the concept of separate pages within a manuscript. They do not support an interface to a collection of related objects such as the manuscript, software, datasets, etc. We chose the term "buckets" because related terms such as "objects", "packages" and "containers" are greatly overloaded in the computer science realm and because "buckets" provide a clear visual metaphor for the concept when speaking with non-computer scientists.

3. Clusters of Dienst Servers

Clusters are a way of aggregating logically grouped sub-collections in a DL along some criteria. NCSTRIL+ provides 3 clusters: organization, data genre, and subject category (see [Fig. 3] for an example). Genre is a term provided by E. Fox in a private communication and refers to distinguishing between journal articles, technical reports, theses and dissertations, etc. For the purposes of this paper, we illustrate the concept of clusters by discussing the subject category cluster. Other clusters are implemented similarly.

Dienst currently carries no concept of subject category in its protocol, despite having provisions for specifying keywords from the title, authors, and abstract. In fact, digital libraries using the Dienst protocol such as NCSTRIL have the implicit assumption that all holdings are computer science related. We propose to modify Dienst by providing cluster arguments to existing message verbs. We have used a set of message verb modifications to demonstrate the concept of subject category based server cluster functionality. The new clustering service will solve the general case of the problem, where our Dienst modifications will support the specific clustering around subject categories in the early stages of the NCSTRIL+ prototype. The purpose of our cluster prototype is to perform experiments with an initial set of clusters and determine user response. NCSTRIL+ reads its known subject categories from a preference file thus the list of subjects can be easily replaced or augmented.

4. Buckets

Buckets are a construct for creating publishing and archival entities for digital libraries. A bucket corresponds to a single logical collection of information. Buckets are designed to be highly customizable and unique. Bucket architecture is illustrated in [Fig. 1]. Large archives could have buckets with many different functionalities. Not all bucket types or applications are known at this time. However, we can describe a generalized bucket as containing many formats of the same data item (PS, Word, Framemaker,
etc.) but more importantly, it can also contain collections of related non-traditional STI materials (manuscripts, software, datasets, etc.). Thus, buckets allow the digital library to address the long standing problem of ignoring software and other supportive material in favor of archiving only the manuscript [Sobieszczanski-Sobieski 1994] by providing a common mechanism to keep related STI products together.

A single bucket can have multiple packages. Packages can correspond to the semantics of the information (manuscript, software, etc.), or can be more abstract entities such as the metadata for the entire bucket, bucket terms and conditions, pointers to other buckets or packages, etc. A single package can have several elements, which are typically different file formats of the same information, such as the manuscript package having both PostScript and PDF elements.

![Bucket Architecture Diagram]

**Figure 1: Bucket Architecture**

### 4.1 Bucket Requirements

Buckets are intended to be either standalone objects or to be placed in digital libraries. They have unique ids (CNRI handles) associated with them. Buckets are intended to be useful even in repositories that are not knowledgeable about buckets in general, or possibly just not about the specific form of buckets. Buckets should not lose functionality when removed from their repository. The envisioned scenario is that NCSTRL+ will eventually have moderate numbers of (10s - 100s of thousands) of intelligent, custom buckets instead of large numbers (millions) of homogenous buckets. With buckets, the repository intelligence and functionality can be split between the repository and individual buckets. This could be most useful when individual buckets require custom terms and conditions for access (security, payment, etc.). A bucket gains some repository intelligence as it is extracted from the archive en route to becoming a standalone bucket. A full discussion of bucket functionality can be found in [Nelson et al 1997].

### 4.2 Bucket Tools

There are two main tools for bucket use. One is the author tool [Fig. 2], which allows the author to construct a bucket with no programming knowledge. Here, the author specifies the metadata for the entire bucket, adds packages to bucket, adds elements to the packages, provides metadata for the packages, and selects applicable clusters (which lead to the cluster options available as shown in [Fig. 3]). The author tool gathers the various packages into a single component and parses the packages based on rules defined at the
author’s site. Many of the options of the author tool will be set locally via the second bucket tool, the management tool. The management tool provides an interface to allow site managers to configure the default settings for all authors at that site. The management tool also provides an interface to query and update buckets at a given repository. Additional methods can be added to buckets residing in a repository by invoking the add_method on them and transmitting the new code. From this interface, the manager can halt the archive and perform operations on it, including updating or adding packages to individual buckets, updating or adding methods to groups of buckets, and performing other archival management functions.

Figure 2: Author Tool

5. Using NCSTRL+

5.1 Searching NCSTRL+

NCSTRL+ searching is similar to searching NCSTRL, with the addition of specifying desired clusters to search. How the advanced fielded search form of NCSTRL+ is modified, allowing the selection of desired subject categories and data genres, is shown in [Fig. 3]. A search results page includes the keyword and cluster hit results. The user will select the desired bucket from this page. At that point, the bucket will return the defined default initial interface of the bucket, which will be dependent on the bucket contents and the rules present. In practice, the bucket presentation will look largely similar to the choices available to current users of NCSTRL. This is especially true if the buckets in which they are interested only contain various manuscript formats. However, the real benefit is the richer presentation formats available if the bucket has non-manuscript packages. The bucket interface is similar to NCSTRL, with the exception that the additional data semantics are presented (software, datasets, etc.).

5.2 Publishing into NCSTRL+

The goal of NCSTRL+ is to produce the least intrusive interface possible to the author. The authoring process for NCSTRL+ is to be as similar to authoring into NCSTRL as possible. Additions include the ability to add to a bucket multiple data semantics and formats through using multiple selection
boxes to select local files. Publishing a manuscript in NCSTRL is equivalent to publishing a package in NCSTRL+, and publishing a bucket is the sum of publishing all of its packages. The author also has to choose the appropriate cluster to place the new bucket in. This step can be skipped if the site manager has defined a default, or if authors have saved a value already in their preferences.

![Fielded Search Screen of NCSTRL+](image)

**Figure 3: The Fielded Search Screen of NCSTRL+**

6. Status and Future Work

We are using the author tool to populate NCSTRL+ to gain insight on how to improve its operation. We are starting with buckets authored at Old Dominion University and NASA Langley Research Center and are choosing the initial entries to be "full" buckets, with special emphasis on buckets relating to NSF projects for ODU and for windtunnel and other experimental data for NASA. Until NCSTRL+ becomes a full production system, we are primarily seeking rich functionality buckets that contain diverse sets of packages.

It is also important to note that adding a subject category mechanism to NCSTRL+ provides the necessary groundwork for additional services for digital libraries using Dienst. These could include subject-based browsing of NCSTRL+ holdings, as well as selected dissemination of information (SDI). This would be most useful if users were offered a subscription option to receive digested updates (i.e., e-mail messages) of new additions to NCSTRL+ in specified subject areas. The initial defined subject categories for NCSTRL+ and cross-listing them with other subject-specific categorization schemes is intended to provide a working framework for evaluating the prototype. As more experience in NCSTRL+'s use is gained, the fine tuning of the subject categories and appropriate cross listing becomes an area that would benefit from the attention of a professional cataloger.
7. Conclusions

To meet the increased requirements for multidisciplinary activities in educational and scientific communities, we have prototypes of NCSTRL+ and are in the process of full implementation. The most significant technology from this project is the concept of buckets as a construct to capture multiple data formats and genres in an intuitive manner. NCSTRL+ provides a platform for experimentation for testing user response to multidiscipline clusters and logical collections of STI. We are in the process of experimenting with users at NASA and Old Dominion University. From the users' perspective, the publishing and searching interfaces are largely unchanged. However, it is unknown what impact the cluster and bucket modifications have on network load, search and retrieval times, the users' perceived quality of searching multiple clusters, etc. To determine these unknowns, NCSTRL+ will have to grow to a large enough size to be considered a useful production system. The authors seek other users and participants for NCSTRL+.

8. References

Abstract: Strictly defined system requirements are a necessary precondition for system modelling as well as for the application of various specification methods during the development of learning software. This paper focuses on the procedure of setting these requirements. The fact that the development of learning software is particularly interdisciplinary process makes the strict definition of system requirements extremely difficult. The method of requirement classification described in this paper takes into account the most important groups of system requirements and presents a simple way for their adjustment for concrete learning systems. The use of this method not only forms a sound basis for a formal system specification but also prevents the requirements from involuntary transformations during the development. This guarantees that the desired results will be achieved at the end of the development process.

1. Introduction

The development of learning software is a particularly interdisciplinary process. A learning system for anorganic chemistry, for example, does not only require knowledge of the domain chemistry. Its didactic concepts are determined by experts in the field of pedagogics and cognitive psychology, subsequently modelled upon abstract mathematical theories and finally implemented by computer scientists and programmers. So, the development of such systems is influenced by a number of domains or fields of science, which sometimes have very little in common. This situation is typical not only for learning systems, but for interactive systems (of which learning systems form a subclass) in general [Monk & Gilbert 1995].

The interdisciplinarity of learning systems is one of the main reasons for the high development costs of this kind of software. The problems for the developer begin already with the very first step of development: the analysis of requirements. It is extremely difficult to select and assess the relevant requirements from the stream of wishes, needs, and system goals presented by the different persons involved in the development process. It is even more difficult to become aware of all interconnections and dependencies that exist between all requirements. However, the appropriate assessment and selection of the system requirements form the basis for all further steps of the development of the learning system. Hence, a mistake during this phase has severe consequences. Such mistakes are a main reason for the high number of development iterations (i.e. developing-testing-redeveloping cycles) needed for the production of learning software (see also [Roast 1994]).

The importance of a more strict procedure for setting requirements is recognised by [Duke & Harisson 1995] in the context of interactive systems in general. Because learning systems can be viewed as a subclass of interactive systems [Nemirovski & Schlageter, 1997], it is possible to apply this statement to a more strictly defined domain.

A classification of all the typical requirements for learning software would help developers in the same way as a fill-in form helps a user to formulate a query to a database system. And not only this. If such a classification is given in a specific form, it is possible to formalize the system requirements using a formal notation such as VDM or Z. This allows to make the modelling process, the further refinement, and the implementation of the learning system more precise [Harrison & Duke 1995], [Took, 1995] and thus reduce the number of mistakes and development iterations. In this paper we will present a classification that distinguishes between three types of requirements for learning Software. This division is substantiated partly by the importance of the requirements and partly by the sequence of their setting.

2. The domain: What is Learning Software?

The purpose of learning software is to support the learner in acquiring knowledge. However, this can be done in many different ways, resulting in different types of learning software. According to [Barnard & Sandberg 1995] learning software can be classified with respect to the aspects of the socio-cultural niche of the learner that is taken into consideration by the software. By the learner's socio-cultural niche they understand not only the
learning material but also the teacher (human or artificial), the learner model (on-line or off-line), the fellow learners with whom the learner can communicate, the learning tools that facilitate the learning process, and external information sources.

Baumgartner and Payr [Baumgartner & Payr 1994] use a sophisticated cube-model to classify learning software. The three axes of the cube represent the learning goals, the learning strategies, and the learning level. The learning goals determine what kind of knowledge the learner is supposed to acquire (context-free rules, context dependent rules, assessing complex situations, problem solving, pattern recognition.) The learning strategies describe whether the learner is taught, tutored or coached by the learning software. Finally, the level of learning depicts the capabilities that are needed in order to use the software (e.g. recalling facts, applying rules, making decisions, discovering connections, developing strategies.)

The classifications of learning software described above are typical examples of this domain. There exist other classifications in literature that vary with respect to the extension of the term 'learning software' and the number and type of suggested subclasses. Furthermore, it can be necessary to adapt such a classification to the needs of a particular learning domain. This situation makes it very difficult to formulate general statements about learning software. In spite of this fact the classification of system requirements defined in the next section of this paper attempts to be more or less universally applicable. In order to be able to make a general assertion it is necessary to describe the fundamental requirements for learning software on a relatively high level of abstraction. For the development of a specific learning software these general requirements have to be given a particular interpretation that reflects the specific circumstances.

3. Classification of Requirements for Learning Software

There are many different principles that can be used for the classification of requirements for learning software. The role that the requirements have in the development process depends on the point of view from which this software is regarded. For the educationist the choice of learning methods used in the learning system is the most important criterion; for the system analyser it is the technology the system is based on; for the sociologists it may be the definition of the user group that is supposed to use the software, etc.

The classification of requirements for any kind of software must correspond to the aim of the software. In the case of learning software the aim is to provide a highly efficient way of learning and at the same time keep the development costs low. For the classification of requirements presented in this paper we assume that the ability to correctly reflect the learning domain and present it to the user with minimal distortion is the main goal of a learning system. Therefore, the central group of requirements for learning software has to define a view on the domain which will be used in the presentation. The other requirements specify this view step by step, bringing more details to the definition. Each group of requirements introduced here describe the system properties in terms comprehensible for the corresponding group of developers. The methodical requirements reflect the way the domain should be presented from the educational point of view; and the interface requirements focus on the methods of this representation with regard to the media of presentation. The three groups of requirements are shown in Figure 3.1.

![Figure 3.1: Classification of requirements](image-url)

- **Domain requirements** include all requirements that result from the domain of the learning software. These requirements answer the question „What should the user learn?“ Therefore, the field of interest of this group of requirements are the contents and the goals of learning. The most important requirement of this class is the

---

**BEST COPY AVAILABLE**

1068
reachability of the learning goals. This means that the user should be able to gain the knowledge or acquire the skills that are defined as learning goals through the contents offered to him by the considered system.

- The second group of requirements, the methodical requirements, answer mainly the question ‘How should the user learn?’ The field of interest of this group of requirements is concerning the general ideas of learning methods, which take into account the media used for learning as well as the selected learning paradigm such as behaviourism, cognitivism, or constructivism. (An overview of these learning paradigms can be found in [Baumgartner & Payer 1994]). On this level of abstraction we have to consider first of all the requirement of strict definition of the learning means. This means that all learning procedures as well as all elements of the learning environment have to be explicitly defined. Often small changes in the learning environment lead to considerably changes of the general concept and methodology of the system.

The means of control for the selected method of learning have to be defined strictly as well. The following requirements help to give such a definition: Well determined examination of the user’s learning success. Here we do not mean an examination of how well the user has understood the material. Sometimes this is neither possible nor sensible. The requirement should be interpreted in a weaker manner: it demands that the user’s recent actions can be classified in relation to the structure of the learning domain. (For example, scoring the user’s actions on a scale from 1 to 100.) An another requirement is exact assessment (Paul, 94), which requires that the information demanded by the previous requirement is made available to the user. The requirement of effective fault diagnosis [Lindgaard 1995] demands that the user is given a detailed explanation of her mistakes.

- The third group of requirements (Interface requirements) reflects the characteristics of the media used for the implementation of learning systems. It considers the properties of the objects given to the user to express her needs and wishes or to interpret the behaviour of the system. This corresponds to the traditional interpretation of interaction. Therefore, the general principles of interaction (as defined by [Dix 1991] must be fulfilled. These principles are: predictability (the user must be able to predict the consequences of her most recent action), observability (the user must be able to perceive all results of her actions from the current state of display), and reachability (objects or actions the user wants to use must be available to her.)

![Figure 3.2: Requirements for learning software](image)

4. Tasks as a way of applying of the requirements to learning software.

How can the requirements described above be applied practically? Generally, learning software makes use of a variety of different approaches for learning and teaching. Therefore, it does usually not make much sense to set an abstract requirement to a learning system as a whole. It is rarely possible to put such an abstract requirement in concrete terms for the entire system. It is much more promising to apply the palette of requirements to a local learning approaches used in the considered learning system. We will call local such learning approaches learning tasks or simply tasks for the remainder of this paper.

The question is now, how the three groups of requirements described in the previous section can be applied to a certain learning task. Take, for example, the task ‘solving of a quadratic equation.’ The general domain requirement (reachability of the learning goal) demands in this case it must be possible to solve the equation using the mathematical methods defined by the software. For a quadratic equation one could use the quadratic extension method or solve the discriminant.

The methodical requirement of strict definition of the learning means defines how the quadratic equation is solved, e.g. by answering multiple choice questions, by filling in the empty fields in a prepared solution form, by writing down the solution with the help of an ASCII editor, by solving the task with a formula editor, etc.
requirement of determined examination of the user’s learning success excludes all situations in which the user suggests a solution of the equation that cannot be classified by the system as correct or incorrect. The requirement of exact assessment demands that the score for the proposed solution reflects the quality of the given answer (which depends, e.g., on the number of mistakes made by the user). The interpretation of the requirement of effective fault diagnosis depends much more on the specific form of the solution than the interpretation of the requirements discussed earlier in this paragraph. When using a formula editor, for example, the incorrect part of the mathematical expression could be highlighted.

For description of the Interface requirements let us again consider a formula editor as a means of solving the quadratic equation. In this case the requirement of predictability means that the effect of formula editing has to correspond to the user’s expectations syntactically as well as semantically. An insert operation, for example, should take place where the user expects it, i.e. at the current cursor position. The requirement of observability demands the full perceptibility of the editing results as well as of the assessment results. All important parts of solution or its diagnosis should be observable by the user. Reachability means that all the actions which appear to the user to be feasible should be available. The user should be able, for example, to edit the area that was highlighted by the diagnosis procedure.

5. Three models of instructional design

After we have given a description of the three groups of requirements for learning software, we will now show how our classification corresponds to modern concepts of computer based learning. We selected three different approaches of instructional design that represent a wide variety of didactical concepts. For these three approaches we demonstrate how their specific characteristics can be made tally with the above given classification of requirements.

Following Schott [Schott 1991] we use the term Instructional Design (ID) to describe the systematic and theoretically grounded development of learning systems (comprising not only the process of development but also the result of this process, e.g. a particular learning software.) There are various models of instructional design that stress different didactical concepts. Three models models that have received a fair amount of attention recently are Anchored Instruction, Cognitive Apprenticeship, and Goal-Based Scenarios. We will briefly summarize the main aspects of these models (a good overview can be found in [Simon 1997]):

Anchored Instruction

Many traditionally learning approaches face the problem of ‘inert knowledge’, i.e. the difficulty of learners to transfer the acquired knowledge to new, unfamiliar situations. The anchored instruction model attempts to solve this problem by creating an anchor that attracts the interests of the learner and allows her to identify and define the relevant tasks. The problem that has to be solved is presented to the learner in form of a stimulating, case-based story. According to the Cognition and Technology Group at Vanderbilt [CTGV1991] the anchored instruction model is based on the following seven design principles:

- Video-based format of presentation of the case-based stories
- Presentation of information within a narrative structure, i.e. the task that has to be solved is embedded in a meaningful context (‘well-formed story’)
- Generative forms of learning, i.e. the presented stories are complete except for the solution, which has to be created by the learners themselves
- Embedded data design, i.e. all information necessary for solving the task is implicitly contained in the story
- Use of sufficiently complex problems in order to give the learner the opportunity to learn how to deal with complex situations
- Use of pairs of corresponding stories in order to help the learner to generalize the relevant knowledge and to abstract from a specific context
- Design of stories that are not restricted to a specific complex problem but that include connections to other areas of the curriculum as well.

Cognitive Apprenticeship

The proponents of the cognitive apprenticeship model hold the view that the traditional form of school education is to abstract and theoretical. Learners acquire only ‘brittle skills’ that cannot be adequately applied to real-life situations. The advocates of this model of instructional design therefore suggest to transform the traditional form of school education into a form of ‘cognitive apprenticeship’ (similar to the apprenticeship in other professions.) Learners should solve realistic tasks that are embedded in an authentic context (embedded learning). Furthermore, learners should learn from and be guided by experts in the specific areas and thus acquire the needed cognitive and metacognitive skills to solve complex and realistic tasks. According to [Collins et al. 1989] the design parameters of cognitive apprenticeship can be divided along four dimensions:
• Content: This dimension comprises domain specific knowledge, heuristic strategies, controll strategies, and learning strategies.
• Methods: The teaching methods that are used, such as modelling, coaching, scaffolding, articulation, reflection, and exploration.
• Sequencing of learning tasks: The three principles, by which the learning tasks are presented to the learner, namely increasing complexity, increasing diversity, and global before local skills.
• Social context of learning: Certain aspects of the social organisation of apprenticeship that are important for the learning process (situated learning, culture of expert practice, intrinsic motivation, exploiting cooperation, exploiting competition.)

**Goal-Based Scenarios**
The proponents of goal-based scenarios (GBS) hold the view that every human action involves the pursuit of a goal [Schank et al. 1993/94]. Learning, as a specific form of human action, is not different. Intrinsic goals (e.g. increasing one's own capacity to act and understand) create the motivation to learn. The traditional form of education fails to make use of the intrinsic goals of students and thus has to rely on less motivating extrinsic goals (e.g. getting good grades or avoiding punishment.) The aim of goal-based scenarios is to create a learning environment in which the learners are given a goal that coincides with their intrinsic goals and which can be reached by acquiring the desired skills. A goal-based scenario consists of four components:

- **Mission**
The mission is the goal that the learner is supposed to reach within the GBS. The goal should be plausible, consistent, and chosen in such a way that it corresponds to the learners' own goals. While the steps necessary to reach this goal should mediate the desired skills, it should be possible to fulfill the mission in different ways.

- **Mission focus**
The mission focus defines the form of organisation that the activities of the learner can take, e.g. designing, explaining, controlling, discovering. The learners should feel responsible for the results they cause.

- **Cover story**
The cover story serves as a framework in which the mission can be fulfilled. The story should be plausible and motivating, describe a situation in which the skills that are to be learned are needed, and provide a context in which these skills can be acquired readily. The cover story can be complimented by additional materials.

- **Scenario operations**
Scenario operations are the activities that are available to the learner in order to fulfill his mission. They should be consistent with the pursued goal and the cover story, and give the learner a sufficient variety of options not only to reach his goal but also to make mistakes. The consequences of all operations should be understandable. Furthermore, the learner should not be burdened with actions that are not central for the learning process.

The following table shows how the components of the different instructional design models can be mapped to the above presented classification of requirements:

<table>

*Table 5.1: Classification of components of different instructional design models*
The fact that no interface requirements are defined for the cognitive apprenticeship model does not mean that these requirements do not exist. They are just not determined strictly by this model, but will be set according to the specific form of the concrete application.

The purpose of this section was to show that the discussed requirement classification can be applied to three rather different didactical approaches. We did not attempt to prove that this is possible for all models of instructional design, though our experiences suggest that it can be done for the vast majority of models.

6. Conclusion

The methodology for setting requirements for learning software described in this paper corresponds to modern concepts of instructional design and can be readily applied in the practice. Furthermore, this methodology displays the following advantages for the development of learning systems:

- **Dividing up of responsibilities** - Each group of requirements presented in this paper defines a certain level of abstraction. Each level determines a class of system properties which belongs to the area of competence of the corresponding group of developers (domain experts, educationists, computer scientists.) This enables an optimal division of responsibilities between the different groups of developers.

- **Low development costs** - The strict definition of the system requirements make it possible to use formal methods of specification (e.g. methods from HCI theory.) In this way a clear definition of the connections between the different levels of abstractions can be given and formal verification methods can be applied. All this increases the efficiency and thereby decreases the costs of development. (The application of HCI methods in the case of coached training systems is demonstrated in [Nemirovski & Schlageter 1997].)

- **Satisfaction of demands** - The definition of requirements according to the above described classification and the application of formal development methods make it possible to take into consideration the system requirements during the whole time of development. This guarantees that the resulting learning system will fulfill all demands set by the different groups of developers.

It's Easy to be Wise after the Event:  
Concepts for Redesigning an Educational System on Logistics  
Derived from Reflecting its Development and Use

Gaby Neumann, Dietrich Ziems, Christian Hüpner  
Department of Logistics and Materials Handling Engineering  
University of Magdeburg  
Postfach 4120, D-39016 Magdeburg, Germany  
E-mail: Gaby.Neumann@masch-bau.uni-magdeburg.de

Abstract: Often the development of an attractive multimedia-based educational system is a long-lasting and lavish process. Especially, if the authoring process is primarily in the hand of the educational system's potential users (the teachers) who are often not very experienced in developing those systems, their support by design guidelines and easy-to-use authoring tools becomes more significant. Besides this, it is necessary to concern oneself repeatedly with the own way of action and its results for deriving experience. Following the example of an educational system on logistics, the contribution will show, how this self-reflection of the educational system's development and use has led to a concept for its future-orientated redesigning and also for a more efficient author-supporting infrastructure.

Initial Situation

As result of a developmental process lasting several years, the first component of a multimedia-based educational system on logistics was created by prototype implementation of a module on warehousing in German and English language [see Neumann, Ziems, and Hüpner 1995, or Ziems and Neumann 1997]. The system is tailor-made for the specific interests of university-level logistics education. It imparts the fundamental knowledge of facts and methods as well as the integrated logistical thought and action orientated towards success. Above all, it presents knowledge concerning possible applications and easily to comprehend by means of procedures enabling experiments. Besides this, the student is supported in using his/her knowledge actively. The methodical-didactic structuring and alternative presentation of logistics knowledge as well as the design of navigation and interaction possibilities are suited to the system's use for self-studies and as a work of reference as well as to support lectures, exercises, and practical training.

The educational system is tested, used and evaluated at the University of Magdeburg but also within a European network of at the moment 24 universities, colleges, and training centers from 13 countries. For the most part, the students met multimedia-based educational systems for the first time. Their opinions, critics, and wishes recorded within interviews and by questionnaires were analyzed together with pedagogical experts to recognize acceptance problems and needs for the educational system's further developments as well as for the way of its integration into the educational process. During the developmental process we gained an increasing experience from our work and improved our knowledge about ideas, approaches, activities, and results from other people's work. Because of this, demands and request for the educational system's functionality and design as well as for the authoring process's way of action and support by appropriate tools were grown as well. Finally, these experiences led to the decision to redesign both the educational system according to contents, methodical-didactic, functional, and design aspects and the concepts and infrastructure supporting the developmental process by making use of the improved hardware and software basis as well as of ideas and concepts derived from the system's development and use.

Experiences from Developing and Using the Educational System
The educational system on logistics was developed by a team of logisticians and computer scientists. As a first step the knowledge available in one's own scripts for lectures, available technical literature as well as graphics, photographs, video and animation sequences was sifted through, selected and structured. Even in this phase, there was a number of questions e. g. for

- the appropriate proportion between texts and pictures, between static and dynamic knowledge presentations,
- the sensible integration of possibilities for a user-specific interaction,
- the appropriate handling and use of the many and diverse photographs and videos, or
- possible ways to avoid conflicts with third-party copyrights of material.

Unfortunately, there was no media expert in the team and guidelines related to this kind of questions were difficult to find, to understand, and to handle. In addition to this, their application in different methodical-didactic scenarios and their effects to varying types of learners as described in [CSUP 1992] were seldom taken into account. Before this background, a repeated reflection to the following fundamental question was of great help for the developmental process: **What are the advantages, and what are differences in knowledge presentation and use of multimedia-based designs in comparison with the traditional print medium?**

To guarantee an efficient authoring process a joint communication basis had to be developed for the cooperation of authors from different fields of knowledge and different worlds of thinking like logisticians and computer scientists. Here, simple guidelines and a story board were very helpful for structuring screen pages and designing their elements, for drafting, discussing and implementing basic layouts, their multimedia elements as well as for integrating all links and possibilities for user-interaction required. About it, the use of only four different basic layouts for the pages has proved to be positive. The students were quickly quite well acquainted of the new media and have used the educational system with curiosity, inquisitiveness, and interest. This process was also supported by providing alternative possibilities for navigation like hyperlinks, search functionality, or navigation buttons and for acquiring additional information about particularly highlighted keywords. Calculation exercises of a varying complexity and with many and diverse possibilities for experiments were offered in relation to a particular context or could be chosen from a separate pool of exercises. That has achieved the educational system's intensive use for self-studies and in phases of preparing for examinations. But the students explained also additional wishes to have more comfort and support. Amongst other things they were related to provide possibilities for a context-specific adding of user-own comments, remarks or questions on integrated note-pads and to give a better on-line support to the student for solving complex exercises.

During the authoring process language-independent components like e. g. graphics, photographs, videos, or animation without additional explanations and language-specific components like e. g. texts, tables, formulae, or explanation elements of graphic presentations were separately saved. This has produced just as positive effects as the concept to separate elementary multimedia resources strictly from possible relations and links that was consequently pursued at any time. This way of action was of considerable importance for developing the German and English versions in parallel. It also guarantees that the educational system is open for a translation into further languages. On the other hand this concept of putting all software components into separate modules of external files made it also clear that the chosen authoring system (Multimedia Toolbook 3.0) was inadequate for supporting those ways of actions. Import and export functions necessary for embedding these modules are only partly provided in a satisfactory form. For that reason a time-consuming development and implementation of own import filters became necessary.

In retrospect we can consider that the integration of alternative forms of knowledge presentation (e. g. text vs. picture vs. video), of alternative technologies for search and navigation (e. g. chapter-based structure, structure map, search) and of alternative tests and exercises has had an exceptional favorable effect. According to our experience, in this way there is a constant demand for user decisions and interactions corresponding to his/her individual learning habit. As a result it is possible to contradict very effectively the still existing image of educational systems to be just "page-turning machines" and to consider that the time, staff, and technical effort needed for their development is justified. Finally, the work done for the first module has shown that the complete integration of an entire field of knowledge into a multimedia-based educational system represents a tremendous effort. Because of the greater range of possibilities for presenting knowledge and for giving access to the learner, it is clearly more substantial than writing a comparable textbook. Before that background the developmental infrastructure must be able to support a future joint authoring process of several distributed logistics educators and experts. For this, the present state of information and communication technologies as well as net services
offered to the customers already provides a main pre-condition and opens up new possibilities for organizing this process in a cooperative way.

Once Again from the Beginning: Ideas and Concepts for Redesigning

On the basis of results from evaluation, reconstruction and self-reflection the general concept for an educational system on logistics was newly thought over. In addition to this, the warehousing module’s redesign was planned to increase its rate of acceptance. Also a concept for a more efficient way of actions and a better support of the developmental and authoring process by the improvement of existing or the development of new tools was worked out. This process of looking for ideas and developing concepts was carried out not only by the previous team of authors and developers, but it was also supported by the educational system’s user group as well as by a group of interested pedagogical and psychological experts, designers, media experts, linguists, computer scientists and multimedia authors for different fields of knowledge organized in a regional association for research on the development and use of educational multimedia. With that, a process of fully redesigning and expanding the educational system as well as developing components for a computer-based integrating authoring infrastructure was started and has already led to first prototype implementations tested and evaluated successfully. Within the following sections the special features of examples for those implementations are presented and discussed.

Expansion and Modification of the Educational System

Works to expand and modify the first component of the educational system on logistics are mainly focused to
- increase the acceptance and user-friendliness by reorganizing the educational system’s structure and reworking its user-interface,
- support more flexible teaching and learning processes by providing learner-specific possibilities for navigation and interaction and producing individual feedback,
- extend the group of users by integrating the module into distance learning courses, by adapting it to the demands of a non-university qualification and training, and by creating the pre-conditions for alternative forms of learner-learner and teacher-learner communication.

Since the previous concept followed strongly the structure of traditional textbooks it is less suitable for supporting the use of particular pages or sequences of pages in flexible educational processes with individual learning paths. Instead of this page-based approach the knowledge is now organized in a structure of nodes and edges of different levels of detail similar to the concept map approach described in [Zeiliger, Reggers, and Peeters 1996]. The nodes represent knowledge units of definite complexity, whereas the edges describe the relations between them. Nodes of a higher degree of complexity like e.g. knowledge complexes consist internally again of structures of nodes and edges. The smallest knowledge unit represented by a node includes the knowledge of a screen page, which results from placing elementary multimedia objects like e.g. texts, graphics, photographs, videos, or animation in standardized layouts by setting parameters. The main advantage of this approach consists in the fact that the knowledge can be structured now both top-down and bottom-up. Besides this, knowledge units of different levels of detail can be combined according to educational targets and levels. In addition to the effects on the authoring process the modified structure of the educational system opens up new possibilities for learner navigation and guidance. Depending on the educational targets and levels as well as interests of the learner, a node could also be excluded from the learning process.

The degree of guiding a learner and if necessary also the degree of one’s freedom in navigation as well as the tests’ and exercises’ degree of difficulty are established as usual by the learner’s self-classification when starting a session. Learners are classified according to both his/her familiarity with the software (beginner, advanced level, expert) and his/her prior knowledge as well as with respect to his/her learning target (overview over a wide range of knowledge or over particular fields of knowledge, detailed knowledge about particular fields of knowledge or about a specific fact etc.). In addition to this, the learner’s behavior according to the frequency of using helps (e.g. in the form of looking for definitions of terms) and preferring alternative or complementary presentations (e.g. textual or pictorial information) is recorded in a log-file. These information are graphically
presented, analyzed by using statistical methods and interpreted by taking the learner's self-assessment (prior knowledge, preferences, learning target) as well as information from previous sessions into account (investigation of preferences). As a result the form of presenting knowledge is automatically suited to the learner's subjective preference of getting access to the knowledge.

In addition to the automatic recording in a log-file, the learner's behavior but also his/her progress in learning can be determined from comments, questions, or extracts from content formulated by the learner himself/herself. This unplugged, context-specific expression of the learner's opinion is directly linked to a particular screen page either by bookmarks or by using the NOTICE button depending on the kind of information. Whereas bookmarks only identify certain knowledge units interesting, important, or necessary to be examined from the learner's point of view, the NOTICE button enables to write down and save any notes within a separate window. As a standard the corresponding screen page's long name is copied to the note-pad. By use of a guiding dialogue the learner can now add further information about the context as well as his/her notes. Those notes can

- refer to the authoring process if including comments to the author about the screen page's design, presentation, clarity, or comprehensibility,
- concern the educational process if summarizing questions or remarks about the subject for being answered or furnished with a commentary by the teacher,
- serve the collection of knowledge about facts in the form of extracts, e.g. for own study works or presentations.

This kind and purpose of a note is also described within the guiding dialogue by selecting it from a menu to clearly relate each particular note. First, all notes are private and belong to the learner. It is always up to the learner whether to make further use of them or not. As a matter of principle no note is automatically forwarded to anybody else. If the learner wants to submit some or all notes to an author or teacher he/she can print them or send them electronically via an integrated communication interface.

Amongst other things the possibility for printing something out was also considerably extended according to functionality and user-friendliness. Instead of producing snapshots by printing the screen as it was in the educational system's first version, the learner is now able to select any element of the educational system and copy it into a different MS Windows application or into a standard printer's copy. These elements, i.e. text phrases, graphics, or photographs as well as notes or results of exercises and tests (but now snapshots from video or animation sequences), could come from different screen pages. In this way the learner can now build simply designed, individual presentations of selected parts of content (e.g. for a study paper or a talk). The implementation of this functionality was deliberately done without providing the pre-conditions for developing lavish presentations or many and diverse printer's copies, because there are already several professional commercial software packages for this purpose. On the contrary, it is just a simple way to support exchange and discussion. In future, the system should also receive a flexible communication interface adaptable to the student's hardware and software basis as well as to his/her pre-conditions in infrastructure. In this way, the student will be able to communicate electronically with other students (e.g. by e-mail, on-line fax, or other net services) or to send questions or comments put together in notes as well as solutions of test questions or exercises to the teacher. If a student has no direct access to a communication network he/she can fall back on conventional, paper-based forms of communication (e.g. mail or fax services) or phases of personal presence at the university by using the improved print function.

Possibilities for a Better and More Effective Authors' Support

Our experience from developing the educational system on logistics have clearly shown that the authoring system used for that purpose often did not cope with the demands resulting from the educational system's development and use. In this way bad authoring systems enable only the development of bad educational systems that are organized as supporting infrastructure for turning screen pages and for confronting a learner with multiple-choice questions [see Korcuska 1996]. In comparison with that good authoring systems enable the development of good and action-orientated educational systems (learning by doing). They are able to capture the author's knowledge and experience to be slipped into the authoring process. Before this background, in [Korcuska 1996] authoring systems existing at present (especially those which belong to the HyperCard category) are assessed as bad and not very suitable to really support the author during the authoring process, because these systems mainly understand computers and not education. In opposite to this he promotes "software
factories” providing highly complex do-it-yourself objects that also contain pedagogical knowledge and guide authors through the whole process on the conceptual level. In addition to this, it is helpful if an educational system’s components and modules created by an author could be managed effectively and made them reusable. For that reason our work for creating a comfortable developmental infrastructure supporting the authoring process mainly concentrates on

- expanding and explaining those conventions for structuring and designing the educational system and its elements, which were used up to now and have proven to be good,
- putting further knowledge of facts and methods into modular form according to content and formal aspects and documenting it in a way that one can search for it, as well as
- supporting the collection, management and finding of resources by a resource pool with a comfortable management system.

The resource pool as kernel of this developmental infrastructure contains different classes of resources necessary for the development of multimedia-based educational systems [see Subrahmanian and Jajodia 1996]:

- Knowledge resources of varying complexity contain modular knowledge within presentation objects (complete multimedia data that can be presented by use of tools for reproducing media) and application modules (executable software that generates presentable multimedia data with the help of suitable tools).
- Concept resources include on the one hand methodical-didactic basic conceptions for the educational process and on the other hand completely described, problem-specific teaching concepts (concept maps, story boards).
- By layout resources e. g. user-interfaces are understood that are standardized for different functions and that can be described by setting parameters.
- Navigation resources are modules of a specific authoring system for controlling an educational application in various forms (e. g. history, summary of contents, buttons).
- As management resources e. g. modules for managing a user’s status, routines for evaluating and analyzing user-interactions, or models for restricting interactions are described.
- Tools summarize help functions like e. g. equation interpreter or calculator.

To guarantee its applicability and searchability each resource has to be completed by a detailed description, which is adapted according to content and structure to the characteristic specific to the corresponding class of resources. For example, a knowledge resource’s description contains at least file name, knowledge characteristics (on the basis of related descriptors), characteristics of presentation form or knowledge (including the author’s copyright). If necessary, different purpose-orientated views specific to the corresponding author can be related to a resource. During the authoring process the developer of a particular educational application can use existing resources and link them according to the point of view of content and methodical-didactic aspects. In this way single screen pages are formed by linking knowledge resources with layout resources, navigation resources and tools. If these pages are linked in sequences or networks by use of a concept resource and completed by the appropriate management resources learning paths are built.

For saving and selecting resources the author uses a management system, which forms the resource pool’s interface to the developmental infrastructure. This interface includes amongst others

- the link management system, which manages links between resources as separate objects with individual characteristics,
- control functions for guaranteeing data consistence for the resources,
- comfortable search functions for a user-friendly access to resources,
- safety functions, which check the access to resources and links by controlling user-rights.

In addition to this, in the developmental infrastructure itself there functions for

- adapting elementary knowledge to texts, pictures, animation, or videos by logisticals (editor),
- developing interactive teaching and learning applications that includes knowledge separated for defined target groups (learners) by use of available knowledge units (authoring system),
- supporting communication between distributed authors within a cooperative authoring process (communication infrastructure),
- using applications developed before individually by teachers and learners in lectures, exercises, self-studies, or as book of reference (presentation system)
are integrated. With that authors can effectively develop educational systems on the basis of their own content, methodical-didactic and design concepts. But as the main pre-condition the resource pool must offer a substantial as well as many and diverse stock of resources. Because of the existing network of European logistics educators this problem is solved for the logistics field of knowledge and a permanent use, expansion, and updating of the resources is guaranteed.

Conclusions

When using this developmental infrastructure for redesigning the educational system on logistics the effects occurred as expected. The main advantage consisted in the fact, that the authors mainly could concentrate on activities like searching for, selecting and editing elementary resources and knowledge units of varying complexity as well as putting modules resulting from this together by use of an authoring system. Because of this, time necessary for the developments during the authoring process could considerably be reduced, although the educational system contains now more flexible learning paths, a more substantial knowledge of facts and methods, and a larger number of multimedia illustrations. The resource pool as kernel of the developmental infrastructure has been proved to be a central source and store of special knowledge within a cooperative authoring process. Now elementary and complex multimedia resources and modules of educational systems can be purposefully saved and reused from different users' points of view. This possibility opens up a variety of applications nearly unlimited according to content, target group, purpose, and technical demands, which goes far beyond the development of educational systems.

References

1. Introduction

In January 1997 the ReMOTE (Research Methods Online Teaching Environment) project received funding for a 12 month period, its purpose to develop a World Wide Web (WWW) site devoted to the teaching of Research Methods, unifying access to a wide range of teaching materials.

2. Background and Rationale

Virtually all UK Higher Education Institutions teach Research Methods, either at the latter stages of undergraduate study or in postgraduate programmes, where Research Methods is seen as a key component in preparing students to undertake study leading to an MA or MSc qualification. Typically the topic is taught as a programme of lectures and seminars.

The key features of Research Methods which make it an appropriate area to develop as an Internet resource are that:

- it is generic and transferable. The end product will be applicable throughout RGU and all HEIs across a wide range of courses.
- because of the wide range of potential topics which it is designed to support, students find that they may have to concentrate their efforts unevenly on different components within Research Methods: some may, for example, require more detail on quantitative analysis, whilst others do not need to study this topic in such depth because it will not be applicable to the type of dissertations or projects in which they are engaged. It is envisaged that the basic units will be extensible to allow students to explore in greater depth areas of the subject which are of interest to them whilst clearly making them aware of the knowledge and procedural requirements for achieving credits on the course, by exploring web links to more specialist sources. As such, the system will be particularly useful on postgraduate programmes of study, where students may require simply to upgrade some specific skills or techniques and can do so on an Open Learning basis.
- the environment in which the project will be operating (the WWW) is one which is intrinsically important in conducting practical research and the mechanism of delivery can be viewed as an important part of the learning process itself.

It is therefore apparent that such a widely applicable skill as Research Methods, and such a ubiquitous medium of delivery as the WWW are ideally suited for the development of a resource centre which will be of global utility.

Although not explicitly stated within the project’s remit, it was recognised early on that the approach adopted was consistent with the broader goals of making use of the Internet in order to enhance:

- the quality of learning
Currently there are several WWW resources available for teaching Research Methods or facilitating the research process, the former typically concentrate on a subset of skills appropriate to a particular discipline or a single aspect of Research Methods, while the latter (e.g. SOSIG\(^2\)) tend to offer sites of use to researchers, and a few selected sites for teaching the subject. Pachnowski et al.\(^3\) provide a useful discussion of some of the sites available which provide databases and examples of surveys of resources (e.g. the US Census Bureau http://www.census.gov/) and the Gallup Organization http://www.gallup.com/) but does not provide any detailed guidance on application of these resources in teaching. Useful resources are also provided by a range of directories - the Educator's Internet Yellow Pages\(^4\) being a particularly good starting point. More specifically related to Research Methods work by Cozby\(^5\) provides an excellent guide to resources - each chapter of the book directing the student to a wide range of web resources and there are a number of web sites which give detailed tutorials on specific Research Methods concerns or techniques (e.g. BeLue's Choosing a research design http://trochim.human.cornell.edu/tutorial/belue/belue.htm and Burn's pages on Securing internal validity http://trochim.human.cornell.edu/tutorial/burns/int.html).

The aim of ReMOTE is to provide an infrastructure which allows direct link to specialist sources which will enable the use of existing materials as “plug ins” when developing tailored Research Methods courses e.g. the use of links to the existing materials in the same way as references to the sources would normally be given in paper based documents. It will also allow interactive CAL packages, which are available freely via the WWW, to be conveniently downloaded and used in teaching or self-study. The researchers will then go on to test the effectiveness of the approach and study the manner in which the ReMOTE pages are used by staff and students within the University.

3. Development

The development of the WWW site required the identification of a wide range of Research Methods materials suitable for inclusion. One of the main aims for the methodology of the development for this project was perceived to be the need to provide rapid delivery of a working model which would act as a catalyst in stimulating ideas and feedback from academic staff who were not necessarily aware of what was achievable in this medium, but who nonetheless had significant teaching resources which could be used in developing the directory of learning materials (a process known as Rapid Prototyping, favoured by courseware designers\(^6\) and suited to the HTML development environment). Thus at an early stage, the deliverables of two previously funded faculty projects which were identified as covering significant portions of the subject area in question, were deemed to be suitable for conversion into WWW format:

- **Self Study Learning Package** for students studying Research Methods in the social sciences: produced by the Robert Gordon University School of Public Administration and Law, and consisting of ten learning papers, each covering a discrete aspect of the subject.

Both packages were in printed format, but also existed in electronic format and would not therefore require laborious verbatim retyping.

\(^2\) SOSIG: the Social Sciences Information Gateway, URL: http://www.sosig.ac.uk

Further materials developed elsewhere were also to be considered for inclusion on the server where permission and copyright clearance could be obtained. It was already known that some materials developed elsewhere already existed in electronic format and might be suited to conversion or at least dissemination via the WWW; the amount of material, developed in isolation by lecturers at diverse institutions can only be speculated at. The overall effect of this approach was successful with some individuals responding enthusiastically to the possibility of making their own notes and lectures available on the WWW.

2.1 Requests for WWW Links

A significant further part of the final deliverable is a collection of WWW links to already-existing materials elsewhere on the WWW. In order to identify materials for evaluation and possible inclusion in the site, input was solicited from a variety of email discussion lists and online forums which have an interest in web site development and teaching Research Methods. An announcement of the project’s intentions, coupled with a request for contributions, was sent out to:

- Mailbase: UK Higher Education’s electronic discussions host. A number of lists were identified which might have an interest in the development of such a resource, including:
  - lis-link@mailbase.ac.uk
  - lis-infoskills@mailbase.ac.uk
  - computer-assisted-learning@mailbase.ac.uk
- Other email lists and electronic forums, including:
  - nettrain@listserv.acsu.buffalo.edu

A number of responses to this message were received, generally of an enthusiastic nature, although most revolved around the theme of “please let me know when it’s ready”. However, several worthwhile resources on the WWW were communicated, and some sites and individuals promised to donate materials, or to look into the practicalities of doing so. Similar messages were sent to individual sources which it was known had produced materials which might be suited to WWW conversion e.g. the PROCARE project at Southampton University. As in the case of the individuals who responded to the initial request offering their own materials for the site, enthusiastic initial responses have been followed by long periods of silence: in the case of PROCARE, copyright clearance deliberations at board level have thus far prevented any progress.

3.2 Searching on the WWW

In addition to asking interest groups to provide references, further materials - finally forming the bulk of the directory - were located using WWW searching techniques. Many materials were located via previously located WWW sites, which often include a list of links to other related sites (“further reading”). This has the advantage of the implicit recommendation by the link-maker in referring to the materials, but also restricts the user to what the individual author has himself already found.

Searching was therefore extended to Internet directories and search engines e.g. Yahoo, The Argus Clearinghouse, AltaVista, Excite, Infoseek. This is a less focused method of identifying suitable resources than by individual recommendations, but has the potential to identify a much wider range of resources, and the majority of the directory’s contents have been located by this method.

3.3 Design

---

7 Directories are here defined as those WWW indexing services which are chosen and classified by human indexers, including Yahoo (http://www.yahoo.com) and the Argus Clearinghouse (http://www.clearinghouse.com).

8 Search engines are defined as those WWW indexing services which identify and index resources by purely automatic means, retrieving matching documents on the basis of keyword matches rather than defined categorisations e.g. AltaVista (http://www.altavista.com), Excite (http://www.excite.com) and Infoseek (http://www.infoseek.com).
The structural and graphical design of the site required careful consideration in order to achieve a consistent and logical appearance. The factors which required to be taken into consideration included the goals of the potential users and of the university itself:

♦ **User Goals:**
  - Navigability: use of logical structures to maximise the ease of use with which a user can locate the information they require, and to prevent them becoming “lost” in a complex structure of information
  - Clarity: the need for all of the possibilities to be presented in an intuitive and visible manner, making it clear at each stage - without the need for undue searching or experimentation on the user’s part - exactly what information can be reached from the current point
  - Attention to design: with all of the alternative sources of information on the WWW, it must be made obvious to the user that the resource has not been developed as a part-time “pet project” by an individual. A professionally designed look will:
    - be appealing on a visual level
    - engender confidence that this is a quality resource

♦ **Institutional Goals:**
  - the need to establish ownership and a corporate identity; to remind users (albeit sub- or semi-consciously) that the Robert Gordon University is providing this resource
  - to provide a robust structure for the resource which will accommodate future changes and additions to the site in a logical manner without the need for excessive re-working of existing structures
  - to provide quality information in a manner which:
    - enhances the pedagogical aims of the university
    - enhances the profile of the university as an innovator in the use of novel techniques for information delivery

On a practical level, these issues fall into two broad categories:

- Structural design
- Graphic design

### 3.3.1 Structure of the Site

The site is built on a hierarchical plan, where the most general resources contain links to the more specific ones. The home page serves to inform users of the purpose of the site and give access to the broad categories (not to the actual materials). The pages on the next level down unify access to i) materials on the server; ii) online courses and iii) the list of categories of materials from the WWW. In the case of (iii), the actual WWW resources are accessed after choosing the category required. In the case of (ii), the individual courses refer to the materials from (i) and (ii). Pages on the top two level of the hierarchy link clearly to each other, so that a user does not have to retreat back to the home page every time a different section is required.
The materials which have been installed on the server are structured in a manner reflecting as far as is possible that of the original materials. There have been some necessary alterations in terms of navigation e.g. the addition of hypertext contents pages.

3.3.2 Graphic Design
3.3.2.1 Graphic Design: Identity

It was decided that the three essential elements to convey as clearly as possible to users were:

- The pedagogical purpose of the site: i.e. the teaching of Research Methods skills
- The use of technology (the WWW) to enable distance or independent learning
- Institutional ownership of the resource

With these in mind, the site's opening page (see fig. 2) was designed to convey these immediately and intuitively:

- The banner graphic uses considerable corporate and research-appropriate imagery:
  - the underlying graphic consists of photographs taken from the 1998 Prospectus which illustrate elements of research: themes represented include use of telephones, interpersonal skills, technology (computer keyboard, CD-ROMs, floppy discs), libraries, study, books, files etc.
  - The RGU shield and corporate colours are prominent

- The title ReMOTE itself is an acronym constructed from the words “Research Methods Online Teaching Environment”. The use of the term “remote” also reinforces the distance learning aspect.

- The site content is overlaid on a background consisting of the undulating margin seen on numerous RGU publications, with the individual elements of the RGU shield (castle, boar’s head, cog, sphere and torch) continuing to the right hand side. The undulating margin serves a functional purpose, containing the navigation “buttons” which enable the user to access the site.
These graphic themes run throughout the contents of the site, and provide a consistent look and feel: it is easy for a user to tell which pages are a part of the ReMOTE site.

![ReMOTE opening screen](image)

**Fig 2: The ReMOTE opening screen**

### 3.3.2.2 Graphic Design: Functionality

In addition to fostering a strong sense of purpose, technology and ownership ("PTO" identity), many of the graphics have a functional purpose. A decision was made that the non-use of graphics should, wherever possible, not inhibit use of the site: non-graphical browsers are still in use and browsing on standard browsers may be speeded by switching off graphics. Therefore functional graphics in the site are of a simple nature, generally only renditions of text with some embellishment e.g.

- **Navigation**: the navigation buttons in the left hand margin, where the current page is highlighted in green with a tick beside it to make it absolutely clear to the user where they currently are in the structure. The functionality will be only marginally less clear if browsing in text only.

- **Pedagogy**: in the actual learning materials, graphics do have an essential purpose. Where they are necessary, they have been kept to the minimum size for legibility on displays of varying resolution. However, the issues which can be discussed here are purely technical, since the use and design of these graphics are issues for the materials' authors.
3.4 Content of ReMOTE:

The contents will be dealt with in three parts:

- The directory of links to other WWW materials
- The materials actually hosted on the server (self study papers for the social sciences and the Communication Skills Guide)
- Courses under development using the above materials

3.4.1 Directory entries

Due to the extensive nature of the directory of links, it has been subdivided into categories for each aspect of Research Methods. Each category of the directory has a separate page, accessed from the main directory page:

![Directory of Research Methods Materials](image)

Fig 3: Categories in the directory of WWW links

The format for directory entries is based on the style used in the NetLearn project. The resource title is given as a hypertext link, followed by a brief abstract describing the resource, its coverage, target group etc. and finally some categorisation information. The information given should be enough to tell the user whether the resource is likely to contain the type of information which they might find useful (fig 4).

9 NetLearn: a directory of resources for teaching and learning the internet. URL: http://www.rgu.ac.uk/sim/research/netlearn/callist.htm
There are a number of drawbacks to the directory in its current form:

- It is not searchable as a database would be. The name, URL, Description and categorisation information could all be used as fields in a database, but at present this is not possible.
- Resources may fit into more than one category, resulting in duplication.
- Updating the directory must be done manually by editing the relevant HTML document: with the amount of information requiring updating, this is unwieldy and prone to errors.

If the directory is to be maintained and promoted as a feature in the future, some investigation must be made into the possibility of converting the information into a database format accessible through a WWW front-end. This would not only make the user's job searching for relevant materials easier, but also the maintainer's job of adding, amending or deleting resources. Scope would then also exist for the addition of a "user comment" feature, where users could add their own annotations as to the usefulness of any individual resource.

### 3.4.2 Materials hosted on the server

The materials hosted on the server currently consist of two extensive packages which have been converted from paper-based versions:

- **Self Study Learning Papers for the Social Sciences** (originally produced by the School of Public Administration and Law). This consists of ten learning papers, each focusing on a particular aspect of research.
- **Communication Skills Guide** (originally produced by Mr. William Robb for the Faculty of Management)

Both packages were deemed suitable for conversion to WWW format due, foremost, to their subject matter and the depth in which this was tackled. They complemented each other in that the former was a 10-step guide to doing research in the social sciences, while the latter presented an in depth tutorial on the presentation and communication of information. In addition to this, both already existed in electronic formats, having been created on word processing and desktop publishing programs, and would not therefore require laborious re-typing of the original text. Each package consisted of over 100 pages of mixed text and illustrations.

First to be tackled was the Social Sciences package. The approach taken was to use a conversion utility (Microsoft Internet Assistant, or IA) which would take existing Word documents as input, converting them into HTML. The process of conversion with IA took only a few hours, but immediately presented problems: each individual Word document was converted into a single HTML document, which was not navigable and required to be broken into sections which would then have to be linked together. The HTML output by IA was also non-standard, and attempted a very literal interpretation of the look of the document when what was required was a representation of its structure and meaning. The parameters of paper and the WWW are not compatible, and the document has required considerable restructuring to make it manageable, and the inclusion of navigational facilities for locating and moving between documents - most notably tables of contents constructed of hypertext links to all of the available pages.

A great number of further problems remained to be rectified due to the shortcomings of IA: many graphics had been discarded, others required re-sizing to make them legible on differing display resolutions and complex text formatting needed to be reinstated. An initial version was presentable after a week of work, but finding and correcting errors produced by IA required much longer, and the assistance of the original authors who were much more familiar with their material. The existence of a template into which content could be "poured" and links added automatically would have saved many days of effort: a single change in style often requires every page to be altered slightly, and there are well over 100 pages in the package.
The final product retains the original material's content 100%, but represented by a different structure suitable for the WWW. The materials are broken down into smaller sections and direct access given to each through tables of contents (a device not used in the original materials). Although changes to the material were not within the scope of the project, in the future it is envisaged that they will gradually be altered to suit their new medium more closely, for example by the inclusion of links to outside WWW materials which might be referenced in the same way as texts would be in a conventional paper.

The Communication Skills Guide required a different approach, as it had been created using Claris Works for the Apple Macintosh computer, which was not compatible with the PC software in use at SIM. The process was aided by the assistance of the Central Printing Unit who copied the text of each constituent file manually into a format which could be read by Word for Windows as used in SIM. The conversion was then undertaken by the manual addition of HTML tags. Navigational enhancements were made in a similar manner to the Social Sciences package, and some additional interactive and graphical features added which introduce a more personable style and stimulus throughout.

3.4.3 Courses

The final element of the site is the development of courses, tailored specifically towards teaching Research Methods in particular disciplines. Materials from the rest of the site may be built into a course, or a list of references, chosen by the lecturer concerned. These may be integrated with the lecturer's own materials and used either as a replacement for or extension to normal modes of tuition: it may be prescribed as an activity or coursework, or it may simply be used for "extended references".

The use of the HTML frames facility is fundamental to this section. In using this, a left-hand column on the screen is used purely as an index for the actual materials. These materials are called up on the main portion of the screen when an item from the index is chosen. Therefore, if the majority of material to be used consists of existing WWW pages, there is a minimal requirement for writing HTML - this will consist of nothing more than a plain list of URLs.

One of the project's original stated aims was to develop such a resource for the Postgraduate Diploma in Information Analysis (PGIA). This is now under development: the standard course information has been put into HTML including the Course Unit Descriptor (CUD) and bibliography, plus references to the Social Sciences package, Communication Skills Guide and selected lecture notes/OHPs. Suitable areas for online study will be identified in co-operation with the lecturers responsible for teaching the Research Methods module and the resulting module is expected to be tested with students in the second semester of the 1997/8 academic session.

4. Next Steps

The site will be announced to a wider audience, initially on a trial basis to elicit feedback and constructive criticism from a section of the academic community. The announcement will be made on a number of Mailbase electronic discussion lists including those previously mentioned, and to a number of selected individuals who are producing materials in the same area. Immediately prior to this, the site will undergo a process of revision in which consistency of style will be ensured, integrity of links checked and existing resources properly documented (there are some links which have not yet been fully investigated and abstracted).

Testing with students will take place during 1998. Suitable online materials will be identified in conjunction with the relevant lecturers, and evaluation instruments applied to test the medium's effectiveness. Evaluation checklists and questionnaires from the LTDI\(^{10}\) have been obtained and will be adapted for use.

The site will at all times continue to be extended, modified and enhanced in line with feedback from the user community and as new resources are discovered.

4.1 Recommendations

\(^{10}\) LTDI: Learning Technology Dissemination Initiative, established by SHEFC in August 1994 to support and encourage staff in the integration of technology with teaching. See URL: http://www.icbl.hw.ac.uk/ltdi
As noted above, the directory feature would be enhanced from the point of view of both of the user and maintainer by the integration of a database for storing the entries and a WWW front end which will make the directory searchable. This will enable greater flexibility, ease of use and functionality. The use of databases on the world wide web should be investigated further: it is envisaged that implementation of such a system would be inexpensive, the only major cost being the time which it would take to set up initially.

Secondly, the requirement for consistency throughout the pages points to the requirement for a system of document management: currently, pages are constructed in a simple text editor with HTML encoding done by hand. This means that any change in the overall design of pages must be individually applied to each and every page affected, a repetitive and error prone process. Software which is capable of developing and using templates which can then be filled with appropriate content would eliminate a considerable amount of low-level repetitive work and make changes much more quickly and reliably.

If large suites of web pages are in the future to be maintained with current information, both of the above issues must be considered: it will not be possible to compete with similar providers, nor to maintain extensive lists of up to date information without an automated system of document management.

5. **Accessing the ReMOTE site**

At the time of writing the site is in a pre-release state: it has been announced to, and is in use by staff and students within RGU on an informal testing basis. Prior to announcing ReMOTE to the wider world, some additional resources are to be added, access restrictions placed on certain materials and the graphic aspects finalised. The site can be found at URL:  http://jura2.eee.rgu.ac.uk/dsk5/research
Human Communication using Eye Movement

Abstract: The refinement of measurement and analysis of man-machine communication using eye movement is reported. Next, we report our development of a new human communication environment in which two testers put on eye mark recorder communicate each other via CRT of computer. New computer game called modified Flipper Game has been developed on this environment and the behavior of two testers are analyzed.

1. Introduction

The so-called multimedia environment on the computer gives us new possibility in education. Various subject matters on multimedia environment on the computer are being developed and used widely in a classroom now. The behavior of a learner who communicate with multimedia environment is complicated and cannot be detected in an ordinary educational system which has mouse and keyboard as input device, so the cognitive motion of a learner cannot be used to guide a learner. Eye movement of a learner is the most important information to know the understanding level of a learner about content on the environment. [Yoshikawa 92], [Furuta & Sakamoto 89]

In the preceding research, we have developed new man-machine interface in which a learner can communicate with the environment using eye movement. [Fig. 1-A], [Fig 1-B]. [Nishiki et al. 97]

Fig.1-A: The used Eyemark Recorder: NAC EMR-600
Fig.1-B: The used Eyemark Recorder: TAKEI T.K.K.2901

To obtain the fundamental aspect of this communication process, we have developed computer game called modified flipper game in which a learner can play game using eye movement. [Fig. 2], [Ueno et al. 96]

There is a computer game called Flipper. A player of this game moves mouse to select the squares divided on the screen, and then he can vary the color of a selected square by clicking mouse. Six colors are used in this game.

Fig.2: The Flipper Game
color of selected square changes in the cyclic sequence by player's mouse clicking. For example, purple, red, green, blue and so on. On the other hand, the color of each square varies randomly at regular intervals in time on the CRT. When the colors of all the squares coincide, then the game is cleared. So, a player of this game must vary the color of squares as fast as possible. The player can confirm which square is selected by seeing a mouse pointer controlled by himself in this original Flipper game. We modified the original Flipper game into one which selects and changes the color of selected square using eye movement. The detail of this modified flipper game can be shown in our preceding paper, (We call this paper 1 hereafter, we have obtained knowledge and experimental skills to understand the real time communication between a learner and system using eye movement.

Several cognitive parameters of human cognition-act process are obtained in this research. These data are necessary to prepare experiment of human communication process using two eye cameras. And these data are necessary to describe human cognition-act schema in SIMPASI which is parallel expert system which can explain the cognition-act process of a testee who plays modified flipper game developed by us.

2. Some technical development

600 data vector are generated per second in our experiment using eye mark recorder and each vector is consists of 11 numerical data corresponding to only one eye mark of a testee. [Fig. 3]. Large scale data is generated in the visual communication of the learner with system. In addition, several action data of a testee such as key input, mouse movement are added to these visual cognition data vector. In some cases, 30 numerical data are generated in each observation, so about 20000 numerical data are detected per second using one eye mark recorder. In our environment, the content of CRT varies by testee's visual action such as gazing. So, we must add more other information concerning the status of CRT to above data vector. It is not easy to analyze these data by human researcher by hand after the communication experiment has ended.

Our final goal of the present research is to help learner using learner's real-time cognitive data such as eye movement in the communication process between learner and intelligent educational environment. The automatically acquisition of the structure of communication process from data vector is very important to understand the meaning of the complicated cognition-act process [Arbib 89] of the human testee. And it is important to generate student model in intelligent learning environment.

The detected data of a testee who plays modified flipper game is shown in Fig. 4. These data consists of coordinate of eyes and several marks such as mouse clicking and change of color generated by testee's gazing. To obtain the symbol which shows the behavior of a testee, the rule-based analysis is necessary. At the present, we use several filters which extract the feature of visual behavior, and then the rule-based analysis is tried in the next step.
3. Eye-movement and detection of understanding level of a learner

It is not so easy to identify the understanding level of a learner who studies computer language such as BASIC interacting with learning environment such as CAI and ITS. Many questions must be given to a learner who interacts with learning environment which assists him to study BASIC language on the computer to decide his student model critically. As the learner feels this Q/A process troublesome, the educational effectiveness of learning environment on the computer is very limited. Some new methods are necessary to identify learner's understanding level without using Q/A process.

The eye-movement data of a learner who is looking at BASIC programing text should have information about the understanding of the learner about BASIC language.

But, the eye movement behavior of a learner who is looking at given normal BASIC text includes many things. So, it is difficult to extract clear information about understanding of a learner from observed eye mark data. So, we have designed the following series of measurements which can extracts clear information. At first, a learner is given a problem by us to make the following program. "To obtain the summation from 1 to 10, then show its value on the CRT." This problem is relatively easy, so our learner succeed in making the correct program shown in Fig. 5. We modified original programs made by the learner by adding only one bug to them. The modified texts are shown in Fig. 5. So, we show our learner original correct program which is made by him, then next we show modified BASIC texts for only 5 sec to the learner who puts on EMR, so he must see modified text as fast as he can. But he has been familiar with these shown texts in his previous program lesson, so he can be aware of the position and kind of error in the program added by us.

We have prepared eye movement action networks about these BASIC programs to catch meaningful eye movement of a learner who is looking at modified programing text. Fig. 6. We can extract the meaningful eye movements of our learner by matching observed eye-movement data with a few action-object templates contained in this network.
The results obtained from three testee A, B, and C are shown in Fig. 7. Testee A is not an expert of programming, but testee C is an expert of programming. The ratio of numbers of meaningful eye movement to numbers of all eye movements of a test who is looking at five modified texts are plotted in Fig. 7.

Redundant eye movements are shown for testee A, but such redundant eye movements decrease in testee C. And eye movement fluctuate for every text for testee A, but there is no fluctuation of eye movement for testee C. Testee C seems to have steady eye movements for different texts.

We have succeeded in obtaining information which gives the understanding levels of a learner from these results obtained in this measurement. [Tsubokura & Tsushima 98]

A learner is not disturbed by imposing unnecessary questions when the present method is used. This type of observation of a learner using eye mark tracer does not change learner's understanding status. It has become possible to carry out undestructive observation of the learner by using our method. This type of observation of a learner is promising to construct comfortable educational environment for a learner.

4. Introduction of one more eye mark recorder

In our preceding research, we concentrated to man-machine communication process using one eye mark recorder. But, multimedia environment is more profound and flexible communication environment in which many learners can communicate with each other via CRT of computer.

So, we extend our research into mutual human communication using eye movement in multimedia environment introducing another eye mark recorder.

In Fig. 8, testee A communicates with testee B via CRT or Projected screen. This communication process is much more complicated than man-machine communication shown in Fig. 9.

The size of analyzed data increases and the analysis of mutual correlation between each testee's data vector is necessary in the experiment using two eye mark recorder. In order to do that, some automatic feature extraction mechanism from observed data is necessary. We have developed it using fundamental feature which is already obtained from experiment using one eye mark recorder.
5. Two types of new Flipper Game

In the preceding paper, we analyzed the fundamental aspect of human visual cognition-act process communicating with CRT. In the present research, we use these results to understand human communication process using mutual eye movement. So, some typical experiment which cast the essential of this type of communication are necessary. So we have developed two types of new Flipper Games, Cooperative Flipper Game and Competitive Flipper Game.

5-A. Cooperative Flipper Game

In the preceding paper, we analyzed the behavior of our testee who was playing flipper game in detail. As it was essentially man-machine communication process, there was not the other person in the communication process. As there are two players in the present research, the situation are affected by the other's intention, so communication process becomes very complicated. There are important factors which affects the efficiency of cooperative work such as existence of common goal and allowance of communication between players. So, we have designed the following four Flipper Games which has different features.

A) Goal color is fixed beforehand and communication between players is not allowed.
B) Goal color is fixed beforehand and communication between players is allowed.
C) Goal color can be changed and communication between players is not allowed
D) Goal color can be changed and communication between players is allowed.

In case A), two players change color of divided subsquares into fixed color beforehand without communicating with each other with voice. So, one cannot assign a role of the other frequently and the used time to clear game becomes long. Two players can take strategy to share the role to clear games considering the situation on CRT in case B), so the used time to clear game become shorter than in case A). It is not easy to guess the present goal color set by the other player from the CRT. So, a player sometimes feels as if the change caused by the other were the change caused by the system in case C).

In the case D), as the the species of present goal color can be heard from the other, he easily understand the situation, and so used time to clear game is reduced. If a player assigns the role of the other considering the real time situation of CRT, the cooperative work goes smoothly.
5-B. Competitive Flipper Game

At first, we designed the competitive flipper game in the following.

Our player must choose his goal color and he must change colors of all sub-square into chosen color. The other testee knows the goal color of the competitor, so he can easily disturb the action of the competitor by changing the color of sub-square.

If each player concentrates into his goal, the game ends is finished in some cases.

But, if they take strategy of preventing competitor's action, so, game does not end for case 4*4.

This type of game may be ill-setting as a game. But we can obtain several cognitive data by analyzing the behavior of players in this ill-setting game.

In the preceding paper, we reported the result of analysis of the communication of a learner putting on eye camera with a computer. We report in this paper the result of communication between two learners putting on eye camera individually via common CRT.[Fig.10].

Fig.10: The new Flipper game for two players

6. conclusion

We have succeeded in constructing the frame which can identify understanding levels of learners who look at the modified BASIC programing text in Chap. 4.

And then we have developed experimental environment in which two testees can communicate through eye movement with each other via CRT of computer in our laboratory. And we have reported some improvement to raise the efficiency of calibration system using new calibration function. We have developed new modified Flipper Game in such an environment as two players play co-operatively or competitively. These two communication process has several parameters and the behavior of player is very complicated. In this game, there are too many strategies which player takes in the game, so more simplified game is desirable to deduce critical results from experimental data.

Abstract: This paper describes the work of the Open School and Open Learning Agency in British Columbia, Canada, especially as it relates to the development of a distributed learning environment for the development and delivery of high-school level courses using technology to promote more interaction and access for students. It covers the application of instructional design principles to the development of such environments, and the special challenges these present.

The Open School—as part of the Open Learning Agency, in British Columbia, Canada—is in the business of supporting the development and delivery of learner-centred programs to approximately 48,000 learners. As a result of this mandate, Open School is in the process of creating a distributed learning environment for the development and delivery of high-school level courses (specifically Grade 11 & 12) using technology to promote more interaction and access for students.

Traditionally, the Open School has primarily developed print-based courses for distance learners—registered through one of the nine Distance Education Schools located throughout British Columbia. In recent years, there has been a move—within the Open Learning Agency and elsewhere—towards the integrated use of technology to enhance students’ flexible access to content, resources, and people. This move has influenced the teaching and learning process, providing what we see as a distributed learning environment. This environment is made up of the following key features:

- learner-centered approach to design, development, and delivery of materials,
- electronic communications between learners and teachers,
- a modular course development process based on structured information,
- choice and flexibility of different delivery formats,
- a resource-rich environment for students, and
- synchronous and asynchronous interaction.

Open School's distributed learning environment makes use of technology and media to provide a student with choices beyond those normally available in a centralized environment like a classroom. This might look like a distance learner using print materials and watching scheduled television broadcasts in order to complete a course; it might also look like a classroom-based learner using the Internet to interact with experts in a particular field. The implementation of a distributed learning environment has helped Open School deal with issues facing the development and management of courses for a variety of learners—learning at different times and in different venues.
The following table outlines some of the issues and strategies the Open School is currently implementing.

**Table 1: Issues and Strategies**

<table>
<thead>
<tr>
<th>Development and Delivery Issues (Drivers and Needs)</th>
<th>Distributed Learning Strategies (Developments and Characteristics)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Completion rates, student success and satisfaction</td>
<td>Teacher-mediated distance delivery model; Rich communications infrastructure; Development of a community of learners</td>
</tr>
<tr>
<td>Enhanced student engagement and greater depth of participation</td>
<td>Active learning encouraged through instructional design strategies; Course materials linked to communications infrastructure: conferencing discussions, collaborative forums</td>
</tr>
<tr>
<td>Reducing student isolation in “distance” model</td>
<td>Collaborative, communication-rich learning environment; Development of a community of learners through the use of technology</td>
</tr>
<tr>
<td>Keeping course materials current and/or dynamic</td>
<td>Tightened revision cycles and content management processes through structured information (SGML); Database integration with document content</td>
</tr>
<tr>
<td>Customizing for differing market needs</td>
<td>Different versions of a course produced from a single, centrally managed source, based on specific criteria (mediated/non-mediated, print/online, skeletal/fully elaborated)</td>
</tr>
<tr>
<td>Flexibility for differing student needs or styles</td>
<td>Resource-based course construction model: parallel strategies to meet specific outcomes</td>
</tr>
<tr>
<td>Multiple modes of access</td>
<td>Print and online courses; text, audio, video, and interactive resources; ensuring integrity across versions by explicitly tying course materials and resources to outcomes</td>
</tr>
</tbody>
</table>

Although a distributed learning environment offers many varied and flexible learning opportunities for learner, it also presents challenges to those involved in the design and development of course materials. From an instructional design perspective the challenges include:

- a learning environment characterized by dynamic content,
- varied instructional support,
- resources and multiple media in varied delivery contexts,
- differing student needs.

To guide the instructional design of courses within this environment, key instructional principles need to be considered, as listed in the following table:

**Table 2: Instructional Design Principles**

<table>
<thead>
<tr>
<th>Learning outcomes</th>
<th>Used to implement a learner-centered approach. Used as building blocks for content development. Provide guidelines for learners to be able to demonstrate what they know and are able to do.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Structure and presentation of content</td>
<td>Content structured to allow flexible and customized learning experiences. Use of multiple media and resources to provide a richer learning environment.</td>
</tr>
</tbody>
</table>
Table 2: Instructional Design Principles

<table>
<thead>
<tr>
<th>Assessment</th>
<th>Application of authentic approaches to assessment (real-life and real meaning for students). Focus on students “demonstrating” their learning. Based on criterion-referenced assessment strategies. Focus on the process of learning versus the end-product.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Feedback</td>
<td>Feedback as a mechanism for change for learners. Providing non-threatening and supportive feedback to assist in the development of learning.</td>
</tr>
<tr>
<td>Role of the instructor</td>
<td>Facilitator or guide. Facilitate the learning process through negotiation, stimulation, and monitoring discussion and project work</td>
</tr>
<tr>
<td>Technology</td>
<td>Help facilitate the learning process by allowing: increased access, improved presentation of content, increased learner interaction, flexibility in selecting most relevant resources, structured content management</td>
</tr>
</tbody>
</table>

These principles support an underlying constructivist approach to design and development while at the same time considering the multi-faceted nature of a distributed learning environment.

Supporting Awareness for Augmenting Participation in Collaborative Learning

Hiroaki OGATA and Yoneo YANO
Faculty of Engineering, Tokushima University, Japan
E-mail: {ogata, yano}@is.tokushima-u.ac.jp
URL: http://www-yano.is.tokushima-u.ac.jp/

Abstract: Knowledge awareness (KA) has been proposed for increasing collaboration opportunities in an open ended and collaborative learning environment. KA consists of information about up-to-minute activities of other learners. For instance, it indicates when someone is looking at the same knowledge that learners are looking at. Multiple collaboration is concurrently realized through KA. This paper describes a concurrent collaborative learning environment supported by awareness, toward augmenting participation in collaborative learning. We tested and verified the effectiveness of this system in an experimental training.

I. Introduction

Recently, a number of collaborative learning environments have been built advocated by educational theories [O'Malley 94], e.g., CoVis [Edelson et al. 96], KIE [Linn 96], and CSILE [Scardamalia & Bereiter 96]. CoVis focus on making a collaboration process visible. KIE succeeds by helping students link, connect, distinguish, compare, and analyze their repertoire of ideas. Moreover, CSILE supports knowledge building for the creation of knowledge. In such environments, the learners actively provide their own knowledge into the system.

Knowledge acquisition and open ended CAI systems [Yano et al. 92] have been proposed to enhance and sustain learners' motivation. Especially, when learners acquire knowledge in the context of an open-ended activities, they are more likely to use that knowledge later. Similarly, in collaborative learning, distributed expertise and multiple perspectives enable learners to accomplish tasks and develop understandings beyond what anyone could achieve alone. Lave and Wenger [Lave & Wenger 91] suggested that the consideration of learning as legitimate peripheral participation (LPP) in communities of practice can be a valuable analytical perspective. Therefore, it is very important for learners to collaborate with each other. However, little attention has been given to the technical support for inducing and augmenting participation in collaboration.

In computer supported cooperative work (CSCW), a collaboration process has been described as a four processes model [Matsushita & Okada 95] which includes the elements of co-presence, awareness, communication, and collaboration. Co-presence gives the feeling that the user is in a shared work space with someone at the same time. Awareness is a process where users recognize each other's activities on the premise of co-presence. In the next process, the user collaborates on the specific task with other users and accomplishes the task and common goals. To increase communication opportunities, awareness is one of the most interesting topics. For example, awareness informs what other users are doing, and where they are working. These information facilitates informal communication between distributed users.

We have suggested that knowledge awareness (KA) is an important factor in collaborative process because not only it assists learners who are interested in the same knowledge but also it creates effective collaboration in an open ended learning environment [Ogata et al. 96a, Ogata & Yano]. KA gives the learner the information about other learners' activities in a shared knowledge space. KA encourages collaboration by exciting learner's curiosity and it fosters active learning.

Sharlok (Sharing, Linking and Looking-for Knowledge) [Ogata et al. 96b] has been developed as a testbed of KA. Sharlok is an open-ended and collaborative learning environment. It integrates a knowledge building tool with a collaborative interface tool. The result of the evaluation of Sharlok was that KA was very effective for inducing collaboration. However, KA has not yet been supported in the middle of collaboration. In this paper, we describe how KA during collaborative learning can be supported by Coconuts (Concurrent Collaborative Learning Environment Supported by Awareness).

We firsts describe the nature of collaborative learning in an open group in section 2. Section 3 presents overview of Sharlok and KA. In section 4, we presents the features and implementation of KA during collaborative learning. Moreover, we describe the experimental results of this system in section 5. Finally, the concluding remarks are given in section 6.

I. Collaborative Learning in an Open Group

A. An open-ended collaborative learning environment
Our research focuses on open-ended collaborative learning using computers and Internet. Table 1 shows several variables of collaborative learning in a closed group and in an open group. In a closed learning environment, like for instance, an ordinary classroom, a teacher organizes groups, gives the subject to the each group, and sets the time table for the discussion in advance. In this case, the learners can easily be very passive in group participation. Compared with this, learning in open groups is very active and learner-centered. The learner can join into discussions spontaneously and the participants of each discussion may be changing during time. Since, the students set the topic of the discussion based on their curiosity, so the beginning of the discussion is not previously defined. Moreover, in the open group, the participant can communicate both with other participants and with non-participants as well. It is very important for the participants to interact with non-participants for gathering information and understanding the topic of the discussion more deeply.

A. Time dimension of open-ended collaborative learning

Figure 1 shows a time chart of open-ended collaboration. There are three parallel sessions in this situation. Learners can be classified into those who:
(1) participate since the beginning of the session;
(2) participate halfway through the session;
(3) leave halfway through the session; and
(4) leave at the end of the session.
From the chart, we can conclude between others, the following facts. Although the participants of discussion C did not change, participants changed during discussion A and B. The learner X did not understand which session to join neither how to participate in the discussion. Therefore, we propose that the system should support the learner to understand the discussions.

A. Taxonomy of participation

In open-ended collaboration, there can be found some different kinds of participants except non-participants (see fig. 2):
(1) Observational participant (OP): In this case, the learner only observes a discussion without utterances. Through observation, the OP can understand multiple discussions and eventually decide to join one of them.
(2) Direct participant (DP): In this situation, the learner joins in a discussion and his/her opinions are shared and can be discussed by all of the DP of the same discussion team.
(3) Indirect participant (IP): In this case, an OP interacts with DPs of any discussion team but without going any particular team. This situation can be motivated in two different ways, either a non-participant (NP) decides by himself/herself to give advice to a DP, or any DP asks a NP to give his/her opinions. The advises from the NP often makes the discussion active. Therefore, indirect participation is very significant to argument participation in collaboration. In this context, the communication may be informal because not all of the DP may know about the communication in which the NP is involved. An OP is a better collaborator than a NP because the OP knows the content of a discussion. Awareness of collaboration is needed to allow users such informal communication.

The learner may concurrently participate in multiple collaboration by combining different kinds of participation. To augmenting participation in collaboration, educational groupware systems should support observational, direct and indirect participation.
I. Overview of Sharlok and Knowledge Awareness

A. Sharlok

Sharlok has an open ended and collaborative learning environment connected via Internet. The characteristics of Sharlok are the following:

1. Sharlok allows learners to share their respective knowledge, consequently the learners can cover the lack of mutual knowledge each other.
2. Learners can explore in a shared knowledge space according to their interests.
3. Learners can link between relevant knowledge by hypertext link. Using such a shared knowledge space, they can learn covering multi-domain.
4. By creating or joining collaboration during its use, learners can confirm or correct the knowledge. This process supports practical learning.

1. Personal learning environment

The personal learning environment of Sharlok has the following functions:

1. the definition of a class;
2. the creation of an instance object of a class;
3. browsing search for objects;
4. authoring of links between heterogeneous objects; and
5. navigation of objects.

Sharlok enables learners to create and define new classes. Learners can create objects and input their knowledge by using pairs of attributes and values, texts and figures. They can start collaboration by asking a question. Sharlok invites learners to do collaboration. If the learner agrees, he/she becomes a participant of the collaboration.

1. Collaborative learning environment

Sharlok allows learners to communicate and collaborate in a collaboration window which consists of a text chat tool, and a group drawing tool. In the text tool, participants can write their respective ideas. Moreover, the drawing tool shows their mouse pointers and it allows them to draw figures at real time. Sharlok records the processes of the collaboration and it makes this information retrievable and accessible for all the learners.

A. Knowledge awareness

In CSCL, awareness is very important for effective collaborative learning and it plays a part in how the learning environment creates collaboration opportunities naturally and efficiently. Awareness may lead with informal interactions, spontaneous connections, and the development of shared knowledge. Although a large number of studies have been made on such awareness in single group collaborative learning, little is known about awareness for multiple and concurrent collaborative learning.

We assume that KA is the information for enhancing collaboration opportunities in a shared knowledge space (see [Ogata et al. 96a]). Its messages are about the other learners' real-time or past-time actions, that have something to do with knowledge on which a learner is doing or had already done. KA makes a learner be aware of someone who: (1) has the same problem or knowledge as the learner, (2) has the different view about the problem or knowledge, and (3) has potential to assist him/her in the problem solution.

There are two ways for providing KA: “passive awareness” and “active awareness”. In the passive way, the system does not show awareness information until the learner requests it. In contrast, active awareness is autonomously informed to the learner. Sharlok induces spontaneous collaboration between learners using active awareness. For instance, User A may start to collaborate with User B by active KA which informs that User B has updated User A’s knowledge. However, it is necessary to inform a learner only the important part of KA instead of all of KA. Therefore, we have proposed a new method for filtering KA [Ogata & Yano 97].
KA has a close relation with learner's curiosity. Hatano & Inagaki [Hatano & Inagaki 73] identified two types of curiosity; convergent curiosity (CC) and divergent curiosity (DC). DC occurs because the desire of learning which makes learner's stock of knowledge well-balanced by widening learner's interests. On the other hand, CC is generated for the lack of sufficient knowledge, it is very useful so that the learner can acquire more detailed knowledge. KA induces collaboration by exciting learner's curiosity. In this way, KA assists creating real-time collaboration. However, awareness for concurrent collaboration is not proposed.

I. Coconuts

A. Overview

We propose Coconuts (Concurrent Collaborative Learning Environment Supported by Awareness) module in Sharlok in order to facilitate the participation into an open-ended collaborative group. Coconuts informs up-to-minute the participants' activities of concurrent collaboration. To augment the participation in collaboration, Coconuts has the following features:

1. Awareness support for observational participants: In order that learners can be aware about what is discussed and who is participating, Coconuts allows them to peep at multiple collaboration. After awareness of collaboration, the user can see the multiple discussion at the same time. Because direct participants do not know the existence of observational participants, the collaboration is not disturbed.

2. Awareness support for indirect participants: Coconuts allows the user to communicate informally in the following ways: (a) from non-participants to participants; and (b) from participants to non-participants.

3. Awareness support for direct participants: Coconuts allows learners to communicate and collaborate in real time. This environment provides workspace awareness for participants. Moreover, the system informs the participants who can help the discussion. Therefore, the participation of discussion increases;

4. Awareness support for non-participants: Coconuts lets non-participants know which discussion to join into. Particular, the system actively shows the users the information about discussion only when users are not doing any operation.

A. System configuration

Sharlok consists of a client and a server program (see fig. 3). The server has four components: a shared database, a history database of learners’ actions, an awareness server and a collaborative tools server. The shared database stores students ideas and collaboration processes. Awareness server manages the history database. On the other hand, a client has a student monitoring module, an awareness client, a collaboration tools client and a user interface module. Sharlok monitors the learners’ activities in the shared knowledge space and it stores them into the history database. Awareness client provides awareness to the learner according to learner’s actions.

![System configuration diagram]

Figure 3: System configuration.

A. User interface

We have developed Coconuts using Sharlok. Figure 4 shows some screen snapshots of Coconuts in Sharlok which is used by two users: “sharlok” and “rinzu”. “rinzu” collaborates about Japanese writers with “sharlok.” Window (A) denotes the titles of current discussions and their respective participants. If the user selects a topic and pushes the peep button, coconuts shows the up-to-minute snapshot of the discussion as shown in window (B). The update button allows users to see the current collaboration state. The user can take part in the discussion with the join button. Coconuts allows users to observe multiple collaborative groups. The user can send a message by pushing the message button. In window (C), “takahasi” informally communicates with “rinzu”. Moreover, a formal participant “rinzu” can ask some question about the discussion by selecting the help
button. "To list" shows who can receive the message from the user. Coconuts provides the user with a message window like this shown on window (C) and "To list" shows who to send the user’s message.

Figure 4: Screen of Coconuts in Sharlok.

I. Experimental Results

To evaluate Coconuts, we integrated a group of nine master course students. They had been using Sharlok during over 4 hours; two hours unsupported by Coconuts (group A), and another two hours supported by Coconuts (group B). Each user explored into the shared database and discussed sixty times about different topics, for example, SGML, OODB and 10Base-T.

Figure 5 shows the experimental result. The total frequency of participation of group B was higher than that of group A because Coconuts provides awareness and different kinds of participation. In particular, IP was very effective for increasing participation. In group B, the provision of awareness decreased wasteful formal participation. Some users mentioned that Coconuts helps to reduce the number of participants who left the discussion before it finishes. By OP, the users could understand the contents of multiple collaboration. The learners learned actively through real-time collaboration, and they felt satisfaction and attainment of learning after the test.

Figure 5: Frequency of participation.

I. Conclusions

In this paper, we proposed Coconuts for supporting awareness in a concurrent collaborative learning environment. We reached the following conclusion based on the experimental result of Coconuts:
1. The provision of awareness facilitates the participation in multiple and concurrent collaboration and it reduces wasteful formal participation.

2. Informal communication activates collaboration.

Although this paper describes a short term experiment, we will continue using and evaluating Coconuts in the future.

A Case Base Reasoning System on the Internet for Reference of Information Technology Education for Teachers

Toshio Okamoto & Masaki Nakagawa
Graduated School of Information Systems, University of Electro-Communication, JAPAN.
e-mail: {okamoto, chusen}@ai.is.uec.ac.jp

Abstract: While our society is becoming increasingly information-oriented, Information Technology Education (IT-Education) has just started from elementary schools to high schools, in nearly all Education sites. We are building a database which covers actual cases of such education, together with a management system based on CBR (case-based reasoning), accessible to the public through the Internet. Teachers can input their experience of IT-Education into this system using the CBR method, or just check among past cases, similar to their present application. By using this system, teachers from any Education environment, urban or local, can share a common knowledge of IT-Education practice.

Foreword

The modern society is more and more information oriented, thanks to the advances of scientific technology we witness in everyday life. We accept this as a fact. This phenomenon has brought about a new kind of teaching which not enough history to refer to and apply in actual class teaching. The existing cases are in reality not known to the public, and there seems to be no market to exchange the ideas and information about such experiments. They are hidden as teachers' private experiences. It is therefore required to create a place where private knowledge may be shared by a wider group of teachers through IT-Education and lead to a global refining of teaching methods, which would lead to quality improvement and to teachers' self improvement [Okamoto 1996, Nishinosono 1996]. Our aim with this research is to construct a Case-Based System for Information Technology being taught at high schools nationwide and put the developed system on the Internet. A great number of teachers could access this system, however far they are located from each other geographically, and use this system anytime in spite of hindrances such as time and location.

Study Purpose and Case-Based System

The users of our system will be teachers who are actually contributing to IT-Education, and also would-be participants. The system enables us to build a database for actual practices of IT-Education, and also accepts searching and registration of cases from anyone. For those who are actively involved in the Education process, reference to past similar cases will help to improve their teaching methods, when they find their teaching process not going as well as they've expected. For the would-be participants the system will offer past good and bad examples of the area, as guiding points for their future research. Our system sear the past history of the cases similar to a particular or possible class lesson, given some profile descriptors as IT-Education search criteria.

Registration of Cases

Registration of cases can be done by any teachers who have experience in teaching IT-Education. Data are input by several formats. Class, teaching method are input by choosing among a set of optional, ready-made items. At the same time, teachers can fill in the free area with their own workout programs and students' reactions without following any specific format. Also, they can put levels of relative value between input cases and actual teaching contents by adjusting some tuning options. Thus the system learns by acquiring new knowledge with every registration of actual teaching contents and methods. Registered cases are to be included in the database and can be a target for future search.

Search of Cases

Case searching is designed for teachers who need to check past cases of IT-Education. They will input profile descriptors which define search patterns. The system actually search past cases using these search patterns and a similarity measurement, and finally returns the case(s) which match the tea need best. If the result corresponds, in the system's conception, to the actual need of the teacher, the system will display it. The result contains information about the actual class procedure, about the topics and
about an overall judgement of the teaching process. If the teacher wishes, he can ask for further
detailed information about each item of these cases.

Adjustment of Cases

If the output is not what the user wants, the system tries to adjust the result by using the rule base of
domain knowledge that is pre-installed, to fit the user's need approximately. When this adjusted result
is considered to be appropriate, according to the similarity function computation, it is called a 'hit',
and the adjusted result is added to the database as a new case.

Figure 1: A typical example of CR
Figure 2: The system architecture

CBR

To construct a system as above, CBR theory of knowledge processing and technology is used
[Riesbeck 1989, Hammond 1990, Kobayashi 1992]. We give here the details of CBR and explain its
efficiency for our system. Expert systems tools such as Rule Based Reasoning and Model Based
Reasoning have been widely used to solve problems within certain intelligent systems. The former is
efficient as it is based upon the expertise of domain specialists, but is vulnerable to knowledge
acquiring. Similarly, Model Based Reasoning, which uses principles and laws of the structure of the
target system, shows high reliability, but low efficiency. CBR consists of a set of problem solving
architectures leading to a solution, while using past cases of success and failure, similar to a given
problem [Hammond 1989]. A typical example of CBR architecture is shown in fig.1. CBR eliminates
the above problems and adds efficiency.

An exhaustive search through the case base takes a lot of time and a vast amount of calculation.
CBR can reduce the tracking space by applying filtering criteria directly to an index file, which saves
search time and volume. Therefore, our system can be implemented on middle range computers.
When the picked-up result match the problem, the result is the desired solution. The result can be,
however, rather far-fetched. Thus the need of adjustment using appropriate domain knowledge with
the case repair module, which finally leads to the desired solution. This adjusted result is applied to
the particular problem, and if it solves it, it is added to the database as a successful case [Kolodner
1993].

System Architecture

The Case Based System is being developed with the use of the WWW so that teachers and common
users spread far from each other geographically may have access to the same system. The system
doesn't require specific browsers, but can function on any desired one, and offers search and
registration service at anytime and in anyplace. Users' information is processed and administrated
systematically with the use of the CGI (Common Gateway System).

The WWW interface offers an interactive process between users and the system. cases are kept as
HTML files. For efficiency's sake, an index file keeps profile descriptors of the cases. This file is
used when the actual searching takes place. The system architecture is shown in Fig.2.

**Case Base**

The Case Base comprises two kinds of files. One is a set of case base files which describe actual class cases in the form of a frame, and the other one is an index file, which keeps specific descriptors of actual class cases. When a case is registered as a HTML file, registration/installation is done in the form of a frame. Three descriptors create each frame: the profile descriptor, the contents descriptor and the address descriptor.

**Profile Descriptor**

The profile descriptor contains the characteristic elements of actual class cases. The practice of IT-Education varies much, depending on the characteristics of each class and on the thematic genre of the specific informational area. The teaching procedure is selected by evaluating both class and specific thematic genre. Computers can be used in a class in a variety of ways. It is presumed that a class, where students actually write programs using computers, gives a different result from when they learn with the aid of ready-made applications such as CAI programs. If computers are used at an inappropriate time during class, we cannot expect good results. We also have to take into consideration that the number of computers available varies from school to school, so that the number of computers available to one student depends on the school the student belongs to. Therefore, the result from using computers is not simple. Also, the teaching/learning procedure is influenced by the different class aims, so that even if the same thematic genre of informational area would be studied, but in different classes with different subjects, the result cannot be the same. With all these circumstances in mind, we defined the profile descriptor slots as follows. Table 1 shows the profile descriptor slots and their possible values (range facets).

<table>

<td>Number of available computers (no upper limit)</td>
</tr>
</tbody>
</table>

**Contents Descriptor**

The contents descriptor shows the details of the teaching contents and the teaching result of each case. The IT-Education knowledge of teachers who have actually participated in the teaching is to be assessed with a value in each slot. Teachers are expected to offer a teaching subject with an appropriate Education purpose and to add also the teaching contents. They have to study the essentials of a certain teaching content and use a variety of teaching materials and machinery devices, in order to create a lesson easily understood by the students. At the end of each class session, teachers grade students from the various points of view of the IT-Education. Moreover, teachers assess their own IT-Education ability themselves, as being either a good or a bad teaching job, and they compile the important points of the education process and add them to the IT-Education curriculum. With these in mind, we designed the slot column and value column of the contents descriptor. Table 2 shows examples of slot and value fields of this descriptor. For the value field, whole text files can be used to fill in the column, so that there is enough place for detailed information.

**Address descriptor**

This descriptor shows the detailed environmental information of each class teaching: school name, where the teaching has been carried out, teacher's name(s), class name(s) (non-specific, science, English, economy, engineering, agriculture, polytechnic, etc.), class tag and students' grade. At the same time, when the school's network topology and the detailed teaching information at that school can be reached through the Internet, the

Interface

The system http://www.ai.is.uec.ac.jp/~chusen/CBR/SYS/ offers two interfaces, the one when users register, and the other one when users search for similar past cases. To make a registration, users have to fill in the above three descriptors, i.e., profile, contents and address descriptor. Input data will be transferred to the registration module of the system server through the Internet. Fig.3 shows the registration menu.

Searching for past cases, the users input characteristics of the data they need, as value columns of the previously shown profile descriptor. Users can input searching weights values by manipulating keywords (Fig.4). As users have three possible outcomes for their search: past successes, failures, and a mixture between the two, they can specify which of these results are to be shown to them. Users can be interested in past failures as well as in past successes, depending on their interest in reiterating success cases or preventing mistakes that have been already made.

Case Registration

The case registration module records values from the above stated three descriptors into one HTML file. At the same time, the system draws a numerical value from the key descriptors, and installs a numerical value in the index file. The index file is there to make case search more efficient. In the registration process, the inputs with no valid value are automatically rejected.
Case Search

The case search module draws search patterns from the information clients have given. These patterns include keywords from the key descriptors' value column and also search formats. Search formats, class genre and class contents determine the system values of the appropriate slot. The system has thus the possibility to choose suitable cases matching all these search conditions from the index file. The system then inputs these similar cases into a similarity function and draws as satisfactory cases as possible from among them. Thus, the output result cases drawn from the vast database are considered to satisfy the search condition best.

Approximate cases

The system starts searching for patterns similar to those input by the user. To apply the similarity function, which can be also seen as a search function, to all the cases in the database, means scanning a vast search space, which can be very inefficient and time-consuming. Therefore, to minimise the search area, the system pinpoints approximate cases with the aid of input values from two kinds of slots here, for instance, slot 'teaching subject' and slot 'name of class' of the profile descriptor. Class names and teaching contents are indispensable search patterns to pinpoint cases. The system will then apply the similarity function to the pinpointed cases, and then will check the final output value of the similarity function. The case with the minimal distance between users input and registered data are considered to be the best result with the highest similarity degree to the user's needs. This pinpoint procedure enables the system to seek through as little case space as possible for the target and leads to an efficient case search.

Similarity Function

The system carries out pinpointing with a matching process referring to the two highly significant slots mentioned before and applies the similarity function to each of the pinpointed cases. This is how the similarity value is computed. The system checks the similarity value to measure the distance between each case and the search pattern input by the user. The shortest distance between them will be the best approximate case. We define the similarity function as:

\[ D(U,T) = \sqrt{\sum_{i=1}^{n} (S_{ui} - S_{ti})^2} \]

Here, \( U \) is the search pattern users input. \( T \) is a case already in the database. \( D(U,T) \) is the distance between \( U \) and \( T \). \( S_{ui} \) is the numerical value of the search pattern, \( S_{ti} \) the numerical value of the registered case, with \( i \) the order of the numerical search pattern in the profile descriptor (Table 1).

\( S_{key} \) is the percentage rate of the input keyword in the value slot corresponding to the slot 'General report on the result' in the contents descriptor (Table 2), with \( key \) the number of letters of the desired pattern, \( n \) the number of occurrences of the desired pattern in the text, and \( S_{text} \) the total number of letters in the database text. As for \( S_{key} \), an example of computation can be found in Fig.5.

Figure 5 : Example of \( S_{key} \)

The slots (1)-(11) in Table 1 are used for the computation of the similarity function used in the searching process. Each value of (1)-(7) is input by the user as values from 0 to 10. These inputs are converted into 0-1 values, and handed over to the similarity function. The evaluation of each slot (1)-(7) means the computation of the Euclidean distance between the searching conditions input by the user and the recorded values. In what concerns slots (8)-(11), they are evaluated from the point of view of computer usage and integrated into a single value, the \( Comp \) value in the similarity function definition equation. \( d(u_i,v_i) \) computes the difference between the stored pattern and the user's input for the usage purpose of the computer (contents of slot (9), profile descriptor, Table 1). Here, \( d(u_i,v_i) \) is computed as follows: it is 1, if \( u_i \) and \( v_i \) values coincide, or 0 if not. (10),(11) are used for the computer per student rate, and generate the value \( Comp \). After computing this presented function, the system returns to the user the result which has the lowest \( D(U,T) \) value.
Learning

In this chapter we explain in more detail the process of CBR learning. The main system's training consists in the usage of the case modification mechanism, the case diagnosis mechanism and the case repair mechanism.

Case Modification

In the case searching process, the most similar case, according to the user's search conditions, is gathered. The profile descriptor of the searched case and the user input search conditions are rarely in perfect concordance. Therefore, cases which don't coincide can be tuned by the modification mechanism, according to the user's conditions. The user is tuning all slots for the case he is looking for. During tuning, the system presents pertinent choices for the slot, so the tuning can be done easily.

Case Diagnosis

The case diagnosis mechanism is testing the validity of the case which was tuned. The diagnosis mechanism is using the domain knowledge base of relations between the slots or the slots' value, a.s.o. If the result of this diagnosis is valid, the case is presented to the user. If it is not valid, the reason of invalidity is shown to the user, and a new tuning is repeated.

Case Repair

After the case diagnosis, the case diagnosed is attached features with the case repair mechanism, that are stored in the case data base. The repair mechanism adds some information and saves it as a case repair information frame. The stored information are 1) an information pointer to the modified case (the most similar case to the user's search conditions) and 2) the case modification frequency flag. This information is used for the case search. In the process of case selection, the system search the case input by the user (we call this case the original case). If nothing matching is found, the system search the modified case base, based on the original case and the case modification frequency flag. This flag expresses a class hierarchy number, that is created together with the modified case, and is equal to the number of modifications of the original case. Therefore, the functioning of the search mechanism reflects the modification experience.

Discussion

As the system requires from users to specify the desired relative value between input case and the actual teaching subjects stored in the database, a precise assessment. The fact that desired patterns that have to appear in the teaching contents allow a more flexible search than simple keyword matching systems.

The system has now been actually implemented and can accept case registration and provides the search function. Future improvement can be done to adjust the output result.

We are installing one case as one HTML file just to make the search procedure efficient, but it is presumed that the registration number will increase to a vast degree. It is impossible to control the whole database by only one domain frame. Therefore, we are planning to split the database into several different divisions, so that a distributed management system may be constructed. After all these adjustments, the system will be able to offer better results to the users.

The Phedias Graphics System:
A 3D Computer Graphics Project Environment

Department of Computer Science,
Dartmouth College, Hanover, NH 03755 USA
email: cowen@dartmouth.edu

Abstract: A common course in Computer Science curriculums is Computer Graphics. This course favors dynamic and interesting projects. The Phedias Graphics System (PGS) is a system for supporting projects in computer graphics courses. It has been designed specifically for instruction and provides for students a powerful tool for practicing new skills. The environment is transparent and allows students to examine the processes involved rather than treating a graphics system as a "black box". It has many unique features useful in pedagogical environment, including separation of modeling and rendering and support for both rendering and modeling projects. This paper describes PGS and its application in courseware. Particular attention is paid to the differences between an instructional system such as PGS and commercial systems such as OpenGL. A list of example student projects is included.

Introduction

Most computer science curriculums include a course in computer graphics. Students are fascinated by the application of computers in the motion picture and television industries and find such a course very attractive. It is a strong course because it teaches interesting and complex material and helps develop newly found programming skills in an environment that is highly visual and very dynamic. Indeed, it is a course that many students find quite entertaining.

This paper describes the Phedias Graphics System (PGS). PGS has been developed specifically for student projects in computer graphics courses. It provides an environment for student projects that is general and uses modern concepts in programming and graphics modeling, but can be installed with "holes" in the environment that can be filled by students. The idea of "holes" or an incomplete environment is similar to that of the NACHOS (Not another completely heuristic operating system) environment which is used to teach courses in operating system design [Christopher, Procter, and Anderson 1993]. The system has many additional features which are designed for maximum effectiveness in an educational project setting.

There are many approaches to teaching computer graphics. See Cunningham, 1987 for examples [Cunningham 1987]. Some instructors choose to emphasize underlying mechanisms and algorithms [Schaller 1993]. Projects in such an environment should necessarily provide more than just exercises in using a programming system, and may include rendering and fundamental algorithms work. The alternative approach is to treat the course as a tools course, teaching a common system, such as OpenGL or VRML, in detail. While this may appear to be attractive from the standpoint of "training for industry", it does limit student exposure to a single approach which may not closely relate to another system they may be required to use. Of course, an ideal structure probably lies between these two extremes. PGS provides such a structure.

PGS provides project infrastructure. Many instructors believe students should be required to write systems from scratch [Schweitzer and Appolloni 1995]. While this may be effective in building new programming skills, it begs the obvious question of if programming of low level features such as matrix manipulations and object organization really adds to the understanding of the particular subject material. In a world progressing to component software, a toolkit of basic structure seems more ideal. Coding from scratch will limit the complexity of projects, effectively preventing loading file objects or dealing with complex
formats such as TIFF and VRML. A toolkit allows students to reach that magic goal of a real image much quicker, thereby receiving instant feedback. Some approaches to toolkits for students do exist. Simple PHIGS (SPHIGS) is a companion to [Foley et al. 1995], a popular text. TUGS uses a replaceable components approach to teaching computer graphics [Clevenger, Chaddock, and Bendig 1991].

Modeling vs. Rendering

A highly visible characteristic of PGS is the complete separation of modeling and rendering. Modeling is the description of a scene or virtual world. All elements of the world must be reduced to simple objects called primitives. The most common primitive is the polygon, a closed planer figure bounded by line segments connecting vertices. Additional primitives include more complex curve descriptions such as Bezier surfaces, spheres, cones, etc. The process of converting 3D objects into primitives can be confusing for students in that they must learn to think in three dimensions (3D).

Rendering is the conversion of a model to an image. While modeling is a relatively generic process, there are many drastically different approaches to rendering. The final location of primitives can be determined by projecting vertices or control points to two dimensional screen coordinates and directly rendering. A depth buffer can be used for visible surface determination. This approach will be referred to in this paper as projection graphics, in that it is based on simply projecting the primitives to their final locations. An alternative approach simulates the path of light through the environment in reverse. This technique is called ray-tracing. Radiosity, simulates the distribution of light throughout a scene using methods similar to finite element modeling.

Each technique has advantages and disadvantages that must be made clear to students. Projection graphics is fast, but does not simulate effects such as shadows very well. Ray-tracing is slow, but produces more dynamic scenes. It is easily extended using recursion to simulate shadows, reflection, and transparency. Radiosity is an advanced topic typically not included as a project in computer graphics courses.

Students should gain experience with more than one rendering methodology. Projection graphics and ray tracing since are in common use and are very distinct in capabilities and performance. It is also desirable that student projects include implementation of rendering algorithms and methods as well.

The Modeling Environment

The modeling environment in PGS is based on polygonal modeling, though students can add additional primitives. Polygons need not be convex, as in OpenGL, but they must be planer. By default, PGS requires all polygon vertices to be entered in counter-clockwise order, though that behavior can be overridden. Students must develop an ability to visualize in 3D. A useful tool in that quest is the requirement that polygons be specified in a specific order. Given such a specification, a graphics system can perform back-face culling, the elimination of backwards facing polygons from consideration. Most systems support back-face culling since it is a significant performance improvement, but by default do not enable the feature. Students are often tempted to leave the feature disabled. PGS discourages that behavior and can be set by the instructor to always perform back-face culling.

The PGS modeling environment is a conventional hierarchical environment consisting of primitives and composite objects. Primitives are added to objects by reference, not copied into objects, so the true directed acyclic graph model of hierarchical modeling is supported. Vertices are unique to polygons, however. There are no shared vertices. This keeps the environment simple for students to work with. Primitives are defined by supplying vertex lists. In addition, primitives can include vertex normal lists, and texture mapping correspondence points. The structure for defining a primitive in code is quite simple:

```cpp
PGSPOLYGON *poly = new PGSPOLYGON;
    // Instantiate a new polygon
poly->Add(v1);           // Add a vertex which already exists
poly->Add(VERTEX(1, 2, 1.75));  // Add a vertex directly
poly->Add3(v3, v4, v5);   // Add 3 vertices
```
Every effort is made to simplify primitive definition in code so the student can spend time creating complex and interesting models rather than copying boilerplate code. Students often prefer the Add3 and Add4 member functions since they allow triangles and quadrilateral to be defined in one step.

Objects are also simply defined:

```c++
PGSOBJECT *obj = new PGSOBJECT; // Instantiate a new object
obj->Add(poly); // Add poly to the object
obj->AddPoly(trans); // Add poly with transform trans
obj->AddPoly(PgsTranslate(0.5, 2, 2)); // Add poly with a translation
```

In most modern graphics systems, transformations (changes in shape, size, or location of graphic elements) are modeled using a 4 by 4 transformation matrix which is multiplied by a 3D coordinate with an extended coordinate called a homogeneous coordinate. This extra coordinate allows many transformations to be modeled, including arbitrary rotation, translation, scaling, and skew. A common approach to creating models is to use transformations to place primitives into objects which can then, in turn, be transformed themselves and referenced in other objects. PGS makes this structure much more visible than systems such as OpenGL, which maintains a complicated, internal matrix stack. Students using PGS can create their own matrices, either by composing operations defined in PGS or by filling in values themselves. This structure can be used as a tool not only for creating models, but for computing vertices in textures, computing normals, etc.

Rendering

Many graphics systems are designed around a single approach to rendering and build this approach into their design. OpenGL uses conventional projection graphics, wherein graphics primitives are rendered immediately upon becoming available. Not only does this limit student exposure to a single rendering methodology, but is also blurs the distinction between modeling and rendering. Most texts, such as Foley, et al, a popular text, indicate this distinction, but it must be emphasized in projects. In PGS all modeling is performed first, then the scene is rendered.

PGS comes with three basic rendering systems (four if the wire-frame rendering in the previewer is counted). A conventional projection graphics renderer based on a polygon fill algorithm, a visible surface ray tracer, and a true recursive ray tracer. Students must have experience in each of these technologies. They are very different and yield different results. However, what is really important in PGS is that a student can implement their own rendering technology.

A common PGS project is to implement a recursive ray tracer. This technology already exists in the system, but can be disabled as described in a following section. Using the concept of replaceable components, a completely new ray tracer can be written using as much or as little help from the system software as is desired. In previous student projects the students have been supplied the polygon intersection components which are highly optimized in PGS and much faster than what students would normally wish to write, though polygon intersection algorithms would make an interesting project as well. The ray tracer implementation can be done in fewer than a hundred lines of code which is very similar to the algorithm presentation in textbooks.

This is an important feature of PGS. Students are typically confronted with either using a graphics system which only supports its own rendering methodology or attempting to write such a system from scratch. Neither approach offers the advantages that PGS can.

Lighting, Views, and Scenes

Lights must be placed in a scene for the scene to be visible (ambient light is also supported and will allow a scene to be viewed dimly without explicit lighting). Lights are defined either as points in space or directions to light sources. This is a very conventional approach. Lighting definition in PGS is simple:

```c++
PGSLIGHTS lights; // Lighting object
lights.Add(VERTEX(100, 100, 100), COLOR(.8, .8, .9));
```
This is contrasted with OpenGL which has multiple lighting modes, different defaults for each light type, and numerous options which must be enabled to use lighting. PGS lights are simple points in space. However, a new class can be derived from the PGSLIGHT class adding any light functionality the student may require. Lighting with exponential falloff or spotlight characteristics is easy to create.

A *view* is the definition of the camera placement in a scene. PGS uses the PHIGS model from Foley, et. al. for views [Foley et al 1995]. A user specifies a view by defining a view coordinate system. Note that students often have difficulty selecting views. There are many parameters to select and it is not obvious what window size or projection reference point setting will properly frame a scene. For this reason, PGS has a *previewer*. The previewer shows a wire-frame rendering of the scene with complete control over the view. The students selected view is used as a starting point and the student can then adjust the view.

A *scene* is the combination of lighting, a view, and something to look at. In PGS, that something is an object. Since objects are hierarchical, all items to be viewed in a scene can easily be combined into a single object. Transformations facilitate the placement of components in the object. This structure of lighting, a view, and an object in the form of a scene has been designed to simplify the representation of a model for a student. Systems such as OpenGL use large quantities of additional information to describe a scene and that information can be modified as the scene is constructed and rendered. There are numerous options which are routinely enabled and disabled. These options are confusing to students.

**Object Oriented vs. Retained Mode**

PGS is a highly object-oriented system. It is implemented as a C++ class library. Many common graphics systems, including OpenGL are referred to as *retained mode graphics systems*. A retained mode graphics system is a system that has global *state*. This state may include the model being created, features which can be enabled and disabled, and intermediate images. Most modern programming theory agrees that state should be localized, often to objects. There is no global state in PGS. This model is meant to better represent programming as it is often taught. Moving a student to a retained state system after exposure to PGS has proved to be simple. The opposite may not be so.

More and more computer science curriculums are emphasizing object oriented programming using C++ or Java. PGS is meant to be a good representation of that technology and is highly object oriented. It encapsulates much of its functionality in classes. The structure has been designed to make a transition to Java in the future very easy to do without an entire rewrite of the system.

**Controlled Distribution and Replaceable Components**

Students need to see many examples. These examples should include code which illustrates how algorithms or methods are implemented, how specific objects are defined, how routines are used, and, above all, good programming style. For this reason, PGS comes with many example programs including a fairly elaborate scene, texture mapping demonstrations, simple box examples, etc. In addition, the PGS code is an example for students of how algorithms are implemented. However, it is important that distributed code not give away the solution to assignments. A common element of a student project might be to create a tessellated sphere. Viewing the source code for PGSSPHERE will simplify that project greatly.

PGS prevents this problem using *controlled distribution*. Features in the system can be enabled or disabled when the library is built and installed. Features can be turned off and, therefore, made unavailable to the student. These features include texture mapping, smooth shading, advanced transformation modeling, etc. Often features should be unavailable in early projects and become available later. There are two levels of control: object and source. A feature which is disabled as an object will not be available for execution at all. An object which is disabled in source will be installed and available to use, but the source code will not be available. User components can be added to this system, making it easy to distribute project solutions.

PGS has a unique structure wherein many components of the system can be replaced or enhanced. As an example, the default color model is the Hall color model. A subset of the model is used for projection
graphics. Students can replace the color computations with their own code which fully implements the model, a common project. The entire model can be replaced at will with another. This is true of many components of the system. New lighting with specific characteristics can be created, and an entirely new renderer can be installed.

Students require projects that will stress specific course material. Most systems treat rendering as a black box: model in, picture out. PGS allows for replacement of components in the supplied rendering algorithms or creation of an entirely new rendering module with as much or as little provided system functionality as required.

Loaded Content

It is important that projects in computer graphics not become bogged down in modeling. Students must go through the process of creating polygonal objects since this is an essential skill. However, it is rare that more than two projects would be devoted to all of the issues of modeling. But, students should be able to create complex and interesting scenes. For this reason, PGS allows loaded content, polygonal models or texture images which are loaded from files. PGS supports the VRML 1.0 and OFF file formats for loading graphical objects. It supports the TIFF format for loading images.

Students are more enthusiastic when the projects they produce are complex and of high quality. However, many are not artistic. Creating only simple geometric figures such as chairs, boxes, etc. will not motivate a student as much as creating a complex scene including textured surfaces and complex objects such as teapots, chess pieces, cows, etc. Loaded content allows students to move beyond “creating things” to “manipulating things” and is a much more realistic portrayal of what their future job function may be. Most computer scientists are not expected to be artists in their job at all.

Conventional Systems?

A common reason for choosing a conventional graphics system for instructional purposes is that these systems are widely used and the student is better prepared for employment than if trained on a proprietary or training system such as PGS. Indeed, it is important at this time that students be exposed to OpenGL. One approach that this author has used successfully is to include an OpenGL project in the course. A limited time is devoted to OpenGL feature description and a simple, usually highly animated, project is assigned. If this assignment follows PGS assignments, students quickly learn the difference in the two environments and pick up OpenGL with no difficulty. It is proposed that education in the basic concepts underlying systems provides students with the tools they need to adapt their thinking to a particular environment. Given that there are many graphics systems in common use, this seems to be an effective instructional technique.

It has been suggested that this question is similar to the question of what language to teach, a clean educational environment such as Pascal or Scheme, or a commercially successful system such as C or C++. However, moving from one language to another is a time consuming process. Learning how to map knowledge in one graphic system to another is not nearly as complicated. Both PGS and OpenGL require that you begin the process of defining a polygon, then add the vertices. OpenGL has an explicit end to that process as well. In nearly all cases, there are equivalent functions, though the many enable/disable features of OpenGL require definition.

Experience and Example Projects

It is useful to describe the experience of the last class to use PGS, the students in CS-43, Computer Graphics, Fall, 1997. The course instructor was Charles B. Owen and there were 21 students. In a ten week term the class participated in four projects.

Project 1: In this project students were asked to create three objects: a chair, a sphere, and one object of their own choice. The objects had to be positioned on a floor also added to the scene. The emphasized
elements in the project were 3D visualization, polygonal modeling, vertex normals and smooth shading, and 3D positioning. During this project the texture mapping features and the PGSSPHERE object were specifically turned off and not available to the students. Student objects naturally included a spaceship, but also included a working clock, a spiral staircase, a hockey stick, and a recursively generated tree.

Project 2: This project expanded to all elements of modeling including texture mapping, using loaded elements (a set of OFF and VRML objects were made available), and creating a carefully composed scene consisting of a room with a window and texture mapped walls. In addition, students were required to map a world map texture onto the sphere they created in project 1. This project emphasized complex texture tiling, geometric transformations, and realism in scenes.

Project 3: As mentioned above, it is very useful to have a project in a commercial graphics system and this project fulfilled that perceived requirement using OpenGL. Students were required to create an maze which they could traverse. Note that this project did generate a large amount of grumbling about quirky OpenGL features, but moving from PGS to OpenGL did not present a large leap of methodology.

Project 4: The final project in the course is a larger project and moves the student entirely into rendering, specifically recursive ray-tracing. Since this is the final project in the course, it is divided into two parts: rendering and enhanced algorithms. There is a “checkpoint” when students must demonstrate only the ray-tracing component of the project. Note that all of the polygon intersection algorithms where enabled in PGS to simplify this project and allow the project solution to be faster than what a student would be expected to write in the short period of time allowed. The specific requirement for the first checkpoint was an anti-aliased recursive ray-tracer using the project 2 scene. It should be noted that this project is not nearly as complicated as expected and students have expressed their surprise that it took as little code as it did to get up and running. Another requirement of the project is a full implementation of the Hall color model.

The second half of project 4 is to implement some extension of this system. A long list was provided for the students to select from, including fish-eye lenses, stochastic ray tracing, depth-of-field, etc. This gives the student a chance to experiment with new technologies while gaining experience modifying an existing algorithm. The student opinions of the project as noted in the course evaluation were very good and students were quite proud of the resulting images.

Summary

The Phedias Graphics system provides an environment for student projects in computer graphics that emphasizes algorithm implementation and experimentation. Major components of the system can be enabled and disabled at will. Multiple rendering methodologies are available to students, and modeling and rendering are distinct entities. The system has been used successfully in student courses and has proved quite popular in that students are excited with they can produce complex and beautiful images using simple code.

The system is currently in final testing and will be made available to many users in the near future. It is C++ based and runs on most Unix workstations. It has been tested on DEC Alpha, HP-UX, and SGI Irix workstations. The software will be available at: http://devlab.dartmouth.edu/pgs/.

Acknowledgments

PGS is based loosely on the NGS graphics system. Though not much of the early history of NGS is known, it is believed to have originated at Harvard. It has been considerably modified over the years at Dartmouth College by Pete Sandon, Scot Drysdale, and the author. It was completely rewritten in the Summer of 1997 adding many of the features described herein. Many thanks to students in CS-43, who endured alpha and beta versions of the software. Thanks to Fillia Makedon for suggesting the name Phedias.

Hypermedia and Learning: The Relationship of Cognitive Style and Knowledge Structure

Rocco Paolucci, Ed.D.
Assoc. Professor & Chairman
Computer Information Science
Cabrini College, Radnor, PA 19087
(paolucci@cabrini.edu)

Abstract: Theoretical research claims that, in order to effectively apply hypermedia to enhance learning, instructional and software designers need to address two major issues: The level of structuring of the knowledge domain (as represented by the hypermedia software) and the cognitive abilities of the learner in navigating the knowledge-base. Over the past decade, a number of empirical studies have explored the effects and relationships of knowledge structure and cognitive style on learner performance when using hypermedia. The purpose of this article is to review the major research literature on this subject. The goal is to identify key and important findings, with the hope that these can better guide the appropriate applications of this technology.

INTRODUCTION

The use of interactive computers and hypermedia as knowledge exploration tools has been attracting much research in the field of computer-assisted learning, both in academia and industry. This fact is reflected by both the increasing number of interactive multimedia systems in schools as well as the number of conferences and publications on the subject [Becker 1993; Snider 1992]. However, the inherent flexibility that hypermedia software provides to students and teachers present a host of challenging questions and issues. At its most basic level, the crux of this research study is to better understand how hypermedia software can enhance the learning process and the transfer of knowledge.

In order to effectively apply hypermedia to enhance learning, there are two classes of issues that need to be addressed. These are authoring-related and learning-related [Locatis et al. 1992]. Authoring issues deal with the decisions that are presented to the hyperdocument's author (hyperdocuments are documents developed with the use of hypermedia authoring software). The more important one for this research study is the structuring of the knowledge domain. This issue deals with how the links of the hypermedia document should be structured (linked and organized) to represent the knowledge of the expert and, at the same time, guide the learning of the student. The learning issue of most concern to this research study is that of cognitive style. Hypermedia has been postulated to be most useful when discovery learning is warranted [Locatis et al. 1992]. Additionally, it has been shown that certain cognitive styles (active or exploratory styles) are more conducive to the effective use of educational hypermedia than others [Jonassen & Wang 1993; Larsen 1992; Yung-Bin 1992].

Finally, it has been widely claimed that the use of hypermedia learning systems promotes higher level cognitive skills, which require the association and linking of different ideas and information rather than the recall of facts and data [Ambrose 1991; Marchionini 1988; Tasi 1989]. It seems that the inherent web-like nature of hypermedia software is ideal for guiding the learner in forming these links.

HYPERMEDIA AND LEARNING

This study will examine the empirical studies associated with these issues. It will address the effects of the learner's characteristics (by specifically examining cognitive style) and the learner's level of self-direction (by addressing the structuring impact of the knowledge domain) on the performance of students when operating in a hypermedia learning environment. The research will be analyzed by examining the learner's overall performance, as well as higher level cognitive skills. The research which addresses the above two factors (cognitive style and knowledge structure) will be more fully described in the following sections.
Cognitive Style

When it comes to the use of educational hypermedia, what type of learner is most likely to effectively utilize a hypermedia environment? Locatis et al. (1992) claim that persons who have high general ability (e.g., cognitive style, Grade Point Average or GPA) should perform well in a hypermediated environment. Lower ability students might benefit if there is extra guidance. Although used interchangeably in the literature, there is a technical difference between the use of the terms cognitive style and learning style. Cognitive style deals with the "form" of cognitive activity (i.e., thinking, perceiving, problem solving, etc.), not its content. It is viewed to be "persuasive dimensions" of personality, bipolar in nature, and stable over time [Whyte et al. 1995]. Learning style, on the other hand, is seen as a broader construct, which includes cognitive along with affective and physiological styles [Keefe 1988].

The distinction being made, it should be clearly stated that this article, in reviewing the empirical research, will deal with cognitive style, even though at times the term learning style will be used (mostly in reference to previous research). A field experiment by Billings & Cobb (1992), with 63 undergraduate students using hypermedia, examined the major effects of learning style, GPA, and attitudes on achievement. No relationship between learning style and performance was observed. However, the study did show that GPA had a significant and positive correlation with achievement when included with the attitude scale into the regression analysis. Similarly, a field study of adult computer technicians located throughout the country examined the relationship between learning style and the effectiveness of a hypermedia instructional system [Larsen 1992]. The results failed to detect any significant correlation between learning style and achievement scores.

On the other hand, a study by Yung-Bin (1992) tested the effects of learning style and instructional advisement on undergraduate students' achievement when using a hypermedia instructional system. The results indicate that achievement test scores were affected by the interaction of learning style and advisement, with active-learning subjects tending to score higher on the achievement test than passive-learning subjects. Furthermore, passive-learning subjects who received the advisory version of the software scored significantly higher on their achievement test than passive-learning subjects who had the non-advisory version.

An experiment by Jonassen and Wang (1993) involving ninety-eight pre-service teachers in an open enrollment college showed that individual differences interacted with learning through the use of hypermedia. The research showed that the "field independent processors" cognitive style subjects generally preferred to impose their own structure on information rather than accommodate the structure that is implicit in the materials. The authors conclude that it is likely that field independent learners are better hypermedia processors, especially as the form of the hypermedia becomes more referential and less overtly structured [Jonassen & Wang 1993].

Knowledge Structure

It has been a commonly held view that discovery learning environments are ideal for stimulating higher-order thinking [Schank 1993]. These views have been discussed and documented at length by such noted cognitive theorists as Bloom (1956) and Gagne (1977). These observations raise interesting questions when applied to hypermediated learning environments: Will learners form better conceptual models using hypermedia or will the richness of the information overload learners and deteriorate effectiveness and efficiency of learning? Are some knowledge structure schema better than others in facilitating and promoting learning in general, and higher-order cognitive skills in particular? Is there a relationship between the hypermedia knowledge-base structure, cognitive style, and the promotion of higher-order cognitive skills?

In using hypermedia environments to teach higher level learning skills, Locatis et al. (1992) claim that hypermedia might best be used when discovery learning is warranted. However, according to Marchionini (1988), "Although self-directed and exploratory learning are worthy objectives to achieve in learning environments, freedom to learn does not seem to be a sufficient condition to assure effective learning." (p. 11). It seems that the rich learning environment may easily become a trip into "hyperspace" [Marchionini 1988]. In response, Tsai (1989) claims that this issue can be adequately addressed, "Even though users can freely choose their browsing paths, a hyperdocument has an intrinsic structure which is determined by how the nodes are linked together. This intrinsic structure should have some effects on users' browsing and commenting activities." (p. 11). This point is similarly noted by Conklin (1987), with his claim that there is no natural topology for an information space. Finally, Brooks, Simutis, and O'Neill (1985) claim that learners may actually be able to process information more effectively if it is presented in a manner that is closely matched by their learning style.
Although earlier research yielded unclear results [Cordell 1991], recent empirical studies have been more conclusive. Jonassen and Wang (1993), in their study involving ninety-eight pre-service teachers in an open enrollment college, conclude that merely showing learners structural relationships is probably not sufficient to result in greater structural knowledge acquisition or performance. The authors hypothesize that “what seem to matter most is the construction of personally relevant knowledge structures” (p. 7). It is claimed that such constructions can promote higher-order thinking in the form of logical reasoning. Stanton (1994) examined the comparison of a learning environment that presented the instruction knowledge in a linear format over which the student had no influence with another in which the student was able to determine the sequence of the instruction freely. The study, involving forty adult students, suggests that performance may be improved with a non-linear learning environment, but this is likely to be dependent upon the ability of the participants to organize the environment in a manner that suits their own learning style.

More recently, a study by Rasmussen and Davidson (1996) with pre-service teachers as subjects showed a significant interaction among hypermedia structure (hierarchical), learning styles (active-reflective), and performance. A more elaborate and extensive experiment by Paolucci (1997) analyzed the effects that knowledge structure (using three major schemas: hierarchical, branching, and networked or conventional hypermedia) and cognitive style (active vs. reflective) had on performance with a hypermedia learning system. Six fifth-grade classrooms from three different elementary schools within the same school district were chosen for the study (115 students). Although the study found no significant differences between the two types of cognitive styles, significant differences were found among the three knowledge structure schema groups, with the branching group performing significantly better than the hierarchical and conventional groups. Furthermore, a significant difference was found for the higher-order cognitive skills performance scores among the three knowledge structure schema groups, with the branching group performing significantly better than the conventional group but not significantly better than the hierarchical group.

**DISCUSSION**

In general, the empirical research shows that the use of hypermedia software as learning systems may not necessarily lead to improved performance, as is widely believed by educators. It seems that when "too much" freedom (as in the case of a conventional or network schemata) or "not enough" freedom (as in the case of a hierarchical schemata), is provided to the learner, performance may suffer. However, the results do indicate that hypermedia can lead to improved performance when the software is "appropriately" structured for the learner. Furthermore, it appears that hypermedia learning systems can provide (once again, when appropriately structured) an effective means for promoting and developing the learner's higher-order cognitive skills [Paolucci 1997]. Additionally, the research shows that learners with certain cognitive styles (labeled active, exploratory, or field-independent) may perform better in a hypermedia learning environment than those with others. This finding seems to be more conclusive when the cognitive style variable interacts with other factors, such as knowledge structure and advisement [Paolucci 1997, Paolucci & Wright 1996; Shin et al. 1994; Brooks et al. 1985].

The results imply that educators and designers need to be careful and pay close attention to how hypermedia software is used in the curriculum. Although the technology has tremendous flexibility in providing dynamic learning environments for all types of students and needs, this quality seems to be a double-edged sword. It seems that if the hypermedia learning environment is too structured, some students lose interest and the learning objectives may not be achieved. On the other hand, if this environment is too unstructured, some students may become confused and lose interest. Strategies for adding structure to hyperdocuments, such as those employed by the research reviewed in this article, are recommended to minimize this problem. This is probably more important for younger students (e.g., adolescents), who perhaps require more structure with their learning environments, and may need to be scaffolded throughout this early learning stage.

It seems that scaffolding students through the learning process is particularly useful when using hypermedia. It may be an appropriate learning strategy to decrease the level of structure of the hypermedia learning system as the students grow intellectually, culminating at the stage where they can actually develop their own hypermedia documents and construct knowledge (as many constructivists advocate). The important point to be made here is that this process will be highly dependent on the individual's skills and knowledge base, thus any strategy should be individualized. Teachers are encouraged to assess their students' cognitive abilities (e.g., cognitive styles) in order to design instructional strategies for optimal learning.

Moreover, it is important that hypermedia software developers use adaptive design strategies to address these issues. Research and development work on this class of hypermedia systems (i.e., adaptive hypermedia systems) is highly encouraged. Similarly, curriculum and instructional designers need to be keenly aware of the proper applications.
of multimedia information. It seems that, although multimedia information may attract the attention of the learner (especially the younger ones), and perhaps enhance the learning of new knowledge, textual information still remains the key component in the transfer of knowledge with hypermedia [Paolucci 1997]. Designers need to make sure that, if multimedia information is used in authoring hypermedia (as it should be), it is used to compel the learner to also read the text.

Currently, with the explosive growth and popularization of the Internet's World Wide Web, many teachers and educators (even at the elementary levels) are using highly hypermediated systems as learning environments. Additionally, the trend within many classrooms seems to be in letting students create their own hypermedia documents. Although these hypermedia projects may be deemed to be "cool" and fun by the students and teachers, very rarely is the question of whether knowledge of the domain has been acquired or learning has taken place. As this research study has shown, if the knowledge domain is too unstructured (as is definitely the case with the World Wide Web), learning becomes very difficult, especially for younger students. Therefore, structuring the World Wide Web or any other similarly hypermediated technology to meet the cognitive skills and knowledge base requirements of the learner is critical.

Finally, it is worthwhile to note that, in his experiment, Paolucci (1997) observed that quite a few subjects (adolescent students) had difficulty concentrating and focusing on the task at hand. Whether hypermedia can be effective for these students is questionable. On the contrary, unfortunately, it may even exacerbate this condition by providing an overly stimulating learning environment.

Abstract In hypertext systems, structure is considered useful but “formality is considered harmful” [Shipman & Marshall 94]. This happens because hypertext authoring is a complicated cognitive process that consists of recursive activities, like emergence of ideas, representation and structuring of ideas, evaluation and update. Our aim is to provide a hypertext model and authoring methodology which combines structured documents, incremental document formalization and document evaluation techniques. A constraint model is used as the underlying foundation of the approach.

1. Introduction

Hypertext has been pointed out as a significant methodology for organizing and presenting course material, primary because it enables instructors to interconnect multimedia pieces of knowledge in a plethora of ways and to offer many access paths for exploration to their students. Incorporating structure in hypertext is considered as a solution to the cognitive overhead and disorientation problems. The objectives of a course presentation are better attained when the students are able to construct a cognitive model of the domain [Brok 97].

On the other hand, hypertext authoring is a complicated cognitive process that consists of recursive activities, like emergence of ideas, representation and structuring of ideas, evaluation and update [Nanard & Nanard 95]. Flexibility in definition of hypertext semantic schemas and authoring of specific documents, is an important prerequisite in order to support the authoring mental process and to avoid “premature organization” problems. Additionally, authors are unwilling to follow the formal schema of a hypertext application from the beginning of the authoring process [Shipman & Marshall 94]. On the contrary, they prefer to start with an informal document and gradually conform it to the schema. Furthermore, these authoring methodologies should be integrated into a document life cycle model, which includes a number of phases, e.g. design, implementation, testing, evaluation and maintenance [Nanard & Nanard 95] [David et al. 97].

A number of hypertext structuring and authoring methodologies and tools have been proposed recently [Marshall et al. 91] [Garzotto et al. 93] [Isakowitz et al. 95]. All these approaches focus mainly on the structural expressiveness of the hypertext model and/or the design of the presentation and navigation aspects of the application. Little or no attention is paid on the support of the mental authoring process. Another critical aspect in educational hypertext environments is the reuse of learning material. This includes not only the reusability of content, such as images or texts, but also the reusability of conceptual structures, such as node and link types. Reusability improves the cost-effectiveness during authoring and ensures the consistent expression of the same concept in different contexts.

The purpose of this paper is to propose a hypertext model and authoring methodology which combines semantic schema definition, incremental document formalization and document evaluation techniques. Our point of view is that a hypertext semantic schema consists of a set of typed nodes and links. Their composition and properties as well as the relationships among them, can be viewed as constraints that express the semantics.
of the domain and restrict author's actions. An informal document is one that does not satisfy some of these constraints. By handling the activation of the constraints, author can determine the level of formality during authoring. A prototype system that supports our model and methodology has been implemented and has been used in two educational scenarios as described later.

The rest of the paper is organized as follows: Sections [Hypertext Model] and [Authoring Methodology] present in detail our hypertext model and authoring methodology, respectively. In section [Implementation] we discuss the implementation of the system, while in section [Conclusions] we conclude and present further work.

2. Hypertext Model

The methodology is based on the use of templates which describe the structure of hypertext applications. Templates are used as patterns in order to construct real applications, i.e. networks of nodes and links, which we call webs. For example, a "Book" template can be devised to enable authoring of books. Obviously, many different webs can be constructed from a single template, thus achieving reusability at the application type level.

A template is constructed by smaller components, node types, which are interconnected by link types, collectively called the schema of the template. Node types and link types are used to model conceptual entities and their relationships. Each of these types may generate one or more nodes and links in the resulting web, interconnected in a similar way. Continuing the book example, a node type could represent a chapter or the table of contents of the book. Node and link types may exist independently of a template, enabling reusability at the component type level. Templates may also employ externally defined templates, a feature that permits modular application design.

The information contained into nodes and links is stored in attributes. Attributes may be defined on the basis of primitive data types or conceptual attribute types. Attribute types represent low level domain semantics, enabling reusability at the data level. Attribute types, node types and link types may be defined either locally in a template or inside a repository of types. In the second case, the same type can be used in many templates that share some low level semantics. Obviously, templates are reused as well and may be included in a repository.

Besides reusability of conceptual types and templates, another dimension is the reusability of real data of nodes. Generally, nodes cannot exist independently of a web, but as a special case, a repository may contain collections of node instances that can be reused in many webs.

The following figure [Fig. 1] depicts the parts of the hypertext model. In the following subsections we present in more detail the parts of the hypertext model.

![Hypertext model](image)

**Figure 1: Hypertext model**

2.1 Basic Objects and Object Types

Attributes and Attribute Types. An attribute is the smallest unit of information and is based on an attribute type or a primitive data type. Attribute types are based on a set of predefined data types (integer, real, string,
enumeration, text, image, html etc.) and may be simple or composite. Composite attribute types contain a set of simple attribute types. Furthermore, an attribute type may have a default value. As an example, consider the concept PersonName that can be modeled as an attribute type based on the string data type. Attributes may be used only in the context of a node or link instance.

Nodes and Node Types. Nodes are the basic building blocks of applications and are based on node types. A node type is a named set of attribute types, each of which may be declared as optional or mandatory and may be constrained to have a bounded (min, max) number of values. Two abstraction mechanisms are supported for node types: specialization (or subclassing) and aggregation. In the case of specialization, a node type is introduced as a subtype of one or more node types and inherits all their attributes types. An aggregate node type is an abstract representation of a set of existing node types. Instances of an aggregate node type may originate from any of the aggregated node types. Node types may be assigned a special meaning and generate the following categories of nodes: Index nodes that contain links to other normal or index nodes, entry nodes that are candidates for starting points while navigating the web and collection nodes that contain a set of other nodes.

Links and Link Types. A link type is a named relationship between node types. Link types may have a set of attributes as well as two sets of allowable source and destination node types, respectively. Links can be anchored to a node as a whole, to an attribute of a node or to an anchor on an attribute's value. Each link type belongs to one of the following categories: Structural link types that denote the basic organization of the application and reference link types that denote cross-references between node types.

2.2 Template Schema

A template schema is a collection of node types, link types and externally defined templates, interconnected in a graph-like structure. A vertex in the graph may be either a node type or another template, while the edges of the graph are link types. When a node type, link type or template is inserted in the schema, it is assigned a specific role and it is called bound. Apparently, a type or template may be bound more than once in a template, under different roles.

Generally speaking, the topology of the schema determines the structure of the resulting webs. In the simplest (default) case, each schema element generates an instance of the same type in the web. For example, a node type under a specific role corresponds to a node of the same type and role in the web. In the general case, one element of the schema may be used to generate multiple instances of the same type in a web. Specifically, bound node types can be constrained in the following ways: a) By the (min, max) number of nodes that can based on them, b) by the (min, max) number of links, possibly of a specific link type, that may depart/arrive from/to the generated nodes. Bound link types may be constrained by the (min, max) number of links of the same type that may exist between two nodes.

2.3 Constraints

As it is inferred from the previous subsection, the definition of a template produces a set of restrictions that directs and (at the same time) limits the author's actions. Examples of such restrictions are the source node type of a link type with a certain role in the schema, the number of nodes that can be generated by a bound node type, or the specification of an attribute type of a node type as mandatory, to outline a few of them. All these restrictions constitute first class objects, that we call constraints and are represented using a constraint model, as it is explained later. Constraints play a central role during the authoring process: by activating and inactivating certain constraints, different levels of formality may be achieved. In this manner, the author is able to create informal webs and evolve them gradually until they conform to all the template constraints. Furthermore, the types of constraints that are produced from the template schema, does not include all the semantic restrictions that the designer may wish to incorporate in the template, e.g., the existence of a path between every pair of instances of two specific node types. For this reason, besides the template schema, the designer is able to express additional constraints such as path restrictions and distances between pairs of node types. The detailed description of all the schema-derived and additional constraints that are supported by our model, is out of the scope of this paper.
Every constraint has the following characteristics:

- The object(s) the constraint is imposed to. This may be a single component (such as a node type or an attribute type of a link type), a set of components of the same type (such as all the node instances of a bound node type), or the web as a whole.
- The strictness of the constraint. Hard constraints should never be violated. Soft constraints generate warnings but do not affect the corresponding operation.
- The stage of the authoring process that the constraint is active. Empirically, we divide the authoring process into four stages: starting, draft, pre-release and final. By declaring the stage, the author is actually determining the level of formality he wants to work with. During authoring, there are active the constraints of the declared stage, plus the constraints of all the previous stages.
- The event(s) that cause(s) evaluation of the constraint. For example, constraints for the node type instances may be defined on the following events: create, save, delete, add-link and delete-link.
- An optional pre-condition expression, a condition expression and an optional message. When an event assigned to a constraint occurs, the pre-condition expression is evaluated. If the result is “true”, (or if there is no pre-condition at all), the condition expression (which represents the constraint itself) is evaluated. A “false” result means that the constraint is violated and the specified message informs the author for the problem. Also, if the constraint is defined as hard, then the event is canceled, as stated above.

More formally [Storey et al. 96], a constraint is defined using the following syntax:

Constraint <constraint name> At <formality level> With <certainty>
On <event> [, <event> ...] 
[If <pre-condition>] Assert <condition> [Else <message>]

For example, if there is a strong reason for a web to have at most 100 nodes of type Person, regardless of the formality level, the following constraint is created:

Constraint MaxPersons At starting With hard
For Person
On create
Assert count(Person)>100
Else "The web has already 100 Persons. You cannot create more."

It should be noted that the designer is not required to express constraints using this syntax. All constraints are automatically derived either from the template schema or from a graphical user interface, dedicated for the definition of additional constraints. The author can only adjust the formality level and certainty of a constraint. The designer of the template defines all the other characteristics. In order to support the designer, certain default values are assigned to the formality level of a constraint, according to the object and event characteristics.

3. Authoring Methodology

The proposed authoring methodology consists of an iteration of the activities of template definition, web authoring and web evaluation [Fig. 2].

- Template definition. This action is carried out by the designer and is divided into three interwoven phases. At the first phase, the designer creates the new node and link types that are necessary for the application. He can create new attribute types or select from a repository. Also, he has the opportunity to add the new created types to a repository for later utilization. At the second phase, he defines the template schema by assigning roles to node and link types and interconnecting them. He can select node types from those previously defined in the template or from a repository. At the third phase, he specifies the various properties of the node types, link types, node-to-link connections and the schema as a whole. During the above phases, the set of constraints of the template is automatically created.

- Web authoring. This action is carried out by the author (who may be the same person as the designer) and involves the creation of a web. The author specifies the desired level of formality to work with. According to this, certain constraints are enabled to prevent invalid actions. The author can modify
certain properties of the objects in the template schema in order to influence the behavior of the constraints. This action is described in detail in subsection [Authoring Flexibility].

- Web evaluation. At any time during authoring, the author is able to evaluate the web. The set of constraints and the current formality level are taken into account and various results are produced: Elements of the web that violate active constraints and suggested modifications that are needed in order the web to conform to the next level of formality. After the evaluation, author may update the web, alter the activation of constraints and trigger a new evaluation.

In the following subsections, two important aspects of the authoring methodology are discussed. The first one is the impact of evolving elements at the repository or at a template, especially when webs are already based on them. The second one is the flexibility that is offered to the author in order to incrementally formalize the web while authoring.

![Authoring actions](image)

**Figure 2: Authoring actions**

### 3.1 Evolution

Evolution operations to the repository or to the templates are performed in a controlled and limited manner, because they may produce inconsistencies to already defined templates and webs, respectively.

Repository evolution should leave the repository as well as the templates based on it, in a consistent state. The basic rule is that an element of a repository cannot be updated if it is used on at least one template. Only the addition of new types is unconditionally permitted. All the other operations (renaming, removal, subclassing, property updating) are permitted only if there are no templates that use the elements that are directly or indirectly affected.

Template evolution is restricted in order to protect existing dependent webs. If no dependent webs exist, then the template may be freely updated. In the contrary, only addition operations may be performed unconditionally by the designer. An exception exists when the designer is also the author of all the depended webs. Then, any evolution operation is permitted to the template. The webs that are affected are marked as "invalid" and the evaluation action is forced to run the next time they will be edited, in order consistency to be achieved. Additionally, if a web is already in edit mode when a template evolution operation takes place, then the propagation of the operation is immediate. Authors can not modify the template. They have only the ability to update certain properties of the elements in the template schema, in order to influence the behavior of the constraints. This latter case is described in the next subsection.

To present the detailed semantics of every evolution operation and its effect when it is propagated to a template or web, is out of the scope of this paper.

### 3.2 Authoring Flexibility

The main contribution of the proposed authoring methodology is the flexibility it offers, inspired by two fundamental observations:
Every creative activity (such as designing or authoring) is a mental process and not only a sequence of formal steps [Haake et al. 94] [Nanard & Nanard 95].

Users are unwilling to provide formal information from the beginning of their interaction with a computer system [Shipman & Marshall 94]. They prefer to start with an informal version of their project and incrementally transform it to the desired level of formality.

As described in the previous subsection, our methodology permits evolution operations to repository, template and web level, although in a controlled manner. In case the designer of the template is also the author of the dependent webs, all evolution operations are permitted and the evaluation action will suggest the update operations needed in the web.

On the other hand, according to the level of formality, certain restrictions are relaxed while authoring. This is possible because each constraint in the template is assigned a formality level of activation. This assignment is made automatically while the designer defines the template. As the template evolves, so does the set of constraints. Additionally, the author of the web, although has not the ability to modify the template, he has access to certain properties of the template elements that influence certain constraints. In this way, the author has the ability to reach formality in his own pace.

4. Implementation

A working prototype of the proposed hypertext model has been implemented in the framework of the “Buildings’ Memory” project and is currently being used for research and educational purposes at the Architecture Engineering Department of the National Technical University of Athens. Aim of the project was the development of a software system to support the analysis and study of traditional buildings. Buildings should be analyzed into various types of construction units, each unit should be described in detail (structured data, text, images, technical drawings, materials etc.) and be interconnected to other entities. The main requirement was to use templates that could exploit the common characteristics of buildings and additionally be able to express the complete structure of each building. Furthermore, during building analysis, domain knowledge is refined, leading to template and building evolution.

The system is successfully used for two educational scenarios. In the first one, the instructor creates a template for a set of traditional buildings. Template is used to analyze and document each building and students use the resulting webs. The second scenario is an exercise for the students. The instructor provides a template and each student is responsible to collect and organize the information needed to construct a valid web for the template. Students start with an informal web and, guided by the web evaluation procedure, evolve it to the required level of formality.

5. Conclusions

The contribution of our approach is that we integrate the concepts of structured hypertext, flexible authoring and evaluation in the same model, using an underlying constraint model. Future work includes three main directions. An important issue is to enhance the presentation features of the system. Right now, a simple WWW interface is used for the presentation of webs. Another issue is to further develop the type and number of template constraints supported by the system, without reducing ease of use [Osterbye 95]. The last issue is to support versioning of templates, in order more flexibility in repository and template evolution to be attained.

Using Interactive Visualization For Teaching The Theory Of NP-completeness

Christian Pape
Universität Karlsruhe, Institut für Logik, Komplexität und Deduktionssysteme, 76128 Karlsruhe
pape@ira.uka.de

Abstract: In this paper we investigate the potential of interactive visualization for teaching the theory of NP-completeness to undergraduate students of computer science. Based on this analysis we developed some interactive Java applets which we use to present an NP-complete tiling problem PUZZLE in our lecture. This software is integrated into our hypertext lecture notes and our students also use it to find an NP-completeness proof for PUZZLE as an exercise.

1. Introduction

The notion of NP-completeness plays an important role in computer science. It is commonly agreed that once a problem is known to be NP-complete it is unlikely to find an efficient, i.e. polynomial time, algorithm to solve it. This has practical consequences: Many existent optimization problems are known to be NP-complete and, hence, it is usually a waste of time to try to develop algorithms for these problems with standard techniques like, for example, divide-and-conquer. Instead other techniques like simulated annealing are employed, that often lead to good and acceptable results in practice. Therefore it is important that students of computer sciences understand the concept of NP-completeness, and are able to check whether a problem is NP-complete or not.

Due to the rigorous mathematical treatment of complexity theory, many (if not most) undergraduate students have a serious problem mastering the concept of NP-completeness and, moreover, in developing their own NP-completeness proofs. We will report in this paper on our ongoing activities to use visualization in teaching theoretical computer science at the undergraduate level and show how the education of the theory of NP-completeness can benefit from multi-media techniques.

After recapitulating basic concepts of complexity theory we investigate the potential of interactive visualization to support the development and presentation of NP-completeness proofs. Then we illustrate our ideas using a certain NP-complete tiling problem as an example, which is presented in our lecture with the help of Java-applets. Furthermore the students use this software to develop an NP-completeness proof as an exercise. These applets and other interactive courseware is integrated into our HTML based hypertext lecture notes (http://iL2www.ira.uka.de/info3/skript/companion/companion.html). It can be used with every Java capable HTML browser.

2. Basic Definitions

To make sure that we are on common grounds we briefly rehash the definitions of Turing machines, the classes P and NP, and the notion of NP-completeness. We refer to [Kfoury et al. 1986] for a detailed description. Turing machines (TM) are the traditional way to formalize the notion of computable functions. They were invented in 1936 by Alan Turing [Turing 1936] and because of their simplicity they are still a very attractive and convincing concept. A deterministic Turing machine (DTM) consists of:

1. A two-way-infinite tape divided into cells. Each cell contains a symbol taken from a fixed set $\Sigma$. A special symbol $B$ (blank) must occur in $\Sigma$.
2. A read/write head scanning exactly one cell at a time and being able to move along the tape.
3. A control unit which at any point in time is known to be in one internal state taken from a fixed set $\Gamma$ of states.
The behavior of the TM is described as follows by a transition function \( \delta : \Gamma \times \Sigma \rightarrow \Gamma \times \Sigma \times \{L, R, U\} \): If \( q \) is the current state of the TM, \( s \) is the symbol currently scanned, and \( \delta(q, s) = (r, t, d) \) holds, then the TM overwrites \( s \) with \( t \), changes to the internal state \( r \), and the read/write head, according to the value of \( d \) moves to the left if \( d = L \), to the right if \( d = R \) or remains at the current position if \( d = U \). The Turing machine \( \text{stops} \) if \( \delta(q, s) \) is undefined for the current state \( q \) and the current symbol \( s \). A configuration of a TM \( T \) consists of the head position, the current tape, and state of \( T \). A configuration is denoted by the relevant part of the tape written as a string with the current state before the symbol corresponding to the cell under the head. For example \( B00q_11B \) is a shorthand for a TM consisting of: the tape with symbols 0, 0, 1 and blanks to the left and to the right; the current state \( q_1 \); and the read/write head over the cell with symbol 1. A DTM \( \text{computes} \) a function \( f : \Sigma^* \rightarrow \Sigma^* \) starting with an initial state and a tape that contains in some way the arguments for \( f \). Instructions are provided to read the function value from the final tape inscription when the TM stops.

Non-deterministic Turing machines (NTM) are defined similar to deterministic TM but with a transition function \( \delta : \Gamma \times \Sigma \rightarrow 2^{\Gamma \times \Sigma \times \{L, R, U\}} \) mapping a state and symbol to a set of possible actions. The behavior of the NTM is defined as follows: If \( q \) is the current state of the NTM and \( s \) is the symbol currently scanned, then one triple \((r, t, d) \in \delta(q, s)\) is chosen non-deterministically and the internal state of the NTM changes accordingly.

A (deterministic or non-deterministic) TM \( \text{decides} \) a language \( L \subseteq \Sigma^* \) iff it stops on every input \( w \in \Sigma^* \) and the final tape contains a 1 if \( w \in L \) holds, and a 0 otherwise.

In complexity theory, problems are encoded into formal languages \( L \subseteq \Sigma^* \) for a fixed signature \( \Sigma \) to abstract from their informal description. An instance of a problem is a word \( w \in \Sigma^* \) and the question is whether \( w \) belongs to \( L \) or not. This makes it much easier to investigate them in a more general way. Therefore we assume that a decidability problem consists of a language \( L \subseteq \Sigma^* \) such that \( x \in L \) iff \( x \) is solvable. By definition \( L \) is decidable iff the question \( x \in L \) can be decided for every \( x \in \Sigma^* \) with a (deterministic or non-deterministic) TM. It is commonly agreed among computer scientists that all problems which can be solved by a DTM within a polynomial time bound are feasible, i.e. an efficient algorithm to decide it exists. All other problems are not feasible. This classification leads to the following definition: The class \( P \) and \( NP \) are the sets of all problems \( L \subseteq \Sigma^* \) which can be decided by a deterministic resp. non-deterministic Turing machine \( T \) in at most \( p(n) \) steps where \( p \) is a polynom and \( n \) the length of the input word \( w \in L \). Because every problem in \( NP \) is bounded by a polynom the following can be proved:

**Theorem 1** For every language \( L \subseteq \Sigma^* \) in \( NP \) there exists a non-deterministic TM that stops on every input with resulting output 1 iff \( w \in L \) holds.

First of all one might guess that NTM are more powerful, i.e. can decide more problems than deterministic ones. However, this impression is wrong and a proof is presented to undergraduates that both models are equally powerful. But one might expect that non-deterministic computations are less complex than deterministic ones. If this is really the case, i.e. \( P = NP \) holds or not, is one of the most important unsolved problems in computer science, because currently only exponential time algorithms are known to solve problems that are in \( NP \) but not in \( P \). The technique of reduction and notion of \( NP \)-completeness can be employed to find such unsolvable problems: A problem \( L' \) is polynomial reducible on a problem \( L \), denoted by \( L' \leq_p L \), if there exists a DTM that computes a function \( f : \Sigma^* \rightarrow \Sigma^* \) in polynomial time such that \( w \in L' \) iff \( f(w) \in L \). A problem \( L \in NP \) is \( NP \)-complete if every problem \( L' \in NP \) is polynomial reducible on \( L \), i.e. \( L' \leq_p L \).

If one could show \( L \in P \) for an \( NP \)-complete problem \( L \) then \( P = NP \) holds. On the other hand, if \( P \neq NP \) then all \( NP \)-complete problems are known to be infeasible. However, in either case it is of practical interest to know whether a problem is \( NP \)-complete or not.

### 3. Developing and Presenting NP-completeness Proofs

There are two general methods for proving the \( NP \)-completeness of a problem \( P_1 \subseteq \Sigma^* \): First, by finding a polynomial reduction from another problem \( P_2 \subseteq \Sigma^* \) which is known to be \( NP \)-complete, i.e. \( P_2 \leq_p P_1 \). Second, by an elementary proof, i.e. by giving a transformation, computable in polynomial time by a DTM, that maps every NTM with a given input tape into an instance \( I_t \in \Sigma^* \) such that \( I_t \in P_1 \) iff the corresponding NTM stops. The main part of both methods is the construction of a mapping from one domain (a NTM or an \( NP \)-complete problem) into another domain (a problem).

Interactive visualization can support the presentation and development of such an \( NP \)-completeness proof in several different manners: If the problem itself is presented in a lecture or textbook, then it is a useful and traditional
approach to give a visualization of some examples of the problem. An electronic text, in addition, can visualize
the problem in many other ways: Instead of presenting static pictures, it is possible to simulate an instance of the
problem, for example, an instance of the traveling salesman problem can be represented as a graph (or map) and
the students can search for a short round tour interactively. This may give them a better comprehension of the
problem and its complexity. Moreover, instead of choosing one instance of the problem, it is possible to provide
an editor for typing in an instance of the problem and then investigating it interactively. If a reduction \( L \leq_p L' \)
is used in a proof, then both problems \( L \) and \( L' \) can be visualized as described. But what is more, we are able to map
an instance of \( L' \) into an instance of \( L \) and investigate the effects and properties of the transformation visually.

If an NP-completeness proof is not given but has to be carried out by the student, e.g. as an exercise, then an
interactive visualization can also help him understanding the problem better. However, the crucial and difficult part
of any NP-completeness proof is the construction of the mapping between the two domains. It is likely that most
students fail on the first attempt to find the correct transformation. Here an interactive software can help them to
test their transformation on suitable problem instances. First of all, the student has to type in the transformation
(which depends on the given problems). An appropriate implementation can focus on the relevant and interesting
parts of the transformation such that nonsensical inputs are impossible. The student then has the opportunity to
test his transformation for errors much easier than doing it by hand. As another advantage, the result can often
be checked automatically (for example if only finitely many correct transformations exist). Thus the student get
immediate feedback on the correctness of his solution. But even if the solution can not be checked automatically,
it may be possible that the student can test his solution on certain instances of the problem interactively with the
help of a simulation of the problem. In many situations it might also be possible to generate counterexamples for
wrong solutions automatically. These counterexamples then can be inspected with the help of the software.

As an additional remark let us note that the technique of reduction is not restricted to the framework of NP-
completeness. In computer science reductions are also used, for example, to prove lower time bounds or the
undecidability of problems; thus most of the above techniques for visualizing reductions can be used in these areas
as well.

4. NP-completeness Proof for a Tiling Problem

Every introduction into the theory of NP-completeness starts with the definition of the classes \( P \), \( NP \) and the notion
of NP-complete problems, and then presents the technique of reduction to prove the NP-completeness of one
problem using the known NP-completeness of another problem. However, this leaves open the question of how to
proof the NP-completeness of the latter problem. In our lecture we do this by presenting Cooks Theorem, which
states that the problem of deciding the satisfiability of propositional formulas is NP-complete [Cook 1971], and
we give an elementary proof based on a transformation of NTMs into propositional formulas.

To understand this transformation one has to be familiar with propositional logic. Though first year students are
taught basic parts of formal logic, many (if not most) of them have problems to understand the proof, in particular
its general scheme and the validity of the transformation. To make sure that the students well understand this proof
and the concept behind it, they have to carry out an elementary NP-completeness proof for another problem — a
tiling problem — as an exercise. In our hypertext the presentation of this problem is supported by an interactive
simulation of some of its instances; and we developed a Java-applet which makes it much easier for the students
trying to solve the exercise.

4.1. The Tiling Problem

Consider the following tiling problem PUZZLE [Wagner 1994];
INSTANCE: Given an alphabet \( \Sigma \), a collection \( T_1, \ldots, T_n \in \Sigma^4 \), \( n \geq 1 \) of “tiles” (where \( \langle a, b, c, d \rangle \) denotes a type
of tile with top side \( a \), right side \( b \), bottom side \( c \), and left side \( d \)), and a quadratic frame \( F \in \Sigma_t^4 \), \( t \geq 1 \).
QUESTION: Is it possible to fill the frame \( F \) with tiles of the type \( T_1, \ldots, T_n \) such the sides of the tiles match
with the corresponding sides of the frame and their neighboring tiles?

In our lecture notes we exemplify this problem with visual representations of two small instances: one which is
solvable and another one which has no solutions. Part (a) of [Fig. 1] shows the paper version of the solvable exam-
ple, where \( \Sigma = \{1, 2, 3, 4, 5\}, t = 3, F = \langle 1, 2, 3, 1, 1, 3, 2, 5, 2, 2, 3, 5 \rangle, T_1 = \langle 2, 3, 2, 4 \rangle, T_2 = \langle 2, 1, 2, 3 \rangle, T_3 =
\langle 1, 4, 2, 2 \rangle, T_4 = \langle 4, 4, 5, 5 \rangle, T_5 = \langle 2, 5, 2, 5 \rangle \). The quadratic frame of an instance of PUZZLE is build from \( F \)
starting from the top left edge in clockwise orientation.
In the hypertext this picture is omitted and replaced by a simulation of the instance (see part (b) of [Fig. 1]): Here, the students can pick the tiles with the mouse and try to fill the frame with them. If two tiles do not fit, i.e. the touching borders have different symbols, then these parts are highlighted black. The advantage of this simulation over the paper version is the immediate response to a wrong or correct attempt to solve the instance, which makes it easier for the student to understand the problem in detail. After some experiments with the simulation most students should be familiar with PUZZLE, in particular because of its obvious relation to jigsaw puzzles.

![Simulated PUZZLE instance](image)

(a) paper version

(b) simulation in hypertext

Figure 1: Example of PUZZLE

For the proof of the NP-completeness of PUZZLE we consider one-way-infinite Turing machines, which differ from two-way-infinite Turing machines only in the restriction that the tape has a leftmost cell (and an infinite supply of cells to the right); in case the transition function attempts to move the head off the tape to the left the machine just stops. In our lecture we prove that the expressive power of one-way-infinite Turing machines does not differ from that of two-way-infinite ones. Its proof is based on a transformation of one type of Turing machine into the other. The proof is given in our hypertext lecture notes; its central parts are visualized with corresponding simulations of the original and the transformed Turing machine (see [Pape and Schmitt 1997] for details).

4.2. Supporting the Development of an NP-completeness Proof for PUZZLE

The central part of the NP-completeness proof of PUZZLE is to show that every problem \( L \in \text{NP}, L \subseteq \Sigma^* \) is polynomial reducible on PUZZLE. By definition of NP and Theorem 1 we conclude that a (one-way-infinite) NTM \( T \) exists that stops on input \( w \in \Sigma^* \) with final output 1 after \( p(|w|) \) steps (where \( p \) is a polynomial) iff \( w \in L \) holds. From the description of \( T \) and given input \( w \) we have to construct an instance of PUZZLE that is solvable iff \( T \) stops on input \( w \) with final output 1.

The main idea of the proof is to simulate \( T \) with the corresponding instance of PUZZLE by encoding a configuration of \( T \) and all possible transitions into a row of tiles. These tiles must be designed such that a row \( r \) of tiles fits under the preceding row iff \( r \) corresponds to a next possible configuration of \( T \). The top side of a tile contains the symbol of the corresponding cell. If the read/write head is over this cell than the current state is added to the top side, too, and the left and right sides of the tiles are used to simulate the head movement over the tape. The bottom side of a tile contains the information for the resulting configuration. The frame of the puzzle has size \( t = p(|w|) \) and is generated as follows: The top side of it is constructed from the given input tape and initial state of \( T \); the bottom side is build from the given output 1 (the rest is filled with blanks); the left and right side is filled with special symbols (#) not occurring in \( \Sigma \).

[Fig. 2] shows an example for a puzzle related to some TM (the details of the TM need not to concern us here): The top side corresponds to the initial configuration \( q_101B \) and the bottom side corresponds to a (desired) final configuration \( q_2100B \). The first row of tiles corresponds to the initial configuration \( q_101B \) (top side of tiles) and the resulting next configuration \( 1q_11B \) (bottom side of tiles); the tile in the top left corner of the puzzle simulates the transition \( \langle q_1, 0 \rangle \rightarrow \langle q_1, 1, R \rangle \).
The difficult part of the proof is to find this transformation. For an introductory course on complexity theory this task is far too complex to solve without any hints. To make the search for a correct transformation easier, we developed a Java-applet with which it is possible to specify the transformation, to type in a Turing machine to which the transformation is automatically applied, and to try to solve the resulting puzzle. The frame is build automatically from the input tape and the output; therefore it is not necessary for the student to specify this part of the transformation. Furthermore, the graphical user interface for the input of the transformation is designed to forbid as much nonsensical inputs as possible without giving too much hints.

It is possible to classify the types of the tiles into six categories depending on the different actions and states of the NTM. Recall that a tile is directly related to a cell of the tape:

1. Neither before nor after the next step of the NTM the head is over this cell of the tape.
2. \((p, b, U) \in \delta(q, a)\), i.e. the head is above this cell, a new symbol is written to it, the head moves to the right, and the internal state of the NTM changes. In the applet the correct solution for this category is given as a hint.
3. \((p, b, R) \in \delta(q, a)\), analogous to 2.
4. \((p, b, L) \in \delta(q, a)\), analogous to 2.
5. The head moves into the cell from the left.
6. The head moves into the cell from the right.

In these categories \(a, b\) and \(q, p\) are placeholders for the corresponding symbols and states of the NTM. The input of the transformation for one category is done by a multiple-choice selection of symbols, states, or pairs of symbols and states (see [Fig. 3] for categories 2 and 5). This approach makes it a lot easier for the students to find the correct transformation and it inhibits too much nonsensical input.

After the transformation is typed in, the students can feed in a NTM and have a closer look at the corresponding instance of PUZZLE, which is automatically generated applying the given transformation. They now can experiment with their solution and get confident about its correctness or they can try to falsify it by finding counterexamples, i.e. Turing machines which stop on a certain input but where the corresponding instance of PUZZLE has no solution or vice versa. If the latter happens then it is possible to modify the transformation and they can try to experiment with the new version again.

5. Conclusion and Further Work

We investigated the potential of interactive visualization for the development and presentation of NP-completeness proofs in computer science education and reported on our implementation of an example which incorporates most
of our ideas. We believe that with this software students can learn certain parts of NP-completeness theory much better than with traditional teaching methods. The next step in our work will be a practical test during the lecture and tutorials. Based on this evaluation we are going to improve our software, e.g. by generating counterexamples for wrong solutions. Currently the students’ solutions are still checked by human tutors, but we are also working on a fully automatic intelligent tutor for helping students with checking NP-completeness proofs based on the reduction technique for certain variants of 3SAT.

Abstract: Modern computer science is dominated by multimedia and networking concepts. A great effort is world-wide applied to integrate these technologies in order to provide advanced multimedia services. Teleworking, distance learning, telemedicine and information kiosks are examples of interactive broadband services where the distribution of video information is assuming more and more importance. In this paper we present a technology and a sample application for real-time or near real-time post-processing of MPEG-2 video streams. Reducing the bit-rate for network distribution and the dimension for storage purposes as well as implementing special effects, such as size reduction and picture in picture, are the results of the proposed application.

Introduction

Multimedia has been one of the most exciting technologies of the last decade: a number of applications have been developed taking advantage of the continuously growing computer power. The great diffusion of networking concepts and technologies, the still increasing number of Internet connections and network applications represent the background for a growing interest in the integration of multimedia tools, particularly broadcast video information, with networking.

Audio and video flows require a transport mechanism that intrinsically supports the concept of quality of service (QoS) in order to guarantee the correct information at the right time. Although fast Asynchronous Transfer Mode (ATM) network installations, natively implementing QoS concepts, are quickly spreading, the most diffused Local Area Networks (LANs) nowadays are Ethernet and its high speed variations, namely Fast Ethernet and 100VG-Anylan [Watson 95]. These network technologies use a best effort approach to data transmission, offering any or nearly any control over the quality of service.

On the other hand video services are heavily bandwidth sensitive and par excellence real time applications, consequently, badly fit to a best effort based transport, and an acceptable degree of reliability for video transport is seldom possible on Ethernet like networks [Stuttgen 95]. Starting from the analysis of video compression algorithms, we propose strategies that, acting at the level of the coding layers, can control and adapt the dimension and, consequently, the bit-rate to the availability of bandwidth. This approach will allow increasing the number of users that can be concurrently satisfied by a video server. As it has been experimented that video
acceptability depends on the content [Apteker 95], the availability of a tool for selecting the reduced frame rate
will allow minimising the leakage on the perceived quality of video sequences.

At present the most diffused video compression algorithm for broadcast and high quality digital video, is
Motion Picture Experts Group 2 (MPEG-2) [LeGall 91], thanks to the extremely high quality and compression
ratio obtainable, and its nature of asymmetric algorithm. While the coding process is highly resource consuming,
real time decoding is obtainable on usual PCs with software or low cost hardware implementations. This article
describes a set of tools to adapt a MPEG-2 compressed video stream to network transport requirements acting on
its hierarchical coding structure.

The MPEG-2 standard

The MPEG-2 lossy compression scheme is based on the Joint Photographic Experts Group (JPEG) standard
developed for continuous tone still image compression. It inherits from the JPEG standard the splitting of images
into blocks, the Discrete Cosine Transform (DCT) and the zigzag order scanning of the transformed coefficients
to remove spatial redundancy, and the Huffmann coding [Rabbani and Jones 91]. In order to further improve the
compression ratio, it exploits the temporal redundancy between successive images by mean of a motion
compensation algorithm [Bhaskaran and Konstantinides 95]. In an MPEG-2 compressed sequence three types of
images are present in a fixed pattern.
Intra (I) frames are coded independently from the near neighbours, predicted (P) frames are coded referring to
the preceding P or I frame and bidirectional (B) frames are coded referring to both the preceding and successive I
or P frames. In this way B frames, the most frequent ones, are encoded using the smallest number of bits, while
the I frames, the least frequent, are encoded as nearly plain JPEG, and P frames score a compression ratio
halfway between Is and Bs. The 12, for PAL systems, or 15, for NTSC systems, picture set is called Group of
Pictures (GOP).
The single picture, or frame, is then split into slices, that are 16 pixels high, and each slice is divided into
macroblocks: 16 by 16 pixels areas. In each slice the first and the last macroblocks must be present in the coded
bit-stream, while other macroblocks may be absent, in order to increase the compression ratio, if not significantly
changed since the preceding frame. Finally macroblocks are further split into blocks, that are 8 by 8 pixels image
areas, in particular one macroblock is composed of 4 blocks representing luminance information and 2 to 8
blocks for the down-sampled chrominance information; DCT coding is applied at block level.
The MPEG-2 stream can be scanned, without necessarily interpret its data, down to the slice level, because
each entity (GOPs, pictures, slices and other extensions) is preceded by a 32 bit unique start code in order to
recover from data errors and to allow pseudo-random access in the sequence. Start codes are not present from
macroblock level down because their overhead would be comparable with pixels data amount. In order to
analyse the single block or macroblock it is necessary to fully interpret the stream, including Huffmann
decoding.
From the description of the algorithm [ITU-T 96] we can derive that a frame drop, more than the usual loss
of smoothness of the sequence, may have disastrous consequences. If, for example, an I frame misses, all the
GOP it belongs to is compromised, so if network workload conditions do not allow the transmission of all the
frames, a mechanism to discard dependent frames (Bs and then, if necessary, Ps) is required in order to preserve
independent ones. Furthermore it is possible to get continuous quality degradation, preserving smoothness or in
addition to frame dropping, discarding some AC coded coefficients at the block level. This level of control over
a compressed stream allows creating, on the fly or off-line, a new version of a given sequence drastically
reduced in frame-rate and image quality. For example, by this process, an end-user can have an idea of the
original movie stored in a server, minimising the impact on network load, and choose the quality of the movie
according to specific needs.

A modular approach to MPEG processing

Thanks to the hierarchical MPEG-2 stream format, a lot of processing is possible on an already existing
encoded sequence, provided to have a proper stream analyser working as a filter. Of course it is important that
the output of the filter is still an MPEG-2 compliant stream in order to be transparent to both an MPEG standard
player and to another eventual cascaded filter. This is the concept at the base of the described technology. As long as a number of different processing can be done operating at different levels of the MPEG hierarchy, a convenient tool to access the correct level in a simple and, at the same time, flexible way is needed. Furthermore the consideration that, in order to operate at a given level, all the higher ones must be processed, leads to the Object Oriented Programming as the most suitable technology for this purpose. Once developed a proper component to analyse the MPEG stream structure, more complex and powerful objects can be easily derived.

The stream analyser

The stream analyser object is the building block of the described work. It does not actively do anything on the input bit-stream more than following its semantics and presenting it at the output unchanged. The stream analyser component is developed as a Software Finite State Machine (SFSM) running as a separate thread and implementing the MPEG-2 stream format (see fig. 1).

The first SFSM simply finds a start code and then passes the control to the bigger one, that changes its state according to the last start code found and, at each level, extracts the available data from the stream. If the last start code is a wrong one, which means its not contemplated by the MPEG2 rules, the SFSM enters an unrecoverable error state.

Furthermore it defines the placeholders to properly handle the various data parts of the stream in the specific descending objects. In this approach, flexibility has been preferred to performance; in fact cascading several specialised objects duplicates the elaboration proper of the stream analyser itself, but allows the building of complex filters by simply combining proper blocks. Such approach could well fit a distributed processing among multiple machines.

Frame skipping

There are two kinds of frame skipping objects, both directly derived from the stream analyser, that provide to selectively discard one out of N B or P frames according to the required bit-rate reduction. Of course before discarding a P image, discarding all the B frames is necessary, otherwise the residual B frames can not be properly decoded due to their reliance on P frames.

The generic frame-skipping module adds the handler for the "Start Of Picture" start code to the stream analyser object. It keeps an internal counter for the proper picture type and selects frames that need to be skipped.

Vertical size reduction
Vertical size reduction is achieved by discarding one slice out of n. Of course, being a slice 16 bits high, not all possible sequences lead to a good visual result, but this is the only way to reduce the vertical size without completely decode and re-encode the sequence. Similarly to the frame skipping component, this object adds a custom handler for the “Start Of Slice” set of start codes to the stream analyzer. Slice start code, in fact, is not a unique number but any 8 bit integer between 01h and afh (175d) representing the vertical position of the slice in 16 pixels units.

Once again the vertical size reduction filter should not be used if dependent pictures are still present in the stream, because it destroys data that are in general necessary for the reconstruction of B and P frames.

Low level stream analyzer

In order to process a stream at sub-slice level, that is macroblock and block level, full decoding of the Huffman Variable Length Codes (VLCs) is required because, as stated before, no start code exists for macroblocks and blocks.

This is achieved deriving a new object, the stream low level analyzer, from the stream analyzer component. Conceptually the new component only adds low level processing by mean of linking proper handlers to the placeholders defined by its direct ancestor. Actually, for performance purposes, the SFSM has been partially rewritten to internally implement many of the needed functions, avoiding too many method calls.

VLC decoding is obtained by a set of tables, containing partially decoded Huffman codes, based on the number of leading zeroes or ones of each code. This seems to be a good trade-off, in terms of efficiency and memory consumption, between using fully decoded tables and bitwise decoding by binary trees.

Horizontal size reduction

Horizontal size reduction is obtained in a very similar way to vertical size reduction: instead of discarding slices one macroblock out of n is discarded. The main difference is that the X size reduction module is derived from the low level stream analyzer instead of the stream analyzer object. The same considerations, true for the vertical size reduction module, are valid for what concerns frame dependencies and resolution: P and B frames should be removed before reducing the horizontal size of a sequence. Furthermore, being macroblocks sixteen pixels wide, not all the possible sequences lead to good results because various, eventually important, details of the original stream may be lost.

Performance summary

Figure 2 lists the results obtained with some test sequences encoded at different bit-rates. It is important to note that some performances are strongly dependent on the sequence characteristics and, in fact, only the horizontal and vertical size reduction behaviour is reliably predictable, but the presented data is definitively not a best case test and can therefore be representative of what can be obtained by the developed technology.

Figure 2 - Components performances

Each “Compr Ratio” column gives the compression ratio obtained applying the preceding module. File sizes are expressed in kilobytes.
Continuous quality degradation

Down to block level very interesting results are obtainable also without completely decode and re-encode the stream data. Taking advantage of the structure of the coded transformed data, and in particular the zigzag order, it is possible to easily modify the amount of bits devoted to sequence details both in the luminance and chrominance components. Dropping a number of AC coefficients in a coded block allows reducing the stream bit-rate by a reasonably arbitrary amount. This process lowers the visual quality of the sequence, without introducing artefacts or affecting the overall smoothness of the video sequence.

In contrast with the previously described components, this means that it is possible to apply continuous quality degradation processing without discarding dependent frames, because no data is completely destroyed but only degenerated. Figure 3 gives an idea of the obtainable results in terms of compression ratio vs original bit-rate.

<table>

</tr>
<tr>
<td>12 mb/s</td>
<td>60 - 70</td>
<td>7 - 15</td>
<td>5 : 1</td>
</tr>
</tbody>
</table>

Figure 3 - Further compression ratio vs original bit-rate

The StreamACCut component allows specifying the number of AC coefficients to be passed through, discarding all the subsequent coefficients, for both the luminance and chrominance components. The MPEG standard devotes an amount of data to colour representation far smaller than the one devoted to luminance coding, accordingly to the studies on the Human Visual System (HVS), far more sensible to luminance information than to colour. As a consequence dropping all the chrominance AC data leads only to small gain in terms of compression but with a similarly small loss in terms of visual quality.

Streams merging

Properly integrating two low-level analysers into a new component, it is possible to obtain a picture in picture (PIP) effect. Data from one stream is inserted into another one in an arbitrary position, specified by slice-macroblock co-ordinates.

This sort of processing, once again, requires that all dependent frames be previously removed in order not to generate artefacts in the transition zones from a sequence to the other.

The FilterBuilder application

In order to demonstrate, test and off-line exploit the described technology, a comprehensive application has been built incorporating all the presented components. FilterBuilder 1.0 (see fig. 4) allows to build an MPEG filter, compile it and run it on an existing stream with the help of a visual interface.

The tool bar in the upper side of the application window contains all the active objects available. They are, from left to right: stream reader, stream writer, B-frame skipper, P-frame skipper, H-size reducer, V-size reducer, streams merger, connection creator, connection eraser, component eraser and filter compiler.

After creating the filter placing the desired components on the grid and properly connecting them to one another by mean of the pipe creator, the filter can be saved to disk with the usual file/save menu selection. Then
it must be compiled. In this phase it is checked for correctness and the user is prompted for the proper parameters of each component. In the end the filter is run by the apposite menu item. In the rightmost field of the status bar the user is informed of the number of running threads (components). When that number reaches zero the filter has finished its processing.

![FilterBuilder 1.0 alpha](image)

**Figure 4 - The FilterBuilder application**

**Conclusions and future work**

The described components are advanced building blocks of a potentially very useful and flexible technology. They will be the object of several enhancements in terms of performances, to target actual real-time sequence processing, and robustness, to recover in presence of particular or even faulty streams. On the other hand further development efforts will be devoted to network integration of the presented technology. This means, first of all, distribution of the processing power on multiple machines on a local area network, working at module connection level. A system for network load measurement and estimation will allow to dynamically and automatically modify the components parameters in order to adapt the stream to instantaneous network conditions. To be noted that, at present, component parameters are set at initialisation time and cannot be modified while the component thread is running. As a final task the system will be applied to World Wide Web technology to implement a high performance adaptive video server system.

ABSTRACT

This tool tries to serve as a guide to teachers who are beginning their navigation in this communication space consisting of the World Wide Web (WWW), in order to facilitate a faster access to these resources with educative interest and their later didactic exploitation.

KEYWORD: Navigation. WWW. Didactic resources. Teachers' training.

INTRODUCTION

The soaring growth of this new communication space has generated an important debate about the possibilities that new mass media can offer to learning in all the educative levels.

Currently there are many places where you can connect to explore questions related to education and joining resources to the educative development in new technologies. Some of these places or linkers, like the new and provocative Engines for Education, offer chances to interact in the training subject and the necessity to raise again the question of the current education structures (Del Moral, 1996).

First of all, let us try to provide teachers with the password to the Web servers so that the curricular integration of the net resources found there can become real, for that purpose it will be essential to have a navigation system that makes our objective possible.

Having access to our own Web servers is in itself an enriching educative experience. However, there are methods to access to the WWW with educative purposes in a structured way, where two approaches can be brought out: which should not be exclusive in any case.

- Conceiving it as a closed environment of educative material useful because of its hypermedia and distance learning capabilities.
- To access to a joint of materials that can be designed with educative or other sort of goals but which can be directed with guided educative explorations.
So then, the educative use of the Web sites is undoubted, besides having the features of a hypermedial system, can also have many applications in different fields such as distance learning or the elaboration of didactic materials with an interactive character from the resources available... However, it could be necessary to have some tools that could help us differentiate those useful resources among the large amount of information available. Nowadays, brochures-applications, electronic magazines resource collections divided into themes and, in general, search tools are being developed as simple and immediate information means.

The compilation of all the educative resources interesting for teacher is not an easy task owing to the large amount of information available in the WWW, in spite of the existing educative, interest resources compilations made up by special groups of researchers or experts in specific themes, joined by other educative institutions creating their own connections and establishing a direct connection with those resources that they consider of interest.

Other initiatives provide a detailed guide of Web servers that can offer certain interest to different teacher groups, trying to introduce a brief synopsis of their contents with the intention of exploiting to the full the research efforts and time (Morlá, 1996). Also, some types of Web servers are pointed out, although superficially, that reflect a specific research to each subject related to the educative field, which is the case of the collection of Web addresses about the science field and the scientific knowledge realized by Lowy (1997).

Our proposal can be understood not only as a simple application but with the aim of qualifying, the teacher for developing certain tasks related to the knowledge of the Internet as a new resources generator.

**TIMON: INTERACTIVE TECHNIQUE THROUGH NAVIGATION ORDERS**

The application has a really attractive interface. You can access from the main screen to all the sections that make up the application. These sections widen the user's knowledge, specially those leaners who are familiar with Internet, and those who want to approach to the Net with a specific goal as in looking for new resources without dedicating too much time in order to carry out a didactic exploitation of them and to integrate them in any curricular area. Hundreds of hours of connection can be saved when looking for information or whatever we need and we can obtain material completely free and discover the most interesting new servers of the World Wide Web.

Thematic chapters or sections that have been included offer a big amount of information with which knowledge about the Net can be widened. The structure is so that accessing to the desired information is very easy. The presenting texts are of easy understanding, accessible to all users, but in a special way it is recommended to learners with educative interest to achieve the Web servers that make up the Internet. Other types of tools included are the hypertexts, that offer definitions of terms that could imply a conflict, comments, explanations, complementary information.
With the help of Web Site Menu you will find addresses of interesting web sites, both national and international, gathered together in subjects such as Sciences, Art, Literature, Music, Language, History..., and you can have access directly to them through the application linkers, direct access to the researches... Thus, curious sites such as the NASA one and many others can be known.

Through that application you can connect to other working application available in the Internet Web servers. It gives information about the different didactic resources, their identification formulas and ways of location and key to access to the information they contain with the purpose of being selected and debugged.

The application would try to facilitate the task of those teachers -of the different areas that make up the Primary and Secondary curriculum- in their determination to make effective the educative achievement of the information to the Web servers, helping them rescue those elements that can be useful to complement and illustrate their classes; or providing them with material that can be used to create their own didactic resources, such as multimedia presentations supported by; articles, unpublished videos about certain topics, computer animations, photographs and images of every type that, having been previously organized, can acquire a special meaning in the teaching-learning process.

We want to facilitate the management of the most interesting webs, allowing the complete organization of its storage. Information folders to define a structure of directories and subdirectories can be created. With this application we try to get a faster access to the Web sites, since it allows the texts to be displayed, and a screen scroll of graphics, sound etc...

Firstly access is offered to a thematic directory which contains a selection of classified addresses of diverse Web servers that leads directly, like a key, to the requested sections in Internet. The revision of the included webs could be changed when necessary and others could be added according to their discovery and educative values, but it does not mean that the teacher cannot research whatever and wherever he wants in the Net.

This tool while recognising the many possibilities the Net offers, only tries to facilitate and to speed up the access to those more common resources for teachers, especially those who are beginning their way in this new communication space and in this information hypermarket. That is to say, this application contains the key addresses that a learner interested in Internet must know at least, some of them of a general character because they are linked to educative institutions or organizations; others because they tackled topics directly related to Education; and others because they are closely bound to similar working areas presenting a large training value.

The pages of this application allow all the recuperated and saved information in a data base to be acceded to by the use of hyperlinkers. The main web site is able to present information organized in categories and indexed by URL addresses and in such a way that only the most recent addresses taken from the last process of research are shown. The application is made up of many pages exported from the Web, where you can view the text files and the access routes to other more consistent and bigger (sound, video..) files.
ADVANTAGES

The connection time to the Net is reduced to a great extent which means economic saving web sites could be explored whenever we want without the necessity to be connected, the data can be used like inclusions in presentations, the access to data will be fast and without waiting, researchs in recuperated webs can be realized and, moreover, you could program the bringing up to date of the sites contained in the data base with the frecuency that we want. To sum up, this tool will enable teachers to become independent of the Intenet connection, by locating all the information they need in their own personal computer.

Evaluation of the EuroMET Web-Based Course in Meteorology

Julia Phelps and Ross Reynolds
Department of Meteorology, University of Reading, Reading, RG6 6BB, UK.
Email: J.E.Phelps@reading.ac.uk, R.Reynolds@reading.ac.uk.

Abstract: EuroMET has been created to address the education and training needs of professional meteorologists and students in tertiary education throughout Europe and more widely. Two courses, each modular in format, have been developed for the WWW. The courses have been evaluated at three key points during their development for their usability, scientific content and perceived pedagogical worth. By performing the evaluation in this way, recommendations for improvement could be made to the developers, these improvements incorporated, and all modifications fully tested before the course was considered ready for use. The final versions of the courses are currently undergoing a summative evaluation as they are used in real teaching and training environments. This paper describes the evaluation methods used during this project and the results obtained thus far.

Introduction

The EuroMET (European Meteorological Education and Training) project arose due to both the emerging interest within the meteorological community for Computer Aided Learning and the decision of the European Commission to foster telematic applications within the 4th programme for research and development. The education and training of meteorologists varies widely across Europe. Basic meteorology is taught in many universities, most often as part of other courses, for example geography or environmental science. In universities where it is offered as a comprehensive course, meteorology is generally taught in specialist departments at both undergraduate and postgraduate level. Due to the relatively small number of universities teaching meteorology at sufficiently advanced levels, National Meteorological Services (NMS) usually recruit employees at university degree level and then offer their own training as is necessary or possible. The NMS' education and training courses that exist at present differ greatly across Europe according to the size and organisation of each service. For example, some NMS run their own training courses, such as in France and the UK, and also offer these to other countries unable to offer their own, eg the Netherlands, while other NMS offer very little formal training, eg in Belgium. An important part of these training programmes is extension training, required because meteorological science and technology is continually developing so that new methods and theories need to be taught. At present no distance or open learning courses in meteorology exist within Europe.

Thus it can be seen that within the European meteorological community there is a need for computer-based learning resources not only to enable universities and NMS' training centres to share material, but also to offer an alternative to those NMS which either send staff on costly and time-consuming courses, or currently offer little or no training or education. EuroMET has therefore been created to meet this need. It aims to address the education and training requirements of professional meteorologists and students in tertiary education throughout Europe by establishing a multimedia, networked-based, open and distance learning service. Moreover, this service will be provided in such a way that it can be easily customised to fit local requirements.

The EuroMET consortium is comprised of 23 meteorological partners, i.e. universities and National Meteorological Services (NMS) from 15 European countries and the University of Quebec. The consortium is divided into two groups, the developers who are responsible for delivering the course, and the evaluators who are responsible for assessing the course. The developers are led by Météo France, where the project co-ordinator is also based, and the University of Edinburgh. The evaluation is lead by EUMETSAT (the European Organisation for the Exploitation of Meteorological Satellites) and the University of Reading. The 30 month
The project commenced in June 1996 and is split into three key stages. The first stage, lasting 6 months, was spent producing prototypes. The second stage lasted 12 months, during which time modules for the course were written by the developers, assessed by the evaluation team, and then returned to the developers for modification if necessary. The final stage, the demonstration phase, began in December 1997 and will run for a year, during which time the course will be used in universities and NMS on existing courses and as stand-alone education and training material.

The Course

It was decided that the course would be web-based, to make it easily accessible to everyone within the consortium, easy to include new developments and up-to-date material and also to make it possible to run powerful simulation models. The meteorological subjects for the course were selected in response to a European-wide needs analysis of National Meteorological Services. The two chosen were Numerical Weather Prediction (NWP) and Satellite Meteorology (SM). Both courses are comprised of nine chapters covering different sub-topics with each chapter containing a number of modules and totalling around 70 modules for each course. This modular approach allows teachers at different locations to choose only those modules which are directly relevant to the course they teach.

A common interface was chosen so that each module would look and feel the same. The interface was designed to be as simple as possible so that users could learn to use it as they went along. There is however an online help facility which explains all the navigation buttons and symbols and icons used throughout the course. It was also designed to be language independent, an important consideration for a multilingual project. Each module was constructed in the same way, opening with a motivation page to introduce the topic and engage the user's interest. The next page lists the learning objectives of the module, any pre-requisite modules the user should study first, any subsequent modules which follow on, and a list of module contents. The following pages then contain the teaching material, whilst the final page contains a summary of the material, which draws out the salient points of the topic. Users navigate through the modules by either clicking on arrows on a button bar at the bottom of the screen to progress page by page, either forwards or backwards, or they can click on the 'module structure' button, which enables the user to go directly to any page of their choice. A 'course structure' button similarly allows the user to select any module.

In support of this learning environment is a glossary to explain commonly-used meteorological terms and a keyword index which lists modules which contain material on important terms. Facilities for one-to-one and one-to-many communication are also included, such as email to subject experts, discussion groups and internet relay chat (IRC) areas. Tools to create adapted packages and extra material are also available from the EuroMET WWW site with full documentation, to allow teachers to create an online course from the EuroMET modules completely tailored for their needs.

Course Evaluation

The aim of the evaluation is to assess the course in terms of its ease of use, pedagogical effectiveness, including ensuring its scientific integrity, and utility in replacing conventional teaching, with emphasis on the multimedia aspects of the modules. The course is being evaluated in two main phases, one phase ran during the development work and the other after the development work was completed. The EuroMET evaluation scheme has been planned and executed by all the evaluation partners with occasional advice from staff at the Institute of Educational Technology, Open University, UK and from the EC-sponsored BASELINE and INUSE centres.

User Evaluation

The user, or formative, evaluation lasted for 8 months and ran concurrently with the development phase, in this
way the developers could incorporate any changes that were considered necessary before the next evaluation phase began. The modules were released on to the WWW in three batches, after each module release the evaluators had 4 - 6 weeks in which to make their assessments and report their findings back to the developers. The modules were tested for their ease of use and pedagogical effectiveness with a view to modifying them, if necessary, so that they meet the learners' needs.

The user evaluation had two components. The first component was a quality check of every module, performed at least once by every partner, and was concerned primarily with the overall look and feel of each module and its ease of use. The second component was a more detailed look at the modules, with each partner being assigned a small number of modules to be assessed by several people within that institution, preferably covering a wide range in meteorological background and experience, such that each module was tested in at least four different institutions. This more detailed examination included checking the scientific integrity, determining users' impressions of different module characteristics, the level of interactivity, whether the module fulfilled its stated objectives, obtaining any suggestions of corrective action or possible improvements for the developers, and wherever possible testing the user's understanding before and after using the module. Two questionnaire forms were designed to fulfil these criteria, these forms were in spreadsheet format and were distributed and collected electronically.

**Demonstration Phase**

The second evaluation phase is the demonstration, or summative, phase. This phase runs for one year, commencing 1 December 1997. The aim of this part of the evaluation is to assess the modules in use on teaching and training courses in a variety of learning environments, and to assess their effectiveness in comparison to existing teaching methods. All partners, developers and evaluators, will participate in this phase. As the consortium includes partners from organisations of different sizes with different needs, as well as different facilities and resources available, the flexibility of the course can be fully tested.

Universities and some weather services can, for example, use the modules in conjunction with existing lecture courses. The modules can be incorporated in various ways ranging from the modules being used as complementary material which students are encouraged to look at in their own time, to full lecture replacement with dedicated classroom computer sessions. NMS which do not have their own training centres may well have to address the challenge of establishing how the modules can be used for 'on-the-job' training in an operational weather forecast environment. Potential use of the modules for these partners includes: giving individuals or groups dedicated time during their duty period for distance learning with the modules, supported by either a virtual tutor or a tutor group that meets at regular intervals; attempting to integrate the modules into the work schedule so that an individual could, for example, use a set of modules related to a weather-producing phenomenon and then look for real examples of the phenomenon while working, and using the modules as 'electronic job aids' that can be referred to as and when necessary during the course of the working day.

The pedagogical effectiveness of the EuroMET course will be assessed in various ways. For example, there is some scope during this project for the same course at an individual institution to be run in successive years with and without using the modules. Another option is to divide a student class into groups with perhaps one group using modules only, one having lectures and using modules, and a third group having lectures only. Examination or test marks could then be compared as a measure of the course's effectiveness. However, this is not always desirable when students' qualifications are at stake, particularly if some students feel they are at a disadvantage. Further evaluation of this sort can also be undertaken by higher degree students. Sometimes these students are required to take taught courses early on in their research programme, and so they could be used as assessors. Not all NMS examine their employees so evaluation of the modules' pedagogical effectiveness could take the form of users giving seminars to their colleagues. In some cases they may be given forecasting exercises to test their understanding of the material covered in the modules. These assessment methods could also be used in universities.

It is also important to gather information on the users' and teachers' opinions and feelings about the course.
This information will come from a range of questionnaires available online. The main questionnaires are the 'user' and 'teacher' questionnaires which will be completed by everyone using the course, either for learning or teaching. They address such issues as how the modules were used, if users received enough support or feedback whilst using the modules, how easy they were to incorporate into their studies/workload, as well as gathering general views on the comparative value of the modules and whether users felt they had learnt from them. The teacher questionnaire asks for views on the comparative value of the modules also, and about the impact it had on them, and provides areas to describe any student assessments, observations or interviews conducted. Both questionnaires also pose questions regarding the usage and usefulness of the communication facilities available with the course.

**Evaluation Results**

Initial results from the user evaluation phase have been collected and analysed. An independent usability study has also been carried out with the EC-supported project INUSE (Information Engineering Usability Support Centres), a network of centres specialising in usability issues.

**User Evaluation Results**

The first user evaluation phase found a disparity in the modules, with some placing the emphasis on using interactive and graphic elements to explain meteorological concepts, while others stuck to a more traditional, text-based approach. Users generally did not like the very heavy use of text, but preferred the use of animation and interactive exercises, as they offer a unique way of visualising concepts. It was felt therefore that the developers should have made more use of the WWW's potential. The navigation tools also caused problems, with users often unsure if they had accessed the whole of the module or feeling that they were 'lost' in the module as occasionally there appeared to be no clear route through it. A further problem was the definition of the objectives of each module. These were sometimes poorly defined in terms of learning goals and very often just resembled the table of contents, making it very hard for a user to decide whether they had successfully completed a module.

There were also some very good features present in some modules and which were recommended to be included in all modules. These features included the 'sensitive' equations and the conclusion pages at the end of a module. Sensitive equations were particularly useful when a module contained complex mathematical expressions with many terms which made it difficult to comprehend. Making each term sensitive, so that when the cursor was positioned over a term a pop-up explanation appeared on the screen, meant users found expressions far easier to understand. The conclusion page was also useful as it summarized the material and concepts covered and reaffirmed the important points. These features were incorporated into the Phase II modules. Further improvements included the use of more interactivity, though the evaluators felt that some modules were still too dry and formal, and the introduction of a timer bar which showed not only the time the user had been in a particular module, but also the fraction of it accessed. Navigation was also improved to guide the user through the module in a more linear manner to avoid being or feeling lost.

The Phase III evaluation showed that there was an overall improvement in quality of the modules since the Phase II evaluation. The amount of interactivity in the modules improved with most considered to have sufficient interactivity. There was also a more imaginative use of interactivity with a wider variety of exercises for the user to perform. The objectives were much better defined, and the navigation had further improved with the introduction of 'course structure' and 'module structure' windows which close automatically once a module or page has been selected. This is a big improvement when navigating round the course. The only potential problem identified is that of variation in material between modules, that is the amount of material in a module and its relative difficulty. Users might become frustrated if, after long exploration of a module, they find it does not meet their expectations because it is either too difficult or too easy. However, this problem has not been tackled and, as the majority of modules have been evaluated out of sequence in this phase, so that sometimes it
has been necessary to test advanced modules without first studying its preceding modules, it remains to be seen whether this is a real problem or is simply an artefact of the evaluation procedure thus far.

Usability Study Results

A usability study was conducted at Reading University in collaboration with INUSE, with representative users using the modules to perform typical tasks in a realistic environment. A representative from an INUSE centre, NPLUS (National Physical Laboratory Usability Services) in Teddington, UK, supervised the study.

The usability study concluded that the course modules were well-designed and meet the needs of the users. Module presentation was good, with the right amount of information on each screen, the graphics and interactive elements were well liked, and the download times were acceptable. Furthermore, the results showed that it was likely that teaching staff will be able to successfully integrate modules into their courses and that the EuroMET course will provide a useful and usable study aid. Minor technical problems occurred during the study, such as graphics not loading correctly and windows that did not close when they should, but these have since been corrected by the developers. A recommendation for the quizzes within the modules was that users expressed a desire for some to be designed where they were required to submit answers of their own rather than merely selecting from a list of possible answers in order to fully test their understanding, this was also addressed in the Phase III modules.

Pre- and Post-test Results

Pre- and post-tests have been carried out only on a small scale during the user evaluation due to a number of reasons. One difficulty was with short time-scales, particularly for the first and third phases. Modules were delivered onto the WWW at the beginning of each evaluation phase, so in order to design pre- and post-tests, the evaluation partners had to read through each module and devise questions before the users could access the modules. This was a lengthy process and with only a few weeks for each evaluation period it simply was not possible for every institute to do this. A further problem was finding representative users to do the tests. As part of the user evaluation both subject experts and novices tested the modules. Subject experts are essential to check that the material in each module is scientifically correct, while novices can test the pedagogical effectiveness. However, due to the tight project timetable, the first two user evaluations occurred out of term time for most universities which have by far the largest proportion of learners. Added to this is the fact that the modules were not delivered in sequence. Some of the more complex modules require users to have covered others in the course first therefore a newcomer may have problems understanding material in a particular module, not because the module is poor, but because they do not have sufficient background knowledge.

Table 1: Improvement in test scores before and after users complete a module.

Despite these problems, the results from the modules for which pre- and post-tests have been undertaken are
encouraging as they suggest that users are able to understand and retain information which helps them improve their level of knowledge (Table 1). They also provided the evaluation team with valuable experience for the demonstration phase when much more extensive tests will be possible as many representative users will be using the modules as part of a structured education or training course.

The Future of EuroMET

The demonstration phase provides an excellent opportunity to fully test the pedagogical effectiveness of the course and its utility in replacing and complementing existing education and training methods. A meeting to be held part-way through this phase, at the end of March 1998, will ensure that the evaluation tools are well-defined and appropriate for all partners, and may hopefully yield some preliminary results on the course’s use and effectiveness.

It is hoped that after the demonstration phase institutions will continue to use the EuroMET course. Maintenance of the course servers for a minimum period of 2 years is guaranteed. Interest in the course has also been expressed by individuals and organisations who are not in the consortium but who have joined the EuroMET user group. It is expected that these members will be allowed access to the course at the end of the project in return for some level of commitment to the consortium, either financial or in terms of developing or evaluating new material.

If this whole exercise is seen to be successful by the Informal Conference of Western European Directors (ICWED) of Weather Services it is hoped that further development of similar modules will be funded through their collaborative "EUMETNET" venture.

Acknowledgements

The authors would like to acknowledge the Telematics Division of the European Union and the participating Weather Services who have funded this project. Many thanks also go to all the EuroMET consortium members for all their hard work in producing and testing the course.
Abstract: Hypertext and Hypermedia systems can be used in many different ways, among others as “cognitive tools”. Such hypermedia systems are supposed to help learners structure their thought processes and gain a deeper understanding of the subject material. The following text describes the way how students at the University of Technology Vienna used a concept mapping tool based on a hypermedia system. The results show that most of the students use such tools in a rather conservative manner. Nevertheless, there is a minority which tries out innovative features in a very creative way.

1. Introduction

Hypertext and hypermedia systems can be used in educational environments in a number of different ways. One possibility how such systems can be employed is the support of students creating externalized versions of their own knowledge structures, especially in the form of graphs. The technique of motivating students to use elaborate learning strategies by drawing spatial representations of their knowledge structures is an old one and has been developed for paper and pencil. Several different names have been used for such techniques, e.g. concept maps, cognitive maps or semantic maps. In the following paper, the term concept maps [Novak & Gowin 1984] will be used. Because of its flexibility and the possibility to re-edit existing concept maps, the computer in general and hypertext systems specifically seem to be especially appropriate media for this methodology.

So far, the majority of investigations of the usage of computer based concept mapping systems have concentrated on the question whether concept mapping is a superior form of learning compared to more traditional methods. Generally, the results of these investigations have been promising although some specific problems can be observed. The aim of the study described in the following paper is different although it is based on the notion that computer based concept mapping tools can be used successfully in an educational context. Initial motivation for the study was our observation that students who develop hypertext documents seldom use novel or innovative structural features of hypertext systems, and if they use them they do it in an unpredictable manner. It was, therefore, the aim of our project to investigate how students develop hypertext documents and especially how they try to structure the information in their documents and which structure-generating features of the system are more attractive than others.

2. The System DarkStar

The topic of our study is based on the experience gained during a project concerning hypermedia and learning which was carried out at our department between 1992 and 1994. Inspired by George Landow [Landow 1992] we asked students to write their own hypertext documents as assignments in seminars. We soon realized that students had serious conceptual problems with this task. The most important of these problems was that they had difficulties to translate the linear texts which they were supposed to read during the seminars into non-linear hypertext. This circumstantial evidence motivated us to develop the system DarkStar which is based on HyperCard and which was supposed to help students create more innovative hypertext documents. Innovative in this context means that students were to a certain extent constrained to use novel features of the hypertext concept like non-
linear links between pieces of text, pop-up fields with examples or explanations, or graphics and animation. All these features are novel in the sense that it is either not possible at all to use them in books or at least very difficult. We assume that hypertext enables students to get insights into the material they study which they cannot get by reading and writing linear text. In this sense, hypertext systems can serve as cognitive tools [see Kommers, Jonassen & Mayes 1992]. As the students seemed to have the most difficulties with the concept of hypertextual structure, the system DarkStar contained many elements to make structuring easier. One of the most popular of these features was the so-called Overview Editor [Fig. 1], a tool which resembles other electronic concept mapping tools to a large extent. The Overview Editor allowed students to create, delete and name links and nodes and to position links and nodes in the two-dimensional space offered by the computer screen.

![Image of the Overview Editor](image1)

**Figure 1: The Overview Editor**

DarkStar was developed iteratively. It was evaluated continually to assess whether it really supported students to fulfill their task. There is some promising evidence that it is possible to improve the quality of the students' documents by offering them a hypertext authoring tool which is specifically adapted to their needs [Pohl, Purgathofer & Prenner 1995].

3. Concept Mapping, Structural Information and Hypertext

According to [Novak & Gowin 1984] concept maps are graphical representations of concepts and their relationships. The concepts represent a small number of key ideas. The formulation of such key ideas are crucial for every learning task. Based on their practical experience, Novak and Gowin suggest several different ways of applying concept maps, among them: exploration of what the learners already know, extracting meaning from textbooks, planning a paper or exposition, etc. Our approach to concept maps is slightly different to the one of Novak & Gowin. On the one hand, we use concept maps in our teaching practice only in combination with "normal" hypertext systems. Structural information is not only conveyed through the concept map but also through the topological organisation of text on the screen and the use of graphical material, and it can be assumed that there is an interaction between these two components. On the other hand, we try to motivate students to organise information in novel ways, among others as non-hierarchical structures. This contradicts Novak and Gowin's ideas to a certain extent as they demand that concept maps have to be hierarchical.

There is some evidence that the use of concept maps in learning environments can have beneficial effects. [Kozma 1992], [Kommers & de de Vries 1992] and [Fisher 1992] who used computer based
concept mapping tools report positive results. [Reader and Hammond 1994] argue that concept mapping is a more time consuming method than traditional forms of learning. Thus, students are motivated to spend more time going through the material and analysing it. This leads to a better performance of those students developing concept maps. [Jonassen and Reeves 1996] also give an overview over research supporting the use of concept maps. They point out that concept maps are a powerful tool to analyse the learning process and students' changing knowledge representations. The studies quoted above also discuss important factors which influence the usage and design of computer based concept mapping tools. Concept mapping is more beneficial with advanced students than with beginners [Kozma 1992]. The introduction of concept mapping tools or more generally hypertext necessitates a modified curriculum and a change of the criteria for testing students' achievements [Kommers & de Vries 1992], [Jonassen & Reeves 1996]. Students have problems with several novel features of concept mapping tools [Fisher 1992].

In general, it can be said that the efficiency of concept mapping as a methodology of learning is to a certain extent supported by empirical evidence. Concept mapping and hypertext as a theoretical concept apparently share a number of traits. Therefore, computer based concept mapping tools are often either integrated into hypertext systems or used in combination with hypertext.

4. The Study - Aims and Methodology

The aim of the study described below is to observe how students using a hypertext system develop their own documents, and especially how they try to convey structural information. We think that structural information can be expressed in at least two ways: in a concept map or content overview and through the use of topological cues on the other pages of the hypertext document. In the tradition of [Novak & Gowin 1984] our students were encouraged to develop documents with little text and much structural information. The task of developing hypertext documents is part of the normal work routine of students at our department. This implies that task and setting were realistic and relevant as far as students' experiences are concerned.

The practical aim of our investigation is, first, to formulate tentative guidelines or principles for the design of concept mapping tools or hypertext systems with an emphasis on the representation of structural knowledge. In this context, it is necessary to find out which features are not accepted by the users and to formulate ideas how to enhance the usability and affordance (Norman 1988) of those features which are accepted. Second, we want to formulate tentative guidelines or principles for the educational practice. We posit that knowledge about how students use hypertext systems can help teachers to advise students more systematically.

For our investigation, we used a sample of 143 documents which are a representative cross-section of all the documents created by students at our departments. All the documents were developed with the system DarkStar. To analyse the documents we used a collection of categories which were partly derived from the relevant literature and partly from our practical experience. These categories sometimes ask for subjective judgements. By defining the categories carefully, we tried to minimize any possible subjective bias. The method of analysis is descriptive. It can be argued that such methods form a valuable contribution to educational research [Knupfer & McLellan 1996].

We used two different sets of categories. One set was mainly concerned with the structure of the whole document as it appeared on the Overview Map. The other set dealt with layout and screen design. The most important question the first set of categories tried to answer was whether students adopted traditional hierarchical forms of structuring information or not. Link types are treated insofar as they can clarify this issue.

The second set of categories examined the question whether students used layout, screen design or graphical elements to convey a sense of structure. Typographic and layout features which play an important role in this context are highlighting [Mayhew 1992], grouping [Mayhew 1992], [Tullis 1991], and the distribution of white and black space on the screen [Watzmann 1993]. Highlighting is a possibility to point out important concepts in the text to the reader. Nevertheless, it should be used sparingly. Grouping is to a certain extent based on the Gestalt laws of proximity. It is a powerful tool
to show which elements belong together and which do not. Factors which influence grouping are proximity, colour, graphical boundaries and highlighting. All these factors should make semantic relationships between the objects on the screen visible [Tullis 1991]. The distribution of white and black space on the screen, which is to a certain extent related to grouping, provides a clear path through the material and gives a conceptual framework of the text [Watzmann 1993]. In more sophisticated forms of page design, information is presented in chunks. These chunks are organised according to the semantic meaning of the text. This results in a complex pattern of black and white on the screen which differs from the traditional "grey" page of a book.

5. Results

5.1. Hierarchical vs. Non-hierarchical Structure

As already mentioned, students predominantly used a hierarchical form of structuring information [Tab 1].

</tbody>
</table>

Table 1: Distribution of hierarchical vs. non-hierarchical links

As we can see, hierarchical links are by far the most frequent form of link type. The category "links to other documents" represents links which students made to other students' hypertext documents. As students who attended the same seminar worked in parallel at their documents this was apparently a problem. Only very few students used this possibility.

There are only three documents with no hierarchical links at all. In contrast to that, there are 83 documents with no non-hierarchical links at all. The document with the maximum number of hierarchical links contains 130 links of that type. The document with the maximum number of non-hierarchical links contains 37 links of that type. There are also several other documents with a considerable amount of non-hierarchical links. This indicates that many students did not realize the possibilities offered by non-hierarchical links. On the other hand, there are several students who realized these possibilities and used this feature extensively.

5.2. Link Types

The term link type in this context is perhaps misleading as it is used in the literature to characterize link types belonging to a complete system of link classification. In contrast to that, the term link type here refers to a few characteristic linking methods which students used to express their ideas about structure. This concept of link types was not developed theoretically but rather deducted from our practical experience with students' hypertext documents.

Link between the same term on two nodes: Students very often use this method of linking two nodes. They happen to notice that one and the same term occurs on two nodes in their document. Therefore, they create a link between those two nodes. The interpretation of this process is ambiguous. On the one hand, it can be argued that this form of linking does not require elaborate thought process and is rather mechanical. We found several examples for fairly useless or even confusing links of that type in students' documents. On the other hand, it sounds plausible that for the reader of a hypertext document it is easier to grasp the structure when the same terms are used on both nodes he has visited. For us it is, therefore an open question whether to advise students to use this kind of link.

3804 (76.4%) out of 4977 links are links between the same term on two nodes.
Examples: Students fairly often use links to refer to examples which illustrate an idea brought up in the text. 1324 (26.6%) out of 4977 links are of that type. Only 26 out of 143 documents do not contain any examples. Students differ considerably in the amount of examples they include in their documents. One document even contained 46 examples.

Explanations: Students also fairly often use links to refer to explanations of terms used in their document. 1890 (37.9%) out of 4977 links are of that type. Only 9 out of 143 documents do not contain any explanatory links. The maximum of explanatory links in a document is 71.

Example links and explanatory links are rather similar in at least two respects. They were categorized as hierarchical links in the category system we used. In contrast to that, examples and explanations are usually seen as a form of digression in a linear text. In this sense, examples and explanations can be seen as a feature which transcends the distinction between hierarchical and non-hierarchical structure. The second similarity is the fact that in both cases some students use this feature quite heavily whereas others do not use it at all. This probably indicates that some students did not realize that they had this possibility whereas others who were aware of it used it quite intensively.

5.3. Typography

126 out of 143 documents use an acceptable font size for text (12 point). 114 documents use bold for highlighting and only 18 italics. All documents either used indentation or empty lines as methods of structuring their text. In general, this shows that students are acquainted with basic principles of screen design and use them to structure their documents.

5.4. Grid

The term "grid" refers to the categories introduced by [Watzmann 1993]. She tries to formulate criteria for the quality of screen design. Good screen design, according to her opinion, is highly structured and uses a range of different topological or graphical cues. [Tab. 2] shows to what extent the students at our department used methods of structuring text and pictures on the screen.

<table>
<thead>
<tr>
<th></th>
<th>yes (no of documents)</th>
<th>no (no of documents)</th>
<th>partly (no of documents)</th>
</tr>
</thead>
<tbody>
<tr>
<td>gray page</td>
<td>25</td>
<td>118</td>

<td>100</td>
<td>43</td>
<td>0</td>
</tr>
<tr>
<td>mixing modes</td>
<td>38</td>
<td>105</td>
<td>0</td>
</tr>
</tbody>
</table>

Table 2: Organisation of information on the screen

The term "gray page" describes a screen which resembles a traditional book with no organisation of the information at all. Chunking means that information is divided into small, meaningful pieces of text. Queuing leads to an even more structured screen. Information is arranged topologically, so that the position of pieces of text conveys meaning. Mixing modes refers to a screen design which includes different modes of expression (text, graphics, pictures, formulas etc.).

Chunking and queuing seem to be very popular with our students. This shows that they have realized that a computer screen offers possibilities which do not exist in a book. Nevertheless, the students we observed in our study did not use pictures, graphics or other modes very often [see 5.5.]

5.5. Use of Pictures and Graphics

Only 41 (29%) documents out of 143 use graphics or pictures. Whereas the students we observed showed a certain ability to develop a satisfying layout they are still not very creative as far as use of other modes of representation are concerned.
6. Conclusion

The aim of the study described in this paper was the observation of students creating structured hypertext documents. The students, in general, had difficulties with novel ways of structuring information, especially with non-hierarchical structure. New possibilities which are offered by electronic text are more easily accepted if they resemble traditional linear text to a certain extent as, for example, links to explanations and examples. Features of structured hypertext which are attractive or at least potentially attractive seem to be characterized by the fact that many students who use them do that quite intensively. This indicates that those students who did realize the advantage of novel structuring possibilities try to apply them fairly often. The study described above still does not give a very comprehensive picture of the activities students are engaged in when they structure their hypertext documents. It would be interesting to assess whether the contents of the material the students have to learn has any influence on their documents or whether there are texts which can be converted to highly structured hypertext only with difficulties. We will investigate these questions in the future.

Peter Purgathofer developed the system DarkStar which was used by students to develop their hypertext documents. Michaela Schuster, Alexander Sogl and Alexander Stadler who are students at our department helped me with the analysis of the documents.
Significant Use of the Internet by Faculty, But Not for Teaching

Howard Poole, Special Education, Western Michigan University, USA, Tel: 1-616-387-6050, Fax: 1-616-387-5703, E-mail: poole@wmich.edu

Abstract: The study found that there is significant use of the Internet by faculty thus confirming for those at Western Michigan University who were responsible for building the wide-area campus network that access to the Internet and other local computer resources was available. Ninety percent of faculty report using the Internet at least several times a year while sixty percent report doing so on a daily basis. A variety of Internet applications were reportedly used by faculty with e-mail being the most frequently used. A disappointing finding suggests that faculty are not widely using the Internet for direct teaching activities. One-half of faculty require students to use email and only one-third require them to explore the world wide web as part of course activities. Use of these activities were requested of students by faculty on average of less than once a month.

1. Introduction

There has been an exponential growth in the use of the Internet by large numbers of people. Computer techies, for the most part, have been the pioneers in Internet use, but other groups, including college and university faculty, have also adapted the new communication technology to their professional and personal use (Adams & Bonk 1995, Halman 1995). In an effort to discover more about the use of the Internet by faculty, a study was undertaken at Western Michigan University, a large midwest regional university serving the State of Michigan, to determine the level of Internet awareness, access, and use by faculty. The study was undertaken, in part, to generate information for a special taskforce charged by the President of the University with reviewing instructional technologies and technology support. The committee, Ad Hoc Taskforce on Educational Technology, was co-chaired by the Dean of Libraries and Director of University Computing Services.

The survey attempted to explore the following areas:

1. faculty awareness of, access to, and frequency of use of the Internet
2. faculty knowledge of, frequency of use, and self-reported expertise of commonly available Internet tools
3. faculty use of the Internet for teaching activities

In recent years (1993-95), there had been significant financial expenditures and manpower commitments made by Western Michigan University (as well as many other institutions) to create a wide-area networks that would allow faculty, students, and university staff access to local computing resources, University online library services, and external resources via the Internet. This study, taken at the end of that period (January 1996), attempted to confirm that faculty were aware of the new computer resources and services available to them, that they had access to the services, and that they were making use of them.

Another common issue at the University was the level of awareness by faculty for using computers and internet related software tools, and faculty expertise in the use of the internet tools and services such as email,
web browsing, and searching data bases. Several agencies (University Computing Services, University Libraries, and Office of Faculty Development) at the University were already invested in offering workshops, consulting services, and technical support to faculty to assist them in the use of computers, the library online services, newly available internet services and resources, and use of computers for teaching activities. Questions at the University focused on the need for additional faculty training, level of training (i.e. introductory, advanced, etc.), and level of technical consulting services that were still needed by faculty.

Of special interest to the Ad Hoc Committee was the need for larger numbers of faculty to make use of the Internet resources and services in direct teaching activities at the University. Previous studies at the University had found that only a small percentage (25% or less) of the faculty were actively using computers in instruction and/or requiring students to use computers as part of their classwork (Poole, Van Valey, & Vakalis 1994, Poole & Van Valey 1994). Was the rapid growth in the use of the internet and the expanded campus computer network generating changes in the way faculty were using computers as part of their teaching activities? This is a critical question for the University to answer to justify, in part, the recent investment in technology.

2. Survey Procedures

The authors have been surveying the faculty and students at Western Michigan University for more than ten years and have developed a reliable survey procedure that includes mailing a multiple choice, fill-in the blank survey to faculty at their offices. A pre-survey postcard was sent to all faculty making them aware of the survey. The survey was mailed in late January after the start of Winter semester. Those faculty filling out and returning the survey were promised a 3.5 inch diskette of University-related internet graphics as a token for completing the survey. Fourty percent, or 376 faculty members, returned the survey. The distribution of faculty in the research sample closely follows the distribution of all faculty surveyed. This was true for the sex of respondents, for distribution by age, for professorial rank, for mean year employed, and for employment by college. Based on these findings, the research sample was deemed representative of the University population of faculty. For this survey the Internet was described as the use of e-mail for off-campus communications, use of gopher and world wide web servers, use of telnet applications, and use of other related Internet applications.

3. Faculty Use of the Internet

Faculty were asked to identify the first year that they used the Internet. Nearly twenty-percent of faculty report using the Internet before 1990. Since 1990 there has been a steady yearly increase in faculty using the Internet with an especially rapid increase (twenty percent) taking place during 1995. More than fifty percent of the faculty report using the Internet before or during 1993. Fewer than ten percent of faculty report that they have never used the Internet. Less than two percent of faculty expect never to use the Internet. Faculty were also

Table 1 - Total Hours Per Week Faculty Use the Computer

| Weekly Use of the Computer For All Things | Range = 0 hours to 70 hours | Average Use = 19.98 hours |
| Weekly Use of the Computer for Only the Internet | Range = 0 hours to 30 hours | Average Use = 6.0 hours |
0 hrs. = 10.3%, 1-6 hrs. = 54.2%, 7-10 hrs. = 24.1%, >10 hrs. = 11.4%

asked to estimate their frequency for using the Internet. On average faculty reported using the Internet several times per week with more than sixty percent using it on a daily or more often basis. Those faculty who report using the Internet do so on average of six hours per week with thirty-five percent of faculty reporting they use it more than six hours per week, see (Tab. 1). The majority of faculty (fifty-four percent) use the Internet between one and six hours per week. Ten percent of faculty reported zero hours of internet use per week. By contrast, faculty report using the computer for all activities an average of twenty hours per week. Use of the Internet (six hours per week) would represent approximately thirty percent of the total time spent each week by faculty using a computer.

4. Faculty Access to the Internet

Having access to the Internet is an important first step in using it. Ninety percent of faculty reported they had access to the Internet, another five percent were not sure, but thought they had access, two percent did not have access but expected to have it within a year, and another two percent did not have access and did not expect it, see (Tab. 2). Faculty were also asked if they had access to personal computers at work and at home. A similar percentage of faculty (ninety-one percent) reported access to personal computers at home and at work. Internet access would seem to closely parallel personal computer access at both work and home.

</tbody>
</table>

Do You Have Access to the Internet?

Yes = 90.9%, Maybe = 4.8%, No, But Expect to = 2.7%, No and Don't Expect To = 1.6%

Faculty were provided nine possible options of access to the Internet, including access from their offices, from their homes, and from other University locations. They were asked to identify all options that were available to them, see (Tab. 3). The two most widely identified access points were a direct (ethernet/campus network) connection in their office (by eighty percent) and a telephone connection from their home (by seventy percent). Forty percent of faculty reported an ethernet/campus network connection from a department location. Twenty percent, or less, of faculty reported Internet access via University or department computer labs, or from an office telephone. Only ten percent reported access via a department telephone while less than one percent reported a direct network (ISDN or other) connection from home.

Faculty were asked to rank locations on campus were access should be made available to the Internet. The top four locations included faculty offices, University and department computer labs, and the University libraries. Also consider important locations were student housing, classrooms and lecture halls. Not as important for campus locations were public kiosks.

5. Faculty Use of Internet Applications

What do faculty use the Internet for? Faculty who reported using the Internet were asked to report the frequency of use of sixteen commonly found Internet applications. The number one rank applications was use of electronic mail (e-mail) by nine-seven percent of faculty, see (Tab. 4). Faculty reported using e-mail on average of once per day with two-thirds of faculty reporting it daily or more often. The next most frequently used Internet applications were searching for reference materials, searching on average of once per week. More than eighty-five percent of faculty report using these second rank applications. Ten percent of faculty report using the second ranked applications on a daily or more often basis.

Searching databases, using online library catalogs, searching for personal information, and use of discussion lists were the third most frequently used Internet applications used on average of once a month, see (Tab. 4). More than seventy percent of faculty reported using these Internet applications. The exception was use of discussion lists where only one-half the faculty report using it. Internet applications used on a less than monthly basis include gathering research summaries, searching for government documents, receiving electronic newsletters and journals, and gathering images and pictures. Two thirds or less of faculty report using this last group of Internet applications. Internet applications used infrequently by faculty include participation in chat rooms, and buying products. Internet applications that are rarely used by faculty include video and audio conferencing.

6. Faculty Use of the Internet for Teaching

Two questions were asked that related to the use of the Internet in teaching activities. One question asked the frequency of requiring students to use the computer for various tasks. Seventy-eight percent of faculty require students to use the computer to prepare papers and reports. The average frequency was once a month. Nearly seventy percent of faculty require students to search databases for reference materials. The frequency of use was less than once a month. "Other" uses of the computer required by faculty averaged less than once a month. A minority of faculty required students to use the computer do e-mail, explore the World Wide Web, and to use graphics and draw programs, see (Tab. 5).

</table>

Scale: 1 = Not At All, 2 = Less Than Once A Month, 3 = Once A Month, 4 = Once A Week, 5 = A Few Times A Week, 6 = Once A Day, 7 = Several Times A Day

Faculty were also asked if they used the computer for various teaching tasks. Using the computer for "other" teaching tasks (other than those asked) averaged once a month and was used by nearly one-half of the faculty, see (Tab. 6). Used by less than a third of the faculty and use less than once a month on average were projecting images/data, demonstrations of e-mail, demonstrations of experiments, and demonstrations of the Internet. Faculty were also asked about requiring students to have computer accounts. Twenty-four percent of faculty require course computer accounts. Another seven percent encourage computer accounts, but do not require it and another six percent require a personal computer account. More than sixty percent of faculty do not require a computer account of any type.

7. Conclusions
A number of conclusions can be drawn from the findings of the Internet survey of faculty at Western Michigan University. Some of the conclusions answer the concerns of the Ad Hoc Taskforce on Educational Technology that was studying technology related resources and services to faculty at the University. Some of the conclusions suggest that additional effort is needed to support faculty in the use of the computers and the Internet.

The study found that there is significant use of the Internet by faculty thus confirming for those at the University who were responsible for building the wide-area campus network that access to the Internet and other local computer resources is available. While nearly thirty percent of the faculty reported using the Internet before the recent University expenditures for expanding the computer network on campus, a majority of faculty reported they started using the Internet during the development period with twenty percent using the Internet the first time in the year immediately preceding the study. Ninety percent of faculty report using the Internet at least several times a year while sixty percent report doing so on a daily basis. Based on these findings, the authors concluded that the Internet is now a commonly used computer resource and service on Western's campus. Access to the Internet by faculty was also not a significant problem with ninety percent of faculty reporting access from their offices via network connections and from their homes via telephones and modems. Access also exists, but is not widely used by faculty in campus computer labs. The authors conclude that faculty at Western have extensive access to the Internet from both on and off-campus which was, in part, made possible by recent network development efforts.

A variety of Internet applications were reportedly used by faculty with e-mail being the most frequently used application. Other Internet applications used by a majority of faculty include searching for reference information, searching for files, searching for scholarly information, and searching online catalogs. These findings demonstrate that the email services provided by the University and the University Libraries online catalogs and database resources are being used by faculty via the Internet. Some applications over the Internet not frequently used include discussion lists, gathering research summaries, searching for government documents, receiving newsletters, gathering images, using chat rooms and conducting audio and video conferences. These infrequently used applications represent, in the opinion of the authors, possible target areas for additional faculty training.

A disappointing finding suggests that faculty are not widely using the Internet for direct teaching activities. Approximately one-half of faculty require students to use email and only one-third require them to explore the world wide web as part of course activities. Use of these activities were requested of students on average of less than once a month. The authors concluded that faculty are not yet requiring students to use the Internet on a regular basis. On a more positive note, a majority of faculty report requiring students to use a computer to prepare papers and reports, to search databases, and to do other computer applications. Other disappointing finding was that less than one-third of faculty use the Internet and email for demonstration purposes during classroom activities The average use of these two Internet related items was less than once a month. On a more positive note, one-half of faculty reported using the computer during classroom teaching activities. The authors conclude that requiring students to explore and use the Internet and demonstrating the Internet or email in class were not frequent teaching activities by faculty.

The authors conclude that recent campus computer network development activities have been successful in providing faculty access to the Internet and other computer resources at the University and that there use has been significant. Many Internet related applications are being used by faculty, but especially email. However, faculty are not yet widely using the Internet and email for teaching related activities.

Abstract: This paper describes a prototype software tool for support of peer-to-peer conversation on distance education courses in text-based asynchronous mode. This goal is accomplished by visualizing multiple threads of conversation. The theoretical basis for this design is a comparative analysis of oral, written and electronic communication which enables the identification of properties of the conversation structure relevant to software design: fragment length and fragment linking mode. Combination of these properties gives rise to linear or multithreaded conversation structures.

1. Introduction

Asynchronous text-based communication, having been available since the earliest days of the Internet, continues to play an important role in almost all electronic communities and, in spite of the development of new multimedia technologies enabling sound and video communication, seems likely to persist for some time. This medium possesses some traits that are very useful for educational purposes. Experience of distance educators shows that this medium is best suited for group discussions and seminar-type studies, rather than for delivery of basic lecture material [Hiltz 1992], [Harasim 1990], [Garrison 1993]. Students interact with each other and with the instructor, discussing, debating and elaborating their growing knowledge.

In a traditional setting interaction between students takes place largely through natural language. It implies intensive message exchange and conversations between participants. [Kaye 1992] stresses the importance of social and linguistic aspects of communication: its active character. Knowledge results from active interaction between students and instructor, or even only among students, as opposed to the understanding of learning as knowledge acquisition from some external source.

In a traditional setting interaction between students takes place largely through natural language. It implies intensive message exchange and conversations between participants. [Kaye 1992] stresses the importance of social and linguistic aspects of communication: its active character. Knowledge results from active interaction between students and instructor, or even only among students, as opposed to the understanding of learning as knowledge acquisition from some external source.

Introduction of a new medium changes the structure and character of communication, and these changes can be for better or for worse [Adrianson & Hjelmquist 1991], [Fulk at al. 1992], [Kiesler et al. 1985], [Er & Ng 1995], [Dubrovsky et al. 1991], [Grote & Baish 1991]. It has been found that users evaluate a medium largely on the basis of its ability to support different types of conversation [Lea 1991], [O'Connell et al. 1993], [Kraut et al. 1992]. Problems in conversation caused by the introduction of a new medium may drastically decrease the quality of learning, so our ultimate aim in the research is to provide software that provides beneficial support for users' conversational activities.

2. Conversation

Having chosen a conversation as an object of the inquiry, we have to work out an approach we will take for analysing it. Conversation is a subject of many disciplines: philosophy, psychology, linguistics, media studies, etc. Each possesses a particular approach, aim and methodology, often incompatible and incomparable to other
disciplines. So it should be explicitly stated how we define the object of the research, and how we observe, measure and evaluate it.

2.1 Conversation Structure

In this work a surface structure of conversation as an indicator of communication processes was chosen. There are several advantages of dealing with conversation structure only. First, it is very easy to observe, since in text conditions transcripts are generated automatically. It is also easier to conjure the problems encountered by users from conversation breakdowns. Application of this method can give new data when analysing conversation [Seller 1995].

2.2 Oral, Written and Electronic Conversation

To gain an insight into the structural aspects of conversation, three forms of verbal communication are compared: oral conversation, writing and conversations that take place in email and computer conferencing. Writing (or, to be more specific, printed text) here is also considered as a form of silent conversation of an author with a reader, or with herself. With most media: writing, TV, special codes, etc. we ultimately end up with messages in the same language. So here the term ‘conversation’ will be used in a broad sense to denote any activity in natural language taking place between interlocutors.

2.2.1 Linearity

Written and oral communication were compared along the linear vs. non-linear lines [McLuhan 1964]. The first was considered linear, the second – non-linear, simultaneous.

It is easily understood that writing (print) is a linear medium. In a book, word is followed by word, sentence by sentence, chapter by chapter, etc. Writing something down allows conceptualisation of the sentence as a spatial object with a linear structure [Lakoff & Johnson 1980].

But oral conversation is to a large extent linear too. Words are pronounced in a linear order, one after another, at one moment only one interlocutor can talk. Consider, for example, a ‘conversation is a thread’ metaphor existing in the language: lost the thread (chain, connection) of his argument; resume or take up the thread of; gather up the threads.

2.2.2 Conversation Fragment Linking

The difference between oral and written conversation structures is in the way the ‘links’ are connected. Due to the ephemeral nature of speech, interlocutors can only refer to something said relatively recently. Topics are changed often; there exist many incomplete, abbreviated sentences. This creates a linear structure with short links.

The persistent nature of text, on the other hand, allows people to refer accurately to something created a long time before. Something can be referred several pages back or forward and looked up when necessary. This in theory allows the building of complex non-linear structures. But the tradition of print downplayed this trait of text. The attempts to break this linearity (e.g. footnotes, cross-references) were marginal (in both the literal and metaphoric sense).

New electronic media inherit the persistent nature of text, but are less hindered by printing tradition. The recent explosive growth of popularity of hypertext shows the huge potential of non-linear structures.

Text-based asynchronous communication allows the weaving of complex webs of argument, where in the same ‘conversation space’ several topics can exist simultaneously. One outcome of this new trait is the multithreaded structures of on-line discussion. Over 80% of messages in computer conferences reference one another [Harasim 1989]; also one message may contain more than one topic [Riedl 1989]. How this new trait can be used for computer tools design will be described later in this paper.
2.2.3 Stylistic Aspects

[McLuhan 1964] stressed the importance of visual versus audio sensory channels in media evaluation, the opposition of ear and eye and consequent differences in style and usage.

Text-based electronic conversation is visible, like text. It is essentially a written form of communication and is usually approached as such. But it has been suggested that electronic media in some aspects are similar to oral communication [Ong 1982], [Bolter 1991]: spontaneity, rapid exchange of messages providing almost immediate feedback, and fluid structure of information are all traits indicative of an oral style. From oral conversation it also borrows the way of referencing other pieces of text. When quoting parts of others' messages in their own, people refer to them as to something said rather than written.

Table 1: Media comparison

[Tab. 1] provides an illustration rather than the precise taxonomy of medium traits. Electronic medium is a very broad term and allows for a wide range of values for any of the traits. Messages can be kept long time or erased immediately. Message exchange speed can vary from almost synchronous, to delays of days, weeks and months. The purpose for including this table is to emphasise the point that electronic medium allows for a special kind of communication that shares some properties with both oral and written communication, being nonetheless unique. That is why it is impossible to directly apply existing theories for oral and text communication to its analysis.

3. Existing Systems

This section will review existing systems that support text-based conversation. It is important to remember that a communication system is always situated in a social context. When users exploit the system, they augment and modify its technical properties with social procedures. This is especially true for conversation, which is very flexible. Conversation patterns change depending on particular media and contexts [Ackerman et. al. 1997]. It seems that users feel that for a particular medium a particular style of communication should be used, so when they had to send their messages with another medium, they often wanted to recompose their messages [Whittaker et al. 1997]. Being aware of this process, we will pay attention to both the technology itself and its usage, because the usage can give us insights into the real needs of users.

3.1 Email and Conferences

Email systems disrupt conversation by putting incoming and outgoing messages into inbox and sent items folders. It is equivalent to taking a dialogue from a book and sorting all the utterances by the interlocutors. The information remains the same, but it is not a dialogue anymore. So users have to rely on their memory and imagination to reconstruct the conversation as it really is. To bypass this restriction, users found a way to transmit a conversation context by quoting the original message in the reply. [Fig. 1] shows an example.

Original message:
I propose to invite Jane on Friday. She will be able to have a good weekend's rest before starting her work.
The University will benefit from her contributions.

Reply:
> I propose to invite Jane on Friday.
I have only been able to make a reservation since Saturday, but I guess it's still OK.
> The University will benefit from her contributions.
I agree completely. We just have to make sure her lectures fit nicely into our overall programme.

Figure 1: Email transcript
The lines marked with '>' in the reply are quotations from the original message. In this fragment we can notice the informal style of the message, similar to oral exchange. Two threads of conversation can be easily identified, but they are 'crammed' into one linear mail message.

Some conferencing systems do provide the threading facility, allowing people to post replies to existing messages, creating thus tree-like multithreaded structures. Among such systems are Lotus Notes™, Collabra included into Netscape Communicator™, and other commercial software. All messages are put into one folder, so conversation is traced easier. Still, such systems design is centred on the message exchange metaphor, e.g. comments are possible to the whole messages only. Very often people also quote the original message in their reply, like in email systems. This reflects the need for finer granularity of a reference unit.

3.2 Coordinator™

A notable attempt was undertaken by Winograd and Flores [Winograd & Flores 1986]. Drawing on Speech Acts theory they developed a tool called Coordinator™. Conversation was conceptualised as a set of building blocks representing particular speech acts that were followed one by another. Users could construct conversation from these blocks. The main drawback in the Coordinator's design was that the authors drew on Speech Acts theory, but, as was shown above, conversation is different in electronic medium. At any one moment the conversation supported by the Coordinator could only be in one state, not accounting for the multithreaded structure of on-line conversation.

3.3 Hypertext Systems

Usually hypertext systems lay stress on the written nature of interaction. With them people write hypertext. Even group systems are conceptualised as a collaborative writing systems, rather than communication systems.

Only some of them support spatial representation, e.g. Aquanet and VIKI [Marshall et al. 1994]. These are hypertext-based tools that exploit free spatial layout to support the task of information structuring. As such, they are aimed at a different mode of structuring 'conversation' than the current work. However their work is a good source of evidence of the power of spatial organisation of text, and the consequent interface and usability challenges.

3.4 Electronic Whiteboards

There exist a number of ‘whiteboard’ tools supporting a shared drawing space. For example, NetMeeting [Microsoft, 1998] is a suite of conferencing tools supporting synchronous multimedia communication between users connected over any kind of computer network, including the Internet. One of the NetMeeting tools is the Whiteboard, which provides a drawing space on which participants can type text and draw lines and other shapes. Whiteboards do not usually have any clear data model underlying the whiteboard display and the focus is on synchronous communication. There exists a subclass - Conversational Props Software. Its main idea is that people would often use some artefacts as conversation props and build their conversation around them [Hill et al. 1994]. Usually such systems are complex multimedia ones. They support several communication channels. For example, on video there can be transmitted an image of some artefact or drawing, and conversation would be in audio mode. The emphasis in such software is more towards the support for different media types, rather than richer support for text communication itself, and so this software is not considered further in the current work.

3.5 Conclusions

The main area where the potential of electronic media is not adequately realised is its ability to support non-linear, multithreaded conversations. Existing software tools do not support effective creation, presentation and navigation of such structure. Some are too restrictive (email, conferences) others (whiteboards) have almost no underlying data model. There is a need to design a data structure that is flexible “in the right direction” and firm enough in others to support conversational activities. All this leads to formulating prototype specifications.
4. The Prototype

In the current research an attempt is made to support a specific property of electronic communication, namely multithreadedness, at the same time preserving the informal, spontaneous style of oral conversation and enhancing the support for the visual nature that it shares with text. This is accomplished by visualising threads and message references spatially.

To illustrate the main idea, let us return to the excerpt of an email message [Fig. 1]. The most obvious improvement is to allow users to comment on items and arrange them spatially [Fig. 2].

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure2.png}
\caption{Threads represented spatially}
\end{figure}

This will allow the construction and presentation of complex hypertext-like structures. Here we will make use of the fast oral way of the connecting remarks. At the same time the textual and visible nature of the communication brings the potential for deeper reflection and continuation of such conversation over longer periods of time. Here are the main properties of the prototype:

- spatial presentation of conversation threads
- granularity of reference unit – any continuous part of text
- oral way of connecting remarks

4.1 Implementation

The most promising platform for the delivery of distance education courses is WWW, so the one technical requirement is that the prototype is integrated into it. So we are implementing it in Java with a client-server architecture. The client is implemented as a Java applet. The server is a Java application that performs queries and stores info in a relational database. Currently, since the system is designed as asynchronous, only one user can be active in a space at any one time. This makes it much simpler from the engineering viewpoint, but enables the basic visual design options to be explored.

Given the limitations on space, here we concentrate on the theoretical aspects of the work. More technical details on the system implementation are available from authors.

5. Conclusions and Further Research

The research showed the possibility of creating software on the basis of conversation surface structure. Further research will concentrate on gathering evaluation data from user trials with the prototype. This will give rise to the second iteration of the prototype, and its evaluation in a more realistic setting. Generally, besides the methodological aspects this research raises major HCI challenges. Supporting speech interaction in such a complex cognitive activity as learning, using a highly spatial style, will require exploration of the need for
optimizing the display, using scaling and perhaps text colouring and shading, and enabling multiple configurable views of the conversation “graph”. All of this would need to be done in such a way as to provide a smooth and more or less “transparent” interaction style, to minimize inhibition of the free, spontaneous nature of such conversations.

Abstract NetDay is a nationwide volunteer grassroots movement to wire every classroom across the United States for Internet access. On NetDay teachers, parents, administrators, community members, industry personnel, and other volunteers meet to pull and terminate CAT 5 cables or wires that provide the infrastructure necessary for connecting our children and their teachers to the vast educational resources available on the World Wide Web. In the fall of 1996, the Ole Miss NetDay Team was formed to help school districts within northern Mississippi hold these “high-tech barn raisings.” To date, the team has assisted seventeen schools with the planning and implementation of their NetDay projects and has helped save the districts over $1,000,000 in labor and materials costs. It is through such cooperative efforts that great achievements in access to technologies can occur.

NetDay is a nationwide volunteer grassroots movement to wire every classroom across the United States for Internet access. On NetDay teachers, parents, administrators, community members, industry personnel, and other volunteers meet to pull and terminate CAT 5 cables or wires that provide the infrastructure necessary for connecting our children and their teachers to the vast educational resources available on the World Wide Web.

In the fall of 1996, a group of faculty, staff, and administration members from the University of Mississippi formed the Ole Miss NetDay Team in order to support the national NetDay initiative. This group's goal was to provide the technical and organizational expertise necessary to assist school districts in conducting their NetDays throughout northern Mississippi.

The Ole Miss NetDay Team’s first task was to gather all information possible about the national NetDay initiative, including the equipment and materials required for wiring the schools, the volunteers and technical expertise necessary for completing each project, the financial and time costs involved, the variety of resources available to support NetDay, etc. Most of this information was available at the National NetDay website at http://www.netday.org. Gathered information was presented and discussed at a series of initial organizational meetings.

Based upon the team’s understanding of the NetDay process, lists were made of the equipment, materials, volunteers, community resources, industry resources, etc., required for the wiring project. A local school, Lafayette Middle/High School, in Oxford, Mississippi, was selected as the first NetDay site. Telecommunications experts from the Ole Miss NetDay Team worked closely with the school district superintendent, school site’s principal, and technology coordinator in conducting a series of technical walk throughs to determine the location and quantity of drops, hubs, servers, etc. Based upon this information, the number of volunteers and the amount of equipment and materials necessary to complete the first NetDay project were calculated.

With these details at hand, a local town meeting was called to kick-off the NetDay initiative in northern Mississippi. Invitations were sent out to local school administrators, PTA officers, community leaders, heads of area business and industry, etc.
The NetDay Town Meeting was held in the late fall of 1996. Participants were informed of the NetDay initiative, how a NetDay was conducted, and the parts they could play in its success. They were called upon to support the NetDay effort either physically (in the form of volunteers and manual expertise), materially (in the form of donated materials and equipment), or financially (in the form of money that could be used for materials and equipment).

The following NetDay subcommittees were formed: volunteer, food, technical, public relations, materials, funding, and wiring equipment and tools. Subcommittees made a commitment to work together until every school in the area was 100 percent wired.

In addition, the first NetDay school site and date were announced, along with a detailed itemization of what the Ole Miss NetDay Team had determined to be necessary for the successful wiring of the school. Subsequent meetings of the subcommittees were scheduled, as well as “sanity check” meetings with all subcommittee heads to assure steady progress of NetDay plans.

Local businesses and industry demonstrated tremendous support for the project. Grocery stores provided food for both the kick-off meeting and NetDay. The Chamber of Commerce provided t-shirts for all NetDay volunteers. The County Board of Supervisors covered the cost of conduit. BellSouth provided a wiring kit and the services of two fully-equipped trucks, as well as a team of trained workers. The Telephone Pioneers provided additional manpower. The Ole Miss Volunteer Services provided individuals to help with food, registration, etc. The local radio and newspaper provided public service announcements. The electric company provided the materials necessary for wiring between the high school and the superintendent’s office, as well as trained personnel. A local hardware stayed open beyond normal business hours and set up an account for the school, just in case there were last minute tools and materials needed. The list of support could go on and on.

Although 70 volunteers had signed up for NetDay, over 100 appeared at the start time of 8:00 a.m. Participants were divided into eight wiring and three conduit teams. Each team was assigned a specific segment of the school building and was provided with color-coded maps and instructions for wiring from the classrooms to the nearest hub.

By 4:30 in the afternoon, the entire school was wired. The infrastructure necessary for Internet connectivity was complete. Our first NetDay was a tremendous success!

Since that time, the university, schools, and local industry have wired every school in our two local districts—Oxford City School District and Lafayette County School District. Now we are branching out to schools in outlying, rural areas. The Ole Miss NetDay Team sends members to help school districts organize their NetDay projects, helps solicit volunteers, and brings students and faculty members to help with every NetDay.

Within the past year, through these collaborative efforts, we have help wire seventeen schools with well over 2,000 Internet connections. Since the estimated cost for Internet wiring is from $500.00 to $1,000.00 per connection (depending upon local prices), we have helped save our local school districts at least $1,000,000 to $2,000,000 so far.

The Ole Miss NetDay Team, in conjunction with the Mississippi Department of Education, recently sponsored a NetDay Workshop for other school districts that were interested in conducting NetDays. Representatives from 22 school districts in northern Mississippi attended the day-long workshop that focused on the organizational and technical skills necessary to make each NetDay a success. Experienced NetDay volunteers from the local schools, the university, and industry presented their roles in the wiring project.

We realize that we have only begun to scratch the surface of helping our school districts in northern Mississippi with their NetDays. In 1997, we saw a doubling of the districts asking for our help in planning and implementing their wiring projects. So far in 1998, there has been a tripling of scheduled NetDays.

We hope that our model of how the collaboration among the university, schools, and industry is helping the students—our children—connect to the future inspires others to conduct their own “high-tech barn raising” or NetDay project. It is through such cooperative efforts that great achievements in access to technologies can occur.
In-Class Use of Course Webs

Samuel A. Rebelsky
Department of Mathematics and Computer Science, Grinnell College, Grinnell, Iowa 50112
515-269-4410, rebelsky@math.grin.edu

Abstract: As increasing numbers of course webs are built, it is increasingly important to evaluate the effects of those webs on student learning. Web usage may depend on student expertise, classroom setting, and available computing resources. In past studies [Rebelsky 1996b] [Rebelsky 1996a] I examined student reactions to a wide variety of web resources, from assignments to transcriptions of individual class sessions. In this present study, I examine student usage of course webs in classroom situations in which computers are readily available and students are comfortable using hypertext systems. For these students, there is significant, but not uniform, use of web-based course supplements during class periods. More importantly, these students report benefits from their self-directed in-class use of those online materials.

1. Introduction

The World-Wide Web [Berners-Lee et al. 1994] continues to change the ways in which we teach and are expected to teach. Many instructors are putting part or all of their courses on the web (for distance learning or as course supplements), and students are expecting to find course resources on the web. In spite of this growth, there is little formal or informal evaluation of usage or impact of these course webs. For example, of the 182 full papers presented at the 1997 World Conference on Educational Multimedia, Hypermedia, and Telecommunications [Muldner & Reeves 1997], only six provided any form of evaluation of student usage of course webs, and many of those included only rough notes on observations. (However, a number of others evaluated student use of particular hypertext learning tools.) This lack of evaluation is surprising, given that "most researchers agree that insufficient evidence exists to determine whether outcomes match the proclaimed promises of hypermedia" [Fitzgerald & Semrau 1997].

As developers of course webs, we must ask ourselves how students use, react to, benefit from, and are otherwise affected by our course webs. The questions developers of course webs might ask themselves and their students include: (1) When do students access the materials? Before, during, or after each class period? (2) Which materials do students regularly use? Outlines? Syllabus? Assignments? Answer Keys? (3) Where do students access the materials? In the classroom? In their dorm rooms? In public laboratories? (4) In what form do students use the materials? Printed? Electronic? Both? Neither?

In previous studies [Rebelsky 1996a] [Rebelsky 1996b] I reported on student usage of resource-intensive course webs that included outlines of the topics to be covered in class period, copies of anything written on the blackboards during class periods, assignments, selected questions and answers, traditional course handouts, and, in one course, transcriptions of each class period. Students reacted positively towards the online availability of the resources, and indicated that they appreciated effort required to produce these webs. At the same time, they felt overwhelmed by the materials, with many deciding that they needed to print and read everything. In an in-depth analysis of the effects of web usage on computing anxiety [King et al. 1997], King, Henderson, and Putt reported that use of course webs does not appreciably affect computing anxiety (either positively or negatively).

The present study approaches the problem from a different perspective: If students have ready access to computers and the web during class time, how does that affect their perception and usage of the web? In particular, what types of pages do they use most frequently, when do they use them, and what do they say about their usage? The study is based on two courses: a second course in computer science, and a mid-level course in software design.
2. Background

In the fall of 1997, I prepared extensive course webs for two courses at Grinnell College, Computer Science 152 and Computer Science 223. The design of these webs was based on previous research on student use and preferences [Rebelsky 1996a]. Each web contained (1) a front door with links to the remainder of the web and appropriate external resources; (2) standard handouts, such as syllabus, rules and regulations, and assignments; (3) moderate-sized outlines for each class period, developed on or before the day of each class; (4) a short news document documenting updates to the web; (5) online quizzes; and (6) appropriate reference materials, including readings and external links. The class outlines had three parts: (1) a short summary of the topics to be covered; (2) a list of administrative information with links to appropriate pages; (3) my notes on the day's topics. A typical outline is four pages long. Students were told about the course web the first day of the course, and were rarely, if ever, given paper handouts. These course webs can be found at www.math.grin.edu/~rebelsky/Courses/CS223/97F and www.math.grin.edu/~rebelsky/Courses/CS152/97F.

Grinnell College's Computer Science 152 is a standard second course in Computer Science, with emphasis on data structures and algorithm analysis. CS152 meets four days per week. We teach the course in Java so that we may emphasize both object-oriented and imperative design. Grinnell has recently adopted a two language/three paradigm strategy in keeping with the new standards for introductory sequences [Walker & Schneider 1996]. In the fall term, there were seven students enrolled in CS 152, three of whom had taken a previous course based on functional programming, and four of whom had other exposure to programming. All students were familiar with the World-Wide Web and were unfamiliar with Java. The text for the course, a preprint of Bailey's Java Structures [Bailey 1997] included an online software library and reference manuals for the library that were included with the course web.

Grinnell College's Computer Science 223 is a mid-level (sophomore to senior) course on issues in software design. CS223 meets three days per week and covers a wide variety of topics, from forming a programming team and building large projects to issues in user interface design. As such, it draws upon a wide variety of texts, from general treatises on software design [Winograd 1996] to collections of articles on programming [Bentley 1986] [Bentley 1988]. This makes students more inclined to rely on instructor-generated resources, such as the course web. Like CS152, CS223 uses Java as the main language so as to better illustrate object-oriented design. In the fall term, there were twenty-four students enrolled. Of these, nineteen were majors and five were nonmajors. Students were generally unfamiliar with Java, but were uniformly familiar with the World-Wide Web. About half were able to write HTML.

Both courses were taught in the department's MathLAN classroom. This room includes sixteen HP 712/60 Unix workstations. In CS223, students were forced to pair up on workstations, but they were accustomed to this pairing from experiences in other courses. There were some in-class exercises given in both courses, as well as some electronic quizzes (in CS223, students could collaborate on a quiz). Students were permitted to use the computers as they deemed fit during class periods. The MathLAN classroom is adjacent to the MathLAN laboratory, where students often look at course pages before and after each class period. The MathLAN laboratory contains an additional sixteen HP 712/60 Unix workstations and is used as an open laboratory for student use and as a classroom for selected classes.

During the term, I observed a number of students loading the course web pages during class periods, doing "research" on in-class questions by looking elsewhere on the web, and using the computer as a notebook. To ground these observations, I gathered data on how they were using computers and the web during and outside of class periods.

3. Methodology

Data on student web usage were gathered in two ways: students took two surveys on their web usage, and web server logs were analyzed using custom tools. The survey focused on students perceived use of the web, particularly of the class outlines. The logs permitted more general analysis.

Before mid-semester break, students were given an electronic survey on the course webs and were told that the intent of the survey was to determine if and how the class web should be changed for the remainder of the term. In CS152, all seven students answered the survey. In CS223, twenty-one of the twenty-four students answered the survey. The survey asked students (1) how often they referred to the class outlines during, before, and after
class sessions (using a scale of 1 to 5 with 1 representing “never” and 5 representing “always”); (2) whether the outlines were a help or a hindrance or both; (3) whether they printed the outlines; (4) whether they took notes on the computer; (5) a number of free-form questions about the course web; and (6) some questions not pertinent to the study at hand.

Because of a problem with the tool used to build the surveys, not all responses to the first survey were recorded accurately. The tool was repaired and the students were again surveyed about web usage at the end of the term as part of an end-of-semester course evaluation. For this survey, all seven students in CS152 answered the survey and twenty-three of twenty-four in CS223 answered the survey. In the final survey, the numeric rankings were described only as "1-never and 5-always." The numeric results in this paper are based only on the second survey. The textual responses are taken from both surveys.

The access logs generated by our httpd daemon were analyzed with a custom Perl script. Cumulative data for the first seven weeks of the course were used for overall analyses. For each course, this script selected pages according to appropriate criteria. For accuracy, the pages counted were limited to those that were (1) part of the course web (i.e., contain the site root as part of their path); (2) accessed from inside the college (i.e., contain grin.edu as part of the requesting machine); (3) accessed from machines the instructor does not regularly use (the instructor’s machines are never used by students, and the instructor does not view the web from student machines); and (4) valid requests (i.e., requests for which a page exists).

For counts of usage of the current day’s outline “during class”, time of access was restricted to the 15 minutes before and 10 minutes after the class period (if a class that met from 1:15 to 2:05, the times were 1:00 to 2:15).

4. Results and Discussion

Because there are few studies on student use of course webs, this study focused on student reactions and the types of pages they used. Most students report making at least occasional use of the course outlines, with the majority (five of seven in CS152, twenty of twenty-three in CS223) reporting that they always or almost always used the outlines at some point (before, during, or after each class period). Many students seem to pick a particular time to use the outlines, and stick to that time. Some students appear to use the outlines before and during class as a guide to what will happen and others use them later for review.

Student comments described a wide variety of uses of the webs during and near class time. As one might hope, some used them to prepare themselves for the topics in a given class.

I read the outlines before class so I know what to expect and to be in a proper mindset. [CS223 student]

Before class, it’s a great way to get in the mindset of what’s going on in class that day. [CS152 student]

Others used them as aids to recall, to answer questions they had during class, or to find other perspectives.

Sometimes they give enough information beyond what is getting written on the whiteboard. That way, I can piece it together for myself without having to slow down the rest of the lecture for a silly question. [CS223 student]

I really like being able to jump back to any point in the lecture if I find that there is something I didn’t quite catch and need repeated. [CS223 student]

One danger of online resources like these is that they adversely affect student note-taking. Since note-taking has a clear role in learning [Carrier 1983], it is worrisome that some students use class notes as a replacement for their own. I attempt to combat this problem, in part, by using my outlines as only a rough guide for what I teach each day. I often develop new or modified examples, and rarely look at the outlines during class. Students reported that they perceived positive effects on their note-taking. For some, this is because they have not yet learned to take good notes:

I have only mediocre note-taking skills so the outlines that you provide are superior to any notes I would take myself. [CS152 student]

It’s nice to have a record of what happened in class (since I’m a poor note taker). [CS223 student]
After class, it's really beneficial to be able to compare your notes to the class notes and see if you got distracted/whatever or if you didn't emphasize the same things as the outlines did. [CS152 student]

It is, however, worrisome that these students do not yet understand the implicit benefits of notetaking.

More importantly, many reported that the in-class availability of outlines permitted them to concentrate more on understanding than on "mindlessly" copying what I write or say.

Since I do not have to take many notes I am able to concentrate more on understanding what you say instead of writing down. [CS152 student]

Instead of taking the time to write down everything and missing stuff, I can watch and listen more closely. [CS152 student]

I can spend more time listening to what you and other people say than take notes. [CS223 student]

Some of those who were confident in their note-taking abilities reported that they used the outlines to supplement their note-taking.

I like to organize notes when I take them and if I know what general subjects you cover, I'm happier. [CS223 student]

One of the perceived benefits of hypertext is that it supports a variety of learning styles. Student answers suggested that this is, indeed, the case.

I have much better comprehension of things that I read instead of hear. Since you do not follow the outline exactly, reading it can be a way of getting things rephrased or put differently. [CS152 student]

Seeing something on the screen, however, makes me much more likely to remember something. [CS223 student]

It has been reported (e.g., in [Rebelsky 1996a] [Windley 1994]) that students tend to print "everything available" in their course webs. Surprisingly, most students in these two courses reported that they did not regularly print the class outlines. In CS152, only one of seven students reported printing the class outlines. In CS223, only three of twenty-three students reported that they printed the class outlines. It is not clear whether or not this is because of the in-class availability of the resources, but it seems more likely that as computers become more available, students feel less needed for printed copies.

A summary of student self-reports of usage of course outlines appears in [Tab. 1]. The first part of the table summarizes their reported usage before, during, and after class. The second part of the table summarizes the computed maximum and minimum for each student across the three categories. That is, if a student reports a value of 1 for before, 3 for during, and 5 for after, that student's maximum and minimum will be recorded as 5 and 1. These categories are used to accommodate different strategies for using the course web.

Table 1: Student's self-reported use of class outlines. A rating of 1 indicates that the student reports never uses the resource during that time. A rating of 5 indicates that the student reports always using the resource during that time. The maximum and minimum categories reflect the greatest and least values students reported across each of the time periods.
Clearly, different students find different times to use the web and place different emphases on web use. In CS152 there was one student who reported making very little use of the course web (a maximum across all three categories of 2). On the final survey, the student indicated a desire to use the web more but did not explain the limited use. In CS223 there were four students who made significant use of the course web before, during, and after class (a minimum of 4 across all three categories).

One unexpected result was that self-reported usage of course webs in CS223 seems to decrease slightly during class. It may be that many students quickly refer to the outline at the beginning of class to get a better perspective on what will be covered and then do not refer back to them during class. This is clearly an area that should be examined further.

Analysis of web log files shows that reported in-class usage of outlines is fairly close to actual usage. In CS152, the outline of the current class was accessed during class 5.9 times on average. These accesses came from an average of 5.0 machines. This is in keeping with the reported numbers. In CS223, the current class outline was accessed during class 15.0 times on average, from an average of 12.5 machines. A small number of in-class (or, presumably, shortly pre- and post-class) access came from machines outside the classroom, but this number was less than one document per day.

Data from the web server log files was used to generate the reports on overall student web usage in [Tab. 2]. A short analysis of the files accessed suggested that certain sets of documents biased the results. In CS152, documentation that accompanied the book was included in the counts, so a separate analysis without that documentation was done. In CS223, some documents generated by javadoc included images that were counted towards the totals. In addition, a directory loop in the examples section resulted in their being multiple paths to the same document, which greatly increased the number of different documents loaded. Again, separate analyses were done to handle those differences.

The number of accesses per document per student is relatively uniform across classes, with each document being accessed approximately twice by each student. While there are clear variation in access patterns (e.g., the root of the web accounts for nearly one-fifth of the accesses, the two classes have different types of pages, different students use the web differently), it is comforting to see that students do, in fact, regularly use the course materials.

Table 2: Overall web usage in first seven weeks. Restrictions are cumulative. A/D is accesses per day. A/D/S is accesses per day per student. A/S/Week is accesses per student per week.

As [Tab. 3] suggests, students look at a wide variety of materials, but most visits are confined to the course root (presumably as a starting point for explorations) and outlines (which, in the webs used in this study, contain most of the information).

Table 3: Page access by category in the first seven weeks of each course. Percentages may not total 100% due to rounding.

As one might expect, the types of documents used varies depending on whether students are inside or outside of class. In particular, use of class outlines increases significantly during class sessions. Presumably, this is due to a number of factors. First, students are less likely to look at "extraneous" material (such as assignments or syllabus) during class sessions. In addition, students who use the web during class time are likely to follow along in the current outline, or sometimes refer back to previous outlines for further information.

5. Summary

For many of the students in these courses, the in-class use of course webs has had an impact on how they learn in class, or at least on how they perceive their in-class learning. During each class period, over half the students load web pages (in CS223, the sharing of workstations makes presumed usage even higher). Students who use the pages in class report that the web helps them learn better in class, and both poor and good note-takers report benefits for their note taking.

Thanks to the students of CS152 and CS223 for their open responses to my surveys and to their willingness to have their web usage monitored. Thanks also to Elaine Marzluff, Elizabeth Queathem, and Michelle Rebelsky for their comments on drafts of this paper.
Abstract: Deakin Australia, the commercial arm of Deakin University, has included computer-mediated communication as an element of the professional development program produced in conjunction with the Australian Society of Certified Practising Accountants (ASCPA). The CPA Program is delivered by distance education to candidates seeking professional accreditation as Certified Practising Accountants. For a number of reasons the use of CMC to date has been disappointing. The role of CMC in the CPA Program is being reviewed in light of this experience. This paper discusses the history of, and future plans for, CMC in the CPA Program.

Introduction

Computer-mediated communication (CMC) represents a potentially rich enhancement to education and training programs, particularly those offered through distance education. The opportunity for asynchronous (and synchronous) interaction using textual communication enables participation in group dialogue and collaborative project work which is quite distinct from equivalent face-to-face communication. These and other strengths of CMC have been documented widely. See, for instance, [Harasim 1989] or [Kaye 1989].

Deakin Australia has introduced CMC into continuing professional educational programs with mixed results. This paper briefly outlines Deakin Australia's experience to date using CMC and explores possible strategies for future application of online education techniques.

The Provision of Continuing Professional Education

Deakin Australia, the commercial arm of Deakin University, provides education and training programs in collaboration with clients from professional associations, government agencies and the corporate sector. Continuing professional development programs are offered, by distance education, in conjunction with a range of professional associations including the Australian Society of Certified Practising Accountants (ASCPA). Candidates in these programs are typically young graduates in full-time employment who are seeking accreditation as full members of their respective professional associations.

The Accounting Society's CPA Program has the following main features:

- Two core and three elective semester units of study ('segments') are to be completed.
- Assessment occurs via invigilated, end-of-semester, multiple-choice-question examinations.
- Distance learning is the mode of delivery.
- A combination of study media and support mechanisms is used, including:
  - printed study manual (the main learning resource)
  - audio cassettes
- CBE via floppy disk
- face-to-face workshops in the larger urban locations
- WWW-page information service and study forum
- academic and administrative support from ASCPA education staff via telephone/fax/email links.

- 22,300 people enrolled in the Program for 1997, generating approximately 16,000 segment enrolments per semester - a much larger enrolment than many university faculties.

- The enrolment pattern is approximately 70% from within Australia and 30% from South East Asia (Hong Kong, Malaysia and Singapore) with a sprinkling of candidates from Europe and other locations.

- Formal evaluation of materials occurs as part of an annual development cycle.

Deakin Australia's education and training programs have used computers extensively for many years: computer-managed learning has underpinned the Technology Management course undertaken by students from corporate and government clients, and computer-aided learning on computer disk has formed part of the distance learning materials distributed to candidates undertaking the ASCPA's CPA Program.

In 1995, Deakin Australia introduced 'Deakinet' into the CPA Program. Deakinet gave candidates access to the Deakin University electronic network which provided email access to and from candidates, tutors and other education staff of the ASCPA, as well as access between candidates. Candidates were also invited to subscribe to discussion groups based on their subject enrolments.

Candidates were required to provide their own personal computer and a suitable modem. Deakin Australia provided the necessary software and documentation on connecting the modem, installing the software and logging into Deakinet.

**The Deakinet Experience**

The rationale behind the introduction of Deakinet was to reinforce the motivation of candidates to participate fully in the study programs and, importantly, to facilitate candidates' maintaining a regular study pattern through the semester program.

The ASCPA Deakinet service included a schedule of weekly study questions for consideration and subsequent discussion. Each subject area was moderated by a member of the ASCPA's education staff.

It was hoped that adding email to the existing ASCPA candidate support network (telephone and fax contact, and face-to-face workshops conducted in the main urban centres in Australia and South East Asia) would produce the positive outcomes reported in case studies of other distance education online study groups. For example, see [Blantern 1992], [McConnell 1991], [Paulsen 1991] and [Steeples et al. 1996].

The Deakinet experience was disappointing. ASCPA study group numbers were abysmally low (less than 3% of enrolments in the CPA Program itself) and there was virtually no discussion traffic in response to the set question topics and no discussion topics generated by the candidates themselves.

The low participation rate was due to a combination of limited access to a personal computer and/or modem (modem access was 26% in 1995, 28% in 1996 and 49% in 1997) and a serious shortage of discretionary time available to candidates contending with full-time employment, part-time study and the usual range of family and related commitments. Of those who did register to participate in Deakinet, many reported technical problems connecting modems and in logging into the network.

The pattern of enrolment in Deakinet and the level of participation by ASCPA candidates did not improve after the initial semester program and Deakinet was withdrawn during 1996 and replaced by a limited information service provided on a WWW page, to which candidates must arrange their own access. Use of the CPA Program information service continues to be low.

**CMC: The Hype and the Reality**
The professional literature discusses the educational functions able to be fulfilled by CMC. For instance, [Chacon 1992] extends Kaye's essential characteristics of CMC into a table of pedagogical functions of the Communication Mode (CM).

**From written medium**
- learning verbal information
- development of expression
- developing skills for analysis and syntheses of text

**From group interaction and co-operation**
- motivational support of distance students
- development of critical judgement
- participative problem-solving
- opportunity for incidental learning

**From audiovisual medium (developing feature of CM)**
- added motivational strength
- substitutive of direct experience
- presentation of abstract knowledge

It appears that CMC is able to offer teaching options across the spectrum of strategies employed in face-to-face and resource-based distance education program settings. Chacon observes that 'the quality of service delivered by computers does not depend as much on their technological sophistication as on their relations to users and other media. Within a given user mode, the corresponding pedagogical functions may be accomplished as well by the "low end" of "cheap" media as by the more sophisticated ... This conclusion has enormous importance for distance education programs, concerned as they are with equal opportunity of access.'

Not surprisingly, educational providers are 'going online' at a great rate of knots. Many institutions appear to be making productive use of CMC. Numerous 'virtual universities' are offering educational programs via the Internet. The bandwagon of online education is gathering momentum.

The Deakin Australia experience with Deakinet has led to a more restrained view of the potential role of CMC in continuing professional education. There is no doubt that CMC does add to the armoury of distance (and face-to-face) education instructional strategies. However, the practicality of these strategies needs to be assessed in relation to the particular instructional circumstances. In the case of the CPA Program, the 1995 cohort of candidates with access to modem links was too small to permit development of a vigorous online discourse. While the 1998 cohort is certainly much larger, the problem of a shortage of study time remains. CPA Program candidates make pragmatic judgements about how their scarce study time is best allocated. Program evaluations suggest that the printed study manual is regarded as the primary resource and that other support resources must be demonstrated to add value as effective means of examination preparation before they will be embraced.

**The Future of CMC in Deakin Australia Programs**

Considering the range of services that is potentially available through CMC in relation to the needs of CPA Program candidates, the following observations may be made:

- An opportunity for dialogue with education staff of the ASCPA and other CPA Program candidates would be valuable.
- Such dialogue would be likely to be oriented to supporting segment study manuals and other segment study resources.
- CMC dialogue may be preferred by some candidates (over present phone and fax services) because of costs involved and for the reasons explored by [Mason 1989], that is, CMC is not seen as being as intrusive on tutors and fellow students as telephone queries and enables students to ask questions at the time an issue arises rather than during office or other specified hours of contact.
Activities which proposed collaboration between candidates to build knowledge and explore academic points of interest within study programs would be bound to fail because of the shortage of study time available to candidates.

Any move to introduce techniques and services which involved CMC becoming a primary teaching medium would raise serious problems of access and equity.

Widespread use of discussion groups and other techniques which involved close moderation of small groups by tutors would impose huge administrative and logistical problems and would be untenable.

Applications which relied on candidates storing and reviewing copious text files would not be popular. Candidates maintain that there is already too much to read in segment programs.

Applications which reinforced a regular reference to the segment study program and encouraged candidates to pace their study evenly through the semester would be a useful timetabling and planning aid.

In addition to enrolled CPA Program candidates, it would be desirable to make Program information available to potential candidates.

Applications which promote 'examination readiness' are likely to be popular.

An update service which provided succinct details of legislative and regulatory changes etc. and other current developments in the segment study discipline would promote candidate interest in the use of CMC within the study program.

Deakin Australia is continuing to explore uses of online communication in continuing professional education. A range of options is being considered to build on the present restricted use of CMC within the CPA Program based on the above observations, the theoretical considerations of CMC discussed earlier in the paper and Deakin Australia's experience with Deakinet. These options, to be offered via WWW pages and associated email links, fall broadly into three categories of CMC activity - an information service, an update service and a tutorial service.

Information service
Information to intending enrollees (and the world at large). Components of the service are presently in place and include:
- CPA Program handbook (pre-requisites for enrolment in CPA Program, CPA Program objectives, segment outlines and objectives etc.)
- Weekly study schedule
- Examiners' reports
- CPA Program enrolment form

Update service
CPA Program updates
- Administrative notices, reminders
- Errata sheets
- Legislative changes, information on new standards and other accounting document releases

Stop press
- Informal information exchange (eg. job vacancies, other items of general interest)
- Notice of topical information (eg. newspaper and journal articles, visiting speakers, seminars etc.)

Tutorial service
Weekly study commentary
- Brief comment or elucidation of some aspect of the segment study program (eg. review question, case study, diagram, reading, CBE program feature, audio cassette discussion etc.) to reinforce the sense of a timetable for regular progress through the segment study guide and to help to integrate the various resources making up the study program. Candidates could be invited to submit questions or make comments on the tutorial entries.
• Examination review (to include practice questions and commentary, candidate queries and other responses to be invited)

Symposium series
• Two or three sessions of dialogue (over the 12- to 14-week semester) involving exchanges between subject experts on some important or difficult segment topic, each could run over one or two weeks.
• Candidate questions/comments would be invited.

Seminar series
• Simulation of face-to-face workshops or seminars in which presenters outline given topic areas within segment study programs.
• Topics to be selected such that scope of presentation, while broader than the planned weekly study commentaries, is confined to discrete, logistically manageable study units.
• Presentation to consist of audio commentary and accompanying graphics and a limited use of text to reinforce and summarise key issues.
• Candidates to be invited to submit email queries and comments.

Segment knowledge base
• Database containing additional information on segment study program (eg. points arising from segment workshops, questions and information arising from phone contact with candidates, links to relevant pages on WWW and any other sundry segment intelligence).

Chat service
• Invitation at nominated times for online chat with tutor and/or other segment specialists.
• This service would be run on a limited trial basis to assess the likely resource implications if offered as a standard feature throughout the CPA Program.

Conclusion

Having entered the domain of CMC and been disappointed with the initial outcome, Deakin Australia is reviewing its experience and devising an alternative online strategy.

The use of CMC in continuing professional education must recognise that significant barriers constrain the intended users. Access to basic equipment will be a problem for a sizeable minority of users for some time yet. Adoption of specific conferencing software in addition to use of the WWW will exclude other potential users. To be of benefit to those users possessing the required hardware and software, services provided through CMC must be perceived to add value within a narrowly focussed study framework. Accordingly, online techniques need to focus on simple applications which facilitate examination readiness (or promote mastery of specified skills outcomes) and economise on study time.

A further complicating factor for Deakin Australia is the large numbers to be catered for within client programs, particularly the CPA Program. Information and update services do not present a problem in this respect, and some of the tutorial activities may be designed to economise on co-ordinating/moderating input. However, trials of the proposed seminar and chat services will need to be closely scrutinised to assess the resource requirements of a wider application of these techniques.

CMC has the potential to powerfully enrich continuing professional education and other forms of distance education. [Carvin 1997] points out that CMC (through the WWW) is able to extend the scope of an education/training organisation in the roles of tutor, publishing house, forum and navigator. It remains to be seen whether this potential is realised across all of these roles or in a less balanced development.

Answering Critics of Media and Technology in Education

Thomas C. Reeves, Ph.D.
Instructional Technology, The University of Georgia
604 Aderhold Hall, Athens, GA 30602-7144 USA
Tel: 706-542-3849, Fax: 706-542-4032, E-mail: treeves@coe.uga.edu

Abstract: Serious critics of media and technology in education must be answered. The response provided in this paper concludes that: 1) media and technology are best used as cognitive tools to learn with rather than as surrogate teachers, 2) media and technology are only vehicles for the content and pedagogy that educators design into them, and 3) future efforts to integrate media and technology into education must be guided by stronger research and evaluation.

Introduction

In the United States of America, the degree of federal government support for the development and use of media and technology in education has never been stronger than it is today. For example, in his 1997 State of the Union address, President Clinton said:

Now, looking ahead, the greatest step of all - the high threshold of the future we now must cross - and my number one priority for the next four years is to ensure that all Americans have the best education in the world. Let's work together to meet these three goals: Every 8-year-old must be able to read; every 12-year-old must be able to log on to the Internet; every 18-year-old must be able to go to college; and every adult American must be able to keep on learning for a lifetime.

Overlooking the fact that the quote above actually contains four goals, not three, all of President Clinton's priorities for his second term of office have direct relevance to media and technology in education. First, the ability to read in the 21st Century demands the development of new forms of media literacy. Negroponte describes the Internet as a place where "children are heard and not seen" [Negroponte, 1995, p. 202]. He predicts that the reading and writing skills of Internet savvy students will improve because "Children will read and write on the Internet to communicate, not just to complete some abstract and artificial exercise" (p. 202). The importance of media and technology in the development of the "new literacy" is obvious.

The second goal regarding Internet access for 12-year-old children has an even more obvious connection to support for media and technology in education. The push to wire all K-12 schools in the USA with full Internet access is proceeding at a rapid rate. According to an Educational Testing Service report, 64% of U.S. schools now have Internet access, and all U.S. schools, and more importantly, many of the classrooms within them, will be "wired" by the year 2000 [Coley et al., 1997]. Of course, whether students and teachers will be prepared to utilize the power of the Internet to support learning remains to be seen.

Third, with respect to higher education opportunities for 18-year-olds, it must be recognized that gaining entrance to higher education is just the beginning. Succeeding there is increasingly unlikely without media and technology skills unimagined in academe even a few years ago. Many university faculty have stopped romanticizing the lecture and are acknowledging the powers of multimedia to provide effective interactive learning opportunities. In fact, many U.S. universities have defined a minimum set of technology skills expected of all students before they enter postsecondary courses, as well as for faculty before they begin to teach [Harrison and Stephen, 1996]. Of course, if students are to enter higher education
possessing robust media and technology skills, they must begin to develop these skills while they are still in K-12 schools.

Fourth, lifelong learning is rapidly changing from a "buzzword" to a mainstream expectation in business, industry, government, and other spheres of human activity. Winslow and Bramer from Andersen Consulting describe integrated performance support systems as essential to the levels of workplace performance required of all workers in organizations that hope to compete in a global economy [Winslow and Bramer, 1994]. They maintain that these support systems must be "multisensory," integrating a variety of media appropriate to the task to be learned or performed. Lifelong learners won't possess the necessary skills and experience with multiple forms of media unless schools include appropriate learning opportunities across the curriculum.

Given the increased investments in technology in education at the federal level in the USA, it is not surprising that educational media and technology are being subjected to severe criticisms by some. These critiques must not be ignored because critical analysis plays an essential role in a democratic society. Hence, the goal of this paper is not to dismiss critics of educational innovations, but to respond to the doubts expressed by three vocal critics of media and technology in education in a responsible manner. These critics render a great service by forcing us to examine our assumptions about media, technology, and education.

**Future Schlock**

In a cover story titled "Future Schlock" in the March 1997 issue of Phi Delta Kappan, Lawrence Baines, a professor at Florida State University, protests the "platitudes and fabrications" that underlie much of what is being proposed in the name of educational reform [Baines, 1997]. He is especially harsh on technology as a reform vehicle, listing as "Fabrication 1," the statement that "Technology is a moral imperative that will increase student achievement and make American students globally competitive" (p. 494). Baines concludes by proclaiming as "Reality" that "Technology can make learning more fun, easier, and cleaner. But no data supports the conclusion that technology causes gains in student achievement" (p. 495).

Baines' reality statement has a grain of truth in it, but it is ultimately misleading. Researchers have failed to reveal "causal" explanations for the impact of technology on learning, but that is because educational research, like all social sciences, is often limited to discovering relationships rather than revealing definitive causal explanations. However, there are hundreds of studies that support the impact of media and technology on achievement [Jonassen, 1996]. For example, meta-analyses of computer-based instruction (CBI) studies have revealed modest, but positive relationships between technology and achievement at all levels of education: elementary (0.47), secondary (0.36), higher (0.26), and adult (0.42) [Kulik, 1994]. Of course, it must be admitted that the average effect sizes for technologies such as CBI do not approach the two-sigma (2.00) difference often promised by commercial interests and other proponents of technology in education. Nonetheless, positive results are dominant in the research literature, as summarized in a 1997 report from the Educational Testing Service (ETS) titled *Computers and Classrooms* [Coley et al., 1997]:

[CBI] can individualize instruction and give instant feedback to students, even explaining the correct answer. The computer is infinitely patient and non-judgmental. This motivates students to continue.... Students usually learn more in classes in which they receive computer-based instruction. Students learn their lessons in less time with computer-based instruction. Students also like their classes more when they receive computer help in them. (p. 35)

Another misleading aspect of Baines statement is that he fails to point out that his critique is limited to studies that have examined the effects of learning "from" computers. Baines appears unaware of the evidence indicating that it may be more effective to engage students in learning "with" computers than "from" them. In most existing applications of computers in education, content and instruction are encoded by specialists such as instructional designers into predefined educational communications
intended to transmit knowledge to students. Students are expected to receive these communications passively with occasional artificial interactions to let the computer know they are ready to receive more information. In this approach, students are expected to learn "from" computers which have been cast in the role of a surrogate instructor. An alternative approach involves using computers as "cognitive tools" that students learn "with" in a cognitive partnership [Jonassen and Reeves, 1996]. Cognitive tools refer to technologies, tangible or intangible, that enhance our cognitive powers during thinking, problem-solving, and learning. Cognitive tools have been around ever since primitive humans used piles of stones, marks on trees, or knots in vines to calculate sums or record events. Something as simple as a grocery list or as complex as calculus can be regarded as a cognitive tool in that each allows us to "off-load" memorization or other mental tasks onto "technology." Computers are extremely powerful cognitive tools. When software programs are used as cognitive tools in education, students use software to analyze complex problems, solve difficult tasks, access information, interpret and organize their personal knowledge, devise unique solutions, and represent what they have learned to others.

Although research studies on using media and technology as cognitive tools are relatively scarce, the results are often notable [Jonassen and Reeves, 1996]. For example, Lehrer has studied the use of multimedia construction software by eighth graders designing their own lessons about the American Civil War [Lehrer, 1993]. His work exemplifies the principle that: "Cognitive tools empower learners to design their own representations of knowledge rather than absorbing knowledge representations preconceived by others." Students in one of Lehrer's studies were high and low ability eighth graders who worked at the multimedia construction tasks for one class period of 45 minutes each day over a period of ten weeks. The students worked in a media center where they had access to computers, a scanner, sound digitizer, multimedia construction software, and numerous print and non-print resources about the Civil War. A teacher was available to coach students in the conceptualization, design, and production of their programs. Students created programs reflecting their unique interests. For example, they created multimedia about the role of women in the Civil War, the perspectives of slaves toward the war, and "not-so-famous people" from that period. According to Lehrer, "The most striking finding was the degree of student involvement and engagement" (p. 209). All students became task-oriented, increasingly so as they gained more autonomy and confidence with the cognitive tools. At the end of the study, students in the multimedia group and a control group of students who had studied the Civil War via traditional classroom methods during the same period of time were given an identical teacher-constructed test. No significant test differences were found. However, a year later, when students in the design and control groups were interviewed by an independent interviewer unconnected with the previous year's work, important differences were found. Students in the control group could recall almost nothing about the historical content, whereas students in the design group displayed elaborate concepts and ideas that they had extended to other areas of history. Most importantly, although students in the control group defined history as the record of the facts of the past, students in the design class defined history as a process of interpreting the past from different perspectives. In short, the cognitive tool approach lead to knowledge that was richer, better connected, and more applicable to subsequent learning and events. After this and other studies, Lehrer concluded that: 1) by using multimedia as cognitive tools, students' on-task behavior increased over time, 2) they perceived the benefits of planning and modifying their work during different stages of development, and 3) they developed generalizable skills such as taking notes, finding information, coordinating their work with other team members, writing interpretations, and designing presentations.

In an extensive review of the literature [Jonassen and Reeves, 1996], the theoretical foundations for using computers as cognitive tools are summarized:

- Cognitive tools are most effective when they are applied within constructivist learning environments.
- Cognitive tools empower learners to design their own representations of knowledge rather than absorbing the representations preconceived by others.
- Cognitive tools can promote the deep reflective thinking that is necessary for meaningful learning.
- Cognitive tools enable mindful, challenging learning rather than the effortless learning promised but rarely realized by other instructional technologies.
- Cognitive tools should be applied to tasks or problems defined by learners with the support of their teachers.
- Cognitive tool use for education should be situated in realistic contexts with results that are personally meaningful for learners.
- Cognitive tools can enable intellectual partnerships in the form of distributed cognitive processing. (p. 698)
The Computer Delusion

Perhaps the most talked-about attack on media and technology in education this year has been Todd Oppenheimer’s cover story, “The Computer Delusion,” published in the July 1997 issue of The Atlantic Monthly [Oppenheimer, 1997]. Oppenheimer starts his critique by reciting some of the overly optimistic predictions made about the educational benefits of earlier technologies such as film, radio, television, programmed instruction, teaching machines, etc. For example, he notes that Thomas Edison predicted that “the motion picture is destined to revolutionize our educational system and....in a few years it will supplant largely, if not entirely, the use of textbooks” (p. 45). Such predictions have always been easy targets, and there are no shortage of similar targets today. Consider this quote from Lewis Perelman’s book School’s Out [Perelman, 1992].

Because of the pervasive and potent impact of HL (hyperlearning) technology, we now are experiencing the turbulent advent of an economic and social transformation more profound than the industrial revolution. The same technology that is transforming work offers new learning systems to solve the problems it creates. In the wake of the HL revolution, the technology called “school” and the social institution commonly thought of as “education” will be as obsolete and ultimately extinct as the dinosaurs. (p. 50)

With hyperbole like Perelman’s, is it really surprising that pundits like Oppenheimer have concluded that many of us are blinded by technology? Ironically, Oppenheimer appears to exaggerate as much as Perelman, albeit in the opposite direction. For example, by taking quotes out of context and citing a few dubious studies, Oppenheimer claims that computers threaten to diminish the reading, writing, and self-expression skills of students while at the same time crushing their imaginations and stunting their socialization. The major thrust of Oppenheimer’s critique is that “school districts are cutting programs - music, art, physical education - that enrich children’s lives to make room” for computers while “there is no good evidence that most uses of computers significantly improve teaching and learning” (p. 45).

As with Baines critique, Oppenheimer’s attack contains a little truth and a great deal of misinformation. Instead of being non-existent, the evidence of the effects of using computers in a tutorial mode is generally positive, albeit modest [Kulik, 1994]. However, when computers are used to enable innovative pedagogical approaches, results are impressive. For example, consider Apple Classrooms of Tomorrow (ACOT) project, a decade long initiative to introduce computers and associated media into schools and homes. The simple presence of technology and media had little impact in ACOT schools, but when the technology was used to enable enhanced pedagogical strategies such as project-based learning, collaboration, and extended time-on-task, the outcomes were quite positive [Fisher et al., 1996]. The results are summarized in an Educational Testing Service Report [Coley et al., 1997] as:

ACOT students:
- Explored and represented information dynamically and in many forms
- Communicated effectively about complex processes
- Used technology routinely and appropriately
- Became independent learners and self-starters
- Knew their areas of expertise and shared their expertise spontaneously
- Worked well collaboratively
- Developed a positive orientation to the future (p. 37)

Oppenheimer argues that it is the improved teaching and learning strategies that make the difference in success stories like ACOT, not the technology. He is correct that the enhanced pedagogy is what matters most [Clark, 1994], but he fails to recognize that such pedagogical enhancements would be impossible without the capabilities of new technology [Kozma, 1994]. The reality is that in most schools, technology is an essential vehicle for pedagogical change.
The End of Education

Neil Postman is probably the best known critic of media and technology in education. In The End of Education, Postman has taken educators to task for the adopting new technologies without questioning their impact on the basic goals and processes of education [Postman, 1995]. For example, Postman wrote:

I do not go as far back as the introduction of the radio and the Victrola, but I am old enough to remember when 16-millimeter film was to be the sure cure, then closed-circuit television, then 8-millimeter film, then teacherproof textbooks. Now computers. I know a false god when I see one. (p. 50)

One response to Postman's concerns is that he too is focusing on media and technology as things that students learn from rather than tools that they learn with. This is hardly surprising given that most of the commercial advertisements promoting the use of media and technology in education emphasize the "from" approach. For example, a recent brochure from Macromedia, the company the markets popular authoring systems such as Authorware and Director, has the following message on its cover: "To better reach your students, don't change your message." Upon opening the brochure, the following message appears in ever bolder type: "Change your medium." The belief that the same old content and instructional strategies will somehow be transformed by delivering them via the latest media and technology is widespread in education, and Postman, Oppenheimer, Baines, and others are wise to question the validity of this approach. Significant educational improvements are more likely to stem from changes in the message (i.e., content and pedagogy) than merely switching to another medium.

Although often castigated as an Information Age Luddite, Postman actually concludes his The End of Education book with support for the integration of "technology education" into schools [Postman, 1995]. He defines technology education as a subject in which students address questions such as:

How does information differ in symbolic form? How do ideographs differ from letters? How are images different from words? Paintings from photographs? Speech from writing? Television from books? Radio from television? Information comes in many forms, and at different velocities and in different quantities. Do the differences matter? Do the differences have varying psychic and social effects? The questions are almost endless. This is a serious subject. (p. 190)

Postman's conception of technology education stands in sharp contrast with more common approaches to technology education that are centered on the teaching of how to use technology. There are only a handful of schools where media and technology are considered as important subjects of disciplined study in and of themselves. Several notable experiments are highlighted in Brave New Schools [Cummins and Sayers, 1995]. For example, they describe an electronic telecommunications project at Cold Spring Harbor High School in New York in which U.S. students engaged Israeli and Palestinian students in a dialog about how the news media cover events in the Middle East with either a pro-Israeli or pro-Palestinian bias. The words of one of the participating students conveys the power of this experience:

I have had the opportunity to accomplish what many other students may never even have a chance to attempt. Even though I do not have the influence to reverse the sometimes harsh sentiments of the people, I would like to come away thinking that at least I did something to help the peace process along.... Many people do not have the opportunity to tap directly into the minds and hearts of their peers who live thousands of miles away in troubled lands. I am very thankful to have worked on a project that has strengthened my communication skills and provided me with some of the most valuable lessons one can learn in life. (p. 76)

Although it is difficult to agree with Postman's conclusion that computers and other technologies are false gods, his concerns for the social and psychological effects of media must not be ignored. Technology affords us many benefits, but rarely without some hidden or unexpected costs. The examination of these costs within educational contexts is an important enterprise.
Conclusion

What can be concluded from this brief response to three of the major criticisms aimed at media and technology in education in the USA? My conclusions are in agreement with those of the Panel on Educational Technology that was part of the U. S. President's Committee of Advisors on Science and Technology. The Panel made the following recommendations [President's Committee of Advisors on Science and Technology, 1997]:

1. Focus on learning with technology, not about technology.
2. Emphasize content and pedagogy, and not just hardware.
3. Give special attention to professional development.
4. Engage in realistic budgeting.
5. Ensure equitable, universal access.
6. Initiate a major program of experimental research.

Numbers 1, 2, and 6 above are especially in sync with my own conclusions. Technology is best used as a cognitive tool to learn with rather than as a surrogate teacher. Pedagogy and content matter most; technology and media are only vehicles, albeit powerful ones. Most importantly, future efforts to use media and technology in schools must be guided by much more rigorous research and evaluation than in the past.

Abstract: This paper highlights the findings of a study to identify evolving changes in Instructional Technology (IT) practitioner competency requirements, and consequent changes in instructional technology curricula. It then speculates on possibilities offered by technologies from a market perspective that does not assume only incremental changes in the education establishment. The study provides a benchmark against which programs can be examined; guidelines for establishing new programs; and another plank in the ongoing discussion about IT in education and society.

1. Introduction

This paper highlights the findings of a study to identify evolving changes in Instructional Technology (IT) practitioner competency requirements, and consequent changes in instructional technology curricula. As used in the North American context, and more specifically within the study, IT means instructional technology. This is defined by [Seels & Richey 1994] as "the theory and practice of design, development, utilization, management, and evaluation of processes and resources for learning." In Europe, the term information technology is used to cover the corresponding field.

We find that key to achieving a quality, future oriented IT program are:
- a strong program core that focuses on ISD — an iterative process of design, development, implementation and evaluation of instruction and training for development or performance improvement — and encompasses the broad base of competencies within the total field that all students will require as IT practitioners; and,
- a program structure that fosters fullest diversity in the options, including highly specialized instructional technologies, in combination with the breadth of the program core; and, demonstrates timely, responsive and cost effective delivery.

In addition, recognizing the inherent applied nature of the field and the growing requirement to demonstrate continuous professional improvement, we anticipate that the preparation of a professional portfolio, now required in some programs, will become a core program requirement.

2. Methodology and Data

In coming to this conclusion the study employed descriptive-comparative analysis methodology, taking an interpretive approach to existing data on IT role competencies and programs, to identify the key domains of the field and develop a generic masters level program profile reflecting the core competencies of those domains.

2.1 Role Data

Roles for which competency data were reviewed included: instructor/trainer, instructional designer, educational media developer, educational computing specialist and distance educator. Over the past decade extensive national surveys have been carried out to identify practitioner competencies related to a number of these roles. In 1996, the British Employment Occupational Standards Council published standards and
qualifications core to training and development roles which "are accepted nationally by all parties having an interest in training and development" [UK EOSC 1996, p. 5]. Canadian data are from 1986 when the Ontario Ministry of Education published the project report for a "review of the literature and field validation of the competencies of industrial and organizational trainers and educators" [Davie et al. 1986, p. 1]. In the U.S., the American Society for Training and Development (ASTD) study of human resources specialists led to identification of 16 core instructional design competencies and standards [IBSTIPI 1986]. Our study utilized the competency data derived from these studies, in conjunction with data from recent studies that have reviewed IT competencies: a) in the context of program content [Morlan & Lu 1993; Dempsey & Rasmussen 1993]; b) on the basis of practitioner surveys [Furst-Bowe 1996; Thach & Murphy 1995]; and, c) on the basis of future needs [Heideman 1991].

2.2 Program Data

Program data were collected to identify how the role competencies might be bundled within graduate courses; the specializations that could be built on these; and benchmark characteristics of quality programs. Initially, North American institutions that have an IT program with a strong reputation for quality or innovation were identified through the literature and WWW presence. Additional criteria for the selection of programs included recent doctoral graduates, and 3 or more full time faculty. This was determined on the basis of the quantitative data available for the 19 selected programs from Educational Media and Technology Yearbook, 1985-1997 and Peterson's Graduate programs in the humanities, arts & social sciences, 1995-1997.

Secondly, descriptive data for the selected programs were gathered, primarily from the Internet. As part of this phase an instructional technology web site was developed which included links to various programs, as well as related background information. Program data were those available as of March 1997 and can be viewed, as updated, at URL http://www.ualberta.ca/~prempel/itfield5.html. The program data were reviewed to identify (a) core and specialization competencies as stated, or as reflected in course descriptions, (b) program entry and exit requirements, and (c) program structure and delivery options.

3. Program Core

Elements from the programs reviewed were utilized to develop a generic program core, with an added emphasis on two aspects that have been identified in the literature as critical — cost-effectiveness and a demonstrated practice of continuous professional improvement. Six program modules encompass the core competencies of the field.

3.1 IT Module 1 - The Field

The proposed program begins with a module that overviews the field as a whole, including definitions, history, relation to cognate fields, current trends and issues. Upon completion of the module students would be able to:

- describe the theoretic base of the field and how it relates to and draws from theories of cognate fields;
- describe how the ISD process relates to reflective teaching and performance technology; and
- discuss trends in research and technologies as they relate to IT practice and options.

3.2 IT Module 2 - Theory of Instructional Design and Development

This module provides a comprehensive overview of instructional theory, including learning and communication, as they relate to instruction, training and performance improvement. It also covers evaluation of instructional products such as CAI for independently meeting identified instructional needs. Upon completion of the module students would be able to:
identify a range of instructional strategies appropriate to various learning objectives, learner characteristics, and settings;
identify appropriate instructional materials to explain or present content; provide practice appropriate to the skill being learned; and
evaluate instructional materials and modules for accuracy of content; against visual and learning design criteria; and for congruency with specified learning objectives, learner characteristics, instructional strategies.

3.3 IT Module 3 - ISD Process

This module covers the design of programs which meet identified learning needs for individuals and groups. Emphasis is on design issues and the selection of options for meeting learner requirements. Students develop individual and/or group projects. Upon completion of the module students would be able to:

- explain the value and application of systems thinking (ISD) in the planning and design of instructional programs and resources;
- explain the importance of evaluation of effectiveness, including cost effectiveness, of instructional sessions, programs and resources;
- explain how the instructional design process is applied in classroom instruction, adult learning settings and business training to improve learning outcomes;
- explain how the instructional design process is applied in classroom instruction, adult learning settings and business training to improve performance through increased transfer of learning; and
- demonstrate a working knowledge of instructional design.

3.4 IT Module 4 - Development

This module introduces students to technologies used for instruction and training and to the entire multimedia production process. The module emphasizes basic skills in instructional media production, quality assurance and group process. Upon completion of the module students would be able to:

- discuss and compare the capabilities and limitations of various instructional technologies;
- discuss the steps in the production process;
- discuss project management methodologies and tools; and
- apply basic skills in instructional media and presentation production.

3.5 IT Module 5 - Implementation and Change

This module provides a comprehensive overview of systemic change in education and business enterprises; innovation and adoption practices; implementation analysis and strategies; productivity; cost-effectiveness; and preparation of training or technology implementation plans. Upon completion of the module students would be able to:

- discuss utilization of personal professional development plans to overcome individual resistance and barriers to change;
- discuss utilization of technology plans to overcome systemic resistance and barriers to change;
- discuss the utilization of cost-effectiveness analysis as a basis for selection among instructional delivery alternatives;
- identify human issues associated with the introduction and use of instructional technologies; and
- demonstrate development of a professional development plan.

3.6 IT Module 6 - Analysis and Evaluation
This module provides a comprehensive overview of data collection and analysis techniques, instructional analysis, measurement and evaluation. Topics covered will include: reporting skills; design of assessment situations; simple data summary, analysis and decision techniques including cost-effectiveness and cost-benefit. Upon completion of the course students would be able to:

- discuss utilization of instructional analysis and implementation analysis for planning;
- discuss utilization of evaluation results to monitor and improve learner outcomes, instructor performance and intervention effectiveness;
- develop effective evaluation forms for instructional sessions; and
- analyze various data types using a variety of methodologies.

3.7 Findings

With regard to content, there is a continual and dynamic trade-off between program breadth and depth; success is more art than science. However, these core modules reflect our findings that the broad competencies identified in various practitioner surveys as most important continue to form a relatively stable foundation in quality programs and in IT practice. What we also found are increasing expectations both in program and position pre-requisites that go beyond the computer based skill shift. Educators and educational systems are being deluged by technology marketing hype that is most particularly exemplified by the plethora of software programs, each of which focus on a minuscule portion of the spectrum of knowledge expected of functioning individuals. This marketing hype surrounding software, which relates to process rather than content, tends to become implicit in our judgments and results in a tendency to interpret the focus of an instructional technology curriculum as technologies of instruction. Education, however, is a combination of process and content and, if one looks to IT education as merely being the sum of these little process components, the end result is something that falls short of prevailing educational expectations.

4. Field Domains

On this basis, we identified four domains as core to IT performance — design, development, implementation and evaluation. The proposed common program core would provide a grounding in each of the four field domains within an ISD framework. Our findings do not support inclusion of a ‘utilization’ domain with demonstration level competencies.

Figure 1: IT field domains and their relationship to potential areas of specialization within the field.
We have maintained an instructional systems approach underlying the inter-relationship of the domains, even though such a broad system approach can result in inflexibility and resistance to change when issues tend to be defined and addressed based on the assumption that, whatever the question, instruction or training is the answer. Furthermore, recognizing that teachers represent a significant program market, it may be critical to program viability to reconcile the current perception wherein North American K-12 teachers generally do not consider the ISD process to be relevant to classroom practice.

Our model is consistent with the programs at Indiana and Florida State. However, adoption of such a program must be tempered by the recognition that the market for IT practitioners is relatively small and is further limited by requiring mastery of all the identified core competencies. The Pennsylvania State program includes a similar core but offers application streams tailored specifically to business and the K-12 environments. A number of IT programs, while offering as options the courses that would encompass the core competencies required by an IT practitioner, maintain a smaller program core that targets a wider market. A major component of that wider market is instructors who do not aspire to be IT professionals but choose to acquire selected IT competencies adjunctive to professional or technical qualifications.

5. Program Structure

Relevance and viability, particularly in the general education market, would appear to mandate a compressed core program supplemented by tailored streams employing active field practitioners as instructors. Such instructors can deliver applied education that bridges content and process in a manner that is timely and cost-effective.

In an applied and dynamic field, the recruitment and use of practitioner-instructors would provide several benefits. Such a coordinated approach maximizes flexibility of organizational competencies at a time when requisite competencies cannot be accurately forecast, as has been ably demonstrated by none other than Bill Gates himself. It minimizes fixed costs, thus allowing effective response to the multiplicity of external demands, opportunities and emerging technologies. It would extend the range of optional course offerings while, at the same time, a strong program core would be maintained by full time faculty.

Quite aside from other tangible benefits, such deliberate and systematic outsourcing would ‘freshen’ the faculty perception, image and capability to delivery a timely and relevant knowledge/skills package applicable to real world demands and providing an identifiable skill base to potential employers. An obvious spillover would be a greater timeliness of faculty through the new ideas, seminars, topics of conversation, subscriptions and book selections, all of which contribute to faculty attractiveness to the student marketplace.

Collaboration could also extend to inter-institutional programs based on complimentary local expertise. At the same time, we suggest that students would choose optional courses that best fit their own background and specialization goals from one or more of the core domains, but would not be limited to courses within the program. For example, an IT student from the U of A might take the multimedia development component from East Anglia University.

Program delivery alternatives were not examined in this study, although it is clear that such alternatives will be an important factor in program restructuring and cost-effectiveness.

6. So — Are we ready for the 21st century?

We believe that IT programs, such as we have proposed, will be well positioned to respond to the exciting technology and market driven educational possibilities that are on the horizon. At the same time, we acknowledge Tom Peter’s caution that, in our global market, excellence today can be irrelevant tomorrow without timely and cost effective responsiveness to market determination of value added.

The future survival of IT programs may well depend on their ability to develop both instructionally sound and commercially viable programs, including programs that could be targeted to specific short term market needs. However, the knowledge and skills required for cost analysis and decision making were conspicuously absent in the program data reviewed for our study. With respect to the programs themselves, market and cost
data that will provide a basis for analysis and decision making are critical in determining readiness in light of the current environment of dynamic change.

Changes in three key elements — standardization, communication and transportation — were the basis of market-place globalization and commoditization. The dynamics underlying the changes in the global goods industry in turn initiated enormous change that, in little over a decade, resulted in the obsolescence of hundreds of billions of dollars in assets, skills of hundreds of millions of people, millions of jobs and the organizational structure and management of thousands of global corporations.

Similar factors are now diffusing through the service sector of the global economy with the expectation of similar consequences. Increasingly sophisticated educative software and hardware products, combining text, image and sound are available at rapidly and continuously declining cost. Already the availability of such off-the-shelf, relatively inexpensive, proven multimedia courseware, is reflected in its growing use [see Molenda et al. 1998]. Further on the horizon are integration of the capabilities of the Internet, NT computers, which are projected to overtake the PC market within the next two years, DVDs, megabit modems and products and services developed by those who, having grown up with these media and explored them unencumbered by our pre-dispositions, fully exploit the potential. Implicit demand for lifelong learning is most notably demonstrated by increased online usage among retirees. In addition, the availability of such options is changing attitudes to time and place of schooling and of employee training [see Molenda et al. 1998].

If we are to remain a developmental and shaping force at all, we must embrace the tools; we must understand the technology and how best to employ it; and, most of all, we must aggressively promote our capabilities in our chosen markets.

Collaborative Technologies as a Catalyst for Changing Teacher Practices

Dr. Paul Resta
Learning Technology Center, The University of Texas at Austin, Austin, Texas 78712, USA
Tel: 512-471-4014, Fax: 512-471-4655, E-mail: resta@mail.utexas.edu

Abstract: Project Circle explored the use of network-based tools to help change teacher practices toward more student-directed and constructivist approaches to learning. Through the use of groupware the project developed collaborative knowledge-building communities within two U.S. high schools. The project demonstrated the efficacy of the tools to help foster collaboration within and between classrooms and the use of high school students as technology mentors for teachers.

1. Introduction

Project CIRCLE, a two year project funded by the U.S. Department of Education, explored the use of collaborative technologies as a catalyst for changing teaching practices and development of knowledge-building communities within U. S. high schools. The study involved secondary teachers and students in two high schools, one is a low-income, inner-city high school, and the second, a high income suburban high school. The project was conducted by the University of Texas Learning Technology Center in collaboration with the Austin Independent School District (AISD), and the Eanes Independent School District (EISD). The study explored the use of Daedalus, FirstClass, and TeamFocus as tools to support collaborative learning projects in the partner schools. The project was designed to foster collaboration both within and between classrooms and schools. A virtual learning community between the project schools and university was created using network-based tools for collaborative learning and intellectual work. Through new collaborative technologies students and teachers accessed community-based curriculum materials, on-line mentoring and collaborative learning projects between university and high school students.

The project provided key teachers and administrators basic training and experience using networked software. They worked individually and collaboratively in designing and applying the tools within their content area courses or in collaborative interdisciplinary projects.

The project also involved the training and apprenticing of selected students at each site to serve as "in-house" mentors and technology assistants for their teachers and fellow students. The first-year cadre of teachers and student-mentors at each site served as the core group to assist and mentor teachers in the second year of the project and to help induct more teachers and student-mentors into project activities.

2. Project Focus and Goals

The project was based on a constructivist approach to the learning process. The constructivist model of knowledge emphasizes the active engagement of the learner to construct meanings in all levels of apprehending, comprehending, and processing the information. It also recognizes the importance of the social context as a required catalyst in the learning process.
The constructivist model of learning holds that new knowledge must be built through the socially dynamic and interpersonal interplay of experiences, beliefs, and prior knowledge each individual possesses and shares within a community of collaborative learners. In this model, knowledge is the result of work of the individual to make meaning out of information and to expand individually-held knowledge through the interaction of other learners in the social context of a learning community. The social component of knowledge-building is the catalyst in the process: as an individual makes sense of new information or experience, she or he expresses it to others who actively enter into the knowledge-building dialogue to confirm, modify, question, contradict, or correct shared information. In this collaborative knowledge-building process, all participants are acting independently and collaboratively to make personal and community meaning of new information as different partners find, question, create, share, correct, and argue ideas, concepts and principles.

Based on this orientation, the specific goals of the project were to:

1. *establish a collaborative knowledge-building community of teachers and students in the schools* to explore and model innovative constructivist uses of technology in the classroom. To accomplish this objective interactive networks were established and new telecommunication approaches were used to connect school and university members of the knowledge-building community to each other as well as to other mentors or experts locally, nationally, and internationally.

2. *develop the CIRCLE model training program.* Training programs were developed to introduce and develop initial levels of competency in use of the specific collaborative learning tools. It involved one day training sessions held in the university computer labs as well as on-site training. Training was also provided to students selected to serve as technology mentors to the teachers and fellow students. They received separately the same training in the application of the tools as the teachers.

3. *develop a self-sustaining program of training and technology infusion in the schools.* The study explored ways of sustaining and widening the circle of participating teachers and students in the use and integration of the collaborative technologies. It also explored the impact of the project on the teacher cultures within the schools.

### 3. Approach and Tools for Collaborative Learning

Project CIRCLE provided computers, modems, and phone lines to the participating schools. The project staff helped the schools configure the computers and, in some instances, helped in networking the computers. During the first year three intensive full-day training sessions were provided at the university for teachers to gain a basic level of understanding and competency in using each of the three collaborative groupware tools. In addition, on-site, one-on-one, and small group training was provided by University project staff. The student mentors received the same training as the teachers. During the week following the training, student mentors helped set up applications for use in class. During the second year, the first year cadre of teachers assumed the leadership role as trainer-mentors for the new participating teachers. All training was provided on-site and no full-day university training sessions were held.

Three major tools were used to support collaborative knowledge-building.

#### 3.1 FirstClass

*FirstClass* provides an integrated cross-platform collaboration environment with powerful, flexible and intuitive features that supported all members of the knowledge-building community. It tied together participating high school teachers, students, university faculty and students and on-
line mentors using state-of-the-art groupware for both LAN and Internet connections. Students and teachers were able to create and maintain their own individualized resumes and conferencing areas. For example, teachers had their own private conferencing area, The Circle Bar and Grill, to share problems and ideas. Teachers and students were able to collaborate with professionals through Internet newsgroups, and socialize through on-line chats. Class discussion conferences were created to support classroom learning projects both within and between the two high schools.

3.2 Daedalus

Daedalus is an integrated cross-platform suite of six programs that encompasses all stages of the writing process, from brainstorming and prewriting to drafting and revising to final production. Daedalus has been developed through years of research and field-testing by English scholars.

The programs include:
- The Write program is a simplified word processor which serves all other Daedalus programs. It is suitable for writing papers and is offered as freeware to the students in order to make their work on the system portable.
- The Invent program presents the student with heuristic prompts, or questions, to guide their writing.
- Respond guides critical reading by asking critiquing questions of a displayed text. Teachers may customize the prompts to fit their own purposes in both Invent and Respond.
- Mail is an E-Mail program specifically designed for use within a class or between many classes.
- InterChange is a real-time conferencing program in which an entire class can simultaneously write to a single document. Each student has his/her remark labeled with his/her name, and may reply to specific remarks that appear in the dialogue.

3.2 TeamFocus

TeamFocus is a network-based environment to support collaborative problem-solving, brainstorming, analysis, prioritizing and decision-making. The tool has been used primarily in industry and it was introduced to explore its values in the science, social science and business curriculum.

4. Project Evaluation Methods

Project evaluation was conducted by an external research team comprised of a university professor and five graduate students from the Department of Education Psychology. The team developed an evaluation model that included both quantitative and qualitative components. Qualitative data included classroom observations, and in-depth teacher and student interviews. Quantitative data included statistical analysis of student responses on the Student Perception of Collaborative Knowledge-Building (SPOCK), an instrument designed and validated for the study, and student test scores on state standardized tests of academic skills.

5. Summary of Findings

5.1 The Project CIRCLE Training Model

The results of interviews suggests that university training and on-site training and support were positively received by the teachers. The first year training and support was highly successful but there were problems with the first year teachers serving as trainers and mentors for the teachers joining the project during the second year. A number of the second year teachers expressed their
concern about the limited level of technology knowledge and skill they were able to develop through the peer mentors. The interviews and observations also indicated that the second year teachers were less successful than the first year teachers in implementing the technology applications within their classrooms. These trends suggest that the use of co-teachers as trainers and mentors related to innovative new technology tools may require more time and support to be successful. Mentoring and collaboration among the teachers and the use of student mentors as a support system, although useful, was not sufficient to help teachers develop levels of comfort and competency in the use of new technological tools. The general response of teachers indicated the need for more intensive training sessions, similar to those provided in Year 1 of the project.

5.2 Developing Collaborative Learning Communities

Over the two years of the grant, Project CIRCLE demonstrated that, with sufficient time, training and on-site support, teachers could infuse collaborative technologies into their classroom instruction. In addition, the application of the collaborative technologies may begin to transform the teaching-learning process, moving it toward a more collaborative, student-directed learning environment. The shared training, on-line communications, and tools for collaboration also helped foster the development of a knowledge-building community. An important attribute of this community was the honoring of the unique expertise and contributions of each member as well as the recognition that we were all co-learners together—students, teachers, and university faculty.

Marked differences were observed between first year and second year project teachers in establishing collaborative communities within their classrooms. This suggests that teachers must have time, training, and support to enable them to embrace and adopt new technologies and teaching practices. As teachers became more experienced, they were able to develop higher levels of competency and comfort with the collaborative tools and explore changes in their classroom instruction. Teachers who had less time and support were less effective in integrating the tools into their instruction and experienced more problems in implementation.

Another critical factor in successful development of collaborative learning communities was the limited access to technology experienced by a number of teachers who were interested in participating in the project.

Results of the study indicated that teachers who used the new collaborative technologies to "do things differently" in their classrooms tended to be the most successful. The least successful were teachers who attempted to fit the collaborative technologies into their traditional teacher-directed approach.

In brief, the project results indicate that success in the adoption of the new collaborative technologies requires extensive training and support and easy access to the technology.

5.3 Develop a Self-Sustaining Program

The CIRCLE project explored factors related to the sustainability of the model of training and technology infusion. Sustainability requires both long term support from the school administration and the retention of an active, committed, and respected core cadre of teachers to continue to engage, interest, and support other teachers in the use of the new technological tools. This was evident from the loss of the two inner city high school teachers who were regarded as the project innovators and leaders. Their departure, coupled with a change in the school administration, greatly diminished the momentum and progress achieved in that school during the two years of the project.

Perhaps the greatest barrier to sustainability is teacher time. Teachers are continually overloaded with their regular duties. It was difficult for the teacher-mentors to have the time and flexibility to help provide one-on-one training or classroom assistance to teachers when needed because of their other duties and time constraints. It was also difficult for interested teachers to find time to be mentored or to explore the use of the new collaborative technologies. All these issues must be addressed in order to sustain and expand the implementation of the new collaborative technologies.
5.4 Teacher Utilization and Perceptions of Student Mentors

A key aspect of the CIRCLE model training program was the use of student mentors [students trained in the software] to provide on-going training and support to teachers and other students. Student mentors helped teachers learn the programs and served as in-classroom technical support staff. For example, student mentors would set up Daedalus interchanges, establish and maintain conference areas on the FirstClass system and assist teachers in other technical applications. Teachers felt that the student mentor component of the program was both useful and innovative. They indicated that, unlike themselves, students showed no anxiety about attempting new and challenging technology applications. They would set up the software programs for the teacher, and consequently, the teacher would begin to use them. Over time, the teachers developed deeper levels of understanding and comfort in the use of the collaborative technology.

5.5 Role of Student Mentors

Teachers noted that the student mentors were a valuable and effective technology resource and support system and was superior to more traditional types of teacher training and support. The student mentors were unanimous in their view that the role of student-mentor was rewarding and an effective means of providing technology training and support within their schools. A number of high-risk students serving as mentors indicated that their relationships and status changed positively both with their classroom teachers and their peers because of their role and expertise as a student mentor. When asked what was good about the model, the student mentors indicated that it was more personal than a class and that it helped ease teacher's anxieties about using computers. They also noted that "teaching the teachers" reinforced their own feelings of worth and contribution to the school. Similar to the teachers, the student mentors indicated that it would be helpful to have more time and flexibility to assist teachers when needed. To partially address this need, the inner city high school established a student mentor class that provided in-depth technology training and allowed the students to assist teachers during the class period.

Teachers indicated that another important benefit of the student mentor program was the improved behavior, attitudes, and engagement of the student mentors who had previously been disengaged from the learning process. Teachers in the inner city school noted that all of the student mentors now expressed aspirations for pursuing post-secondary education.

5.6 Effects of the CIRCLE Learning Model on Students' Learning, Performance, Behavior, and Attitudes

The results of the quantitative analyses, using the student perceptions survey, suggests that the integration of collaborative technologies facilitates students' knowledge building and intentional learning in the classroom. Students in classrooms where CIRCLE software was implemented perceived increased cooperation, question asking, and knowledge building activities. These quantitative findings were supported by teacher comments indicating higher levels of cooperation between students and between themselves and students when they used CIRCLE software. These findings suggest that the CIRCLE learning model was successful in its goal of creating a collaborative, knowledge building community in the classroom. In addition, the study results indicated that, in the inner city high school, students in classes integrating the collaborative technologies had higher standardized test achievement scores than a control group within the same school.

The results also indicate a positive effect on students attitudes and motivation. Teacher responses suggest that implementation of the CIRCLE software improves student motivation, engagement, and attitudes toward learning, particularly among students who are not currently successful or highly motivated in the traditional classroom. Some students who are very successful in traditional teacher-directed classroom settings, however, are not as comfortable with the collaborative learning environment.
6. Conclusions

Results of the two year project indicate that the introduction of new network-based environments and tools for collaborative learning can be an effective means for helping teachers develop more collaborative, student-directed learning environments. The infusion of collaborative technologies, however, must be accompanied by extensive training, on-site support, easy access to the technology, and strong support from the school administration.

Sustainability of the innovative practices is dependent on the retention of a core cadre of teacher-leaders who continue to model and extend the circle of participants. In addition, the findings indicate that the use of teachers as mentors to their fellow teachers may not be effective unless the mentor teachers are provided with adequate release time to take on the added responsibilities and be available to respond to fellow teacher's needs.

The project results suggest that student mentors can serve as an effective technical support system for teachers who are implementing the new technology tools and applications. The role of student mentor may also produce benefits to the students including improved motivation, status, attitudes and post-secondary aspirations. In addition, it appears that "at-risk" students selected as teacher mentors may demonstrate greatly improved relationships with the teachers and increased interest in school and academic work.

Lastly, the study indicates that the creation of collaborative knowledge-building communities within the classroom results in an increase in student engagement, motivation and improved performance on standardized tests of academic skills by inner city high school students.

Acknowledgements

The author wishes to thank the members of the evaluation team including: Dr. Duane F. Shell, Jenefer Husman, Deborah Cliffel, Indira Nath, Noelle Sweany, and Jeannine Turner for their contributions to the Project CIRCLE study. Appreciate is also expressed to my co-directors, Jay Pierson and Dr. Hope Erickson for their commitment to the project.
A Methodology for Evaluating the Effectiveness of the Use of New Technologies in ODL

Abstract: Developments in information and communication technologies, particularly those related to computer networks and hypermedia, offer new challenges in Open and Distance Learning (ODL). Evaluation of the effectiveness of the use of innovative technological media in ODL becomes of primary importance. In this paper, we will present a methodology which was used for evaluating the effectiveness of the use of new technologies, i.e. the hypermedia systems and computer networks, in ODL as a complementary delivery vehicle to the conventional mode of instruction. This methodology had been used within a European partnership project called "An Experiment in Open and Distance Learning using New Technologies (EONT)".

1. The context of study

Contemporary educational systems have been criticized as having many drawbacks. In particular, conventional Universities have been denounced for the constraints they impose on time and place of instruction delivery. Open and Distance Learning (ODL) can be used as a means for overcoming these constraints and contributing to the improvement of the state of higher education by complementing the conventional instruction delivery method.

ODL can be implemented with the use of various technologies. Among them, the most promising ones seem to be the computer networks and the hypermedia systems. The reason is that these technologies integrate various media like text, sound, graphics, images, animation and video in a single learning environment. In such an environment the courseware (i.e. a set of digital multimedia learning resources) can be stored in a server computer and accessed by client computers with multimedia capabilities that are connected to the server. This gives, among other things, the advantage of the easy update of the courseware. Furthermore, the interaction between the students and the instructor as well as between the students themselves is possible and easy through the communication facilities of the network.

The effectiveness of ODL implemented by computer networks and multimedia systems can be tested only through experimentation. Such an experiment was in progress within the EONT project [Papaspyrou et al. 1996]. EONT was a partnership project between seven Universities from seven EU countries. The partnership had been formed on the basis of the common interest the partners had in experimenting in ODL using computer networks and hypermedia systems with main objective to assess the effectiveness of this instructional delivery mode as a complementary approach to the traditional one.

In the first year (Dec. 1995-Nov. 1996) of the project, work was concentrated on the development of the required infrastructure, the EONT-ODL system, in order to perform the experiment (course delivery trials through ODL). The EONT-ODL system consisted of two basic components: (a) the learning environment and (b) the courseware. The former is a networked environment in which the courseware is stored in a server computer and the learners access it through client computers that are multimedia computers connected to the server via a computer network [Koutoumanos et al. 1996]. This networked environment is based on the hypermedia system HyperWave [Maurer 1996] which was provided by the Austrian partner who has developed it. It was chosen because it possesses innovative features, such as:

- powerful structuring mechanisms;
- private and public annotations;
- multilinguality;
The subjects of the courseware developed were related to the wide area of Informatics since all partner universities specialized in this area. Each partner developed courseware for one course. The courseware was initially developed in the native language of the respective partner (national version).

In the second year (Dec. 1996 - Aug. 1997) of the project, work had been focused on the user trials using the infrastructure created in the previous year (first evaluation round). Each partner delivered one course for which he had developed the national version of the courseware and a common evaluation process of the experiment had been followed. Furthermore, the courseware was translated into English (international version) in order to motivate students from the partner universities (and not only) to follow the courses for which the courseware had been developed. Table 1 shows the EONT project consortium and the courseware that each partner developed.

Table 1. Courseware developed by the EONT project consortium

In the third year (Sep. 1997 - Aug. 1998) of the project, work was being conducted (not by all partners) on the delivery of the revised national and the international versions of the courseware, so that students from one country will be able to take courses offered in another country. The project works for the third year continue with the personal initiative and internal financial support of the partners.

2. Stages of the evaluation process

The evaluation methodology presented in this paper and followed in the EONT project, indicates that this process consists of a series of different stages which will guide the evaluators (or educators/trainers) in their choice of methods and tools appropriate at each stage. The stages which comprise the evaluation process are the following:

- Identification of the area of concern
- Theoretical foundation
- Decisions about the methods to be used
- Development of evaluation instruments/tools
- Data collection
- Data analysis and interpretation of results
- Dissemination of findings and policy implications

The sequencing of the stages does not always operate as shown above and the process often enables feedback looping, especially between the first three stages. This section will analyze each stage making references to the EONT project when necessary.

Identification of the area of concern

This stage is the triggering point of the evaluation process in so far as decisions must be taken with respect to what will be evaluated, why and for whom. Within the EONT project, the evaluation study focused on the measurement of the effectiveness of the use of new technologies in ODL. The EONT partners were interested in examining if the use of new technologies in ODL as a complimentary delivery mode to the conventional one was pedagogically effective. Not only that, but their concern was also to identify the main factors that could lead to draw a conclusion about the effectiveness.
Theoretical foundation

The detailed evaluation plan for a courseware will, to a considerable extent, depend on the theoretical approach used. The theoretical approach is also determined by the aims and objectives of the evaluation and in general the rationale for undertaking an evaluation effort. In this evaluation, it has been hypothesized that the “learning effectiveness” would be influenced by a number of independent variables such as:

- design of the learning material: composite variable consisted of eight items;
- learners’ preference of mode of study: composite variable consisted of five items;
- learners’ previous experience in computers: uni-variable;
- time spent by learners on working through the EONT-ODL environment: uni-variable;

Decisions about the methods to be used

Two are the basic evaluation methods: formative and summative. Evaluation is formative when it is used with the intention of reviewing, supplementing or improving the functioning of components of the courseware. When the intention is to form a judgment or conclusion about the end-product, a summative evaluation method is adopted.

Although it was initially planned in the EONT to perform a common formative evaluation procedure, the project consortium decided not to do it. Instead, each partner’s development team used its own methods for testing the course materials and the learning systems during the development phase and proceeded in identifying where improvements should have been made according to their experience and preferences. Nevertheless, internal quality criteria for the learning material had been formed within the EONT project, which had been used as a framework for performing the formative evaluation. The EONT internal quality criteria are the following [Chambers 1995]:

- criterion of appropriateness: the courseware is appropriate to the learner body for which it is intended, i.e. expectations, preferences, learning styles, etc.
- criterion of engagement: the learners find the courseware and the instruction delivery mode interesting, challenging, easy to follow, etc.
- criterion of learner performance: the learners have acquired some knowledge and increased their skills.

Development of evaluation instruments/tools

Observation, interviews with the learners, educators, tutors, etc., questionnaires are the main instruments/tools commonly used in evaluation studies. Within the EONT evaluation study, two kinds of questionnaires had been given to students attended the course.

The first questionnaire was a “pre-test” one, aimed at identifying the expectations of the learners from such an instruction delivery model. This questionnaire was administered during the first days of the course delivery and not later than the first week and it consisted of 12 questions measured by a five-point Likert type scale.

The second questionnaire was a "post-test" consisted of the pre-test questions properly rephrased and a wide number of close-ended and open-ended questions, which reflected the concepts that formed the conceptual approach of the evaluation study. The first part of this questionnaire aimed at eliciting quantitative data and the second part qualitative data. These two sets of data, although the qualitative part played a supplementary role, were necessary in understanding and interpreting the quantitative outcomes [Makrakis 1997]. The open-ended questions concerned with issues related to preferences and the dislikes of the learners concerning the course content, the design of the learning material, the mode of instructional delivery and their suggestions for improving the system and the courseware. The "post-test" questionnaire can be found in [EONT 1997].

All the composite variables developed of multiple items, each measuring a slightly different aspect of the main variable, were first scrutinized for 'face validity' and in the sequence each composite variable was subjected to a Cronbach's Alpha reliability analysis for internal consistency. To arrive at the final composite measurement indexes, every item which substantially lowered the Alpha coefficient was omitted and a new analysis was conducted in order to arrive at an index which had the highest possible reliability measure. The reliability tests
revealed that the three composite variables developed, that is «effectiveness», «design of course material» and «preferred mode of study» reached ALPHA coefficients of 0.93, 0.82 and 0.81, respectively.

Data Collection

Experience from practice shows that there is a high possibility in collecting less amount of data than expected. The reason is that learners are not keen on filling in questionnaires. Learners need a lot of pressure and high degree of motivation in order that the goals of this stage are to be accomplished. The EONT project was not the exception from the rule and the amount of the collected data were not the expected ones. Only one institute, the ICCS, managed to get a significant high number of "post-test" questionnaires with a 90 percent response rate. However, the returned "pre-test" questionnaires fell ultimately short to the expectations of the consortium.

Data analysis

The analysis of the structured part of the questionnaire was based on univariate and multivariate statistical analysis and the open-ended part on qualitative content analysis, employing the constant comparative method of analyzing qualitative data [Lincoln & Guba 1985, Maykut and Morehouse, 1994]. This method started with an inductive category coding and simultaneous comparing of units of meaning across categories identified in the text of open-ended questions. A refinement of categories followed which led to the exploration of patterns and relationships across categories.

Dissemination of findings and policy implications

The target group of the dissemination of findings is those primarily concerned with the design and development of the system and courseware. Other target groups less close to the evaluation study might also be interested in it is of primary importance to disseminate the findings as much as possible. Moreover, the findings should not only be disseminated but seriously taken into consideration especially in cases when the study has shown that certain changes need to be made in the area of concern. As far as the EONT evaluation study is concerned, the findings were distributed among the key interested people, i.e. the EONT partners and the Socrates ODL committee. Furthermore, each partner used the findings and the lessons learned in his own way in order to improve the instruction delivery mode based on the new technologies and review/supplement some of the issues that the learners have identified. More details about the EONT evaluation results can be found in [EONT 1997, Makrakis et al. 1998].

Concluding remarks

The convergence of new information and communication technologies as well as the pervasiveness of the computer networks and hypermedia systems—the Internet and the World Wide Web in particular—have great potential for transforming ODL to meet the contemporary needs of the learners and educators. Evaluation of the various experimental efforts in using new technologies in ODL need to be made in order to reach a tentative or firm conclusion about the learning effectiveness of such efforts.

However, evaluation must not be ad hoc. Methodological approaches suitable for the specific area of concern are needed [Garzoto et al. 1995]. In this paper, an evaluation methodology was presented which was followed in the EONT European partnership project. The main advantage of this methodology is that the evaluation process was divided into manageable stages, each one with clear objectives, inputs and outputs.

Nevertheless, a number of lessons learned while the evaluation process following this methodology.

1. Things did not always go as planned. For example, the formative methods were performed individually (though a general framework had been designed) and the questionnaire response rates for most institutions were low. There is a need to identify the reasons for not answering and find solutions for increasing the rate of return. Unfortunately, there is no "silver bullet" or "rule of thumb" for persuading learners to participate in the evaluation process.

2. The evaluation process should focus more on the design of the learning material. Learners should have been observed while using of navigational aids, metaphors, etc. of the learning material because the design and the interface can actually hinder learning and undermine the learning effectiveness.
Concluding, the evaluation methodology was going to be further evolved during the life cycle of the EONT project which was initially three years. A second evaluation round adjusted to the findings from the first round and modified according to the lessons learned was intended to be performed. However, due to the reject of the renewal application for a third year funding, both the project’s evaluation findings fell short to the initial expectation of the project consortium and the evaluation methodology will be evolved within future projects.

Abstract: This paper outlines CLEW a collaborative learning environment for the Web. The project combines MUD, workflow, VRML and educational concepts like Constructivism in a learning environment, where students actively participate in the learning process. The MUD shapes the environment structure. The workflow system allows the execution and coordination of the course activities. The VRML establishes the presentation format of the courses' virtual worlds. Finally, the educational concepts influence the way the didactic material is published.

1. Introduction

CLEW (the thread used by Theseus as a guide out of the Labyrinth) combines the presentational format of the VRML with the MUD's interaction style and the coordination mechanism associated to workflow management systems. The objective of CLEW is to create a cooperative platform of structured courses. Constructivism, learning metaphors and immersion shape the educational basis of the project.

The structure of CLEW follows the main aspects of a MUD, which is to divide the environment into regions. A MUD is an environment based on the interaction between its participants, providing access to a shared database of rooms, other objects and exits [Pavel and Nichols, 1993], thus creating a kind of virtual world [Busey, 1995]. Virtual worlds supporting multiple users give rise to a virtual community [Hughes and Moshell, 1997] which can provide the settings for productive, remote cooperative work [Rheingold, 1994].

The interactive aspects of a MUD allow the creation of a powerful collaborative environment; however, it lacks coordination. CLEW uses the characteristics of workflow to provide a way of coordinating this loose environment. As defined in [Casati, Ceri, Pernici and Pozzi, 1995], a workflow is a set of activities evolving the coordinated execution of multiple tasks. A workflow management system (WFMS) is a system that completely defines, manages and executes workflow [Hollingsworth, 1995]. The CLEW environment uses the presentation format of the VRML, allowing its users to navigate through a graphical virtual world. So the users can construct their knowledge by actively interacting with the graphical environment objects.

1.1 Related Work

Some other systems bear similarities to CLEW. The coMentor [Gibbs and Henry, 1996] is a multi-user learning environment for part-time students on theoretical social science or humanities modules, developed at Huddersfield University. The coMentor is a visual MUD on the WWW, structured in rooms. Besides these rooms, a student can access information repositories that contain previous discussion data. The coMentor does not have mechanisms to support the generation of courses and student evaluations.

Another MUD environment on the Web is the Athena - Virtual Online University (VOU) [Duckett et al., 1995]. In VOU, participants can interact simultaneously, carrying out discussions, mediated by instructors, about the study topics. Again, mechanisms to support the generation of courses and student evaluations are not provided.
ExploreNet [Hughes and Moshell, 1997] is a graphic environment used to create virtual worlds in which learners and mentors can interact. Players interact in a virtual world via their animated alter egos, called "avatars". ExploreNet uses the concepts of immersion to elaborate a course.

1.2 Outline

The paper is organized as follows. The next section discusses the educational background that guides the environment. Section 3 presents the main elements that compose CLEW. Section 4 describes the system architecture. Section 5 comments on the environment structure, describing learner participation and the services available. The last section concludes this work.

2. Educational Background

The educational theory used in CLEW is Constructivism [Bruner, Goodnow and Austin, 1956]. Through this approach, the learning process becomes more effective since the knowledge is actively built [Sherman, 1991]. In constructivism control of the learning process is shifted to the students, [Henderson, 1986; Garner, 1992]. As stated in [Salomon, 1992], the computer has an important role in the transformation of the learning process from a simple assimilation [Piaget, 1950] to an active process.

Immersion and learning metaphors complement the constructivist ideas used in CLEW. Learners needed to be engaged deeply enough to feel they are part of the environment both physically and psychologically [Low, Venkataraman and Srivatsan, 1994; Laurel, 1991]. As stated in [Wynn, 1996], situated cognition gives learning a context similar to that of the real world, providing authenticity to learning. This makes learning an exciting task. Taking advantage of the motivation induced by immersion, learning metaphors shape the semantics of learning subjects, suggesting a comparison between the system characteristics and the experiences of the real world. As stressed in [Davis and Bell, 1995], it is important to create learning models that get close to the students’ reality, so that they can better assimilate a new concept.

3. The Environment Components

3.1 Participant

A participant is a player in the environment who is identified by a name and his avatar. An avatar is the element that represents a user in a virtual world. Avatars communicate with each other to engage in cooperative missions. Each mission has a pedagogical semantics specially designed to present a specific learning material. A participant also has a memory that is able to store the information he considers relevant. This memory could be shared with other participants, allowing the creation of a group memory.

The participants are categorized in types. Each type defines how a participant interacts with the environment, assigning him functions and privileges. The learner uses the environment as a consumer, participating in courses. The administrator manages the environment, accomplishing the activities related to the course, region and object supervision and maintenance. Professors are responsible for the didactic part of a course. Since a professor has several specific tasks, this type is subdivided into:

a. designer: he designs the course structure through the specification of its workflow. He is able to create, modify and remove regions and objects from the environment, allowing the adaptation of these elements to the course needs;

b. author: he is able to elaborate and insert the didactic contents of a course, which was previously structured by a designer;

c. evaluator: he works on the questions, tests and challenges that evaluate a learner during a course;

d. instructor. An instructor directly interacts with the learners during a course, helping with the participants’ doubts.

3.2 Region

A region is an area without a severe border that groups participants and objects. The creation of regions may follow a learning metaphor to provide the participants’ engagement with the learning activities. For example,
in a course intended to teach the basic mechanisms of chained lists, a region could be configured to give the idea that a participant is travelling through the cells of a list.

These regions offer a structured way of expansion. Each new region is connected to the others, increasing the environment dimensions and its richness of metaphors. VRML files are used to generate the regions’ 3D interface. The environment provides a main region where a participant has access to information regarding courses and enrollment procedures.

A region contains different objects and metaphors depending upon the course in which it is being used. Vision of a region is a set of properties that define its semantics in a specific situation. The creation of several visions of a region allows the designers to reuse the same set of regions.

A vision of a region has a memory. This memory lets the participant leave some information telling the other participants about his experiences in this region. This facility assists the collaboration between the participants and may stimulate the interest of each one in exploring the environment. This approach does not force the cooperation, letting the participant choose if he wants to cooperate or not.

3.3 Object

Interaction between participants and the environment is carried out through the objects. The objects are elements similar to those found in the real world; however, in CLEW, these objects have specific properties to provide didactic information. The objects are created using VRML files. There are two types of objects in the environment: local and shared objects.

Local objects are instantiated for each participant’s interface. If a participant acts on a local object, the other participants in the same region cannot see the result of his action. If this object were shared, all the other participants would be aware of its changes. The shared objects have one instance for all the course participant interfaces.

Like the regions, objects can also have different semantics according to the course they are in. For example, a Greek geographical map could represent a map of present day Greece or of Ancient Greece. Visions of the same object increase the flexibility of CLEW, allowing its reuse in different courses.

4. System Architecture

The architecture consists of six layers: the presentation layer, the application layer, the management and control layer, the adaptation layer, the external services layer and the data layer [Fig. 1].

The Presentation Layer comprises the interface modules customized for each existing participant type. It groups the available services according to the participant’s function.

The Application Layer includes the modules concerned with the creation and maintenance of the courses and with the administrative tasks. This layer provides the functions that the participants use to create objects and regions and to perform the course maintenance.

The Management and Control Layer groups the environment servers. These servers control all the functions related to the environment simulations.

The Adaption Layer consists of the communication interfaces between the environment and all the external services.

The External Services Layer embraces the tools that the environment uses to control the sequence of the course’s activities and to create and correct the students’ assessment.

The databases needed to uphold the environment structure, supporting the use and integration of the available services constitute the Data Layer. This layer also comprises the VRML files that presents the environment objects and regions of CLEW.
5. Course Development

The regions and integration between the participants and the objects that are inside them define the activities that will be carried out in a course. These activities compose a workflow that should be enacted by a participant.

5.1 Structuring a Course

The first task in a course elaboration is to create the regions and objects it uses. This can be done by a modeling tool provided by the environment. The second step is the definition of the course workflow process. This includes information about its starting and completion conditions, constituent activities and rules for navigating between them.
The starting conditions of a course are usually related to administrative information such as enrollment or attendance to a pre-requisite course. The completion ones depend upon the participant performance computed by the indexes previously described.

The activities and the rules for navigating between them make the instructional sequence of a course. To define an activity means to build part of the virtual world since an activity happens in one or more regions. The designer may use a learning metaphor and create or reuse regions, inserting or configuring the necessary objects. An activity consists of three parts: the pre-activity conditions, the actions and the post-activity conditions. The pre-activity conditions indicate a set of attributes a participant must have to be able to start the activity. The pre-activity conditions of the first activity form the starting conditions of a course. The actions define the interaction rules between a participant and the elements of a virtual world; that is, they define the tasks to be performed. Some examples of actions would be to catch an object, to talk to another participant, to answer a question posed by an active object, etc. The post-activity conditions consist of a set of attributes a participant shall obtain after he completes the actions of the activity. The post-activity conditions of the last activity are the completion conditions of the process, pointing the end of a course.

5.2 The Participant’s Perspective

A course appears to a participant as a journey in a virtual world specially built to learn about a subject. To construct their knowledge, participants should complete the tasks described in the course activities. Those activities should convey engagement as a challenge or a game, to catch the learners’ attention.

Let us see an example of a course on data structure. One activity would be to learn search algorithms in sequential lists. An audio tape could be used as a metaphor to represent a sequential list. There could be an active object that would ask a participant or a group of participants to look for some specific song in the tape. In order to “win the game”, the participants would have to learn the search algorithms.

Another important aspect of a course is the evaluations. The evaluations should be elaborated to keep the motion of the play; thus they can not only be simple tests as a final exam. It is interesting that evaluations indicate the progress of participants as does the score of a player in a game. To offer this way of evaluating, some defiance questions may appear during the completion of the tasks, looking like obstacles in a game. This “show me what you know as you go” approach [Wiggins, 1997] provides more didactic resources to professors, and is more stimulating than only using more conventional examinations which can sometimes be boring.

6. Conclusion

The creation of learning environments that renders learning more active is initiating new challenges for research on learning [Barfurth, 1995]. The first prototype of the proposed environment is now under construction and clearly, it will need further development to be able to become a really useful learning framework.

Although the environment is still at an early stage, some other aspects may be considered such as: free navigation, to provide a way for a participant to use the environment without being enrolled in a course; co-authoring tools, to help the different types of professor coordinate their activities while constructing a course; and distributed VRML objects, to allow the insertion of objects at run-time in a region scene.

Write Once, Publish Many: Multimodal Courseware Development

Jan Ring
Learning Systems Division
Edith Cowan University: Australia
j.ring@cowan.edu.au

Abstract: Edith Cowan University is developing interactive WWW courseware which offers flexible, integrated delivery to both internal, external and mixed mode students. Content units are developed using a template which readily translates to a variety of publishing mediums including print, WWW, Acrobat and CD-ROM. The notion of 'Write Once, Publish Many' is being used to streamline unit development and to allow for regular updates to unit content. Units mounted on the WWW and on CD-ROM are enhanced by the inclusion of interactive multimedia techniques and are supported with a variety of computer mediated communications methods. In this paper, the process is described and experiences from the first pass through the process are related.

Introduction

Edith Cowan University (ECU) is one of the larger universities in Australia with some 20,000 students. Of these students, approximately 4000 study in external or off campus mode making ECU the seventh largest university provider of distance education in Australia. In addition to this, approximately 900 students study in mixed mode with some units taken on campus and some off campus. Most of these external students undertake courses off-campus due to geographic isolation however an increasing number are undertaking off-campus study due to personal circumstances including: employment, family commitments, international students returning home and also preferred learning styles. As personal circumstances can change unexpectedly, the university is designing its learning materials to be equally flexible to ensure that any transition between on and off-campus modes of study is undertaken with minimal disruption to course progress.

The Way We Were

Distance education at ECU has its roots in the correspondence system of the past. Traditionally, it has centred around some form of printed study material and written communications between the student and university tutors and administration. For many years, printed and written correspondence by mail was the only mode of delivery utilised. However, with recent technological advancements, this has since developed into a comprehensive range of academic and administrative support services. Students who previously needed to write a letter or make a telephone call can now perform many administrative functions interactively via computer-based telecommunications giving faster turn around time on queries and changes.

Study materials have also changed and today often incorporate a variety of media including audio and video tapes, personal computer floppy disks and compact disks (CDs). At ECU, these technologies have been integrated into the teaching of a number of external courses. For example, several courses use a program of online tutorials which enable students and tutors to engage in meaningful "conversation" electronically while others courses are using listservs and web-boards to facilitate ongoing debate of issues and to encourage participation in group activities. However, despite the increasing availability of multimedia, print still seems to be the medium most widely utilised for distance education packages at ECU and at other institutions [Kember 1995].
The Need for Flexible Delivery and Development

The development of distance education programmes in Australian universities over the last 25 years has largely been in response to the growing demand for places in higher education. Whereas, historically, distance education students were those living in rural and isolated communities, an increasing number of students today complete part of their course on-campus and the remainder off-campus as an external student. There are also international students who enrol externally to be able to complete an Australian degree without the associated expense of living away from home. In addition to the traditional undergraduate courses, an increasing number of post-graduate courses are being offered to meet the needs of busy professionals who are not able to attend regular classes. Many of the students in these courses live in SE Asia.

At ECU there is an equivalence of content between subjects taught face-to-face and those taught from a distance and often the same tutor is responsible for both modes of learning. There is no distinction on the student's parchment to indicate whether they came on-campus or whether they completed their award externally.

ECU has developed its own Virtual Campus which provides an extensive range of services which allow users to have the electronic equivalent of on-campus facilities. Users can now interact with ECU from anywhere in Australia, Southeast Asia and beyond. This allows for delivery of learning materials, access to computer mediated communication support such as email, bulletin boards and internet chat, and generally provides students with increased flexibility in choosing how, where and when to learn.

In times of constant change, particularly in technology related fields, it is essential that course content is updated on a regular basis to maintain its 'leading edge' focus. In some courses offered at ECU, for example computer security, multimedia and information engineering, material needs to be constantly monitored as new developments and latest technologies and methods are released. Published course materials, particularly in bound book form, can lag behind current developments due to inherent time delays between authoring, production and delivery to students. In order to be responsive to student-client needs and to keep materials current in all delivery modes it is essential to have a flexible, efficient and effective method of course development and delivery.

Student Access to Technologies

An increasing number of households within Australia now possess computers with multimedia capabilities, and it is anticipated that in the next year or two a much higher proportion of students will have the equipment and the skills to communicate with the university electronically. The Australian Bureau of Statistics reported that in February 1996, 30% of all Australian homes used a computer. Surveys conducted at ECU in recent years report that 82% of internal students have access to a computer at home [Oliver 1997] and that 79% of external students had access to a computer with 80% of these having access at home [Ring & Omari 1996].

In addition, teaching materials for a growing number of courses world-wide are now available on-line (WWW) or off-line through the use of CD-ROM, cable TV and video. It is therefore expected that in the near future most students will access learning materials using modern methods of tele-communication. Although the numbers with access to technology are growing, some students still have little or no access. To enable all students to continue their studies it will be necessary in the next few years to provide a dual system in many courses. This will allow some students a choice of whether or not to access information electronically, while others will have no choice but to continue to receive their materials in the traditional print format. However, care must be taken not to educationally disadvantage those students who do not have access in this transition period.

The Importance of the Content-Expert Author

The most important part of courseware development is the quality of the content and this is determined by the quality of the authors. Good authors are usually academics or industry specialists who are experts in their field. They know their field intimately and are experienced in writing and teaching in the discipline. They are also
the most expensive part of the courseware production cycle. Their time is valuable and often limited. To have an author prepare one set of materials for print, another for WWW and yet another for CD-ROM is prohibitively expensive.

An additional problem is that most authors are not experts in Web authoring or multimedia development and concern about the perceived need to become experts in WWW and multimedia development has caused some potential authors to avoid involvement in multimodal courseware development. The loss of their valuable input into the courseware development process must be minimised through the use of a methodology that allows them content input but does not require them to have multimodal expertise. It is a waste of valuable time to have content experts grappling with technologies such as Web authoring or multimedia development when this could be handled far more cost efficiently by a technical person.

**Write Once, Publish Many**

The main aim of the Write Once Publish Many methodology is that authors only have to do what they do best - write about their subject. The written materials are then published in a variety of mediums for delivery to students. Currently the delivery mediums supported at ECU are: print-based for students without access to computer technology; WWW or 'on-line delivery' and CD-ROM or 'off-line delivery'.

Authors write the content once into a prepared word-processing template, using prescribed styles. The final document is printed as photo-ready material for paper-based delivery. An electronic version of the document is handed to technical team members who pass it through a conversion process to produce Web documents. The web documents then form the basis of the CD-ROM version of the courseware.

The master copy of the courseware is the word processed version. As time passes and evaluations of the running courseware indicate that revisions and updates are required, the process begins again with the author working at the word processor. The revised document then passes through the other stages to emerge as revised versions of the original multimodal courseware. The cycle with its four developmental stages is represented graphically below [Fig. 1].

![Figure 1: The Four Stage Multimodal Courseware Development Cycle.](image)

The integrity of the content is maintained by having a single content entry point. Support materials may differ according to mode. For example, the CD-ROM version may contain interactive multimedia examples while the print version may be supplemented by video tapes that allow students to 'walk-through' an interactive experience.

**Multimodal Courseware Development Team**
An efficient methodology needs to be cost effective and provide timely delivery in a variety of modes. To do this, the methodology must minimise the number of steps between authoring and production. It needs to divide up tasks and apportion them to appropriate personnel within a multimodal courseware development team. The team assembled by ECU in the School of Computer, Information and Mathematical Sciences (SCIMS) consists of the following personnel:

- **Team Manager**: overall coordinator of the project. The manager is responsible for timelines, budgets and all administrative matters.
- **Instructional Designer**: works with authors and other development team members to ensure that the courseware materials are educationally and instructionally sound.
- **Authors**: academics or other content experts with expertise in the content area, often working in teams. They write the content and design other supporting materials.
- **Library Technician**: responsible for copyright clearances, referencing and location of additional reference and support materials.
- **Web Programmer**: converts material into WWW format, creates and tests links, builds additional pages such as content indexes and course organisers.
- **Multimedia Programmer**: develops interactive animations and interactions, converts them to Shockwave for WWW delivery, responsible for the preparation and production of CD-ROM masters.
- **Graphics Designer**: creation of original graphics for print and electronic delivery.

The team also has access to ECU’s Media Production Unit who create digitised video clips and prepare them for inclusion in online courseware, mounting on CD-ROM and outputting to video tapes.

### The Flexible Development Process

The flexible development process has four major stages and these are outlined below along with comments related to our first pass through the process.

#### Stage One: Preparation of Content Materials

In this stage, the author writes the text directly into the prepared word processing template, designs tutorial and workshop exercises and locates relevant references and supporting resources. Authors are encouraged to use full colour illustrations and diagrams in their documents.

The instructional designer works closely with the author to provide the best possible instructional framework for the courseware. The author and the instructional designer work together to design interactive multimedia modules to complement the text-based instruction while the library technician is active gathering copyright clearances and locating additional resources and reference materials.

At the end of Stage One, the courseware is printed off as camera ready originals for print based materials. In addition, original multimedia and graphical materials have been designed for use in Stages 2 and 3.

#### Stage Two: Production of WWW Version

The web programmer passes the word processed document through the web conversion process. The process uses a ‘black-box’ program which takes the original file and generates a full web site with the contents broken down into navigable sections and any illustrations converted to web file format. Each web page is automatically given headers and footers that identify the unit and the place of the current page in the content. An email link to the tutor is added to each page and any URLs embedded in the content become live.

The web materials are then edited to incorporate any interactive applets, digital video clips or animations previously designed by the author and instructional designer. Master menus and links to other modules and units within the course are developed, pdf versions of content are added for download, and the whole structure is tested for functionality and correctness.

In addition to the content modules, the process adds other interactive components to the home page of each unit in the course. These include a web-based notice board, a link which dynamically creates an IRC session or
Chat Room for the unit and links to resources needed to use the site. A listserv is also created for the unit but not as part of the automatic process. The content area is passworded to protect intellectual property however a public area, usually with sample modules, is left open.

Problems Associated with Stages One and Two

The problems in the first pass were mainly related to time, delays with copyright clearances, and some template and word processing problems. The authoring of quality instructional material is a time consuming task and most of the authors underestimated the time it would take to complete content modules and the associated independent learning activities. This lead to panic as the print-copy deadlines, driven by the need to get materials into the large external studies print queue, approached. By comparison the conversion to web form took only minutes. Most web conversions were trouble free with the notable exception of two cataloguing units that required detailed pictures of book covers, title and verso pages. The need to reproduce images of essentially textual information proved to be troublesome and held up web production until suitable image techniques could be devised.

The word processing template presented no problems for those authors accustomed to using styles. The commonest error was to forget to set the unit code in the header, an error usually discovered on final print out. However, those who’s knowledge of word processing was more of the electronic typewriter variety needed instruction in style use. If the styles were applied correctly, the web conversion process was trouble free. However, some authors refused to give up their word processor of choice or to adapt to new word processing techniques. Their documents were camera ready so could be placed in the print queue but the web conversion of their documents was held up. A support person was required to go through and clean up the document to prepare it for conversion. In most cases the clean up took several hours however one document filled with tabs and line-feeds took several days.

Copyright clearances were ruthlessly followed up by the Library Technician who maintained a database of all requests and replies. Replies ranged from good natured authors who offered to update their work first before letting us use it copyright clear in all mediums, through those who gave limited permission based on medium and/or time to those who wanted huge sums of money and charged by the word. Where clearances were denied or considered too costly to pursue, the Library Technician then sought alternatives. In most units, some articles could only be distributed in a paper based reader as covered by the standard "fair dealing" copyright laws. As full paper mode had to be supported this did not prove to be a problem however in future years, it may be that articles not cleared for electronic reproduction cannot be included in the course materials.

The development of enhancements such as digital video and animations has lagged behind the conversion of the text-based content. These elements take longer to produce and require specialist staff and equipment. The production unit in its current form has not been to handle the sudden increase in demand and a priority queue has been established to bring units up to full digitally enhanced mode. Plans are now in hand to expand the size of the media production unit.

Stage Three: CD-ROM Production

The programmer edits the web materials so that links to sites for which copy permission has not been obtained are returned to URL reference only. Electronic versions of copy cleared materials are gathered together and linked to the existing structure. The multimedia programmer prepares a CD-ROM master that contains the altered web materials plus additional interactive multimedia activities, sample programs and other electronic materials. The CD-ROM version is then checked to ensure that content and instructional integrity have been retained before copies are made.

The CD-ROM version is essentially an enhanced local web site with added resources. Students can browse the site at their leisure without the overheads of connection costs. However, if they require access to materials other than those on the CD-ROM, or if they wish to join an online tutorial, then they need to go online.

In the first pass of the process, only two units reached this stage; a multimedia unit and an information technology unit. Write-many, multiple format CDs were used and the process proved to be trouble free.
Stage Four: Evaluation and Revision

Formative evaluation takes place in each of the first three stages. Authoring is often done in teams or groups where several authors are working in related content areas, possibly on different units within a course. Authors are encouraged to critically evaluate each other's work to ensure the overall consistency and quality of the courseware. The instructional designer is also active in the early stages, working with authors and evaluating materials as they are in progress.

Stages Two and Three involve user testing of the courseware environments to ensure that students will be able to navigate through the content modules and that they will be able to successfully complete set interactions. Internal students have proved to be very helpful in this activity. Units are developed a semester or two ahead of delivery to off-campus students and as content and resources are developed they are made available to internal students in the same unit or course. The internal students work with the materials and offer constructive feedback on methods, content coverage and resources provided.

Summative evaluation takes place at the completion of each semester. Student feedback is gathered and collated with the aim of improving the courseware for the following semester. Student achievement is being reviewed to find out if the courseware is achieving its intended aims and objectives. At the time of writing, no summative evaluations are available. However, a detailed evaluation of the multimedia unit that passed through the process is currently being carried out [Ring, Jadav & Pagram 1997].

Revisions are normally made at the end of each semester to update content for the next run. Interim updates, revisions or errata information are made available to students as necessary in a form suited to their mode. Print-based and off-line students receive a mail-out while on-line students have the same material placed on the web. The next developmental cycle would then incorporate the new material into the courseware.

Document and version control is a particularly important aspect of the review and re-publish cycle, particularly where units are offered in a variety of mediums and modes. Several alternative systems and approaches are currently being investigated.

The Way Forward at ECU

In 1997, SCIMS at ECU mounted the first 30 units in full multimodal format, 15 in semester one and another 15 in semester two. These are drawn from courses in Multimedia, Teacher Librarianship, Library Technology, Computer Science, Computer Security, Mathematics, and Communications and Information Science. In the first semester of 1998, 98 units were available online. The majority of these are in the first stage of the process and do not yet have extensive media enhancements.

Over the next three years, further development will be undertaken so that all courses in SCIMS will be available in multimodal format. This initiative is in line with ECU's strategic planning directive which aims to have the majority of its courses available via flexible delivery through the ECU Virtual Campus by the year 2002.

The Multimodal Courseware Development initiative will assist academics in the preparation of flexible delivery materials and therefore provide students with the flexibility to study on or off campus, within or outside of Australia using their own choice of medium with the confidence that they are gaining the same quality education and support as any other student in the course.

Abstract: This paper reviews the development and delivery of a higher education module as part of the University of Plymouth's Integrated Masters Programme (IMP) through the Rural Area Training and Information Opportunities (RATIO) telematic centres. The aim of the project was to provide computer supported solutions that could assist remote learners living in the South West of England to access higher education as part of a technology assisted distance education programme. The module represented a shift from traditional educational delivery systems with the use of Internet web site pages, email and videoconferencing in its delivery. Out of the 16 participants who enrolled in the Masters module, four completed the learning sessions and 2 submitted final assignments. The mainly positive experiences of the remote tutor and the students in such an initiative and the implications for the use of the Internet for distance education are discussed.

The key purpose of this project was to take advantage of the opportunities offered by the Rural Area Training and Information Opportunities (RATIO) initiative to create an experimental web site through which to offer a Masters degree module. Because it was considered that students who were interested in information technology might be attracted to such a format, it was decided to develop a module with high information technology (IT) content entitled 'IT for Personal Development and Project Management' into appropriate telematic course ware, capable of both dissemination and assessment through interactive student participation using the facilities at selected sites. Careful development of both a telematics quality policy and model needed to be identified in order to meet the underpinning academic task criteria for all Masters modules. These tasks require learning opportunities to enable learners to develop academic skills covering the following five assessment areas: critical review of a body of knowledge, data collection and analysis, developing practice through a project, reflecting on practice and making an argument. All of these areas are underpinned by deep criteria where the learner is expected to demonstrate abilities covering personal skills which involve research and investigation, organisation and preparation, appropriateness of medium and process, practical competence, coherence, legibility, inventiveness and independence of thought, understanding of relevant historical, critical and cultural contexts and critical evaluation. The challenge of this project was to ensure that the technology-assisted solutions developed were suited to fulfilling the learning requirements outlined above. This project aimed to field test the telematic resources developed with a small group of remote learners. The experiences of these remote learners were collected in order to evaluate the effectiveness of the technology adopted and the distance education delivery systems implemented. The identification, development and testing of a web-page authoring kit, suitable for practical university staff development, represented both an original contribution towards staff development. It also achieved viable solutions to some of the recently raised issues highlighted in the Higginson report regarding implementation of flexible distance education, information technology learning curricula and superhighway learning resources (Higginson, 1996). These issues have also been recognised in the European Union's recent white paper on education and training which has implemented a wide range of telematic-assisted learning projects (EU DGXII, 1995).

Aims

1. To develop a University of Plymouth Internet web facility for the Masters programme, capable of telematic organisation of flexible distance learning packages;
2. To pilot the conversion of the module 'IT for Personal Development and Project Management' into such an flexible distance learning package;
3. To develop flexible distance learning real-time interactive face-to-face solutions for seminars, tutorials etc., through RATIO video-conference centres across the region;
4. To evaluate the effectiveness of the flexible distance learning solutions developed in terms of key findings gleaned from involved staff and distance education participants, identifying key lessons learnt with consequent implications for teaching and learning in higher education.

The implementation of the project

The implementation of the module is described in three stages: the recruitment of participants, the delivery of the module and the evaluation of student and tutor experience.

1. The recruitment of participants.
Given that this project was an experimental initiative, it was advertised apart from the University's normal advertising for Master's programme. From this mail out to selected post graduate student groups and through word of mouth, approximately 60 people requested additional information about the module. Twenty prospective students attended an Introduction and Induction evening with 16 people completing formal enrolment procedures. All of the students had appropriate entry qualifications for enrolment in the Integrated Masters Programme and were mature adults who were or had previously worked in education, training or related fields. Difficulties in obtaining access to suitable hard ware and venue sites were the reasons that four people did not complete enrolment. This factor proved to be significant in later drop outs from the module. During the course of the session, the 16 students were asked to complete a short questionnaire relating to previous IT experience in order to ascertain anticipated need for IT support during the module.

2. The delivery of the module
Once enrolled, the 16 students were provided with the module's world wide web address, user name and password to access the seven learning sessions. The module was authored in such a way to allow public access to some information but the learning sessions were protected by a user name and password. Students were asked to signal their participation in the content of the module by constructing an email of introduction about themselves for the tutors and fellow students. Shortly after that, students were asked to respond to the tutor's email requesting details about their assignment. A distribution list was set up to facilitate communication between tutors and students. Students then were required to access and complete the learning sessions in their preferred venue, own time and at their own pace. The tutors encouraged students to communicate about difficulties encountered during the module and distributed email responses to frequently asked questions to the group members. Students were also encouraged to communicate with fellow students about their experiences encountered while undertaking the module, thereby encouraging the establishment of a support group. The learning sessions needed to be completed in sufficient time for students to prepare and submit an appropriate assignment by a set date. At least one videoconference session was planned during the delivery of the module. Numerous problems related to the delivery of the module emerged.

3. Evaluation of student and tutor experience
Project evaluation was carried out in a number of areas. Qualitative analysis of the following key areas was investigated:
1. the ease and social pragmatics of developing a flexible distance learning package by university staff;
2. the extent to which the aims of the module were actually achieved through flexible distance learning assessment methods;
3. student attitudes regarding both participation and learning through a flexible distance learning delivery format. Interviews, personal and e-mail, coupled with post-module evaluation feedback reports were deployed;
4. tutor experience of, and attitudes to, teaching and delivering a module in this particular format via chronological recording of key personal learning events in a personal learning biography.

Research findings
Data were collected on student attrition, previous experience in using IT, email correspondence, personal reflections of the tutor as means of evaluation.

1. Student attrition
Student attrition was a major issue in the delivery of this distance learning module. In the four weeks following the Introduction and Induction evening, 50% (N=8) of the enrolled students withdrew from the module. The main reasons were associated with lack of accessibility to suitable hardware and pressure from employment. The project was dependent upon the operation of RATIO centres throughout the south west of England. The delivery and installation of equipment for accessing the world wide web and to participate in videoconferences was running well behind schedule which meant that none of the RATIO centres were able to be used by students. Students then had to find alternative venues which proved extremely difficult and resulted in 5 students abandoning the module. Pressure from employment proved to be another factor in student attrition. A majority of the students worked in higher or further education as trainers. These sectors were and are experiencing major structural upheaval which resulted in three students having to take on additional responsibilities in order to retain their jobs. These students would have withdrawn from the module regardless of its mode of delivery.

During the next four weeks, another four students withdrew. Two students considered that their low level of competence with IT would result in their inability to successfully complete the module. One student who suffered from multiple disabilities withdrew because the University finally was unable to meet her need for a voice activated computer. The final student withdrew because he was returning to Cyprus for the summer and was not able to access suitable equipment in Cyprus which would permit him to meet the assignment deadlines. The remaining group of four students progressed through the learning sessions over a period of approximately four months. However, only two students completed the module by submitting and passing an action research assignment. The other two students were lecturers from a partner FE college who merely wanted to experience distance learning as a means of evaluating its suitability for FE courses. While they completed the requirements of the learning sessions, they were not prepared to put the effort required in submitting a rigorous post-graduate project assignment.

2. Survey of previous experience with IT
All of the original 16 students who enrolled in the module completed a short one page questionnaire which aimed to identify their previous experience with the type of technologies on which the module was based. The results revealed that 96.8% of the students were experienced in word processing, while 43.8% had experience with email, and 56.3% had experience with the Internet. Only 6.35% of the students had previous experience with videoconferencing. In relation to the venue where the module would be accessed, the workplace (50%) and home (25%) were specified by the majority of students. Other venues specified were the University's computer centre (12.5%) and various RATIO centres (12.5%). 68.75% of the students (N=11) indicated that they probably would use a combination of the above venues to participate in the module. Given that the RATIO centres were not fully operational during the module, two students eventually had to find other suitable venues. Finally, the students were asked to rate themselves in terms of their level of confidence for using IT on a four point scale (very confident, confident, unconfident, very unconfident). Half of the students (50%) reported that they felt 'confident', 43.75% (N=7) reported feeling 'unconfident' and one student reported feeling 'very confident' in using IT. Interestingly, only two students withdrew because of feelings of incompetence with using IT. These data suggest that student attrition mainly was associated with factors unrelated to lack of confidence in using IT.

3. Qualitative analysis of email correspondence
Email correspondence (and four telephone calls) generally related to technical and academic related problems. The biggest technical problems were related to obtaining the correct address for accessing the module on the world wide web and incorrect or changed email addresses. Unfortunately, following the Introduction and Induction evening when the module's address on the Internet was provided to students, it was decided by technical support staff from the University's Computer Services to change the address. Although inserting the new address into the home page rectified the problem, it resulted in considerable student confusion. The change of address was followed almost immediately by the University's system 'going down' for a couple of days, a situation for which the students had not been forewarned. In setting up the module on the Internet, technical staff from both the Faculty and Computer Services had been involved. It is important that one department only be responsible for 'webministration' services, especially for creating the address and setting the
password so that responsibility for coordination of all information may be disseminated to all system users.

Owing to a lack of central webministration service, the distance education learners were not adequately informed about any vital system changes, such as incorrect and changes in email addresses. In the early stage of the module's delivery, one of the tutor's took up employment in Singapore resulting in a change of email address. Some students who had limited understanding about the precise nature of email addresses provided incorrect contact details. One student changed her email address during the module and provided incorrect details which took some time to unravel. Consequently, the distribution lists became incorrect at frequent intervals which resulted in students not receiving replies to emails or emailed correspondence. As initial technical problems were overcome and the student group decreased to four, the type of technical query changed from simple problems as described above to more complex problems, such as encoding and decoding email attachments between different systems, accessing different web sites, creating and saving of graphics as GIF files and word processed material so that they can be sent as split text and graphics and queries related to the setting up of and preparation for a videoconference. It is essential that students have immediate access to technical support for such a technology-dependent learning system.

Because of tutor unavailability due to holiday periods and absences related to other academic duties, some students reported concern about delays in responses to emailed correspondence. Students also could not be raised by tutors sometimes which created uncertainty about their continued participation in the module. It is important that all participants alert group members if they are going to be 'off line' for any period of time. A transparent communications protocol linked to webministration, administrative and technical support services, tutor academic support and distance learner participants are recommended as essential infrastructure for any expansion of this service. A range of academic queries were raised in student emails. These related mainly to definitions of academic terminology, requests for feedback on student work, questions about theoretical and methodological issues, requests for traditional printed resource materials, request for information about administrative and library matters, the use and value of reflection in academic work and other matters directly related to the academic content of the module. Where appropriate, the tutor's reply was distributed to all of the group members as were relevant suggestions and comments from students.

Although traditional written end of module evaluation could have been undertaken with the completing students, the small number of completing students made this less relevant. Instead, the two students who successfully completed all seven learning sessions and submitted an appropriate assignment were contacted personally to discuss their experiences, the strengths and weaknesses of distance learning. The general consensus was that there was more time and work associated with undertaking a module in this format than in traditionally delivery modes. While the students thought that they had learned a lot, they described some of the theoretical on line reading as 'heavy going'. The students thought that two demands were made on them: first, the learning of IT skills to enable them to undertake the distance learning module and second, the learning related to academic content requirements. The students recognised that there were initial 'teething problems' associated with technical aspects of the module but considered that these were overcome by the regular emails and encouraging personal support offered by the tutors. The lack of face to face interaction with the group was considered to be a disadvantage. It was thought that this aspect would have been overcome with videoconferencing. As it turned out, only one videoconference was able to be organised in which only one of the students could participate at the University due to technical and time difficulties. The other student linked up separately via her school's videoconferencing resource but all three venues could only communicate via point to point. A multi point bridge server was not available between the three venues, so three way communication was stymied. The tutors recognised that some of the students' problems with the module were associated with their inexperience in authoring telematic based course ware, that is disseminating appropriately formatted graphics and text files over the email Internet systems used. These problems are likely to be overcome in future distance learning packages.

4. Personal reflective journal of the tutor
The remote tutor identified and recorded a wide range of problems and successes associated with the delivery of this module, with the key issues as follows.
1. The lack of a distance learning systems protocol that delineates open support between the three core user areas of on-line administration services, IT technical services and academic services. These were mostly left to the on-line module tutor to sort out.
2. The lack of a user-friendly videoconference facility that could easily connect the tutor and the group together for multi-point private conversations.
3. The need for a clear web etiquette and on-line protocol from which both distance learners and module tutors can overcome the problems of remoteness and lack of face-to-face contact.
4. While the student attrition dropout from the module was high the completed projects were of a very high standard and validated the academic value of accrediting community-based action research projects via a university distance learning programme.

From these problems the tutor has recommended the following solutions towards any future expansion of the distance learning IMP. First, the creation of a webministration service to centrally co-ordinate the distance learning support service. That is, both a forum and intermediary through which the IMP distance learning modules may be administered. The service would include on-line registrations, dissemination of necessary regulations and user contact protocols, assistance with IT technical problems. The webministration coordinating facility would form the academic support infrastructure of a distance learning virtual faculty and could offer global access to the IMP. Second, the 'big' studio-based videoconference facility offered by providers such as PictureTel Corporation are considered to be inappropriate and inflexible to the distance learner's needs for an easy-access face-to-face solution. Instead, the tutor has recommended a desktop videoconference solution which offers server space for 'bridging' multi-point desktop videoconference sessions via the client-users own PC.

Outcomes and discussion

Several key benefits and outcomes stemmed from this project and included the following:
1. the development and running of a dedicated web site which included full interactive student participative features such as Internet e-mail;
2. the conversion of an existing module into suitable flexible distance learning format;
3. the identification and development of a suitable HTML editor which was capable of being used as a staff development authoring tool by current staff;
4. the piloting of videoconference resources as a means of satisfying the perceived face-to-face requirements underpinning delivery of a higher education programme;
5. a demonstration of applying telematics in the delivery of higher education programmes.

Although the final group of students was small, the quality of their submitted responses to the seven learning sessions and assignments demonstrated that the project had a significant impact on the quality of learning. The most important quality-related issue is that of improved student access to postgraduate professional training programmes. The students who completed the module would not have enrolled in a traditional delivery mode because of various commitments. Higher education learning opportunities were therefore realised through the medium of telematic assisted flexible distance learning in a geographically sparsely populated region, with consequent lessons and implications for similar programmes adopting the same model.

An important impact on the quality of learning was the creation of a flexible distance learning medium which promoted the ethos of student autonomy with regards to their own learning, thus underpinning the aims of effective adult learning and the deep learning criteria previously outlined. Good quality telematic assisted learning programmes, with proper higher education accredited status, can achieve Boud's vision of developing the educational qualities and personal skills that underpin the successful performance and capability of the autonomous learner (Boud, 1981). This is further underpinned by Harri-Augstein's and Thomas' notion of the self-organised learner (Harri-Augstein & Thomas, 1991), whereby an individual's learning capabilities can be enhanced through technology assistants which they refer to as an Intelligent Learning System.

Coombs (1995) further elaborates this notion of an Intelligent Learning System in terms of a Knowledge Elicitation System, whereby, information technology-assisted learning is considered in terms of its interactive learning capability with an individual learner. It is therefore understood that the quality of learner-learning with an information technology software system can be explained in terms of the learner being able to systematically manage their own elicitations in the form of self-organised reflective constructing experiences. From this perspective, knowledge is considered as being relative to the user - as learner - via focused information technology-assisted reflections, construed and elicited by the person in the form of meaningful Learning Conversations. Given this understanding of how information technology/telematic learning systems may impact upon the personal learning capability of the learner, coupled with the demands of higher education, such as
developing the learner's reflective skills, it can be seen that appropriate learning technologies could bring considerable benefits to outreach members of the community participating in a distance education scheme.

Additionally, the personal involvement of the tutor in developing his/her curriculum through an action research project is supported by educational critical thinkers such as Stenhouse (1975) and Elliot (1991) who support the notion of teacher as an experiencer of his/her curriculum. Evaluation of the on-going curriculum development experiences of the tutor involved in converting a module into a flexible distance learning format was a valuable staff development exercise. A reflective learning biography was kept as a means of project management review and evaluation of important lessons learnt, as experienced in real time, on the job.

The module chosen as a pilot for this project offered a diverse curriculum range which both embodied the spirit of the central IMP tasks and deep criteria, whilst lending itself towards the use of technology-assisted reflective tools. Clearly, the telematic media adopted, that is, Internet web pages and PictureTel videoconference facilities lent themselves to the central ethos of the module itself. This enabled participants to critically appraise information technology-assisted learning systems in terms of their ability to operate them successfully as knowledge elicitation systems. A central axiom of the module critically appraises information technology in terms of its ability to be used as a conversational learning tool that can be employed as a means of personal development. These IT reflective tools assist participants to carry out a small scale action research project from within their own social and working environment. Information technology project management techniques included the use of the Internet to research contemporary background information of a participant's subject/professional development field, e-mail to share research questions and concerns with project supervisors and other team members, spreadsheets for quantitative data analysis and graphical presentation and wordprocessing facilities to keep a computerised reflective log/account of key project events and submit the final assessment dissertation.

A key part of the module required one-to-one tutorials to negotiate the participants' project and discuss individual needs and assessment methods best suited to achieving the assessment task. Videoconferencing provided a means of giving this kind of support to distance learners but in practice proved to be impossible to implement owing to the unwieldy nature of studio based videoconference solutions such as PictureTel. However, PictureTel does provide the bonus of sharing an information technology task with a distance learner despite the fact that it was difficult to access and use. Therefore, it is possible to conduct interactive information technology software demonstrations and exercises from the module that currently involve the use of Excel and SPSS. However, a more user-friendly desk top videoconference system would allow for easier user access and is recommended for future use.

Difficulties Encountered

A number of obstacles to the development and delivery of the module were encountered by the tutor and students. For the tutor, lack of support in the administrative, library and technical areas, inadequate time allocation and resourcing for the development of the module and recognition by the university administration of the needs of a remote and/or home tutor were identified. For students, the major obstacle was accessing equipment to undertake the module tasks. Contrary to expectation, the RATIO centres were not resourced with the equipment necessary for students to undertake the module during the trial period. In addition, a student with multiple disabilities was not able to gain access to equipment which would have enabled her to undertake the module. Where alternative venues were identified, such as colleges, schools or home systems, the capacity of these systems could not always handle the demands of the technology. Some students found that the challenge of mastering the technology were greater than expected and thought that they could not handle both the technology and content together. However, most students reported that the major advantages of the module were working in their chosen venue, in their own time and at their own pace.

Conclusion

In conclusion, the key benefits of this project should impact upon those participating students drawn principally from the South West of England who wish to pursue professional development in Higher Education. Another key benefit is the staff development of all those involved in this project, including the participating project team, through personal experiences of innovative practice that leads to new and further pedagogical knowledge and skills. As a consequence of cross-institutional collaborative involvement, the RATIO partner institutions will clearly benefit in the future through
the perceived enhancement of their reputation as leaders in distance education, despite the set backs reported in this project. The general education profession will gain some valuable insights from this distance learning project which has made an original contribution impacting upon the management, theory and practice of teaching and learning in Higher Education.

References

Abstract: Oregon State University (OSU) has been challenged by the State Board of Higher Education, and the University president to create a “Next Generation University” that is more accessible and better meets the needs of the citizens of Oregon. The initiative to transform the university to one that provides access to all Oregonians as a primary goal is called OSU STATEWIDE. This initiative includes practices for rapidly developing a distance education program that are transferable to other universities. These practices include empowerment of a distance education program development team, completion of a business plan, and focusing important university assets and resources - particularly distance education development and delivery assets, and faculty and student services. This paper describes some of the important changes necessary to develop a comprehensive distance education program within an existing university structure.

1. Introduction

Fundamental change is required to move from a primarily campus-based institution to an institution that supports its claim that the “State is our campus”. During the past year, Oregon State University established “OSU STATEWIDE” as one of its primary initiatives. This initiative which envisions making the university accessible throughout the State of Oregon, is closely aligned with the three University goals that have been articulated by the University president, Dr. Paul Risser. The goals are:

- To create a compelling learning experience for students, staff, and faculty
- To be recognized as a top-tier university on all scales of measurement
- To serve the State of Oregon as the campus of Oregon State University

2. Background

Oregon State University is an American Land Grant University, and has had throughout its history a responsibility for providing research, education and service throughout the State. The OSU STATEWIDE initiative serves to focus those responsibilities. While the research and services areas of these responsibilities have been well served by organizations such as the OSU Extension Service, the Agricultural Experimentation Station, the Marine Science Center, and others which are separately funded by the Oregon Legislature, the instructional aspect of this responsibility has not been as forward moving and has had to function on a self-support basis.
3. Approach

OSU STATEWIDE instructional outreach is being developed for several reasons, including, and foremost, the need to provide access and choices to Oregonians who are place or professionally bound and cannot come to either the OSU campus for programs that are unique to the university, or do not have a four year institution near where they live for more general degree programs. OSU STATEWIDE has economic development as its underpinning. In addition to being a primary University goal, as previously noted, providing access is also part of the long term vision of the Oregon University System Board. The initiative is also seen as a way to increase declining enrollments and to help the image of the University, which may lead to improved funding.

3.1 Extended Education Development Team

To help meet the goals of this ambitious program during a time of declining resources, it has been necessary for Oregon State University to significantly refocus existing resources. To start, an extended education development team was formed. This team included the following:

- Provost (stature and access to the entire university resources)
- Director of Extension Service (statewide responsibility)
- Associate Provost for Information Services (technology assets, ideas)
- Faculty Associate to the Provost (curriculum expert)
- Director of Continuing Education (logistics, student services support, marketing)
- Director of Distance Education (technology and faculty training emphasis)
- Support from the Media Center (instructional development and delivery)
- Registrar (university admissions and student records/management systems)

The establishment of this working team proved to be extremely valuable. As a team with the expertise and contacts to develop a distance education program, it was able to work very quickly, bringing together other areas of the university to deliver the program. Each in their own specialty area of expertise and responsibilities, the team members went about making the necessary changes to foster the development of distance education on the campus. Important to its success, the team leadership was empowered to have contact with all levels of the university along with direct and continuous access to the top administrators.

3.2 Business Plan

The university had been delivering a limited number of distance education offerings in key locations for a number of years. In order to determine how to move forward with new offerings, a business plan was developed that included assessments of need, a technology strategy, recommendations for student and faculty services, income and cost analysis, funding strategies, recommended programs for delivery, and marketing and sales strategies. The business plan also demonstrated the need for focusing campus instructional development resources to the distance learning program.

3.3 Delivery of the Distance Education Program

Historically, Oregon State University has provided distance education programs for over twelve years. Beginning with computer science courses transmitted over microwave to the high tech community near Portland, Oregon, the program expanded to include other engineering courses in electrical and manufacturing, as well as education, and liberal studies programs. Some of this growth can be contributed to a state infrastructure consisting of two-way compressed satellite video that was made available in the early 1990s. Part of the growth was also spawned by place-bound persons or professionals who requested direct access to a four year institution.
Today, through OSU STATEWIDE, the program delivery has expanded to five baccalaureate completion programs in partnership with the community colleges in Oregon, and five masters level degree programs. Many of these are developed as "cluster" programs. Courses are chosen for development and delivery that meet the needs of multiple programs. By clustering programs that require common courses (e.g. a course in environmental policy will work equally well for Liberal Studies, Environmental Science, and Natural Resources) the STATEWIDE initiative is better able to aggregate student numbers to make the initial offerings cost effective, and to provide the necessary resources during the startup years.

3.4 Partnerships with other Education Institutions

In order to provide degree programs in a relatively sparsely populated state, OSU has actively pursued partnerships with other educational institutions, particularly the Oregon community colleges and other Oregon University System (OUS) four year institutions. Numerous community colleges are engaged in the baccalaureate completion 2+2 programs where the students can take the two year lower division instruction in the local community, and then, while staying in the community can complete the upper division course work from OSU on the community college campus through OSU STATEWIDE. Several of the OUS four year institutions are also partnering in both baccalaureate completion and graduate level programs. These joint program arrangements provide access to specialized coursework from OSU at distant locations, while at the same time, provide courses from the other institutions to the students.

3.5 Technical Delivery Systems

The goal of OSU STATEWIDE is to offer access to a 21st century education through various delivery systems - including traveling faculty, video workbooks, Internet and Web based courses, interactive video courses, and a combination of technologies - for learners who cannot relocate to a university setting to pursue a degree or a new minor. The primary technology that is being employed at this time is interactive video through several technical systems including compressed two-way satellite video, terrestrial two-way compressed video (PictureTel), IP video over fiber, and Instructional Television Fixed Service (ITFS). There is also a growing number of Web based courses being developed as instructional management tools improve and more faculty are exposed to this methodology.

3.6 Development of the Distance Education Alliance
In order to meet the challenge of providing adequate faculty resources, particularly in the area of instructional development, it was necessary to focus the majority of the instructional development resources present on the campus to this initiative. This was accomplished through the development of the Distance Education Alliance. The Oregon State University Distance Education Alliance is a place for intensive faculty training, course development, and research on the effectiveness of distance education. It is the goal of the founders to have it become nationally known as an Oregon State University Center of Excellence.

The following activities are examples of how the Alliance serves OSU as a site for the development and promotion of distance education instruction.

- Prepare faculty and support staff to have intensive knowledge of new distance education delivery methods through workshops, seminars, and mentoring.
- Provide instructional design elements and course development, with staff producing courseware for the expressed needs of the faculty.
- Adapt new technologies to the instructors’ needs.
- Provide training on-line, thereby modeling the technology to be used and making it available to a broader audience.
- Research and test resources, including focus groups and lab research to test effectiveness of distance education methods. From the knowledge that is created, articles and other output will result, marking OSU as a center of excellence in distance education.
- Create an environment that will stimulate faculty work in distance education. Faculty course developers will serve as researchers, training assistants and mentors to other faculty researchers. The Alliance will be a physical location where faculty can come to receive support and/or to help mentor other faculty.
- Assure OSU currency in new technologies for both asynchronous and interactive video instruction. Research and track state of the art technologies and tools so the Alliance can provide the highest possible quality work.
- Provide central resources and training for collaborative projects with faculty from other institutions.
- Provide technology transfer, facilitating the sales of new instructional management software and technology based content developed by OSU faculty or through collaborative projects.
- Represent the university in national activities relating to the development and growth of distance education.
- Provide adaptive technologies for students and faculty with disabilities.

3.7 Faculty Training

Through the Distance Education Alliance, faculty workshops are provided to train faculty on the uses of the technologies available for delivering instruction. These training workshops are conducted by the expert on-campus staff and includes hands-on experiences using the technologies. The training sessions are provided in group sessions at several times during the year. Training assistance is also available to faculty on a personal one-on-one basis throughout the year. Instructional design consulting help is also available for the faculty as they develop their distance education courses.

3.8 Other Distance Education Services

In addition to training, course development and program delivery, other distance education services are being coordinated by the Distance and Continuing Education, STATEWIDE office to better facilitate the needs of the students and teaching faculty. These additional coordinated services include library support, on-line registration, tuition payment, transcripting offered through the OSU Valley Library and the Registrars office, on-line student writing assistance, technology infrastructure development and support, and other student services support. The STATEWIDE team also provides facility and technology scheduling, travel arrangements, class materials distribution, proctoring exams, program marketing, evaluations, catalog
development, and more. The STATEWIDE team also works closely with on-campus services available in the Financial Aid office.

Through the engagement of the university marketing office, the distance education program is marketed in a comprehensive way through a variety of methods. This includes, radio, newspapers, community college catalogs, ads on computer mouse pads for partnering community college computer labs, infomercials for the interactive video courses and outdoor billboard advertising.

4. Conclusions

The OSU STATEWIDE program is changing the university culture by providing degree programs to numerous locations around the state. This change is substantial, one that involves presidential and provost support, and the empowerment of a small leadership group to move forward quickly. It also involves the reorganization and refocusing existing resources, significant course development by those early adopter faculty and active conversations and debates with the others, and continuing hard work by the leadership of the initiative.

OSU STATEWIDE will provide access to the numerous programs in areas of the state and elsewhere where they are not now available. It is likely that this new direction will change the way the university is perceived around the state and nation. Will it lead to most of the programs presently being offered on campus, eventually being offered at a distance as well? That is doubtful. However, numerous offerings will be made available in a variety of formats, some through partnerships with other institutions, and some through multiple modes of technology and instructional methods which may or may not include face to face instruction. Are we helping to shape the “Next Generation University”? For Oregon State University, we believe the answer is yes.
Abstract: Educational applications of distributed hypermedial systems constitute a research sector which is presently in fervent activity. The advent of the WWW, which offers access to hypermedial resources available on Internet, has facilitated the use of hypermedial resources in teaching and learning phases. However, the original problems regarding the question of control of the learning phase, together with the problem of the passivity of the courseware, in practice no more than a text-book, have remained unsolved.

To ensure that an interactive educational environment promotes effective learning, an adaptive component should be incorporated to guide the learner towards valid learning goals. In this paper we describe our approach to the development of an Internet-based course designed for distance education and aiming to support the learning of medical English. The course embodies a tutoring system which can be activated on request by the student, to orient his choice of learning path.

Its implementation on the Javascript platform circumvents the limitations of the World Wide Web.

Introduction

The phenomenal growth of the Internet over the last years and the development of various multimedia applications have led to far-reaching changes in educational models.

Beside the traditional didactic method based on a teacher standing in front of a class, distance learning is gradually taking its place thanks to the World Wide Web. This provides a unique challenge as a new delivery mechanism for course material allowing learners to take a course from anywhere in the world.

Marchionini and Maurer have pointed out that an important factor which will have a strong influence on teaching and learning methods in years to come is the possibility of consulting enormous digital libraries which will constitute a most valuable teaching resource as sources of updated and updatable material [Marchionini & Maurer 1995].

Thus, World Wide Web offers a platform which allows didactic systems to be defined having global education as their aim.

As reported by Bouras et al., a hypermedia tool for distance education (HTDE) aims to provide its user with the ability to access educational material that has been created by experts, structured as a hypermedia document and stored in a library [Bouras et al.1997]. They emphasize that the distance education system using the Web as the underlying platform for its implementation exhibits all the advantages of the Web itself (support for hypermedia documents and links, universal and standardized graphical user interface, excellent navigational control, adequate support functions, independence of hardware platform, reusability of courseware and ability to connect with database systems). However, it also features all the Web's disadvantages, such as poor support of stream data, small degree of interactivity, poor support of one-to-many sessions and so on. Using
programming environments like Java, Javascript and ActiveX, sophisticated networking applications can be
developed that exploit the advantages of the Web.
Schank speaks of “active learning” and says that interactive multimedia training can enhance learning by
allowing students to go back over a subject or else fast-forward over an area that they already understand or do
not need [Schank 1994]. On the other hand, although WWW inspires enthusiasm among educators, it creates
some problems due to the passivity of the courseware, in reality no more than a textbook, and to the lack of
monitoring and control exerted by the system on the student learning process.
Several papers [Beumont & Brusilovsky 1995] [Hekmatpour 1995] have focused on adaptative educational
hypermedia interface while Nkambou [Nkambou & Gauthier 1996] presents a system which uses HTML
documents as pedagogical material under the control of an Intelligent Tutoring System.
Earlier experiments [Altamura & Roselli 1995] [Roselli 1995] [Roselli et al. 1996] with standalone
hypermedial courseware have demonstrated that the freedom of action offered by the hypermedial educational
system needs to be integrated with more explicit control and direction to make sure that the learner is guided
toward valid learning goals.
In this paper we describe our approach to the development of an WWW-based course designed for distance
education and aiming to support the learning of medical English.
The course embodies a tutoring system which can be activated on request by the student, to orient his choice of
learning path. The development platform used is the Javascript language developed by Netscape which has
made it possible to circumvent some of the WWW limitations.

NetMedEnglish Architecture

NetMedEnglish constitutes hypermedia courseware possessing some of the features of the ITS. Its main
characteristic is that it can adapt to the level of knowledge and understanding acquired by the student. It is
presented as a traditional hypermedia but supports student interaction in order to reduce the disorientation and
cognitive load problems that typically affect hypermedial systems.
NetMedEnglish has a server/client structure based on the architecture of WWW and the hypermedia
courseware resides on the server. The latter consists of a conventional WWW daemon used for communication
between server and client, while the client system includes a WWW browser: Netscape, as well as the
NetMedEnglish process and student information.
The system is organized in the form of four basic modules[Fig. 1]: Interface, Tutor, Student and Domain
Modules. These are explained in the relative subsections below.

![NetMedEnglish Architecture Diagram](image)
Interface Module

This module interacts with the user and consults with the domain to see which node comes next after selection of an anchor. It then decides which nodes should be presented on the basis of the information received from the Tutor Module.

Tutor Module

This performs intelligent decisions adapting the courseware to the student, basing its behaviour on the data received from the Interface Module and the Student Module. Unlike the classical Tutor Module present in ITS, it works fully transparently and intervenes only on specific request by the student who asks for guidance. Thus, the philosophy underlying the use of hypermedial systems is preserved intact for those students who are able to manage their learning processes alone.

When the Tutor Module is activated it carries out the following functions:
- it interacts with the Interface Module to receive the requests for access to a new logic node in the hyperspace;
- it verifies that this information can be presented, by consulting the Student Module and activating the instructional rules. If the information cannot be presented, it informs the student, by means of an explicit warning message, of the next step he should take to ensure correct use of the course.

Student Module

The Student Module needs to be easy to construct and modify and should accurately reflect the characteristics of different students.

It has been divided into two sections: Student Model and Student History. The first section is independent of the subject of the domain and describes the student's learning characteristics. The system classifies three types of student: novice, intermediate and expert. In addition, this section represents the domain concepts acquired by the student during his learning process. Student History includes information about how the student's instructional process has developed, and in particular the progress he has made, which exercises have been proposed and how he got on with each exercise.

Domain Module

The domain module represents the knowledge which should be transferred to the student. In our system, this is constituted by basic anatomical and physiological concepts belonging to the field of medicine. It is represented using links and nodes, there are various types of node according to their function:
- ordinary nodes contain only static information to be presented (e.g. text, images, sound, animation);
- navigational nodes contain the tools for activating links to other nodes (e.g. menu, index, information cross-links, etc.). The student can access the voice glossary of medical terms which contains the significant keywords: on selecting the relative term, he will hear it pronounced in English and the theory card which deals with the given concept will then be automatically accessed;
- exercise nodes contain different types of exercises to be solved by the student.
For example, he must insert the answers to an exercise in a visualized field, or solve a comprehension exercise by selecting the right answer among multiple choices, or place the words in the correct order to form meaningful sentences with the mouse drag and drop technique.
Implementation Choices

Although there are many tools now available for managing the student model in stand-alone didactic systems, this management is more problematic for didactic systems on the Web. Memorization of the data on the server is very expensive and complex, because it is necessary to keep track of each student who has access to the course and to obtain the relative information from the server, involving a continual exchange of data between client and server.

One solution which seems to be satisfactory is memorizing this information on the client, because in this way several learners can have access to the same client system, while the tracks of their instructional paths are kept distinct. This solution could be adopted thanks to the use of Javascript. Using cookies.txt files it is possible to memorize the student model, and then call up such information as the pages visited, the number of times each page has been accessed, the exercises carried out and their outcome. This use of cookies avoided the need for server-side solutions, like the CGI script or applet written in Java, to be able to act on the database. Javascript allows access to these cookies to save information on the situation as regards previous sessions using the courseware. A cookie cannot of course replace a database on the server but it is very useful for such applications as the student model.

Conclusion

This new dimension for the provision of courseware is of great interest. It can certainly stimulate learning but the freedom of navigating in the WWW hyperspace raises the risk of exacerbating the disorientation and cognitive overhead drawbacks that had already been observed in standalone systems. Integration of an individual adaptation mechanism can help to guide the student and contain him within paths promoting effective learning.

The NetMedEnglish hypermedial system proposed in this paper is an interactive educational environment on WWW which embodies a tutoring component aiming to help solve the above problems and exploits the Javascript platform to overcome the limitations of the World Wide Web.

"DreamTeam" - a Synchronous CSCW Environment for Distance Education

Jörg Roth, Claus Unger
University of Hagen, Department for Computer Science, 58084 Hagen, Germany
Joerg.Roth@Fernuni-Hagen.de, Claus.Unger@Fernuni-Hagen.de

Abstract: This paper presents a platform for the development and execution of synchronous co-operative shared applications in a distributed education environment. Even though several co-operative environments are existing nowadays, specific problems in real student environments are not treated satisfactorily. Students often have to deal with unstable network connections and low bandwidths; they are using different hardware and software platforms; their computers are off-line most of the time.

The DreamTeam platform addresses the special needs of distance education environments. It comprises a development environment, a runtime environment and a simulation environment; it is based upon the concept of a de-centralised architecture. It minimises the development cycle for co-operative applications and encourages rapid prototyping.

DreamView, a co-operative Web browser developed in the DreamTeam environment, demonstrates the strengths of the DreamTeam environment.

1 Introduction

Co-operative (CSCW) applications are playing a major role in distance education, e.g. for group discussions, jointly working on electronic courses, jointly visiting Web pages, remote laboratories, video conferencing, joint program development, co-operative publishing, etc. To develop such a co-operative application is a difficult and time-consuming task.

Dommel et al. [Dommel et al. 97] distinguish three types of co-operative applications:

- **Collaboration unaware applications** offer no collaboration services themselves; they are single user applications, running in a shared environment.
- **Collaboration aware applications** are developed for co-operative environments, but their services for collaboration are hard-coded.
- **Collaboration transparent applications** provide their services for collaboration by using high level services of a standard collaboration environment.

Taking the last approach, a developer can concentrate on the application specific details of his application and can use the collaboration oriented services from the standard collaboration environment.

In the following, we describe DreamTeam, a Java oriented development and runtime environment for synchronous, collaboration transparent applications for distance education. As an example for such an application we further describe DreamView, a co-operative Web browser, which has been developed within the DreamTeam environment. In the following, the terms co-operative application or groupware are used as shorthands for a collaboration transparent application running in a shared distributed environment.

2 Co-operative Applications for Distance Education

Co-operative applications for distance education have to take into account our students' special needs and requirements.

**User interface:** Especially for remote students it should be as easy as possible to install and run a co-operative application. Different applications should provide consistent interfaces, at least for all aspects of installation and general collaboration.
System platforms: Most of our students are using PCs with a variety of different operating systems. A co-operative application should make as few assumptions as possible about the system platform with regard to hardware requirements (screen resolution, system performance etc.) and software requirements (operating system, version, installed software etc.). PCs tend to be unstable. A co-operative application should be tolerant against local breakdowns and should easily allow to restart a system and rejoin an existing group.

Network: Most of our students are using the Internet for communication, mainly through dial-up modem connections, connecting them to the university either directly or via a service provider. These connections are exposed to network delays, bandwidth degradations, as well as sudden, unexpected disconnections. A co-operative application should handle such situations itself without requesting any additional actions from the user, e.g. by reconnecting to the active group. Usually, students are off-line most of the time and their Internet addresses may change between consecutive dial-ins. It is the task of a rendezvous component to find out which students are actually available for a meeting and how they can be reached via the Internet.

3 The DreamTeam Environment

The DreamTeam environment allows the developer to develop co-operative applications like single user applications, without struggling with network details, synchronisation algorithms, etc. The environment consists of three components, a development environment, a runtime environment and a simulation environment. In the following, the basic DreamTeam concept as well as the three components are described in more detail.

3.1 The Concept

Architecture: Co-operative applications can either be implemented in a centralised or in a de-centralised way. In a centralised architecture, all messages are routed via a single group server, thus group events and data accesses can easily be synchronised. On the other hand, group servers often are performance bottlenecks, a shut down of a group server shuts down the session; all messages, even those between clients residing in the same host, have to be sent through the group server.

In a de-centralised architecture, availability and bandwidth problems can be avoided, but synchronisation and serialisation have to be handled by higher level protocols. On the other hand, a de-centralised architecture allows different kinds of communication channels, e.g. via ISDN connections.

The actual version of DreamTeam supports de-centralised architectures without the need for any central server.

Session management: In a de-centralised architecture, session management has to be handled in a de-centralised way too. The originator of a session defines a session profile and generates the session. As soon as he has started the session, other users can join and leave the session. When the originator himself leaves the session, the session can continue with the remaining members but no new members can join in.

Information distribution: To distribute information among session members, DreamTeam uses a special kind of Multicast Remote Procedure Calls, through which a local system can call a procedure at all participating remote systems. Complex data structures can be serialised, transferred as procedure parameters and rebuilt at the target site. All objects defining a DreamTeam session can be serialised; thus even for a late-comer the actual session state can easily be generated.

3.2 The Development Environment

The development environment provides a big object oriented class library based upon the standard Java library. It contains 190 classes with more than 2500 methods and is steadily expanded for new kinds of co-operative applications. It is structured into three layers.

The base layer offers general classes for user interface design, general data structures, general network services and other utilities, which are not groupware specific but are missing in the standard Java library.

The service layer contains groupware-specific classes. For, e.g., session management, data sharing, file transfer, distributed dialogues and special groupware widgets (telepointers, tracking of document views etc.).
The *application service layer* defines the only access to the service layer for application programmers. It includes security checks for all method calls, and thus protects the runtime system. Invalid calls are documented in a message log file. Details can be found in [Roth 97] and [Roth 98].

Using this class library, the DreamTeam front-end (see [The Runtime Environment]) as well as several co-operative applications have been developed so far, a co-operative Web browser will be described in more detail in ["DreamView" - a Co-operative Web Browser].

3.3 The Runtime Environment

Besides providing services to shared applications, the runtime environment offers a set of functions to the end user. [Fig. 1] shows a typical DreamTeam desktop.

![](image)

**Figure 1. The DreamTeam working environment**

The upper left main window allows to
- configure host and user profiles;
- retrieve user profiles of participants of previous sessions (lower left window);
- define and edit session profiles;
- start and stop sessions (icons representing open sessions are shown in the upper right window);
- start private applications (icons are shown in the lower right window);
- view users currently connected to a session.

3.4 The Simulation Environment

The DreamTeam simulation system allows the developer to test his distributed application on a single computer, and to simulate network effects like delays, reduced bandwidths, network failures, etc. To simulate the network, the participating applications are connected to each other via a special program (network simulator) rather than a real network. The simulator transmits every data block to the corresponding receiver. To produce delays and bandwidth effects, data blocks can be stored inside the simulator for a specified time before they are delivered to the receivers. To simulate network failures, the simulation can interrupt the data traffic for a certain time. A user can interactively control the simulator by a user interface, which also provides statistical functions.
4 "DreamView" - A Co-operative Web Browser

4.1 The Concept

DreamView is the first substantial co-operative application developed in the DreamTeam environment. Beside providing a useful tool for distributed education, DreamView has been developed to test and validate the DreamTeam design concept.

DreamView allows a group of users to co-operatively browse the World-Wide Web. The reasons for implementing a co-operative Web browser are manifold. In addition to browsing remote documents, Web browsers can be used to browse local HTML documents; manuals and course materials can be published as HTML trees and distributed on CD-ROMs. In the following, three possible usage scenarios for DreamView are sketched:

A co-operative Web browser as a background tool: In a group session, it would be helpful to have a Web browser as a background tool. For example, a group is developing a program with a shared editor. Suddenly, a specific algorithm is needed. A Web browser is activated and the group visits a site with the corresponding course material. The participants read the specific chapter, find the algorithm, and continue working on their main task.

A co-operative Web browser as a document presentation tool: A Web browser can present formatted documents. In this case, the Web browser is the main tool in a co-operative session. It can be used, for example, to discuss software design documents, graphs and sketches etc. In contrast to the first scenario, internal group documents rather than external documents are discussed and can be annotated by all group members.

A browser as a presentation tool for computer mediated lectures: A co-operative Web browser can be used to give lectures to a student group. The teacher prepares a set of HTML pages. The students put their browsers into tracking mode. Each page and section is synchronised with the teacher's view. In addition, the teacher can use a telepointer to point to relevant items.

![Figure 2. The DreamView browser environment](image)

The browser represents itself as a normal Web browser [Fig. 2]. The largest area is used by the page contents. In contrast to other Web browsers, DreamView provides a separate area for annotations. In the annotation area, textual comments which can be anchored to the page items, can be stored. If necessary, it is possible to hide the annotation area in order to enlarge the page area.

4.2 Group-specific Services

To observe the activities of other users, a special window can be opened (see right bottom window in [Fig. 2]). It presents a radar view of the page area of another user. Each group member can open such a window for each other group member. If desired, a user can jump immediately to the shown page location. In addition, two views can be synchronised (follow mode) in order to follow the same page sections. This mode is helpful for lectures.
To point to specific page elements, a telepointer can be installed. Every user can make his mouse cursor public to other participants. A problem arises when transferring position information between users: because each user has his or her own workspace settings (e.g. screen resolution, window sizes or fonts), it is not meaningful to transfer platform dependent absolute co-ordinates (e.g. pixel positions). In the case of telepointers, e.g., a textual mapping is more useful than a mapping based upon cartesian co-ordinates. For each mouse position, the browser determines the referenced item (e.g. a word or image). Then it transfers a reference to this item as well as the relative position of the telepointer inside the bounding box of this item to other users. The recipient can now restore the corresponding position, relative to his individual screen settings. If someone points to a specific word, a letter inside a word, or a detail inside an image, on every participant’s desktop the telepointer points to the same corresponding item.

4.3 Development Costs

DreamView consists of the following parts:
- the main program, providing the browser window and configuration services;
- classes for the administration of annotations;
- classes for the HTTP connection, for parsing HTML pages and for loading images;
- classes for processing page contents and generating graphical output.

The following tables show the amount of code produced for each of these parts:

<table>

</tbody>
</table>

Table 1. Development costs

The right table shows the amount of code related to collaboration aspects.

As a result, 7.6% of the source code is used to realise co-operative functions;
92.4% of the source code is used to realise functions of a single user browser.

This result proves that the uncompromising usage of the DreamTeam platform allows a developer of shared applications to concentrate on the application itself rather than on re-implementing co-operative services.

5 Related Work

This section relates DreamTeam to other synchronous co-operative platforms. The Groupkit system [Roseman et al. 96] is a package for implementing shared applications under TCL-TK. A library offers services for session management, communication and shared dialogue management. It is mostly based upon a de-centralised architecture, only for the group rendezvous a central server is needed. A co-operative Web server called Groupweb is built on the Groupkit platform. In addition to telepointers and co-operative browsing, it allows the annotation of Web pages. In contrast to DreamView, a page can only be annotated as a whole. Annotations cannot be anchored to page items.

Habanero [NCSAa] has completely been implemented in Java. Its architecture is centralised, i.e. requires a Habanero server application in order to enable group activities. A co-operative Web browser is available, called WWW shared session [NCSAb]. Actually, this browser is the Mosaic browser, which is controlled via a data channel. Thus, group specific services (e.g. telepointers) are not available.
The Rendezvous system [Hill et al. 93] provides a distribution mechanism based upon X-windows events. This approach is completely different to our approach, since its emphasis lies on distributing windows contents and user events via the X-protocol. It is difficult to apply this approach to non-X-windows environments.

Share-Kit [Edlich 93] is a Unix-based platform which provides multicast RPC for C programs. Neither session management nor group specific widgets are included in this platform.

Dolphin [Streiz et al. 94] is a co-operative hypermedia system. The emphasis lies on the co-operative editing of hypermedia documents. It is written in Smalltalk and provides one hardcoded application, a shared hypermedia editor.

Compared to other platforms, DreamTeam offers a straightforward implementation of shared application and encourages rapid prototyping. A simulation environment helps to find out weak points and ensures stability before delivering applications to the end users. The de-centralised structure of DreamTeam avoids bottleneck problems with central servers.

6 Conclusion and Future Work

DreamTeam is a platform for synchronous co-operative applications. It consists of a runtime environment, a development environment and a simulation environment. The platform is designed to minimise the development cycle for co-operative applications and to encourage rapid prototyping. The implementation of the co-operative Web browser DreamView indicates the validity of our approach. Only small code segments had to be added to the code for a single user browser to make the application available in a co-operative environment.

The development of the DreamTeam environment is an ongoing process. Each new kind of shared applications requires new services in the service or base layer. In order to define a 'complete' set of services, we are planning to realise a variety of different co-operative applications. In addition to the co-operative Web browser, a chat tool, a drawing tool, a two player game and a co-operative, object oriented graphical editor have been implemented so far. Presently, a sophisticated, co-operative text editor is being implemented.

In order to reduce the time for implementing new co-operative applications, we are working on the definition of a high-level programming language for co-operative application, which supports the development of fully collaboration transparent applications with a minimum of extra source code.

Impact of Computer Mediated Communication (CMC) on Distance Tutoring

Malcolm Ryan, School of P.C.E.T., University of Greenwich, London, UK
E-mail: M.Ryan@gre.ac.uk

Lynn Woodward, School of Health, University of Greenwich, London, UK
E-mail: L.M.Woodward@gre.ac.uk

Abstract: This paper explores how computer mediated communication (CMC) impacts on distance tutoring. It describes the experiences of tutors undertaking staff development in the form of the On-Line Tutors Module (OLTM) to equip them with the necessary skills to deliver innovative programmes employing CMC. It focuses its discussion on some of the issues and concepts that we believe significantly alter the nature and role of distance tutoring within a CMC context.

The Context

In the UK there is growing demand from adult learners for education programmes that are flexible in terms of curriculum, modes of delivery and attendance requirements. Many professional bodies are introducing regulations demanding evidence of Continuing Professional Development (CPD) in order to maintain a licence to practice and professionals are looking to Universities to provide innovative and adaptable programmes which will enable them to fulfill these requirements.

Distance learning is of particular appeal to the autonomous self-directed, intrinsically motivated student and would seem to provide the right environment in which the academic, vocational and social demands of busy professionals may be met. However, distance learners often experience feelings of isolation, difficulties in networking with peers and perceived lack of support. Research suggests that communication technologies in the form of computer conferencing and electronic mail have the potential to address some of these problems [Mason, 1994].

Based on earlier, successful pilot projects [Ryan, 1994; Lewis, et.al. 1997] the School of Health at the University of Greenwich in London has recently embarked on an international masters programme which employs Computer Mediated Communication (CMC) at the core of the curriculum process. The philosophy underlying the programme is that learning is a life-long process of active enquiry in which reflection, questioning and re-evaluation are key components [Knowles, 1983]. Adults learn most effectively when they are in control of the process, are encouraged to value, reflect and build on their experiences and are able to interact in a collaborative environment which fosters self esteem and supports both personal and professional growth.

An asynchronous conferencing medium facilitates reflection in a spirit of co-operative enquiry [Heron, 1985] enabling students to apply the skills of critical thinking because there is time to consider the implication of ideas and suggestions in the messages received before a response has to be made. In this way knowledge emerges from the active dialogue through which participants share ideas and information [Gundry, 1992]. Peer-to-peer collaborative interactions have been shown to increase learner satisfaction and involvement in the development of theories of professionalism and professional practice [Tornebohm, 1993]. Geographically dispersed students are thus given the unique opportunity of collaborating in order to develop their professional practice. For the purposes of clarity we define CMC as, "The use of computers, telephone lines and specialist software to facilitate interaction between students and tutors irrespective of geographical location or time zone." [Ryan, 1997]

On-Line Tutors Module (OLTM)
OLTM was a curriculum rather than technology led initiative based on a perceived need by tutors that they should acquire new skills if they were going to employ CMC to deliver a new Masters programme. The students in this module were colleagues from Health, Education, Learning Resources and Academic Development, because the innovative nature of this MSc demands a broad range of skills and expertise. Many were novice I.T. users with little experience of distance education and most only had computers at work.

The module aimed to facilitate experiential, on-line learning and tutoring, and the development of CMC skills and concepts over a period of 20 weeks. It included face to face sessions and structured activities delivered and supported by computer conferencing and mirrored how we anticipated the tutors would deliver the MSc programme. The topics chosen were relevant to the role of tutoring as well as the nature and function of CMC. The activities moved the students progressively from the known (tutoring) to the unknown (the application of CMC).

OLTM has been evaluated by monitoring inputs to the conference topics, and student reflection on the skills and concepts acquired and their feelings and views as participants [Woodward & Ryan, 1996]. This evaluation will lead to guidelines being formulated to help tutors organise and deliver CMC based units. Reflection on the curriculum processes of this module has raised issues and concerns about the potential impact of CMC on tutoring skills and styles [Davie, 1989] as we now discuss.

Practicalities of CMC Tutoring

When devising on-line activities it was found desirable, as with face-to-face (F2F) teaching, to produce an overall plan of a module/unit and to publish it to students - a bit like a scheme of work. It is very important to write clear instructions when composing activities as unlike F2F encounters, students do not have non-verbal cues such as tone of voice or intonation to help them understand the nuances and vagaries of written language.

To maintain the dynamic of conferencing it is also advisable to set deadlines. Students engaged in CMC should always be encouraged to make regular and frequent connection to the system and deadlines help to guide them towards the meeting of outcomes and the maintaining of pace which is essential to effective conferencing. We believe that the dynamic and pace of the conference (as in F2F classes) may affect motivation.

A conference may consist of activities very like those encountered in the physical classroom. It is useful to design activities so that they begin with individual and reflective student inputs based on existing experience, moving through pair to small then whole group activities. Such a developmental approach results in a rich store of information that can be used by students and can be a valuable aid to further reflection.

In F2F modes it is perhaps easier to interpret student inputs and to ask supplemental questions to aid understanding. Misinterpretation of virtual speech or say-writing is a common problem encountered in CMC environments and tutors must learn to respond appropriately, seek clarification and use the written word unambiguously. It has become evident that both tutors and students use a range of different styles when responding to conference inputs.

At the end of an activity it is good practice for the tutor to summarise, refer back to overall plan and then move on to next activity. Whilst this is equally true of F2F teaching, in CMC everything is on display for future reference as a sort of visual reminder. This can be a very valuable resource but needs to be fairly tightly structured to be of maximum benefit [Harasim, 1989].

The need for tutors to log on regularly and frequently to the system to monitor student activity, respond to and re-inforce points made is fundamental to a successful virtual environment. Students need encouragement and support to enable them to participate fully and effectively in using e-mail and the conference areas. It is helpful if tutors provide clear guidelines for use of all virtual areas.

A CMC environment is possibly more learner-centred because students, especially within a CPD context, are more likely to focus on personally meaningful issues and will keep the topic moving. This to some extent
empowers the student to take an active role in their learning process but also means that they must accept the responsibility for that learning.

Impact of CMC on Tutors

CMC tutoring requires a complex, inter-related set of skills to be employed if relationships with students are to be effective and productive. In a CMC environment the absence of non-verbal communication, the potential for mis-interpretation of textual messages and the asynchronous nature of conferencing in combination provide the inexperienced tutor with further complications. Additional skills are required to address these new complexities. Devices employed to provide a form of non-verbal substitute include the use of ‘smileys’ or emoticons (faces made up of punctuation marks that denote smiles, sadness, anger, etc.) and placing qualifying words and phrases in brackets such as, what I really mean by that remark is . . .

Unlike many traditional distance programmes, when using CMC the tutor has an ongoing responsibility for managing a group (as in F2F teaching) as well as individuals. This may also impact on the distance experience and in particular on the quality of relationships between students and tutors engaged in the programme. Indeed, opportunities for interaction between tutors and students are potentially greater in CMC environments, where better access to tutors raises student expectations, may increase contact time, and become more resource-intensive.

CMC facilitates team teaching which is perhaps one of the most innovative features of the application of this new technology to distance education. This can be achieved in a relatively seamless manner and without the same financial implications of traditional team teaching. The technology may also be used effectively for aspects of the planning, administering and managing of a programme and can be seen to be effective in promoting collaboration with other colleagues using CMC. Tutors need to be effective time managers and should develop or adopt strategies and working practices which make the most effective use of the system.

Timetabling of distance education by CMC is both desirable and a problem! The nature of distance programmes, whilst facilitating a flexible use of time may lead to insufficient note being taken of a tutor’s overall work load and make it difficult for them to make sufficient time available on a regular basis for the necessary preparation and virtual contact. Whilst distance tutoring using CMC allows for considerable flexibility in terms of time and place of the interaction, in our view it is still necessary that the tutor be available to carry out these tasks on a regular basis and not be overloaded with other duties. It is too easy for the apparent flexibility of distance tutoring to become completely dominated and then submerged in the realities of day to day, F2F teaching and administration. This may result in such tutoring being accorded a lower priority than other forms of timetabled contact and lead to less than satisfactory use of CMC which may ultimately impact negatively on students.

Issues and Challenges

An issue which remains unresolved is how one deals with non-participants (lurkers) in the virtual classroom. It is suggested that CMC environments generate an intense need to respond and that any unusual delay is interpreted as rejection. This may be one reason why lurkers are not popular with other participants. We need to design and explore appropriate strategies to address lurking as well as discovering what effect, if any, non-participants have on the rest of the cohort.

There is a tension between the suggested practice of regular and frequent connection to a CMC system and deadlines and the more flexible use of time often associated with distance learning. A further tension exists between structured activities with deadlines v more flexible, free-flowing discourse.

In Britain, and we suspect across the world, the issue of copyright and electronic delivery of resources remains a problem. Until publishers allow the use of their materials within secure, virtual communities, other ways of providing resources at an appropriate level and in sufficient quantity will remain a problem.
The nature, quality and extent of technical support may vary according to the institution. The development and maintenance of CMC environments require a blend of skills. A partnership approach embracing technical, networking, curriculum and subject specialist knowledge is more likely to result in an environment conducive to quality learning and teaching.

One of our concerns is to what extent staff need to be trained and experienced in both distance education and CMC? In our view any tutor who is going to operate within a virtual community needs to experience being in such an environment. This was one of the principles underlying the original OLTM which has now been developed into a validated Computer Mediated Tutoring Unit (CMT).

Some Observations

Our experience suggests that employing CMC actually changes the nature of distance education and that those who tutor using this medium need to operate differently from either face to face or traditional distance tutors. As well as the development of new skills, aspects of managing and teaching a group of students remotely have been identified. The issues raised may impact not only on the tutors who employ this technology but also on the students, the curriculum and the institution. This confirms our belief that to become effective on-line tutors, staff need to have the opportunity to acquire, develop and reflect on these skills in order to recognise and appreciate the impact of CMC on the role of the tutor.

An area for future study would be the extent to which CMC impacts on different teaching and learning styles. It is also evident from our work with tutors and a number of students on a range of programmes that a series of new concepts are emerging including virtual attendance, listening, socialising and speaking amongst others. Further research into these phenomena and the precise nature of the interaction that occurs may help us to understand and exploit this technology more fully.

Abstract: Emerging educational scenarios propose to try together new forms of distance learning and networking capabilities. Moreover, these scenarios are only sketched, suggesting that soundest conceptual frameworks must be designed for improving available networking tools. In this paper, we propose a framework for distance learning courses, which current focus is the authoring process. Educational applications embrace pedagogical specifics and goals, needing strong support for the authoring process. Aiming to test a design methodology behavior face an educational application to be delivered on the WEB, we modeled a distance learning course about "OO Technology".

1. Introduction

Evolving information technology demands new knowledge and skills. Distributed educational hypermedia delivered via WWW can become effective way to access education resources. The rapid expansion of the Web makes people on the need of continuing education. Moreover, organizations are becoming geographically dispersed and networked. Training is turning financially impractical to bring participants together in the same classroom. All these factors accent the need of deliver education material in a distributed way.

Distance learning has always taken advantage from the development of communication technologies. In the past, post service and new forms of mail delivery have allowed a rise of courses by mail. Today the networking technologies are playing the same role: in developed countries, the technological development already available or currently under development will result in a useful and friendly desktop computer in every home. This development will be available on a mass scale within the next 10 years. The networking technologies are becoming the main focus point of a distance learning system. Facing the networking technologies' growth, innovative distance learning scenarios must be drawn.

Emerging educational propose to try together new forms of distance learning and networking capabilities. Moreover, these scenarios are only sketched, suggesting that soundest conceptual frameworks must be designed, for improving available networking tools and services.

In this work, we propose a framework for supporting the authoring process of distance learning courses. The paper is organized as follow: section 2 presents briefly Web-based distance learning courses; in the section 3, the proposed framework is presented and details about how to design a course are shown. We also present the use of the design methodology OOHDM adapted to model this kind of courses. A course, about Object Oriented Technology, is modeled, aiming to illustrate how pedagogical strategies can be related with design decision. Section 4 offers our conclusions and further works.

2. Distance learning Courses and the Web

The Web is an effective tool for providing information to individuals, teachers, administrators and others. Access to learning resources has never been as easy as it is today. Participants could acquire material from
whatever place by clicking on the screen. Internet today provides a wide set of tools like, web browsers, ftp clients, emails clients that become easier the learning process in a distance learning environment. Nowadays, there are millions of users sharing experiences, products and projects on the Web and a lot of them are accessing distance learning materials.

The Web provides a set of standards for handling a wide variety of media types, browser software and server environments that can be integrated fruitfully into a framework that allows a collaborative learning process among students. However, building these kinds of interactive WWW application requires Web browser powered. From a distance learning point of view WWW environment must be more flexible and dynamic and enable one to customize if it is necessary. Java opens up these possibilities by allowing programs to be sent over the Web [Hardlin & Ziebarth, 1995].

Besides the delivering of instructional material, Web-based courses allow asynchronous and synchronous collaboration among peers, real communication among teacher-students and students-students; and a wide access to complementary instructional materials on-line. These features make the Web a rich and powerful learning environment. A critical aspect for developing distance courses seems to be what we can and what we can not simulate of the real classrooms, but overcoming their conventional approach. The Internet provides tools and software applications that enable us to mimic remotely important components of real classes, in addition to features provided by the Web.

Moreover, the success of distance learning courses lays on an effective authoring design. Distance courses must present well-organized contents and clarify the user's pre-requirements, the kinds of student assessments, the ways of interaction among peers, answer-judging procedures and safe and clear manners of communication with the teachers. As result, the design of web-based courses has to be carried out by domain experts, hypermedia experts and skilled instructional designers. During the whole design process it is important keep in mind that students will be working remotely, so they will be alone.

Educational applications embrace pedagogical specifications and goals, needing strong support in the authoring process. Hypermedia models can provide a convenient approach for accessing educational resources and bring us the ability to customize courses, according to customer needs. The diffusing Web brings to the users the opportunity to access to the educational material when and where they want. Therefore, there are striking authoring features that must be improved, but using hypermedia models, the authoring process becomes better.

3. Framework for Distance Learning Course on the Web

Designing and developing web applications is a complex task that involves a variety of activities, either at the storage level, access level and presentation level. As result, the constituencies participating in hypermedia projects differ from those of traditional software development environments. Hypermedia projects involve content-authors, musicians and graphic designers, as well as programmers, software managers, and users. Moreover, aesthetic and cognitive aspects, so important for hypermedia applications, are foreign to existing software engineering environments. Thus, there is a need for special methodologies and tools to support the software development process of hypermedia applications [Diaz et al., 1996].

On the other hand, building an educational hypermedia has differences with conventional ones. Conventional hypermedia systems have a definable structure to be modeled. Educational ones have to deal with abstract concepts and have a high grade of interaction.

To minimize this complexity, frameworks and authoring systems for helping the developing and delivering of distance learning courses have being presented, such as [site Habanero], [site Web Course in a Box], [site Top Class] and [site WebCT]. Therefore, both frameworks and authoring systems neglect the courses authoring process. We propose a framework for distance learning, which core is the authoring process of courses [Fig. 1]. The framework is composed of:

- a hypermedia design methodology for authoring the course which help the building of the nodes and links network;
- links to related Web sites;
- a set of Internet tools;
- a site specifying the students kinds of assessment;
In this work, we detail the authoring process and offer an overview of the other components of the framework. In order to model distributed educational hypermedia, we also propose to use a flexible hypermedia design model - OOHDM [Schwabe & Rossi, 1995]. To show how OOHDM works we designed an Object Oriented Technology course.

3.1 The Educational Hypermedia Design Process

Authoring educational hypermedia application is a critical point. The author must follow the educational goals and an instructional approach for creating associative and meaningful links among nodes. Nodes could support individuals knowledge webs. The complexity of the authoring process demands effective design models. Considering the complexity of developing Web-based applications and the pedagogical specifies of educational hypermedia, we include in the framework a well known and reported model - Object-Oriented Hypermedia Design Method. The OOHDM - Object-Oriented Hypermedia Design Method, is a model-based approach for building hypermedia applications. It comprises four different activities: conceptual design, navigational design, abstract interface design and implementation.

**Conceptual Design:** during this activity, a model of the application domain is built using well known object-oriented modeling principles, augmented with some primitives such as attributes, perspectives and sub-systems.

**Navigational Design:** in OOHDM, an application is seen as a navigational view over the conceptual domain. This reflects the point of view that one of the keys distinguishing features of hypermedia applications is the notion of navigation. Different navigational models may be built for the same conceptual schema thus expressing different views (applications) on the same domain. In OOHDM, there is a set of pre-defined types of navigational classes: nodes, links and access structures. The semantics of nodes and links are the usual in hypermedia applications while access structures may represent alternative ways of accessing nodes.

**Abstract Interface Design:** once the navigational structure has been defined, it must be made perceptible to the user through the application’s interface, which is done in this step by defining an abstract interface model. This means defining which interface objects the user will perceive, and in particular the way in which different navigational objects will look like, which interface objects will activate navigation, the way in which multimedia interface objects will be synchronized and which interface transformations will take place. A clean separation between both concerns, navigational and abstract interface designs.

**Implementation:** to obtain a running implementation, the designer has to map the navigational and abstract interface models into concrete objects available in the chosen implementation environment.
**OO Technology: An Example Design:** In the first step, we define a conceptual design. The output is illustrated in [Fig. 2]. We can see entities of the application domain and relationship between them. In our example, appear entities such as class, object, method, polymorphism and others that would be studied by the learner. Domain specialist is involved in this step.

Conceptual classes may also be built using aggregation, for example node class **Class** is composed by **Behavior** and **Internal State**. Notice that it is a simplified version of the conceptual model, in a complete version, attributes for each node class we must be added. In the second step, the information represented in the conceptual model is reorganized to achieve the navigational model. We define the intended users establishing a set of operations for each of them. In OOHDM this is accomplished defining views of the conceptual model.

In our example we have two kinds of user: Initial Learner and Advanced Learner. Every node class shown in the [Fig. 3] has two views, one to be used when the learner is an initial student and the other to be used when it is an advanced one. Figure 3 shows a subschema taken from the model of [Fig. 2], and it represent the navigational space experimented by a initial learner.
In [Fig. 4] we illustrate the navigational schema for the course of Object Oriented Programming. Next, we define the navigational contexts, and the navigational classes related to these contexts. It allows us to see each class of the conceptual design.

**Figure 4: OOHDM - Navigational Scheme**

### 3.2 Implementation Issues

Until a few years ago, software developing in the Internet was a hard task. The improvement of programming language, such as JavaScript, and some ease-to-use new features, such as available plug ins and applets Java, have turned the WEB environment more stable and robust.

The proposed framework runs over a Web browser, and integrates available communication and collaboration tools via Internet protocols such as: FTP (File Transfer Protocol) for downloading files, NNTP (Network News Transfer Protocol) for accessing discussion groups, POP 3 (Post Office Protocol) for accessing electronic mail and IRC (Internet Relay Chat) for conducting multi-user meetings (chat).

For helping the authoring process of distance learning courses, the framework provides a Web link to the OOHDM site and, in a near future, we are intending to integrate an automated tool - the RMCase [Diaz et al. 1995]. Other features of the framework are being implemented as HTML pages and forms.

Distance learning courses in the framework are Web sites composed of HTML pages and forms, added to some synchronous and asynchronous cooperative tools available in the Internet. Since it is already hard to
reach real interaction in the Internet, the interaction was been placed in cooperative virtual spaces. A set of cooperation and communication tools was integrated to applications via Internet protocols. In the framework, distance learning courses include improving students learning process, giving them an active participation and letting to maintain contact with teachers and other students through electronic mail, discussion groups and chat sessions for questions or comments about the instruction.

Our first distance learning course - OO Technology, is just modeled. Then, we do not know the students' aptitudes face the distance learning approach and some questions arise:

- Will the users learn better with this approach?
- Will they work cooperatively?
- Will distance learning improve their autonomy?
- How to assess their performance?
- How to avoid the disorientation and cognitive overhead when they are exposed to the WEB?
- How much time professors will must to spend logged in the Internet to supervise and help users?

4. Conclusions and Further Works

The Internet expanding and the need for distance learning are bringing new educational challenges. We are facing this challenge and have started the developing and delivering of distance learning courses in hypermedia format.

The emphasis of our work is the belief that a strong authoring process can result in well-designed distance learning courses. The modeling of OO Technology course shows how pedagogical strategies are related to design process. OOHDM gives the necessary support for the process of designing the OO Technology course. The chosen methodology supports pedagogical specifics found in educational hypermedia and performs well in networking environment, since all its modeling steps keep independence from hardware and software platform.

Further works are related to:

- refine, implement and evaluate all framework features;
- test the distance learning course effectiveness and consistency, both in pedagogical and computational points of view; and
- verify the reuse level of the OOHDM conceptual design for developing other similar courses.

This research has been partially funded by CYTED - Project VIII - Educational Hypermedia, under the Dr. Jaime Sanchez management, from the Dept. of Computer Science - Universidad de Chile.

Creating a Psychological Foundation for the Evaluation of Pre-Packaged Software in Second Language Learning

Rachel E. Saury, Ph.D., Director
Arts & Sciences Center for Instructional Technologies
University of Virginia, Charlottesville, VA, USA

Abstract
For over three decades, scholars have been struggling to determine whether computers truly enhance foreign language learning and, more recently, specifically how. In this paper, we attempt to merge specific psychological theories of knowledge acquisition, the impact of pictures on cognitive processes, and theories of effective pedagogical approaches to foreign language learning in order to assess commercially available software for its effectiveness, specific impact on learning, and classroom uses. Within a psychological paradigm which includes an awareness of how mental models are formed, how domain knowledge enhances the process, and how images can impact upon learning against the backdrop of dual-code processing, an adherence to doctrinaire beliefs in one methodology can be broken down, leaving room for progressive pedagogical approaches which attempt to integrate what is valuable from cognitivist, behaviorist, and communicative approaches. Having made selection of method our first priority, we look at a variety of software packages currently available and consider how they may be impacting upon the learner.

I. Theoretical Framework
The research in the psychology of language learning is staggering in its quantity and approaches. On top of this, for over three decades, scholars have been struggling to determine whether computers truly enhance foreign language learning and, more recently, specifically how. The clash of hyperbolic positivism versus dogmatic skepticism about whether or not computers are effective tools makes it imperative that scholars and teachers accurately and thoughtfully start to articulate goals and methodologies when multimedia, hypermedia or any media is integrated into any curricula. Carol Chapelle writes: “Advancements in the design and use of computer-assisted language learning (CALL) activities require that key questions about CALL be identified and effective research methods be used to answer them...[Second language] classroom research suggests the need for descriptive research documenting the nature of the interaction that learners engage in within various CALL contexts [Chapelle 97].” In this paper, we attempt to merge specific psychological theories of knowledge acquisition, the impact of pictures on cognitive processes, and theories of effective pedagogical approaches to foreign language learning in order to then assess commercially available software for its effectiveness, specific impact on learning, and classroom uses. Three questions are key to such an exploration:

1) Can the potential effectiveness or use of these software programs be systematically evaluated based upon a psychology of language learning?
2) What is the psychological impact of the linking of text, sound, and pictures? Does the ability to do so through the use of multimedia somehow make the computer a more potent tool for learning than ever before? And does the way the program links these elements further determine how they impact the learner?
3) Is it possible to articulate an integrated use of these tools within a curriculum based upon the answers to these questions?

The process of learning alone and the shifting terrain in our approaches to teaching are complex even without the complicating factor of selection of medium. It has been pointed out that in recent years, emphasis in language instruction has shifted to process, rather than product and to attaining communicative competence over and above learning structure [Puscak & Otto 97; Littlewood 92]. Language learning is increasingly considered to be a process in which set of habits or automatized skills are created which then become imbedded as mental models in the mind [Littlewood 92]. More and more studies of computers in learning are implicitly or explicitly based upon the understanding from cognitivist theories that the computer creates, acts upon and reacts from mental models [Seel et al. 89; Cousins & Ross 93; Mayer & Sims 94; Mayer & Gallini 90; Bernhardt 84; Snow 84; Masny 84]. A mental model can be loosely defined as a “construction of an internal model of the world” which is “persistent and stable” [Seel et al. 89]. On top of the layer of mental models, there is the level of skill and control, according to Ellen Bialystok. “Language processing...is based on a set of two interacting subskills, or skill components. The skill components are called analysis of linguistic knowledge and control of linguistic
processing. These skill components are part of the cognitive mechanisms for learning, organising [sic] information, and solving problems [Bialystok 91].”

In order to impact upon pre-existing mental models or to create a new mental model, domain-knowledge has been found to be important. Domain knowledge has been defined as pre-existing knowledge of a particular subject matter. In a study of how learners processed pictures of katagana and hiragana through observation of eye movements, it was demonstrated that when learners were exposed to the characters without any prior introduction, eye movements were random and processing apparently shallow. However, when they were given a general introduction to how characters are formed and read, their eye movements showed regular patterns which indicated perception of meaning and content within form [Koga & Groner 89]. This study again emphasizes an integrated approach to learning, in which lower-level and higher-level processes in learning can be accessed depending upon the learning context.

Karen Swan and Carla Meskill have postulated that a computer represents cognitive processes so habits of thought are internalized [Swan & Meskill 96]. The use of a computer program can build new mental habits and plans of lower- to higher-levels of complexity throughout an overall class plan, as well as doing so cyclically, depending upon areas where students may hit a plateau or need to regroup to focus on particulate skills rather than communicative competencies. This is consistent with Littlewood’s holistic view of how language use works: “When we use language, we are constantly having to create new higher-level plans at the level of ideas, meanings, and conversational strategies. The effective execution of these plans depends upon a high degree of automaticity at the lower levels [Littlewood 93].” A common complaint among language teachers is how difficult it is to adapt materials developed independently of textbooks. However, if the goal is to bundle a variety of different types of exercises in order to immerse the learner in varied contexts and to provide varied and targeted communicative input, then any tool such as software, video, or an audiotape can enhance what is offered in a textbook. Modality must suit the method. “Sometimes the question arises whether a specific medium, as a result of its mode of presentation, may create certain symbols and codes in the domain of knowledge representation by favoring the storage of information in a format which is congruent to the modality of presentation [Seel 89].”

How do images enhance language acquisition or affect mental modes? This is particularly crucial in light of the capacity of digital media to provide more direct, varied, easily controlled and mediated visual input to support and enhance aural comprehension and use of the target language. It is illuminating to reflect on the fact that in the evolution of cognition, writing developed from sketches [Molitor et al. 89]. In a sense then, it could be said that as digital media infiltrate more and more of our communication and learning processes, we are returning to a dependence upon a cognitive tool predating writing. Innumerable studies have proven conclusively that pictures enhance learning, especially in high-ability learners. Stephen Krashen, who developed the natural learning theory of language acquisition, notes “whatever helps comprehension is important. This is why visual aids are so useful. Pictures and other visuals ...supply the extra-linguistic context that helps the acquirer to understand and thereby to acquire [Krashen 83].”

Articulating a psychological theory of how pictures affect learning, Sylvie Molitor and her colleagues echo Krashen’s view: “texts and pictures... visualize parts of reality which are not immediately present or accessible in one’s direct experience” and are “mental models” in which “reality is represented in an analogous, predominantly imaginative form...Corresponding to their prior knowledge and their cognitive strategies, learners build up a specific knowledge structure based on the information obtained from texts and pictures [Molitor et al. 89].” This view is shared by G. Salomon who notes that when texts and pictures are combined, “they often determine how stimuli are perceived and processed [Salomon 89].” When studying a new language, a learner starts with very little, if any, prior knowledge. In the process of acquiring this knowledge, according to Krashen’s theories of natural learning, the learner must “acquire...language by understanding input that is a little beyond [his] current level of (acquired) competence [Krashen 83].” Just as a child’s knowledge base is increased by external stimuli, so images as teaching tools can push this envelope in direct and indirect ways.

One of the most obvious ways in which pictures interact with text is through modeling. Just as a learner might use a grammatical model to understand personal pronouns, so she might depend upon a picture to illuminate the content of a conversation in German. In the former example, modeling is being used as a skill-based or non-communicative learning exercise, while in the latter example, the modeling as exhibited by the picture can be used either for a task-oriented or communicative practice. Ultimately, both modalities serve to build up and reinforce increasingly complex layers of knowledge that can be tapped into when needed, consciously or unconsciously. But more than the function of images as models or for spurring language production by giving the students something to talk about using new forms, what seems particularly significant is the concept that pictures “activate schemata” and support comprehension. The implication may be that if a learner has built up a body of knowledge through a variety of skill-based and communicative practices, that images will lower what Krashen calls the affective filter or break down learner resistance to acquisition and production of new forms on a neurological basis.
This theory essentially postulates that the more modalities properly targeted, as is suggested in theories of dual-coding, the capacity for learning is expanded. According to dual-code theory, the learner uses two distinct information-processing systems—one that represents information verbally and one that represents information visually. For learning to be meaningful, there must be a connection constructed between the two [Mayer & Sims 94]. This means that it is better if material is presented in two or more formats to construct knowledge models promoting visual, verbal, and referential connections. When this is done, studies have shown that learning is likely to be more successful [Mayer & Gallini 90]. This idea is similar to Chun and Plass' speculation that text "represents information in symbolic structures of a language and is processed sequentially, that is, word by word or sentence by sentence. Pictures, on the other hand, convey their information by means of a visuo-spatial structure...and thus represent the subject matter by employing an analogy based on common structure properties and encode information parallel or simultaneously [Chun & Plass 97]."

Dual-code theories make clear how and why images can enhance learning. The next question is how pictures work specifically so that the appropriate modality can be selected. Molitor provides four functions of pictures in learning useful in discussing the impact of foreign language software on learning.

- In the representation function, "the picture overlaps the contents of a text...the picture is a redundant source of information to constantly check text comprehension by offering...a second opportunity for learning.
- The organization function of a picture "provides an organized, coherent, reductive macrostructure of the text content."
- The interpretation function "illustrates text contents which are difficult to understand (e.g. by analogies, visual metaphors, etc.)."
- The transformation function "offer a mnemonically useful form of recoding, being a kind of visual mnemonic. This is the function pictures often have in the ‘keyword’ or ‘hook’ technique for learning vocabulary in foreign language instruction [Molitar 89]."

Other studies have shown that visual and verbal processes can also compete with one another. It is therefore important to determine that the pedagogical motivation behind the combination of text and visuals is not creating conflicts in processing and retention of materials [Loew 95]. Robert Kozma theorizes that computers primarily have transformational capabilities, or the ability to make connections between symbolic learning and real world situations. “First, an important attribute of the computer is its ability to symbolically represent entities in ways that might inform mental models. They can graphically represent not only concrete objects but also formal, abstract entities that novices do not normally include in their models. Second, the computer has the important capability of being able to proceduralize the relationships among these symbols [Kozma 91].”

In a study researching the effectiveness of a program called Thinker Tools which teaches Newtonian mechanics, students who used the program scored significantly higher than the control group. In another study, students using a software program called the Jasper Woodbury Series also scored higher than the control group. According to Kozma, it was the computer’s ability to model objects in motion in the Thinker Tools program Which enabled student to construct complex and dynamic mental models of the materials. In the case of the Jasper Woodbury Series, Kozma states that “the visual and social nature of the story, as presented with video [was] more likely to activate relevant situation-based prior knowledge so that students can use this to solve the problem. They are also more likely to connect their new learning to representations of situations as it is stored in memory. This will increase the likelihood that when similar problem situations are encountered, they will evoke an appropriate solution response. “By repeating the same kinds of analyses and solutions in multiple contexts or situations with very different surface characteristics but common underlying task demands, these learned solution strategies are connected to a variety of situation schemas in memory and this promotes transfer across a variety of subsequently encountered problem situations [Kozma 95].” Kozma concludes in another discussion on learning with media that these effects would be particularly true in foreign language learning [Kozma 91].

Vitor Duarte Teodoro reflects this emphasis on targeting a cluster of learning modalities. He calls for computer environments which “demand cognitive and metacognitive skills.” Cognitive skills are defined as the ability “to manipulate and integrate information” and metacognitive skills as the ability “to regulate and control their actions and knowledge in order to build new knowledge.” Extrapolating from this idea, Teodoro is interested in the development of exploratory programs which “allow students to get a strong degree of familiarization with an idea. With exploratory software, students can see many situations, explore what happens in different conditions, discuss what happens if they change conditions...When they become more familiar with new ideas, they can establish more meaningful relations with ideas they already have [Teodoro 1994].”

Within a psychological paradigm which includes an awareness of how mental models are formed, how domain knowledge enhances the process, and how images can impact upon learning against the backdrop of dual-code processing, an adherence to doctrinaire beliefs in one methodology can be broken down, leaving room for progressive pedagogical approaches which attempt to integrate what is valuable from cognitivist, behaviorist, and communicative approaches. Having made selection of method our first priority, the medium can
complement the learner and facilitate operations the learner is capable of performing and perform those which
the learner cannot [Kozma 91 & 95]. Our view of media in learning can then be similarly integrated, holistic, and
flexible as Robert Kozma notes:
Specifically, to understand the role of media in learning, we must ground a theory of media in the
cognitive and social processes by which knowledge is constructed; we must define media in ways that
are compatible and complementary with these processes, we must conduct research on the mechanisms
by which characteristics of media might interact with and influence these processes, and we must
design our interventions in ways that embed media in these processes [Kozma 95].

II. Putting Theory to Work: Evaluating Commercially Available Software
Software currently available on the market for educational or mass-market use stretches across a wide
spectrum of quality and thoughtfulness in design. When initially considering the use of any type of media which
uses video or pictures, it is important to know that studies have shown that audio support has no positive effect
on retention of words [Puscak & Otto 97]. This is probably true because it is postulated that processing of
spoken and written text involves similar cognitive processes because they are symbolic representations of
information [Chun & Plass 97]. On the other hand, as we have already said, other studies have shown
conclusively that pictures increase recall if they illustrate information central to the text [Kozma 91 &
Weidenmann 89]. The most basic computer programs developed now in foreign languages mainly differ from
traditional audiocassettes in their attempt to provide moving or repetitively appearing pictures to model the text
and act as a visual hook for memorization. Therefore, even when the capability of multimedia is used only at this
basic level, it follows from the research that these programs might be slightly more successful than a similar
audiocassette exercise with only oral input. Since such programs are generally designed for beginning learners
who have little domain knowledge of the subject matter, they will be more successful if they focus on smaller
units of sound and speech.

Programs such as Talk Now! and Learnware fall into this category and explicitly work on lower-level
processes such as pronunciation and aural recognition of words. In Talk Now! multiple exercises around the
same content in which the same pictures appear and reappear seem to be an attempt to reinforce and stabilize a
learner's basic knowledge base of pronunciation and intonation, and, in the case of the less-commonly-taught
languages, such as Russian, of recognition of the non-Latin alphabet, a huge cognitive leap in and of itself for
which a whole new mental model must be created. Especially in the case of Learnware, which provides eight
"Teaching" segments on pronunciation (and character writing for the non-Latin scripts) and eight "Games"
where the student works with the knowledge acquired through teaching, the learner is being immersed in varied
contexts, thus providing varied communicative input. The fact that studies have also shown that learners adjust
their behavior according to the amount of instruction they receive would lean in the favor of programs providing
many exercises [Hannafin 95 and Vosniadou 94]. Additionally, in the case of Learnware Chinese, the learner is
guided into a study of pronunciation with an introduction to the Chinese tonal system. The intention is clearly to
acclimatize the learner to listening with a different intent at the outset by creating the minimal needed level of
domain knowledge.

Other visual hooks used in pronunciation exercises are included in Learnware and The Rhythm of
French. The movement of lips, tongue, and breath are modeled through moving diagrams and can be clicked on
repeatedly so that the learner can attempt to imitate the action of the model. In The Rhythm of French, focus on
pronunciation is robust, with extensive explanatory text used to create domain knowledge, audio to allow
learners to hear the differences as the text is read aloud to them, and multiple exercises involving the diagrams
and other mnemonic hooks to reinforce aural recognition and production. Indeed, The Rhythm of French, a
three-volume CD set, uses the benefits of multimedia to complete advantage with probable high learner success
in this area high, even with low-ability learners. What is the most powerful about this program is how much
control the learner has over all the material and the pace of instruction. In this sense, it is capitalizing on the fact
that "Hypermedia supports constructionist views of learning, which hold that learning takes place when students
actively and collectively build internal knowledge structures." In the case of The Rhythm of French, as Swan
points out, this process has been made "explicit, thus increasing the likelihood that students will internalize what
they learn [Swan 96]."

Many programs at various levels of difficulty use audio waveforms to graphically illustrate the audio
pattern of speech. The program Transparent Language calls this feature the "sound palette." The learner is
expected to record her own voice and attempt to match the wave form of the native speaker's voice, an example
of the organization function in which the image provides summary of the content. In addition, by providing
additional visual input to match the aural input, these programs are conceivably creating "additive effects in
recall" by coding the information through the verbal and nonverbal systems. As Chun and Plass point out,
"Information in a symbolic representation is stored in the verbal system; information in a nonverbal, analog
representation is stored in the nonverbal system [Chun & Plass 97]."
One of the few software programs designed with an awareness of how multimedia can capitalize on the psychological processes of language learning is The Rosetta Stone. Indeed, because of this fact, The Rosetta Stone is perhaps one of the more powerful learning tools on the market today. Its developers explicitly based their methodology on Krashen's theories of natural learning. In their promotional flyer, they write: "the best model for learning a new language is the natural way in which we learned our native language. This idea has been espoused by a school of thought that emphasizes comprehension of spoken language as the first step to acquiring fluency. This is called 'the comprehension approach' or 'the natural approach.'" The Rosetta Stone provides the learner with graduated comprehensible input, always pushing the envelope of the learner's knowledge just a little above what they have just acquired. Their flyer reads: "The native language is learned by hearing simplified speech in a context which provides the cues that make this speech comprehensible. This context also provides immediate reinforcement to the child...[The Rosetta Stone] works in the same way. It uses hearing simplified speech in a context which provides the cues that make this speech comprehensible. This program could be said to be "activating subjective knowledge about the world." Its developers explicitly based their methodology on Krashen's theories of natural learning. In their promotional flyer, they write: "the best model for learning a new language is the natural way in which we learned our native language. This idea has been espoused by a school of thought that emphasizes comprehension of spoken language as the first step to acquiring fluency. This is called 'the comprehension approach' or 'the natural approach.' The Rosetta Stone is designed directly from the concept that media can be a mediator of information or is an 'external model' of reality. This program could be said to be "activating subjective knowledge about the significant facts and the available modes of presentation...Thus external and mental modeling...is intended to produce a plausible (subjective) explanation of a particular appearance existing in the external world. External modeling is intended to evoke cognitive processes in itself in another (known) recipient of information, to facilitate or to cause mental modeling [Seel and Strittmatter 89]." For instance, in one of the units of the Russian version, students are exposed to individual words. Then each lesson increases in grammatical and syntactical complexity. Each unit can be worked with in a variety of different formats: sound with pictures, sound and text pictures, text and pictures, and so on. In other words, the learner or teacher can select the modality to be used depending upon the skill to be acquired and activated: aural, oral or reading comprehension. A selection of emphasis can also be based upon learning styles: Is the learner visually oriented? Does text help them understand spoken language at the outset? Do they want to work on becoming more accustomed to the new alphabet and spelling rules?

The language in The Rosetta Stone is consciously decontextualized or disembedded in an external context in order to affect deeply the internal model. By gradually wearing away the affective filter, or lowering the learner's resistance to the activation of new knowledge structures in communicative contexts, new communicative plans are replaced and created. With the new schemata in place, the learner can then extrapolate grammar in similar structures. For instance, The Rosetta Stone for Russian provides a series of exercises on the genitive declension using a small selection of adjectives and nouns. The material, presented amodally with increasing levels of complexity in each segment, gradually allows the learner to build lower- to higher-level skills. "Identifying needed information and disembedding it from a context is an important component of learning to solve problems and this ability contributes to successful transfer and performance in subsequent real-world situations [Kozma 95]." Eventually, when the new case is needed, having been disembedded for the purpose of creating an internal model in relationship to other structures and forms, it can be activated in communicative scenarios in direct relationship to other components of language structure relevant to meaning.

This process occurs because of the unconscious associations established through the use of text, sound, and pictures. The pictures in The Rosetta Stone fulfill a "representational function": they support the initial process of comprehension by helping the student link text and sound with a picture. Once the necessary connection is made between sound, text, and picture, then the image acts in a transformational way, becoming a mnemonic or hook leading the student repeatedly back to the previously imprinted knowledge. The active involvement of the learner in selecting pictures to match text and sound also successfully hooks especially the low-spatial ability learner who has been shown to "only be able to keep referential connections when visual and verbal information are presented simultaneously [Mayer 94]."

Such an active and complex engagement of the picture in the learning process in these programs is unusual. In many programs, pictures serve no purpose other than to illustrate the overall content of a dialogue, much as a picture in a book might do, and seem to be thrown in as an afterthought to the pedagogy, rather than as central to it. In a program called French Your Way, each "Study Conversation" has a picture illustrating the action in the dialogue. Although the picture technically serves an organization function, learning at the level of internal models are not being significantly helped or hindered by the pictures because the dialogues are relatively complex. In a Spanish program developed by Holt, Rinehart, and Winston called Encuentros, the pictorial backdrop is clever, but seems to be more illustrative than interpretive or transformational. In short, the power of multimedia is in its ability to use images, whether static or in motion, as a recoding device, as illustrative of difficult to understand content, or as representative of unknown content. What is lacking in Encuentros and French Your Way when considering what multimedia is capable of doing is that the pictures are not focusing the reader's attention on certain aspects of the information, thus improving the chance that the information is processed. Nor are they supporting the reader's building an internal connection among units of information.
presented or building connections through the images between the ideas in the text into existing mental models [Chun & Plass 97].

However, the strength of French Your Way and Encuentros is the degree of control given to the learner to determine different outcomes within established scenarios, such as “Dining Out” in the former [Vosniadou 94 & Snow 96]. They are attempting to use the computer to provide as real a communicative scenario as possible where higher-level processes are completely engaged. Another very popular and pedagogically successful program called, A la rencontre de Philippe, also does this by allowing learners to accompany the protagonist, Philippe, on a journey through Paris to find a new apartment. The story is videotaped and learners can determine the outcome of the story depending upon their choices from a multiple-choice menu offered at each juncture in the story. It is in Philippe that we see the power of digital media to provide as complete an immersion experience as possible through the use of video and random access leading to use of higher-level processes. It is exemplary of how “the visual and social nature of the story, as presented with video, is more likely to activate relevant situation-based prior knowledge so that students can use this to solve the problem...By repeating the same kinds of analyses and solutions in multiple contexts or situations with very different surface characteristics but common underlying task demands, these learned solution strategies are connected to a variety of situation schemed in memory and this promotes transfer across a variety of subsequently encountered problem situations [Kozma 95].”

We are all aware that the best way for learners to acquire a second language is visit a country where that language is spoken and to experience the stress of needing to communicate actively. Most of our students who return from overseas come back far more fluent in all or some of the four basic skills depending upon their individual strengths and weaknesses: aural and oral comprehension, reading and writing. In Philippe, the images presented not only enhance or support comprehension, but in fact engage the learner in as real-life a conversation as possible. Learners are able to read and interpret various non-verbal and sociolinguistic clues to extrapolate meaning, just as they would in a real-world conversation. Vosniadou wrote that approaches in computer-assisted-language-learning were needed which would “emphasize the need to construct learning environments that engage students in culturally meaningful, purposeful and authentic activities that make deliberate use of the physical and social context... and which allow them to experience higher-level processes [Vosniadou 94].”

Philippe, Encuentros, and French Your Way attempt to do this with relative success.

Other features found to be empowering in the learning process include interactive pages, construction tools, note-taking capabilities, nonlinear access to background information, and open-ended questioning [Swan 96]. Programs like Transparent Language, CineInteractive, French Your Way, and CyberBuch, a CD on German literature, provide some combination of the above elements. In French Your Way, in addition, learners can also control the speed of speech in addition to having access to textual help when something is not understood. This latter feature is consistent with studies suggesting “that annotating lexical items with different modes of information presentation has positive effects on vocabulary acquisition [Chun & Plass 97].”

Transparent Language which provides authentic literary texts replete with grammatical and cultural notes, annotations, translations of the entire text, a dictionary, various games emphasizing grammar, vocabulary, and pronunciation, and either a slide show or a video accompanying each text, is a very successful program probably because of its multi-layered design. When learners can approach material in a variety of different ways depending upon individual preferences and needs, it has been shown the deeper the level of knowledge acquired [Hannafin 95].

III. Conclusion

It is striking that even in the past six years, research on the effectiveness of computer-assisted learning has increased dramatically. Whereas studies in the seventies and eighties were largely inconclusive as to the effectiveness of computer assisted learning, as the technologies have become more powerful, so has their potential and proven impact on learning in many disciplines. As Puscak and Otto point out, current technologies have created a “paradigm shift” that “will challenge traditional definitions and assumptions about the role of the student, the teacher, and the print textbook in language study. The basis for such a challenge is anchored in the prospect that multimedia can provide self-contained instructional experiences in a way that non-interactive media cannot [Puscak & Otto 97].”

Many of these software programs can be used independently or as a supplement to regular classroom instruction, giving the learner more control over the learning process than ever before. In addition, the wide array of modalities used to impact upon knowledge acquisition through a variety of different means promises to make more multidimensional what can be done in an ordinary classroom with just a textbook and a single speaker of the target language. These analyses of software are only meant to be suggestive; the next step would be to initiate studies testing these theories. We anticipate that such focused research methods will show that
these tools are even more powerful than we had originally hoped and will dramatically change the ongoing dialogue about the effectiveness of the new technologies.

Abstract: This paper reports on a major and innovative project called Education Direct, where the next generation Internet technology, based on IP multicasting, has been used in practice over large geographic distances involving a wide variety of students and teachers. Education Direct utilizes the mStar tool suite, which exploits IP multicasting to provide fully symmetric use of audio, video, group-synchronized web-browsers, whiteboards, chat, voting, recording, replay, annotation and editing. All integrated into the end users regular desktop computer, making education both more available, independent of place and to some extent time, as well as of higher perceived quality.

While many observers would judge the large scale application of this rather advanced technology less realistic, we can hereby report the contrary. The experience has been surprisingly positive, and the resulting environment is, by many people, considered to give better quality than the alternative of physically attending a lecture. The paper reports on the methodology, context, technology, and experiences gained over a year of practical use.

1.0 Background and Context

Education Direct is part of a larger effort to deploy new technology to better support all kinds of cooperation, interaction and information access. The goal is to create an environment where people can work, learn, do business, socialize and be entertained, with less regard for their geographic location. While this paper is about education, we believe it is important not to isolate this aspect from all other parts of life, but to integrate it. As a consequence of this philosophy, the tools used in this project have been designed to be equally useful in other contexts, such as distributed projects, marketing and support, and even media and entertainment.

The project is part of an ambitious effort of making the County of Norrbotten a pilot example of an electronic marketplace in a wide sense, where many of the everyday tasks should be possible to carry out over the network. This includes governmental and community services, marketing, purchase, and other business interactions, distributed work and consultation, medical support, education, media and entertainment.

The basic communication infrastructure consists of 155 mbit/s ATM links going to all communitity centers, which may be small villages down to a few thousand people. More important is however that multicast capable IP is run on top of this transport network, enabling the use of realtime streams of audio, video and data events to large audiences as part of the regular Internet connection. The Norrbotten County Network is actually just a segment of the Internet that happens to be unusually well equipped with quality of bandwidth and information contents.

Education Direct is part of this, and represents significant progress towards the vision of the electronic presentation and education environment, according to which most courses at the Luleå University of Technology and CDT will be possible to attend independent of physical location. While this would be enough of a challenge, the goal was in fact even broader than so: to transfer not only courses but the use of the technology itself to regional high-schools, secondary schools, small and medium sized companies.

The county of Norrbotten consists of the northernmost fourth of Sweden and covers an area of 400x400 kilometers. The population is sparse, with about 260,000 people. This has meant that many high-schools cannot gather the critical mass and competence to offer the courses and subjects that are possible at other places. The Education Direct project is part of the solution to this problem, because it allows schools to specialize in a subject and amortize its cost over more students than otherwise would be possible. By giving the courses over the network, a sufficient critical mass is generated, creating a county-wide virtual high-school with a breadth and quality of subjects that would otherwise not be possible. The effects on society are evident.
2.0 Participant profiles and usage patterns

The Education Direct involves, in various ways, several hundred people. It was initiated during the spring of 1996, and spent significant effort on getting a firm rooting among end-users outside the already knowledgeable kernel of technologists. The operational phase started during the fall of 1996. The project involves four kinds of people:

- **Technicians**, who must be able to manage computers and communication equipment to ensure continuous operation.
- **Advanced Users**, who should be able to utilize the technology for doing own productions, presentations, and information searches.
- **End Users**, who need to be able to use the technology to benefit from the information provided by others.
- **Technologists**, who in addition should have an overview of how the technology works, ongoing trends, and principles of the area.

In the first phase of the project an undergraduate course in Internet and distributed multimedia was distributed. The participants came from all over the county, many of which were secondary-school teachers, (as those will act as local technology transfer persons) and local undergraduate students. The local students had the choice of following the course by attending the lectures physically or virtually using the mStar environment. By choosing the technology itself as the subject for the first main course, the transfer and introduction became much smoother. Explanation of technology, tools, and network became part of the subject rather than a distracting element. The students were in many cases high school teachers, which have become local competence centers and advocates for further deployment of the technology.

Since this first course, during the winter and spring 1996, dozens of courses and seminars have been distributed. All computer science graduate courses, and a growing number of undergraduate courses at the University of Luleå, have been carried out this way. Many seminars have been carried out between high schools, and the usage has even found its way down to rather exotic examples like sixth class students learning Spanish in remote villages.

The mStar system allows for many different patterns of use. The initial, and most straightforward, approach was however been to mimic the traditional lecture where a teacher presents her view of the material to the students, using various forms of presentation material. As a basic measure, all material used is made available in WWW accessible form. The traditional overhead-slide projector is replaced by computers and screen projection equipment, (the latter for those who wish to attend the presentations physically), which also run the communication and distribution software. The presenter and the local audience has, therefore, continuous contact with all remote participants.

3.0 Technology

IP-multicast has been used for several years with success on a world global scale under the label of MBone, (www.mbone.com). In addition, it has proven its maturity in a multitude of local contexts, within regions, universities, and company Intranets. It is by most observers judged to be the best, (maybe only), way of providing large scale distribution of interactive multimedia. It tightly integrates with other existing Internet technologies, including the World Wide Web. At an international level, the IP Multicast Initiative, (http://www.ipmulticast.com/), is a consortia of major industrial players promoting its deployment. Both the MBone and IP Multicast site include good tutorials on the subject. At the most basic level, multicasting ensures efficiency by duplicating data packets at distribution branching points, rather than using today's extremely inefficient and non-scalable use of duplicate streams of the same material for each viewer involved. Multicasting is however much more than so, but represents a rich body of standards on how to define, join, and leave distribution channels, and how to construct tools that utilize it.

Because multicasting is inherently two-way, it also bears in it a new depth of meaning for the word "interactive" that has not been provided by previous technologies. The mStar environment, (http://www.cdt.luth.se/mstar) exploits this potential, and currently includes the following components:

- **Audio.** mAudio for telephone level quality audio, mRadio for high quality mono, and mIR for distribution of CD quality stereo, (using MPEG audio).
- **Whiteboard.** mWB for shared whiteboard, documents, and pictures. Distributed Presentations. mWeb is used for distributing web-pages and synchronizing audiences web-browsers on common pages.
• Chat. mChat for textual group interactions. Voting. mVote for definition, issuing, and immediate graphical visualization of voting alternatives.
• Video. mStar is reusing the well known "vic" application for low to medium quality video, (such as H.261).
• Floor control and attention getting. mWave allows for people to electronically "wave their hand" and maintain the order among multiple wavers.
• Application sharing. mShare for integration of application sharing system.
• Media Recording and Replay. mMOD records and replays multicast sessions, (not only audio/video, but all tools involved).
• Session/channel information. mSD is web-based application for presentation and joining of multicast channels.
• Session Editing. mEdit allows for indexing, editing, and annotation of recorded sessions.
• Presentation authoring. SlideBurster allows for easy creation of Web based material for distributed presentations (as is used for mWeb above).
• Network adaptions. mTunnel is used for transfer and scaling of multicast traffic over unicast links, which is important for deployment in areas where multicasting is not completely settled.

While the usage scenario described here is distributed education, mStar is in fact largely developed within the ongoing Esprit project Mates (Esprit 20.598, http://mates.cdt.luth.se/), with the original purpose of supporting distributed engineering projects. Being written completely in Java, mStar is an example of the emergence of another important technology, the dynamically platform independent and mobile code approach. While Java has been a big step forward, we have not yet seen the arrival of its potentially most important aspect: the on-demand delivery of software in modular components. This is a property of utmost importance in a groupware context, where penetration and success depends on fast growth of a user community, and where the value of a service increases, (and cost decreases), with audience size.

The applications above, (as well as many other tools), are running on top of a rich set of protocol standards at many levels. The Realtime Transport Protocol, [RTP], is a well known foundation, as well as implementations of reliable multicast based on extensions of SRM, [SRM, RMP]. Recent ITU standards such as H.323 have directly adopted multicasting and RTP, and are therefore inherently compatible to a large extent.

4.0 Network and Preparations

To ensure that the rather extensive software and networking technology would work at all sites, there has been several intensive courses given to local system administrators. The largest part of the preparation work was however in ensuring the existence of a network with a quality sufficient to carry out the tasks. In this section, we describe the basic communication platform.

The Norrbotten county network is a TCP/IP broadband backbone network based on ATM. It is operational today, but has an extensive plan for further extending its capacity. Late 1997, 155 Mbit/s ATM links were established to 15 major connection points. This will support all 14 community centers, and the hospital areas, with broadband services. The backbone will be used for private networks and an open regional network with connection to Internet. Using connections to the open region network, (that is Internet), is preferred to get connectivity to other organizations as well as locally, regionally and globally through the Internet.

Connections to the open region network, (that is Internet), are universally available at very low prices. Connection speeds are ranging from ISDN up to 100 Mbit/s over optical fibers and can quickly be upgraded in convenient steps. As part of this project every school, (down to first year), have at least an ISDN connection. This ensures an extremely wide coverage, giving potential for an unusually wide impact on society. During 1998, a major programme for launching ADSL/ADSL Lite technology is under deployment, which utilizes standard telephone copper wire for communication speeds in the order of 1-10 Mbit/s (downstream) and 256-800 kbit/s upstream. The early pilot network, in use from 1995 - 1997 was a TCP/IP leased line router network with 2 Mbit/s connections, with a 2 Mbit/s connection to the Internet. There were about 9000 connected systems in the region. Surrounding the University of Luleå, (where CDT is located), are 2000 appartments connected by 10 Mbit/s through LAN technology.

In many places IP-Multicast has been, and still is, regarded an area of research and experimental usage. Not so in this case, where it has been in native and productive use since 1995. As the pilot network has been a large network
with local administration it has been perfect for testing different ways of distributing multimedia with IP-Multicast. It should be noted that while the underlying transport technology is ATM, that is not really a concern of end user nor of applications. IP, (Internet Protocols), is run on top of the ATM transport and is the interface of concern - a pattern we believe is here to stay. Therefore speaking about "ATM networks" is less relevant.

5.0 Experiences and observations

While initial focus usually is on video distribution, our experience is that this medium is not the most important. Rather, most users regard it, after a while, as somewhat fun to have but not essential. Its most important role is actually as a "state-indicator", telling others that a person is actually in place, and maybe what he is doing, (listening, speaking in telephone or talking to someone else).

The reason for the decreased focus on video is probably the rich availability of other media, of which the "mWeb" application has proven to be essential. mWeb fulfills the role of the distributed slide projector, ensuring that all remote participants get to see exactly the slides/Web-pages that the presenter shows. It works by catching all Web-page requests at the presenters Web-browser, multicasting those to all participants, where the same pages are given to the local Web-browser. In this way, all participants get a high quality picture of what the presenter is referring to. This approach generates a surprisingly large number of extra benefits: Since the "slides" are now actually HTML pages presented by a local browser, every user can tune the font size and other layout details to his own preferences. For the same reason, the listener can easily browse back and forth in the teachers material, to further consider some part that was especially interesting, even while the teacher proceeds.

Furthermore, since the slides are regular Web pages, including links and Applets, each participant has the freedom to explore those individually. As a consequence of moving all presentation material to HTML, we have also noticed a sharp increase of quality of slides. Teachers now tend to include pointers to background material directly in their presentations.

The quality achieved is far outperforming any alternative known, like document cameras and the previously much used Internet whiteboard tool wb. It may sound impossible to some readers, but fact is that many people, including the authors, mostly prefer to attend lectures over the network. The reason is simple: the perceived quality is better than attending live sessions. It has also been observed that the other media, like Chat and Whiteboard, are creating an orthogonal communication pattern, where comments and questions are circulating, and being answered, during presentations.

Another component which has become especially essential is the multicast Media on Demand server, mMOD, which allows for recording and replay of any presentation session. This has created a freedom in the time-dimension that was not possible before, and has been used extensively. Collisions of events and lectures become less serious, and many students go through selected parts after initial presentations, and can directly mail the teacher any questions. mMOD also allows for indexes, (comparable to bookmarks), to be inserted at any place in the presentation, and later be used for quick jumping between various places. This facility also adds another view on the concept of annotations. Besides using indexes for giving the presentation an overall structure, (such as a table of contents), it can be used as a link between a point in a presentation and a comment of any kind, (which in principle can be another multimedia presentation). From an educational point of view, the mStar offers support for many aspects of the educational process. The table below shows examples of it's possible usage.

<table>
<thead>
<tr>
<th>Teacher activities</th>
<th>Student activities</th>
<th>Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>Planning and cooperation with other teachers</td>
<td>Cooperation with other students</td>

</tr>
</tbody>
</table>

An important aspect of the mStar system is that although it's most prominent feature is the possibility to work in a synchronous mode, the possibility to record and review lectures and sessions adds an asynchronous mode of usage. This means that although the system has been built on the metaphor of the traditional lecture with slides, the teacher using the system, must take the possible asynchronous use into account while planning his lectures. Further-
more, the practical use of the mStar system indicates the need of a knowledge of methods for distance teaching involving a more active behaviour on the teacher's part towards remote students. The system has already in it’s development phase shown a remarkable reliability, which together with user-friendliness is of high importance in educational use. Regarding user friendliness, experiences from the use of mStar by secondary school teachers indicate that it takes some learning to master the system and that more development work needs to be done in this area.

Searching for negative aspects, it is clear that the current tools create an disadvantage for teachers who like to improvise, emphasize their points by drawing on the whiteboard, or depend on a dynamic body language. The reason is obvious from the above, which emphasize well and in advance prepared material. While it is certainly possible to use the distributed whiteboard for all written presentations, it requires more investments in peripheral equipment like large electronic whiteboards and electronic pens.

6.0 The mStar system as an Educational Innovation

An innovation, according to [Rogers, EM, 1995] is an idea, practice or object perceived as new by the adopting unit whether it is an individual or an organization. A technology as the mStar system has a hardware aspect consisting of the tool that embodies the technology as a material or physical object and a software aspect consisting of the knowledge base for the tool. The software aspects also contain the underlying ideas on how the technology can be used and on the possible social embedding of the technology. Innovations are also related to some kind of change in the practices of the adoption unit. An educational innovation is something that is new to adopting units in the educational system. Some educational innovations consist of ideas and theories, other educational innovations also contain some kind of technology. In the Swedish educational system, innovations and change have been closely related, though research results [Ekholm & Sandström 1984] indicate that the process of adoption and change is slower than in business and industry.

While the underlying metaphor for the design of mStar has been the traditional lecture, which most of it’s tools support, it is a distributed and distance bridging system that can be used in an synchronous as well as an asynchronous mode. It is therefore no doubt regarded as an educational innovation, or as an innovation capable of strongly sponsoring educational innovations.

Diffusion is a process by which an innovation is communicated through certain channels over time among the members of a social system. Results from research on the diffusion of innovations have shown that the diffusion process follows a certain pattern resulting in a S-shaped curve, if time is plotted along the x-axis and the number of adopters on the y-axis. It has also been noted that adopters can be grouped according to their innovativeness (the degree to which a unit of adoption is relatively earlier in adopting new ideas compared to other members of a social system). It is also familiar that adopter distributions follow a bell-shaped curve over time and approach normality.

During the process of adoption, adopters in a social system can be placed in five major categories based on their innovativeness, which in time order are named innovators (who sometimes fulfill the role och change agents), early adopters, early majority, late majority and laggards. Individuals in the categories differ in innovativeness, but it is also known that other important differences can be found between categories in patterns of communication, search for information, and the degree of homophily (to what extent a persons that interact are similar in background, values, patterns of communication, etc.). These differences are important for the development of the process of adoption. When it comes to an innovation with a high technological content information on software aspects embodied in the technology and innovation-evaluation information are regarded as of central importance. It has been found that interpersonal communication is very important for information on an innovation and that a higher degree of homophily between members of a social system is important for the diffusion process. Information from a peer is given higher credibility than information from someone with a lower degree of homophily. Thus, results from research in the diffusion of innovations show that early adopters are generally more important for the development of the diffusion process than innovators or change agents.

In the project Utbildning Direct where 17 upper secondary schools from 13 municipalities in the county of Norrbotten participate, we can find a hard kernel of roughly 10 individuals that we can call innovators or change agents. These individuals have been more actively involved in the project and combine a relatively high competence in using the mStar system with an interest in educational development. Outside this hard kernel we can find a larger number of what can be characterized as belonging to the early adopters. This indicates that the process of adoption of the mStar system is still in an early stage, though the process of diffusion has lead to a spread of the technology to all municipalities in the county.
The adoption of an innovation is dependent on previous practice, experienced needs and problems, the degree of innovativeness and the norms of the unit of adoption. Inside the project Education Direct, there is a tendency that sparsely populated inland municipalities regard the mStar system as a solution for needs to keep schools in villages with a diminishing population, and as a means to offer courses to these schools in subjects, that would otherwise be impossible to offer.

Reinvention is the degree to which an innovation is changed or modified by a user in the process of adoption or implementation. While mStar is starting from the lecturing metaphor, it has however been observed that a secondary school teacher has used the system in a way characterized by a much richer interaction between teacher and students, than is normally the case in a lecture. This and other cases indicates that although the system is based on the lecture metaphor, it is flexible enough to allow for other forms of interactions. At the same time it is important for the further development of the mStar system to note and evaluate occuring tendencies of reinvention among educational users.

7.0 Related Work

The MBone [MBone] has been used for distributed presentations for several years, and is rather well described in many references. What distinguishes this project is however the broad use in less specialized education environments together with the novel tool-suite of mStar. Reference [Parnes 1997] describes the mStar environment in more detail, and its usage from the distributed project scenario. Concerning the use of WWW as a distributed and synchronized presentation medium, there have been at least two earlier attempts:

In 1995, Ed Burns presented his work on Web-Cast [WebCast], a platform for sharing WWW documents over the MBone by either multicasting URLs or HTML-documents. It interfaced the WWW browser X MOSAIC [Mosaic] through the Common Client Interface (CCI) and distributed WWW pages and corresponding inline images using the Reliable Multicast Protocol [RMP]. Tests were conducted during the spring of 1995 which showed that the multicast distribution model used by that version of RMP was not suitable for wide-area-networks, because only the original sender of the data could do a repair of lost packets. In more recent versions of RMP the distribution problems have been solved.

mMOSAIC [mMosaic] is another tool for sharing WWW-documents over the MBone and is an extended version of the WWW browser X MOSAIC. Initial tests show that mMosaic works well with HTML-pages and smaller images, but the distribution delay gets too large with bigger images. A drawback is that it is very tightly coupled to X MOSAIC. Both these tools and other earlier Web-distribution tools are all tightly connected to the X MOSAIC browser. One of the main design-constraints on the mWeb application is that it should be browser independent.

Abstract: Fast changing environments generating new requirements create the demand for „life long learning“ - for individuals, groups, as well as for corporations.
Therefore there is a growing need to support new ways of learning. This paper describes a Web-based system for the support of cooperative learning which allows for joint learning in a flexible, open environment. In contrast to currently available systems, which mainly focus on maximizing shared information and do rarely support dynamic group interaction, our approach concentrates on three important aspects: (1) awareness of other learners, (2) support of interaction, and (3) dynamic and structured building of groups according to the learner’s interest, wish, and will.

1 Introduction

Nowadays the available knowledge is steadily increasing. Fast changing environments generating new tasks, new technologies, new requirements create the demand for „life long learning“. People as well as corporations are forced to constantly build up new knowledge, to maintain it, to share it and also to make it accessible for others.
Therefore there is a growing need to provide structured, user-oriented information and learning facilities to support learning besides traditional, school-based education. But also using new technologies, an important and often neglected element of learning is the presence of a social context (i.e. learning in interaction with others) whenever isolated work is not effective or not wished. To support this kind of joint learning some basic requirements have to be fulfilled. In particular there is a need for a shared information space which is easy accessible and easy to use, for awareness of other people in the „virtual learning room“ and for adequate ways to communicate with each other.
To meet these requirements we have chosen the World Wide Web (WWW) technology as the basic platform. It is independent of hardware and software platforms, accessible at relatively low costs and therefore in wide spread use. Since it is ideally suited for information browsing it supports the worldwide information exchange in a very efficient manner. Additionally, the Web continues to evolve from its role of being a simple document-based information pool - e.g. as a low-cost electronic advertising medium - to a platform providing more complex services as well. Moreover, we are using the WWW also as distributed and easy-to-use platform to support the interaction within our Telelearning Service.
The paper first describes requirements and a prototypical implementation of the Telelearning Service. Secondly it introduces special mechanisms that allow structured and dynamic building of learning groups. Then available forms of group interaction are presented, before the basic architecture is shortly described. A brief overview of the related work and a conclusion finish the paper.
2 Requirements and Implementation

Learning in the above described environment requires a distributed structure and also implies the support of loosely coupled interaction schemes. The Telelearning Service is not focussed on fixed classes with well-defined roles (teacher, pupils) and tasks. Our emphasis is more on supporting joint learning in a flexible, changing system regarding contents and participants. Resulting questions of this kind of joint learning are for example: Where can I find interesting information? Who else is interested in this information? Is there somebody who could give me a help? Is somebody interested in learning together with me? Can I help somebody? How do others learn?

To support joint learning in this context we have identified three major requirements: (1) the awareness of others, (2) flexible building of learning groups, and (3) different forms of interaction between users.

Awareness serves as a prerequisite for group interaction and group building, and is thus strongly related to the perception of other users. The question is which people in our Telelearning Service should get into contact in which way? It is intended that our system will handle this in a flexible manner by the definition of generic measurement methods, so-called metrics. Each user can specify some criteria, e.g. his knowledge, his interests, his intention and so on. They are then used as group building mechanisms for clustering learners into groups. In addition to just recognizing related users, group building gives an user a social context for his interactions: The individual turns into a group member. Different group building methods result in different types of learning groups. Depending on group types and user interests different interaction schemes are necessary. Group interaction support is oriented on the specific needs of a learning group.

A first prototype for a general group interaction system has been developed to illustrate parts of the abstract concepts and to evaluate the usability and performance of an implementation. The following scenario and prototypical application illustrate the focus of our web-based Telelearning Service (figure 1).

Figure 1: The Telelearning Service for Cooperative Learning

When loading the entry page of the demonstrator the browser splits in two horizontal frames. In the upper frame the Web client runs as a Java applet. In the lower frame the homepage of the web-based interactive telelearning service is loaded (fig. 1 f). A user, called Peter, enters the service. Since the button „current location“ (fig. 1 b) is preset, a map (Map Panel, fig. 1 c) provides an overview for Peter. It contains all learning rooms within the service together with Peter's current location. Peter is in a location group with Heiko (fig. 1 e) because he is currently on the same level in the Map Panel. Peter then decides to enter the mathematical room. The system allows him to choose for every room in a pop-up menu between predefmed entries, e.g. for the
menu mathematics the entries: linear algebra, analysis, stochastic, number theory, numerics, game theory. This set of topics is easily extendable. The user can choose a combination of entries out of one or more menus.

Peter chooses the entry „analysis“ in the mathematics menu and enters the mathematics class room (fig. 2). After a specific evaluation he is grouped with Bernd and Andrea, whose lists of interests match his list. They can start to discuss the topic given in the content area by communication via the chat panel (fig. 1 d).

Our support of the application scenario „telelearning“ features an automatic and dynamic grouping by regarding the interests of the participants. This is different to the usual „telelearning“ support where groups are built on the fixed roles of teacher and students.

---

3 Dynamic Grouping by Metrics

An idea for the grouping process is to bring people together who share the same interest and knowledge or have the same questions. This can be achieved by the introduction of special mechanisms, called metrics, which allow a more flexible realization of awareness and grouping. Nevertheless the process of grouping still depends on the users will and wish.

Metrics are defined application-independent and therefore offer advantages for different web-based applications. They help web users to benefit from each other dependent on their intention. Structured group building allows to perform dynamic evaluation based on the learner’s choice of metrics. He can choose just one metric or combine some of them.

3.1 The Space Metric

Like the Web, the Telelearning Service is organized as a mesh of hypermedia-based HTML-documents. This corresponds to a graph represented by arcs and nodes. Structured grouping based on the space metric brings people together who request an URL in a certain part of this graph. The part is determined by the definition of...
the link-distance LD which gives the shortest path between two HTML-documents (spec_URL, URL_i) in the corresponding graph. Mathematically spoken, space grouping means to find coverings in the graph. For this computation several existing graph algorithms can be applied. Two clients (client_1, client_2) are grouped together when the following predicate „Distance“ evaluates to „TRUE“:

\[ \text{Distance} (\text{spec}_\text{URL}(\text{client}_1), \text{URL}_i(\text{client}_2)) \leq \text{LD} \]

The space metric groups people browsing in a spatial environment, e.g. the same classroom, defined by the relationship of the documents via the embedded links. This metric can be interpreted both human-centered (in the sense of user behaviour) and document-centered.

### 3.2 The Semantical Metric

The **semantical metric** is based on the content of a HTML document in the Telelearning Service. The semantical metric is document-centered. This metric is useful to get into contact with people resp. groups who share interest in HTML-documents with similar contents. The semantics can be covered by introducing **weighted hyperlinks** or by extracting **content-based** information from the documents.

For the **weighted links metric**, the links between HTML documents are tagged with weight attributes. This weight expresses the intensity of the relation between both documents as a hint for content correlation. A high weight implies a strong correlation. Given is a threshold value W. Two clients are grouped, when each link on the path from URL_i to URL_j has a weight \( \geq W \). Weights can be integrated in the corresponding documents explicitly by the author or semi-automatically by analysis tools based on e.g. keyword matching algorithms.

\[ \text{Weight} (\text{URL}_i(\text{client}_1), \text{URL}_j(\text{client}_2)) \geq W \]

The **content-based metric** is more challenging to realize. Here People should be grouped, which request documents, that are not necessarily linked but address the same topic. To obtain the relevant content of a document, information retrieval algorithms are necessary. The required search algorithms can be executed as periodical background tasks to generate the correlation information in the Web in a semi-static fashion to moderate the algorithm's NP complexity characteristic. On the other hand heuristics, for instance keyword matching and their statistical evaluation over all requested documents, can be used. The following predicate have to be „TRUE“ to group two clients (client_1, client_2), requesting URL_i and URL_j.

\[ \text{Content-match} (\text{URL}_i(\text{client}_1), \text{URL}_j(\text{client}_2)) = 1 \]

### 3.3 The User Interest Metric

Whereas the previous metrics have been mainly document-centered, the user interest metric is human-centered. Here grouping is defined by a correlation of users according to attributes assigned to them. Attributes can include sharing of interests, speaking the same language, belonging to the same cultural group, having the same knowledge (e.g. mathematics with a special emphasis on linear algebra) and many other definable attributes. Attributes could be collected at the client side and exchanged with servers during browsing. Similar techniques as with the content-based semantical metric can be used on the server side to match user attributes (Attribute-List). The predicate to be evaluated is the following:

\[ \text{Int-Match} (\text{Attribute-List}(\text{client}_1), \text{Attribute-List}(\text{client}_2)) = 1 \]

For an implementation two starting points can be chosen: (1) Constructing the users attributes through user tracking, or (2) get a collection by directly asking the user to select attributes. This can be easily done e.g. by clicking buttons in a predefined table.

Complexity and implementation issues play important roles in the choice of a metric or a combination of metrics. Each metric requires different manipulations at the server side. Combinations of metrics are useful since they considerably reduce the search space and herewith the computational complexity. They also limit the group size, which is necessary to foster synchronous collaboration.
4 Possible Forms of User Interaction

The previous chapter explained how dynamic grouping of different learners might be performed in the Telelearning Service according to the learner's preferences. This chapter now describes four available features of interaction of the current prototype: User Perception, Location Chat, Acquaintance Chat and Cooperative Navigation:

The challenge of User Perception is to gather the clients URLs and to generate the information needed to visualize the visitors in a 2D environment. Each location, which represents a logical related set of URLs, is represented in a room plan that additionally visualizes all the learners residing in the current location or a subordinated place (see fig. 1.c).

The feature Location Chat enables an user to communicate with others because they reside in the same environment or have been grouped by the use of the metrics in later versions (fig 1d). If an user navigates to another room in the service the chat members may change since the chat group may dynamically be build from the visitors current locations.

In contrast to the Location Chat, where people normally do not know each other, Acquaintance Chat can be used for communication within a closed social group (e.g. class mates, relatives...). The participants of such a chat group are independent from a member's current location.

Within the Acquaintance Chat group Cooperative Navigation is supported. It enables the members to jump to another one's current page by simply pressing a button. For guided tours or if a person is a non-experienced user of the Telelearning Service it is possible to give navigation support. Each time the leader moves to another page the browsers of all other group members are automatically synchronized.

The above features for grouping are currently "hardwired" and could be enhanced by the application of one or more metric(s).

5 Architecture of the Prototype

As a conceptual basis for the implementation of the basic system named GIA a client-server architecture has been designed (figure 3) [Manhart et al. 1998]. The giaServer manages all client information, e.g. every student's name, his current location, or information about groups, their members, and the two basic features "user perception" and "acquaintance chat". The server runs as an additional service on an Internet server. The giaClient is conceptually structured into two basic building blocks. One is managing the map of the classrooms and implements user awareness, since it visualizes the location of the currently visible users in the room map. The other realizes ASCII chat of each group having been built.

![Figure 3: The Client/Server Architecture of the GIA-system](image-url)
6 Related Work

User awareness is a main criterion to support user interaction in groups [Fitzpatrick et al. 1996]. In [Palfreyman and Rodden 1996] a protocol for “user awareness” in the Web has been presented, but without addressing the group aspect.

Depending on the increasing amount of new knowledge and developments there is growing demand for organizations, groups and persons to augment knowledge and expertise. In the following a few synchronous and asynchronous learning systems are mentioned:

“Answer Garden 2” [Ackerman and McDonald 1996] consists of a 2nd generation system architecture for organizational memory and collaborative help support in an asynchronous fashion. Examples for synchronous learning are: “GestureCam” [Kuzuoka et al. 1994], an approach that supports spatial workspace collaboration via a video-mediated communication system. “CLARE” [Wan and Johnson 1994] represents a collaborative learning system which allows also for knowledge construction. In [Nakabayashi et al. 1995] several advantages of constructing an interactive educational system based on the Web are collected. [Benford et al. 1996] developed “The Internet Foyer”, which provides awareness only via the definition of an unified entry point. But it is only a collaborative virtual environment and not dedicated to learning.

Current collaborative learning systems focus more on maximizing shared information and have neither group support (only predefined teacher-pupil) nor dynamic group building support.

7 Conclusions

We have introduced a Web-based Tele learning Service to support joint learning in a flexible and open environment. The implementation is based on existing Web technology to allow wide-spread use. To provide a social context for the users a focus was set on the awareness of other learners. Innovative methods for dynamic and structured group building were introduced. They allow new and effective ways to build up learning groups according to the participants wish, will, and interest. Dependent on the user needs and the learning context different forms of interaction between the users were presented.

Abstract: Most efforts concerning the idea of “agents” as human-like interaction modules are concentrated on technical questions, like features which can be implemented, and how. In contrast, this paper describes an attempt to tackle the question: What use is an “agent” for its human counterpart? Do people actually perceive the agent metaphor the way software developers expect them to do? We integrated an adaptive pedagogical agent into a sample tutorial system based on earlier work in the field of adaptive hypermedia courseware [Specht, Weber, Heitmeyer, & Schöch 1997]. The agent developed is supposed to help learners optimize the learning sequence for their individual interests and knowledge. In the study, the agent’s “abilities” were varied, students’ skills were measured, and it was expected that learning efficiency would significantly increase when the agent was offering more sophisticated support. Results generally matched the expected effects.

1. Introduction

1.1 Why Do People Need Pedagogical Agents?

Becoming increasingly accepted as an ordinary medium just like everybody’s TV-set, the WWW is a superb chance for individual training — if taken seriously. Meanwhile, a lot of so called “courseware” is spread all over the net which is often not only based on an ordinary book, but simply reprinted in HTML. This way, possible advantages of hypertext vanish immediately and certain disadvantages become dominant.

Hypertext courseware should be easy to use. This obviously is the fact for an ordinary book, because everybody is familiar with using books — so why hypertext? Hypertext courseware can free the learner from the static structure of the material given by the author, an aspect that cannot be provided with an ordinary book [cf. Dillon 1996]. But freedom must not end up in a loss. To avoid the effect Hammond and Allison called “lost in hyperspace” [Hammond 1992] there is a compelling need for a mediating instance such as a personal teacher. In the best case, a personal teacher knows the domain, knows the student, has some didactic experience, and thus provides the student with learning material individually selected and structured for him or her. Moreover, a personal teacher keeps close interactive contact to the student, always regarding his or her personal goals and preferences. Altogether, the personal teacher’s tasks are to optimize learning efficiency and motivation. And exactly these are a tutorial agent’s tasks, too. But is it possible to achieve sufficient student support through anything else than a human teacher’s attendance?
1.2 What is our goal?

We hypothesize that any "agent" equipped with some "intelligence" even far behind the latest technical state-of-the-art would generally raise learners' learning efficiency and motivation in comparison to plain hypertext. Our goal was to verify the hypothesized effects by means of a sample agent. At the same time we wanted to study students' acceptance and perception of this user interface component that was unusual to our subjects.
1.3 Background

Earlier work in the field of computer-based education had led to our Adaptive Statistics Tutor “AST” [Specht et al. 1997]. AST is a tutorial system for WWW-based distance learning [1] that integrates several adaptive resp. adaptable features. We decided to add to the adaptivity already implemented in AST and to present certain individually adapted guidance features by a newly invented user interface component: The agent.

In parallel with the AST implementation, the tutorial system described in this paper is based on dynamically generated HTML enhanced by a handful of illustrations. As a TCP/IP server platform we again chose the Common Lisp Hypermedia Server [2] described in [Mallery 1994] that proved to be an efficient development tool for these purposes.

![Diagram of a Unit structure](image)

**Figure 1: Schematic structure of a Unit.** There is information on the subject matter (teaching materials, printed in italics) as well as features relevant for presentation (introduction and summary), in-depth-information (subunits), features relevant for evaluation (tests) and meta information aimed at an adaptive presentation (global domain, prerequisites, and implications).

2. System Architecture

Essentially, there are two different types of databases that provide the basis for adaptivity in a tutorial system: A “Domain Knowledge Base” and a “Learner/User Model”. While [Murray 1996], among others, stresses the necessity to clearly distinguish two aspects of a tutorial’s knowledge base — what to teach vs. how to teach —, our system represents an alternative point of view: We implemented static procedures that derive the suitable presentation (“how”) from the implications arising when the knowledge base data (“what”) is incorporated with the learner model data. For reasons of the evaluation we had in mind, besides the agent’s recommendations the learner is free to decide which item to learn next and to choose convenient learning media.

---

[1] as well as some other ITSs, AST is fully WWW-accessible at http://specht.gmd.de or http://cogpsy.uni-trier.de:8000/TLserv-e.html

2.1 Knowledge Base

We denote our knowledge base *curriculum*. It contains the teaching material and meta information aimed at a flexible presentation. The curriculum is built up from *units* representing narrow pieces of subject matter information. Subject matter information is stored by means of *teaching materials*. The number and kind of teaching materials depends on the information to teach. It may vary significantly between different units. [cf. Fig. 1]
The units are structured in three ways:

- The subunit principle results in a hierarchy, as it can be found in an ordinary book. This hierarchy serves for a "red thread" and for the presentation of a table of contents.
- The prerequisites/implications paradigm as thoroughly described in [Dannenberg, et al. 1990] allows for adaptive recommendations based on learner model information.
- The global domain meta information serves for cross-reference generation and for sequencing recommendations based on the learner's special interests.

2.2 Learner Model

Each student is assigned a personal learner model. It is initialized by means of one demographic and one subject oriented questionnaire at a learner's first login procedure. This model is kept and continuously updated while the student works on the curriculum. A learner model includes the following data:

- static data, e.g., name and password. This data is only of formal interest and does not influence adaptation.
- adaptable data, like special interests and preferred learning strategy. This data is taken into account for adaptational features and can be changed whenever the student feels like.
- dynamic data, i.e., past learning episodes and their implications on the presumed knowledge level on a certain topic. Adaptive features are based on this data.

3. The Agent

3.1 Interactive Personal Teacher

One of our agent's learner support features is the ability to calculate advisable units to proceed with from a given learner state. The implicitly given teaching goals are promoting and retaining learner motivation and evoking students' interest even in lessons they otherwise might have avoided. More precisely, the goal is to present the lessons of a curriculum in such a way to promote a structured and well balanced learning process.

Several propositions can be calculated, each according to one set of priorities. Any of these findings are presented, for it is our philosophy not to force students to a sequence that is postulated to be ideal. In contrast, the idea is to help the students find their own sensible way through the curriculum. This position is both supported by considerations concerning the effects of (at least perceived) learner control and by the purpose of our implementation designed for collecting empirical data and finding out what precisely determines individually ideal sequencing. A controversial discussion on learner control and its impacts is drawn up in [Schulmeister 1996].

When a student asks for help, an appropriate subset of the following recommendations on how to proceed is presented together with short comments:

- a learning material of the current unit, corresponding with the student's preferences. Following this proposal, the student may acquire the current unit by means of a type of learning material that he or she claimed to be especially convenient.
- a learning material of the current unit, to complete knowledge about this unit. This proposal draws the student's attention to a learning material of the current unit that has not yet been seen.
- a unit related to the current unit and corresponding with the student's preferences. This proposition may attract the student's interest because it shows the idea of the current concept in the light of a global domain the student has claimed to be especially interested in.
- a unit to complete most recently acquired knowledge. The student's attention is drawn to another unit within the current subunit.
- a completely new, unrelated, unvisited chapter. A student who is bored or annoyed by the section he or she is just working at, may like to follow this link.
• proceed with the current unit. In case, none of the above is considered convenient the student may simply continue where he or she interrupted to ask the agent for advice.

The calculation tasks include comparing the learner model data with the data in the knowledge base, selecting possible units, bringing them into an appropriate order and presenting the one which fits best. Duplicate findings and units already presented are filtered out.
3.2 Student Interaction with the Learner Model

In addition to these adaptive features, we decided to implement some adaptable features. This was another aspect we wanted to test in our study that had its roots in a discussion on learner control [cf. Schulmeister 1996]. Therefore our agent cannot only be asked, but also be told:

- The student's preferences for global domains such as "biology" or "history" as well as preferred types of learning material can be adjusted whenever the student feels like.
- The student may inspect parts of the learner model by means of a "knowledge barometer". This serves as feedback for the learner and, at the same time, gives the learner the chance to improve the model through direct interaction. [Fig. 2]

![Figure 2: Inspecting the Learner Model. The student may decide to visit a topic of low knowledge valuation (e.g., "History of Heroin") or to "protest" against the agent's estimation. In case of a protest, after the student performed some tests, the model will be updated.]

4. The Empirical Study

The idea of the study was to clarify implications our agent might have on learning. We wanted to investigate on the acceptance, motivational effects, and learning efficiency both of (a) adaptive guidance by proposals and (b) learner model adaptability. On the basis of the technology described above we decided to put up a small curriculum on narcotics we called "Adaptives Drogen Informationssystem" (ADI). The acronym "ADI" became a synonym for our implementation of an agent and will be used as such from now on.

4.1 Method

Subjects had to visit every concept of the curriculum at least once. The curriculum consisted of three chapters, each chapter containing two or three subunits with a total of 23 units. It could usually be completed within less than one hour. A total of \( N = 40 \) students took part in the experiment. Subjects were randomly assigned to the following treatments:

- **ADIproposals**: Students could ask ADI for proposals, but were neither allowed to change preferences once they had started the course, nor to inspect their learner model.
- **ADIproposals+model**: Students were given ADI's full functionality, i.e., ask for proposals and inspect/adjust the learner model.
NoADI (control): Students had to complete the course with plain ordinary navigation tools, i.e., without having any of ADI's features at their disposals. To realize the control group and for reasons of a realistic setting, in addition to the agent our system was equipped with standard navigation tools such as next, previous, table of contents, and next unvisited. As we will see later, this revealed to be a problem for our evaluation.
We evaluated performance differences in a questionnaire on the curriculum's contents that had to be completed before and after the learning phase. Moreover, before the learning phase students could select special interest domains and preferred types of learning material. At the very end, subjects completed a questionnaire concerned with demographical features, possible side effects such as computer experiences, and acceptance of ADI's presence and assistance, as far as appropriate to the subject's treatment.

4.2 Results

Evaluation of the final questionnaires indicated no problems with the interface (91%) and high acceptance of adaptive support in general (94%). Another general finding was that learning with ADI's assistance takes some extra time, an effect we consider to be an impact of such a small curriculum.

<tr>
<td>ManyInformationRequests</td>
<td>3,14</td>
<td>4,71</td>
</tr>
</tbody>
</table>

Table 2: Performance increase after course completion inside treatment ADIavailable. Post hoc split by InformationRequests and ADIrequests.

We post hoc split data into FewInformationRequests and ManyInformationRequests. This split could explain large portions of the observed deviation ($F_{(1,39)} = 5,06; p < 0,05$). A closer look revealed some correlation between the quantity of information requests and the quantity of ADI requests which could be explained by splitting ADIavailable into FewADIrequests and ManyADIrequests [Tab. 2]. This explained another large part of deviation ($F_{(1,39)} = 7,26; p < 0,05$) and reveals clear positive effects of ADI's assistance on learning performance, if requested by the student. However, these findings have to be interpreted with care, for they are based on two post hoc splits. Nonetheless, they can be taken seriously: There is no correlation between the post hoc variables and computer experience or WWW experience measured by means of the final questionnaire.

4.3 Discussion

The presence of various navigation tools combined with such a small curriculum exceeded the effects of ADI's features. Therefore, this design was not ideal to find effects of treatments ADIavailable vs. NoADI. Subjects had to browse some 23 concepts, so they did it just in order and did not mind any features which just seemed to cost some extra time. In addition, an average student is not used to the idea of being helped by an agent, but is definitely used to browse books in a given static order. Thus, to make everybody profit from support by an agent, one has to consider aspects of salience and training.
Nonetheless there is remarkable evidence, that the actual use of ADI as a personal mediator to individual sequencing has positive effects on learning performance. This partly may be due to motivational effects when interacting with “someone” in contrast to just being left with a stupid machine.

Regrettably enough, due to the fact that most students just ignored this feature, we cannot state any results concerning the effects of learner model inspection. To clarify this point, another experiment is required that makes students stumble across this feature and try it out.
5. Conclusions and Future Prospects

ADI is a prototypical implementation of a pedagogical agent integrated into the previously developed WWW-courseware AST. The way our agent supports the learner is both adaptive to the learner’s knowledge state and learning history and adaptable to the learner’s personal interests and preferred learning strategies. Equipped with a small curriculum on narcotics, we used this design for an empirical study.

The results of our study indicate that students do not always ask ADI for advice, though they might profit from some assistance. From this emerges the idea to equip ADI with a “self activation feature” that might increase learning efficiency for students who otherwise would not make use of adaptive support. At the same time, a certain “autonomy” may improve the perception of ADI as a “personal teacher”.

Our idea is to analyze the sequence chosen by the student and to intervene:

- if a student jumps from one unit to another in an inefficient manner, e.g., without looking at any learning materials.
- if a student gets stuck in one particular section of the curriculum and simply ignores the rest.

To make recognition of these situations possible, it is necessary to take down the student’s path from login up to the presence and to find ways to animate the ADI-figure. For learner control reasons, the student’s attention should be drawn to ADI and help should be offered, but the student should not be irrevocably interrupted in the sequence he or she chose.

However, results of our study gave evidence of positive efficacy of our onset of an agent. These findings are encouraging enough for us to go on investigating this field from an empirical point of view. The idea of an “agent” in general, i.e., a user adaptive tool presented as a manikin inside the computer and perceived as a personal contact for the user, definitely has a great potential. This is demonstrated by several promising onsets of adaptive tutorial agents, often presented by means of latest multimedia techniques [e.g., André, T., & Müller 1997; Rickel & Johnson 1997]. Future versions of ADI and his colleagues are not to be considered as yet another weird sprout of IT but as useful tools that may become common in the near future.

A version of ADI with an enlarged curriculum, and some other experimental ITSs may be tried out at http://specht.gmd.de or http://cogpsy.uni-trier.de:8000/TLServ-e.html.

Abstract: One benefit often expected to flow from Internet use in schools is an increase in equality of educational opportunity as all kinds of schools gain access to the same extraordinary set of resources. Yet, prior research suggests that patterns of technology access often mirror existing inequalities rather than mitigate them. This paper discusses the issues pertinent to equality that arose in a project bringing Internet access to a large urban school district. It concludes that even though this project strongly valued equality, competing considerations led to some inequality of Internet access between schools serving different kinds of students. Furthermore, within given schools numerous factors, including the perception of Internet use as an optional privilege and many teachers' lack of familiarity with the Internet and computing more generally, resulted in greater access for students who were already ahead of their peers academically and/or with regard to knowledge of computing.

In recent years there have been many calls to connect teachers and students to the Internet [Carlitz 1991; Hunter 1992; Newman 1992]. Among the many benefits predicted are increased communication and collaboration between teachers, increased connection of the schools to the outside world, and increased equality of educational opportunity as students from schools of all types gain access to the same extraordinary set of informational resources. This emphasis on increased equality of opportunity as a potentially important outcome of school-based Internet use is epitomized in President Clinton's belief that the Internet will "revolutionize" education since "for the first time in the history of America...we can make available the same learning from all over the world at the same level of quality and the same time to all our children" [Clinton 1996].

There is no doubt that the Internet has the potential to help equalize educational opportunity by making the information resources available to students in all schools more similar than has been the case before. However, prior research on computer use in schools suggests that patterns of technology access and use often mirror and reinforce existing inequalities rather than mitigate them. For example, affluent schools provide their students with more computers on a per pupil basis than do poorer ones [Becker & Sterling 1987; Heaviside et al. 1996]. Furthermore, the amount and kind of computer use within a given district often vary in ways that reflect and sometimes reinforce existing social differences [Becker & Sterling 1987; Schofield 1995; Sutton 1991].

The goal of this paper is to shed light on the complex relation between the use of computer technology in schools and equality of educational opportunity by describing and analyzing the issues that arose pertinent to this topic in a project designed to bring Internet access to a major urban school district. Specifically, this paper will focus on two important aspects of equality -- equality of inputs and of processes [Good & Brophy 1986; Harvey & Klein 1989]. Educational inputs are the physical, financial, and human resources a school starts with. The input of interest here is Internet access. For the purposes of this paper, equality of Internet access is defined as there being no relationship between the kind and amount of Internet access in a given school (or program within a school) and the characteristics of the students that school (or program within the school) serves. An input, however, may be differentially available to or differentially utilized by different kinds of students within a school or even within a subsection of that school. Thus, educational processes -- what happens within the school -- are also very relevant to actual equality of opportunity. Before turning to our findings, we briefly describe the project studied, the district
in which it was located, and the methods used in this research.

Common Knowledge: Pittsburgh and Its Setting

This paper is based on a four-year study of a NSF funded project called Common Knowledge: Pittsburgh (CK:P) -- one of four national testbeds in the United States designed to explore the Internet's potential for improving education. CK:P's goal, at the most general level, was to bring Internet access to teachers in the Pittsburgh public schools for use in instruction. During its first four years (mid-1993 to mid-97), CK:P provided a substantial amount of training and support, as well as hardware and Internet connections, to teams of educators at 20 schools.

Like many other urban school districts in the U.S., Pittsburgh has a substantial minority group population, with roughly 55% of its students being African American. Many of its students also face problems of familial poverty, with almost two-thirds receiving free or reduced-price school lunches because of low family income. In addition, there are major differences in the average socioeconomic status of white and African American students, with an accompanying marked achievement gap between the two groups overall. Addressing this gap is one of the district's prominently stated goals. Given this, it should come as no surprise that, as a project, CK:P placed an emphasis on enhancing equality of educational opportunity. To give just two very different examples, the proposal CK:P submitted to the NSF prominently featured promoting equality as one of the opportunities potentially provided by Internet access in the schools, and project staff commonly strove to achieve gender and racial balance when selecting students for Internet-related projects.

Methods

The major data-gathering methods used in this research were qualitative observations, semi-structured interviews, and the collection of archival material. Since the project began in 1993, we have conducted repeated observations in a wide variety of settings. This includes over 160 hours of observation in over 40 classrooms in which the Internet was being used. It also includes observation of over 125 meetings between different groups of teachers who have been involved with the project, and dozens of meetings of CK:P's educational and technical support staff. Trained observers used the "full field note" method of data collection [Olson 1976] which involves taking extensive hand-written notes during the events being observed. All notes were made as factual and as concretely descriptive as possible.

To gain insight into participants’ perspectives, over 300 semi-structured open-ended interviews were conducted with a wide variety of individuals including over 100 teachers, 30 school district personnel, 14 CK:P staff, and 130 students. Archival materials, especially e-mail, were another important source of information pertinent to the issues discussed here. With participants’ permission, the research team’s address was added to virtually all group mailing lists connected with the project. This permitted collection of most normal e-mail between members of the various groups working on this project.

Both field notes and interviews were audiotaped, transcribed, coded and then analyzed using established qualitative methods [Miles & Huberman 1984; Strauss & Corbin 1990]. In the data analysis, our primary emphasis was on the development and systematic application of thematic categories to all data. Further, we paid close attention to triangulating data from the different kinds of sources.
Results

Equality of Inputs: Distribution of Internet Access Across the School System

CK·P did not have enough funds to provide Internet access and extensive support to every school and classroom in the district, although it did have a budget of over five million dollars. Thus, the issue of how this potentially valuable educational input should be allocated arose early in the project, just as it is likely to arise in any school district that must decide how to spend limited tax dollars. Since lead time was short during the project's first year, the first three projects to be supported by CK·P were selected by weighing considerations such as which schools had teachers knowledgeable and enthusiastic enough to successfully carry out Internet projects with little lead time and where the district already had decided to place new computer equipment and/or local area networks.

However, during CK·P's second year the project staff decided to select future schools based on an annual competition to which teams made up of small groups of interested teachers could submit proposals. The staff saw the development and successful implementation of this process as a major achievement, since they felt that the competition would encourage teachers to develop high quality curriculum projects and that support of the strongest of these would further CK·P's goal of stimulating creative and productive uses of the Internet in education. For a variety of reasons, including the desire to build political support for CK·P, the staff did not select these projects themselves. Rather, this task was left to a broadly representative and racially-mixed group that included individuals ranging from school board members to central administrators to community members.

In spite of the diversity of the group making the selection, the issue of equality of inputs arose almost immediately at the end of the first competition when a prominent African American member of the school board charged that the competitive process built in a bias against the very schools where the need was greatest. Critics of the process argued that teachers working in the schools facing the greatest social and academic challenges would have less time and energy to devote to writing proposals and developing new curricular approaches employing the Internet than their peers working in less difficult situations. In addition, since schools with higher achieving students, or with special programs likely to attract such students, were generally seen as more desirable places to work, teachers who were experienced or reputed to be unusually energetic and skilled were more likely to be able to secure positions there than their peers. It seemed reasonable to expect that such teachers would be more likely to write proposals, and to propose projects strong enough to win. Given this, it seemed plausible that district-wide competitions would end up favoring the schools with the higher achieving students. Since socioeconomic status and race were clearly connected to academic achievement in the district, as they are nationally, this would tend to work to the disadvantage of the students who were already disadvantaged by minority status or their relative poverty.

Examination of the seven schools selected in the first competition held by CK·P suggested that there was some basis for this concern. The one high school selected was only 20% African American, although almost 50% of the students in the district's high schools were African American. Students in this school were also somewhat, although not strikingly, better off economically than the average student. For example, 18% of them, as opposed to 25% of high school students district wide, came from families receiving public assistance. Similarly, the one middle school selected was a magnet school which had a somewhat lower percentage of African Americans than middle schools in the district in general (48% vs. 56%) and which served fewer students from families receiving public assistance than middle schools did on the average (17% vs. 40%).

The five elementary schools selected presented a somewhat more mixed picture. However, taken as a group, they did appear to enroll children who were somewhat more advantaged than the average child in the district. For example, two of the district's five most affluent elementary schools were selected, giving them a remarkably high success rate given that only three elementary schools were selected from the remaining forty-four. One of the three other schools selected was one of the few in the district with a student body containing less than 10% African Americans. (However, its students' socioeconomic status was somewhat below the district average since 52% of its students came from families receiving public assistance compared to 46% of elementary school families district wide). Only one of the elementary schools selected had a substantially higher proportion of African American students than average. Its student body had a socioeconomic status very similar to that of the heavily white school just described. Finally, although the district had 12 elementary schools that were 80% or
more African American, all but one of which were characterized by higher than average levels of poverty, none of these schools ended up with CK:P projects through this competition.

The issue of which schools got access to the Internet through CK:P, and what the implications of this were for educational equality and equity, received a substantial amount of attention from policy makers. However, even if access were equal across schools enrolling different kinds of students, the possibility remained that the Internet projects might be focused in niches in the schools which served non-representative samples of students since small teams of educators, ranging in size from 5-12 people from within a given school, served as the CK:P Internet teams and their students typically had greater access than others. This did occur and, when it did so, the students served were generally advantaged in one way or another compared to their peers. So, for example, one project in a school which was 99% African American and which had a student body characterized by high poverty rates was located in the honors track, which by definition served the most academically able students. As a group, these students tended to come from somewhat less poverty stricken families than their peers. Similarly, another CK:P team in a different high school which was 57% African American ended up using the Internet heavily in their smaller advanced language classes, which generally speaking had a lower proportion of African American students than the school.

As a project, CK:P made strong efforts to be inclusive and to mitigate the impact of existing inequalities on Internet access. For example, it secured additional funding targeted for schools serving the most disadvantaged populations. Also, project staff provided extensive training covering topics ranging from Internet use to proposal writing so that teachers from all schools could receive the help they needed to write strong proposals. In addition, CK:P provided modest levels of Internet access and support to sites that were not selected for more intensive focus, so that by the end of CK:P’s fourth year over two-thirds of the schools in the district, including many of those serving the most disadvantaged students, had some form of access. However, the problems that arose regarding equality of access in this project, in spite of the relatively high priority this issue held in the minds of those responsible for implementing it, suggest just how complicated it may be to achieve. Furthermore, they highlight the fact that hard tradeoffs may need to be made between equality, equity, and maximizing the likely impact of any given dollar invested in educational technology.

Equality of Educational Processes: Distribution of Internet Access Inside Classrooms

Even if there is no relationship between the demographic characteristics of the students in a school or classroom and the likelihood that resources such as Internet access are located there, the question of whether or not students actually end up with equal access remains. At the classroom level we saw few if any cases where teachers blatantly used student characteristics such as race, gender, or socioeconomic status in a way that systematically denied or minimized access to any particular group. In fact, when such criteria were explicitly considered it was virtually always in a way that promoted equality of access across groups -- such as a teacher’s consciously deciding to select one boy and one girl to engage in a particular Internet activity even though more boys than girls had volunteered. However, several educational process issues did lead to advantaged students often obtaining more Internet access than their peers. Ironically, this occurred in spite of the fact that many teachers believed that Internet access was particularly valuable for at-risk students.

First, teachers, especially those working in noncomputer lab settings, tended to see Internet access as an optional privilege rather than as a basic resource, such as textbooks or library materials, to which all students should have access. This view stemmed from several sources, including the fact that even in classes receiving full CK:P support teachers generally had many more students than Internet access points, which meant that Internet access was a scarce good. As such, it was most easily dealt with as a privilege, rather than something to which every student should or could have equal access. The view of Internet access as a privilege was also connected to a positive view of it on the part of teachers who went to the trouble to write a proposal to bring it to their classrooms. Students’ generally very positive reactions to access reinforced the image of access as a privilege.

Another factor contributing to this view of Internet use was that work done on the Internet was often not part of the core curriculum upon which students were tested, so that teachers did not feel a responsibility to assure that all students got to use it in order to do the work expected of them. Although this situation was partly due to the relative scarcity of Internet-linked computers, it did not appear to be completely due to this. Rather, teachers had curriculum materials and accompanying tests that reflected the core of what they expected students to learn.
Internet work tended to be added on to this as enrichment, rather than integrated into the core curriculum. Since class time was limited, time spent on the Internet was sometimes seen as time not available for more pressing work.

Since Internet work was often seen as an optional privilege, the question of which students would gain access arose. Teachers frequently used access as a reward for good behavior, especially strong academic performance. Similarly, behavior of which the teachers' disapproved, especially social behavior of this nature, was seen as reason for removal of this privilege or for failure to bestow it. This tendency was exacerbated by teachers' concerns about students' inappropriate use of the Internet and by their concerns regarding the possibility that students might intentionally or unintentionally damage the computers to which they had access. Taken together, these factors tended to increase usage by students who were academically strong and to decrease use by those who were either weaker academically or less attuned to the schools' behavioral norms.

Teachers' genuine concern about the academic progress of their weakest students also often contributed to this inequality in access. Since Internet usage was generally not conceptualized as the quickest and clearest route to helping students master the core of the curriculum, some teachers believed that weaker students' time was better spent on more traditional activities. It is certainly possible that the teachers were correct in this assessment. However, to the extent that familiarity with computer use in general, and the Internet in particular, is useful in today's world, inequality in Internet access for weaker students created yet another potentially important dimension on which they were behind others. Furthermore, the stronger students' greater access to the Internet had the potential to increase any pre-existing motivational differences between them and their academically weaker peers since there was widespread agreement on the part of teachers and students that Internet use was motivating.

Another factor that contributed to disparity in access was that many teachers' lacked highly developed knowledge about the Internet and about computers in general. This led them to give greater access to students who were already knowledgeable in these areas rather than to spread access more broadly, since such students could use this resource most effectively and in a way that made the least demands on the teachers' already heavily obligated time. Such students were disproportionately white, male, and from relatively privileged socioeconomic backgrounds. Enhanced access, in turn, increased and highlighted the knowledge gap between them and their peers. One factor that appeared to contribute to creating the initial gap in expertise was home access. Previous research suggests that both males and relatively affluent students are more likely to have home computers and to engage in other activities such as attending computer camps than their female and less affluent counterparts [Hess & Miura 1965; Kraut et al. 1995; Sutton 1991]. Such appeared to be the case here as well.

Students' behavior sometime tended to reinforce the disproportionate access created by the kinds of process issues discussed above. For example, males and students of somewhat higher socioeconomic status than their peers sometimes made disproportionate voluntary use of the Internet in the school library before or after school. Similarly, teachers noted that girls were sometimes less assertive than boys in laying claim to computers when both they and others wanted to use them.

Conclusions

This study suggests that bringing the Internet to schools in a way that enhances educational equity is likely to be a complex process. First, there is the issue of whether this educational input will be distributed across schools and classrooms in ways that exacerbate or mitigate existing inequalities. In prior research, the association between access and advantage has usually been understood to reflect the differential tax base in poor and affluent communities. In CK-P's case, the inequality stemmed from something else entirely -- a desire to deploy scarce resources where they were most likely to be well utilized. Yet other considerations could also be weighed, and might lead to different kinds of inequalities. For example, there were those who suggested that CK-P should place more emphasis on concentrating resources where the need was greatest -- a strategy intended to enhance equity, although not necessarily equality of inputs. Furthermore, this study highlights the fact that distributing access equally across different kinds of schools and classrooms does not insure equality of use. Numerous educational process issues, from the way that teachers think about Internet use to differential pre-existing expertise on the part of different kinds of students, also shape usage patterns in ways that often reinforce existing inequalities.

Teaching Shakespeare: Materials and Outcomes for Web-based Instruction and Class Adjunct

Helen J. Schwartz
Department of English
Indiana University
Indianapolis, Indiana, USA
hschwart@iupui.edu

Abstract: Multi-media hypertext materials have instructional advantages when used as adjuncts in traditional classes and as the primary means of instruction, as illustrated in this case study of college level Shakespeare classes. Plays become more accessible through use of audio and video resources, including video clips from play productions. Student work can be included as models, and updating or expansion of texts is as easy as changing html files. With over 40 hours of instruction per play module, assignments can be individualized to student needs and used repeatedly—for instruction, clarification, make-up on missed classes or review for exams. Materials for each play include three lectures and seven topics for exploration (Issues, Character, Plotting, Genre, Critics, Staging and Background); instructional aids on cast, story-line, literary terms, and references, as well as access to a searchable text of Shakespeare's works, are included. Results over five years of development and revision are reported.

How can hypertext help teach an academic subject such as Shakespeare's plays? Can a class be taught completely on the Web or should Web materials simply serve as adjuncts to classroom presentations and homework sessions? Over the past five years I've experimented with the interface of hypertexts to teach nine Shakespearean plays (including sound, pictures and video clips as well as text in the instructional material) and have modified the ways these hypertexts were used in face-to-face classes and in Web-based courses. This paper reports on the philosophy and pedagogy underlying the design of materials as well as the results.

At first, the Shakespeare Hypertext Guides (SHG) were used as resources for classroom presentation and for student use in making up missed classes, reviewing students' knowledge of plays and supplementing classroom instruction. After using the SHGs in three face-to-face classes, I initiated a hypertext-based course in Fall 1995. Initially the hypertexts were HyperCard stacks with delivery of course assignments through the campus network and email. In Fall 1996, four of the seven plays were delivered on the World Wide Web, again with email as an adjunct. In Spring 1998, an upper-level version of the course was offered that is completely Web-based, including the delivery of student work to the instructor, the posting on a class bulletin board and posting of grades (with the course management presented through WebCT, a Web-based teaching environment developed at the University of British Columbia: http://homebrew.cs.ubc.ca/webct/).

Structure

The Web-based SHGs call for student response while providing guidance and learning aids in the form of texts, sound clips of speeches, relevant pictures and comparative video clips. Each play has its own Web site. Each play provides instruction with

- "Lectures" (usually three per play) that provide a coherent interpretation of the play while suggesting alternate interpretations
- "Explorations": seven per play on Issues of Interpretation, Characterization, Plotting, Genre, Critics, Staging and Background (use of sources and textual variation). These Explorations provide material to help students with more open-ended questions. They also contain samples of student response, whenever such work is available.
Each "Lecture" or "Exploration" segment has a form by which the student can send a response to the instructor. It is the instructor's job to select how many or which forms will be required and at what pace. For example, in Spring 1998 I required on-line students to respond to one "Lecture" and one "Exploration" of their choice, as well as working on a group-paper in response to another Lecture. But after the first exam I recommended which "Exploration" is recommended for a particular student based on their exam results—with the Explorations on Genre, Critics, Staging and Background usually suggested only for students who have earned at least a B on the essays and identification of quotations on the exam. In Fall 1998, with a different instructor, on-line students will generally respond to a Lecture or Exploration of their choice, work on a group-paper and fill out a more factually oriented short-answer form. (An additional paper requiring use of critical sources is also required, but independent of the course materials described in this paper.)

Additional aids to instruction (as shown in Figure 1) are given in the header for each Lecture or Exploration. A student can review a scene-by-scene summary of the play, an interactive graphic of the cast of characters, a glossary, references to secondary sources or Shakespeare's playtext (with the opportunity to search or copy the text at MIT's Shakespeare Web site at http://the-tech.mit.edu/Shakespeare/works.html).

Figure 1: Sample page for Web-based instructional delivery on Shakespeare's A Midsummer Night's Dream

Advantages:

Hypertextual instructional materials provide several important pedagogical advantages:
1) Hypertexts use audio and video resources that make Shakespearean drama more "accessible" to students.
2) Students see different versions of actual productions juxtaposed to show the range of interpretation possible and the necessity to explain quotations.
3) Student work can be included in the stacks as samples and videos of scene production.
4) In individual sessions, students control the pace of their learning, with the ability to print most text resources, to answer questions in one or several sittings.
5) The range of topics (with over 40 hours of instruction possible per play) allows supplemental activities geared to individual learning needs (on the basis of an early diagnostic exam) and allows inclusion of challenging materials (such as discussion of historical adaptations or textual variants) that are not normally covered in class.
6) Frequent writing supports learning when students process what they are learning in a mode in addition to reading and listening.

Advantages for the logistics of teaching in various contexts are:
7) The random-access of hypertext makes it easy for teachers to have flexible control of audio and video resources without excessive equipment.
8) Coordination of the syllabus with hypertextual activities allows commuter students to make up missed class sessions and keeps students responsible for their learning, despite missed classes.
9) The teacher can use stacks repeatedly, but can also change text as easily as modifying an html textfile.

Process: From Theory to Prototype to Evaluation to Revision

The SHGs have evolved over time as I learned from practice about problems and opportunities. The first prototype, created using HyperCard, was designed to achieve advantages of random access to audio, graphic and video resources, especially different productions of the same scene (Advantages 1, 2 and 7 above). In Spring 1994, the prototype on A Midsummer Night's Dream established the basic structure for the SHGs (Lectures and Explorations, Cast graphic, Story summary, Glossary, References, Playtext access and Samples), used in English L315: Major Plays of Shakespeare. A year later (Spring 1995), I had HyperCard versions of 4 plays (Taming of the Shrew, Midsummer Night's Dream, Hamlet, and Macbeth) available for use in class and as an adjunct for out-of-class student use. Bugs in scripting and limit to use on Macintoshes on campus were very restrictive, but student response in class and on questionnaires encouraged me to continue development to test the SHGs as an adjunct to a traditional section of the class and as the primary means of instruction in an on-line class. Before a full-scale test in Fall 1995, however, one student worked on the stacks for an independent study in the summer. (She had been taking a Shakespeare course by correspondence and had earned an A on her first paper, but she had not worked further for several months. Although this student earned a B in the hypertext course, she finished in eight weeks.)

The comparative sections of the course in Fall 1995 established that the on-line course was logistically possible and academically sound. Students had the opportunity to switch sections at the beginning of the semester, and transfers in both directions occurred, though mainly from the on-line section to the face-to-face section. I was the instructor for both classes: most educational studies show that the greatest variable between classes is the teacher. Besides, I was the only person prepared to deal with both the subject matter and the technology, even with the help of a student technician from my Spring 1994 class. In Fall 1995, the sophomore-level class (L220: Introduction to Shakespeare) used the same hypertext materials as earlier 300-level classes, but set the work in a different set of goals and requirements. The section of the course which met face-to-face employed the SHGs for classroom presentation and to provide makeup for missed classes. The other section used HyperCard hypertexts for seven plays, with students required to use the campus broadband network on-campus and only on a Macintosh platform, but with automatic sending of work to the instructor and automatic printout of student work. On-line students were also required to post at least once per play on a class listserv. On the hypertext materials, questions (some optional and some required) were interspersed in the Lecture and Exploration materials, usually with about eight required responses per play—a great deal of writing and a great deal of responding required from the instructor. (Students in the on-line section averaged four single-spaced pages of writing per play.)
Table 1 summarizes the mode of instructional delivery and course requirements for these sections--shown in boldface for paired sections--(as well as earlier and later sections that used the SHGs in any way), along with a summary of completion rates, grades and student evaluations of the course. Since students in the two sections took the same exams, the only significant difference was the mode of instructional delivery. The grades and student evaluations in the two sections were comparable, suggesting that the on-line students had as academically sound a learning experience as the students in the traditional classroom. However, there were important problems, in my estimation, with both sections. In the face-to-face class, I felt that I was being pushed away from discussion or class activities and toward traditional lecturing because the make-up assignments covered certain lectures and explorations; that is, the supplementary material was organizing the

main instructional activity. In the on-line class, students complained that they worked harder than in a traditional class, and as a teacher I certainly worked harder. Although I knew the minds of my on-line students better, I felt less satisfaction as a teacher, compared to the affect from a traditional class.
Transferring materials from HyperCard to the Web has made the instructional material more accessible to students and has given the opportunity to revise the way opportunities for response are included in the materials. In Fall 1996, I offered the two sections of the class again, but with some instructional material available in HyperCard and some as Web materials (with greater access). In Spring 1998, all materials were on the Web, with one or more questions available for each Lecture and Exploration. The administrative part of the class, separate from (though linked to) the SHGs and on a different server, included: posting of assignments and information as well as a class bulletin board (including separate forums for sub-groups), a grade book and a chat room. The syllabi of the two sections are now significantly different, with activities in the face-to-face class that require in-person group work, and with a group-paper in the on-line class that would be logistically difficult except on-line. Instead of 8-12 short responses, on-line students are asked to give two substantial responses and one group response for each play. The group paper cuts the grading to 20% for the third assignment, since there are five people in each group: one paper to grade per group instead of five individual responses.

I have been willing to cut the number of responses once it became clear to me that simply asking students to write a great deal was not necessarily improving their writing skills. The group project, which called for faith and good will in the first semester of use, is an attempt to include some metacognitive analysis with the writing. Each person in the group gets a slightly different part of the assignment to write about—due at the end of the first week of study (after the posting of the first individual assignment). Two days later the Writer for the group (a job that rotates throughout the group from play to play) posts a coherent draft incorporating the work of all group members; two days later the Editor posts revisions. Others in the group have the possibility of sending their comments via the Bulletin Board, by email, by meeting in a chat room or by meeting in person—before the Writer posts the final draft to the Main Bulletin Board for the class at the end of the second week of study on the play. In this way, students compare their work to that of others who are "on their side"; it is to their advantage to try to strengthen the work of the Writer. All students get the same grade for the response, except for group members who post too late for their work to be used (and they get a D).

It's clear to me now that there is no ideal form, though some are better than others. The SHGs are instructionally sound (according to an outside review I commissioned as part of project evaluation and available on request). Creation of the SHGs is labor intensive. Once the interface was established, it took me about 50 hours per play to write the instructional material and about 100 hours for a trained student assistant to create machine-readable resources; in addition there was debugging of the text. At this point I'm more interested in designing different course matrices than in producing additional SHGs. The html code is easy to adapt or add to (although SHGs will now be available on CD-ROM to cut the time students are required to spend on-line). Perhaps the best use of the SHGs is as modules within a course structure that can be designed by many different teachers to serve different students. The next test therefore involves use of the materials by other teachers: are they willing to adopt the SHGs? are they able to adapt them into their own course goals, student needs and pedagogical philosophy?

Acknowledgments:

The hypertext stacks were created through support of a technology grant from the School of Liberal Arts at Indiana University Indianapolis and the help of students Mollie Bean, Meghan Hicks, David LeFevre, Amy Rosenberg and Alice Wong. Technical help was made available through the School of Liberal Arts' Multimedia Language Resource Lab and the campus Center for Teaching and Learning. Feedback has been through student questionnaires, interviews by student aides with students, support personnel and colleagues at regional and national presentations. An agreement to support the course on an on-going basis has made funds available for external review.
Co-constructing Learning Environments and Learner Identities-
Language Learning in Virtual Reality

Klaus Schwienhorst,
Centre for Language and Communication Studies,
Trinity College Dublin
Ireland
E-mail: kschwien@tcd.ie

Abstract: This paper describes the changing roles of language learners in a collaborative learning environment (MOO). The role of the learner is defined within the concept of learner autonomy, and we use both Kelly’s theory of personal constructs and Vygotsky’s concept of the zone of proximal development to explore it. These theoretical notions, especially regarding learner identities, are supported by some concepts of virtual reality that emphasise its communicative and participatory nature. Finally, I will look at organisational issues that need to be considered when implementing learner autonomy, on the one hand the Tandem network, on the other hand the integration of MOO activities within an inter-curricular framework between Trinity College, Dublin, and the University of Bochum, Germany.

Introduction

Although the recent past has provided numerous computer resources for students, the underlying concepts and aims of language learning software and general notions of how to use a computer in the language classroom have not always had the effect teachers and learners would have wished for. Language learning CD ROMs have been produced at a rapidly increasing rate, and with the increased accessibility of the Internet many Internet resources have adopted the technical and pedagogical limitations of that static medium.

Personal Constructs and Collaborative Learning

The underlying framework for a collaborative learning environment as an alternative to the traditional classroom is partly based on George Kelly’s theory of personal constructs. The second major string of thought is derived from the work of the Russian psychologist Vygotsky and his view that mental abilities are determined by social relationships. Both were used in language learning theories to explore the concept of learner autonomy, developed particularly by David Little [Little 1991]. Kelly emphasises that each individual has different personal constructs that he uses to deal with a learning task: “Different men construe [the universe] in different ways (...) Some of the alternative ways of construing are better adapted to man’s purposes than are others. Thus, man comes to understand his world through an infinite series of successive approximations” [Kelly 1963]. The learner’s view of the world is characterised by a “continuous process of hypothesis-testing and theory-revision” [Little 1991] to make sense of the world around him. When this view of the world requires little or no adjustments of the underlying hypotheses and theories, learning will take place without great difficulty, when it requires substantial changes, learning will be difficult or even painful [Little 1991]. One of the strongest points Kelly makes is that these diverse personal constructs need to be explored and laid open. In language learning terms, learners need to become more aware of their personal constructs and thus of their personal learning process. Another important consequence of this approach is the need for the creation of personally meaningful learning environments and materials, private spaces that can be constructed by each learner. This idea can also be found in Seymour Papert’s theory of constructionism [Papert 1993]. Papert adopted Jean Piaget’s idea that people construct new knowledge from their experiences in the world and added that they do so “with
particular effectiveness when they are engaged in constructing personally-meaningful products" [Bruckman & Resnick 1995].

The other major influence on learner autonomy arises from the work by the Soviet psychologist Vygotsky. His emphasis on social relationships in the development of mental abilities and thus also learning underlines the importance of peer support for any form of learning. Central to his theory is the idea of “the zone of proximal development. It is the distance between the actual developmental level as determined by independent problem solving and the level of potential development as determined through problem solving under adult guidance or in collaboration with more capable peers” [Vygotsky 1978]. David Little mentions that “[t]he developmental learning that unimpaired small children undergo takes place in interaction with parents, brothers and sisters, grandparents, family friends, neighbours and so on. Education, whether institutionalised or not, is likewise an interactive, social process. For most of us, important learning experiences are likely to be remembered at least partly in terms of our relationships with one or more other learners or with a teacher” [Little 1991]. The Vygotskian approach, then, emphasises the need for a collaborative learning environment where learners are enabled and encouraged to interact and give each other support with their language learning, a public space characterised by interaction and scaffolding.

The concept of learner autonomy integrates these approaches: “Essentially, autonomy is a capacity - for detachment, critical reflection, decision-making, and independent action. It presupposes, but also entails, that the learner will develop a particular kind of psychological relation to the process and content of his learning. The capacity for autonomy will be displayed both in the way the learner learns and in the way he or she transfers what has been learned to wider contexts” [Little 1991]. Virtual reality could realise some of these goals, in particular the kind of virtual reality that is presented in the following chapter.

The Framework of Virtual Reality

At the grassroots level, and indeed subconsciously by most users, the Internet has developed a number of communication modes, one of which- e-mail- is probably the one Internet tool that is used most extensively. For reasons of limited bandwidth and computer power, it was not feasible until now to use other communication modes, or so it seems. Unnoticed by many, a number of communities have formed over the last 15 years that have been communicating and collaborating “live” via the Internet. Using at first only asynchronous modes like Bulletin Board Services, mailing lists, and newsgroups, they soon discovered Multiple User Dungeons (MUDs), first developed by Richard Bartle and others in 1979 [Bartle 1990]. Within MUDs, people create characters and engage mostly in adventure role plays, many of which still exist today. Those games were and still are solely text-based, and messages are exchanged by typing them on the keyboard. In the early 1990’s, thanks to Pavel Curtis and others, the MOO (MUD object-oriented) programming language was created. This allowed for the creation of text-based virtual realities where every user with little or no programming knowledge could participate in creating new spaces, “rooms”, and new and sometimes quite diverse social identities. Within these worlds, they could meet and communicate with each other.

Many of these MOO-based worlds were and are quite different from the adventure MOOs. Some MOOs started as social worlds, were people collaborated and worked together rather than slay dragons and monsters or “kill” each other in adventure scenarios. Quite recently a number of educational MOOs were created, where people are encouraged to learn and study together and where teachers and educators can experiment with new teaching tools and/or implement recent learning theories. In addition, the MOO language has constantly been revised and updated. Recent developments include the BioGate interface [Mercer 1997], an Internet-based access system to MOOs where the usual text description of virtual worlds is supplemented by WWW-based hypertext and a VRML interface, all of these as an add-on, not as a replacement of text-based virtual reality. This increased redundancy in mirroring object presentations in three separate programs may sound superfluous, but is a feature that compared to sophisticated 3D chat systems [Roehl 1996] allows for impaired users and different access systems and bandwidths. For language learning these recent developments have led to the creation of a number of foreign language MOOs, where students can meet with target language speakers to improve their proficiency.

I consider the framework of virtual reality very important in the context of language learning. Right from the beginning, the element of communication between participants has always been emphasised.
to create the impression of VR. Chip Morningstar, one of the co-founders of Habitat, today maybe the biggest commercial text-based community, stated that "a cyberspace is defined more by the interactions among the (users) than by the technology with which it is implemented" [Hamit 1993]. Another important element that can be found in several definitions of VR is the active collaboration between participants, the in principle open and extendible nature of VR and its intuitive nature as an interface. This applies to text-based VR as well as VRML that is still evolving as a standard for 3D walkthrough VR.

In contrast to most proprietary systems that use 3D walkthrough systems and allow for chat facilities, the modular nature of the MOO interface (including increased redundancy of representation), its wide distribution and reliability, its participatory nature even for students, and its recent option to integrate all other interactive Internet development tools within a common interface, makes it a powerful tool for any subject area.

Two aspects that I mentioned earlier are vital for language learning. First, the MOO allows for asynchronous communication modes via a built-in system of email and mailing lists, but first and foremost for synchronous communication via the keyboard. As these “live” conversations between two or more participants can be recorded to a so-called log file (an ordinary text file) or to a virtual tape on a virtual tape recorder, they can form a powerful future learning resource. One of the first impressions in the MOO environment, namely that people do not exist on screen unless they act or speak, leads to much higher participation in larger groups. The basis of MOO is, after all, text, or, for language learners, language. Participants can only define themselves in terms of language. Live communication becomes measurable and occupies a vast majority of the textual space compared to object descriptions. In a vital sense, most of the virtual environment that participants experience is built through the use of their own language. This also means that learner identities are created only through written language; personas are created and recreated in collaboration and interaction with their partners Sherry Turkle describes in detail the sociological processes that take place in MOOs [see Turkle 1995]. The permanence of the written medium also allows for another important feature. Compared to modes like audio conferencing or video conferencing, which may provide more natural ways of communicating live, the conversations in MOO are not lost, transcripts can be retrieved and printed out straight after the event. A ten minute bilingual conversation can thus provide a vast learning resource, where both learners will end up having a wealth of personally meaningful material, partly own efforts in the target language that can be reviewed and analysed alone or with their partner and partly authentic target language input by a native speaker, their partner. This shift from an interactively constructed corpus of learning material towards intrapersonal learning reflects Vygotsky’s theory of learning a foreign language: “In one’s native language, the primitive aspects of speech are required before the more complex ones. The latter presupposes more awareness of phonetic, grammatical and syntactical forms. With a foreign language, the higher forms develop before spontaneous fluent speech” [Vygotsky 1986]. By constant analysis of his own performance in the target language and his native speaker's input, the learner approaches the fluency that only arises from external processes having been internalised.

Secondly, the participatory nature of the MOO makes it easy for teachers and even learners to create their ideal learning environment. Creating a room in the MOO is as easy as editing a text in an old DOS word processor. Linking up WWW resources to objects is just as easy, and the extensive help system within the MOO helps any newcomer with obstacles they may encounter. The increasing availability of WYSIWYG-editors for HTML and VRML simplifies the use of more advanced technologies.

For the Tandem language learning project between the universities of Bochum, Germany, and Trinity College Dublin, Ireland, I decided to develop language learning environments in Diversity University MOO (http://moo.du.org:8888), one of the pioneering MOOs and (together with BioMOO) origin of the BioGate interface. Although the MOO is written completely in English (a German alternative is currently being prepared), it provides a rich campus-like environment and features a number of very useful teaching tools that were not yet available elsewhere at the planning stage of the project. I also installed links to foreign language resources in German, French, Italian, and English and a variety of task templates that tandem pairs can adapt to their own needs and work on in self-access time. These facilities only serve as a starting point for students to explore the virtual campus and select their favourite areas for collaboration. If they want to build their own environments, they can quite easily do so, either as private spaces or as public spaces, for example for class projects or presentations. However, it is not sufficient to simply provide these tools for language learners. Maybe the most important factor within a successful language learning partnership is a solid organisational framework.
based on learner autonomy, such as the concept of tandem learning developed within the Tandem Network in Bochum, Germany.

The Dublin Bochum Tandem Project

In 1995, we joined the Tandem Network. The organisation of the Tandem Network is divided into an ever increasing number of bilingual sub nets that on the one hand provide tandem partners through a central agency, and on the other hand allow for group work via bilingual discussion lists. The agency would pair for example an Irish student of German with a German student of English. The major principles behind tandem learning are reciprocity, which implies the commitment to a partnership and the use of both languages involved in equal amounts, and the previously mentioned concept of learner autonomy. For more information on tandem learning, see [Little & Brammerts 1996]. However, during a pilot phase with our students we discovered a number of organisational drawbacks. As a mere add-on to a course, a tandem partnership was only pursued by a small minority of our students. Partners did not respond, and when even a second or third attempt to get a reliable partner failed, students simply got frustrated. Furthermore, traffic from the mailing lists, at least the English-French and especially the English-German lists had become so big that they were receiving from 5 to 15 messages a day, many of which the students considered overwhelming and irrelevant to their own course work. The Dublin Bochum project grew out of the dissatisfaction with our efforts at implementing the principles of tandem learning. While a few tandem partnerships remained, these took on the form of no more than penpalships. Sometimes one language took over (the target language of the more proficient learner), in most cases the exchanges were highly irregular in their use of bilingualism. Learners did not relate the exchange to their language courses and the projects and course work they were involved in. The tandem principle of reciprocity was in most cases not followed. For the 1997/98 project year we implemented a number of changes. Thus we created our own mailing list, dealing only with a number of around 160 students on each side of the project. We also took over the dating of students ourselves, and we started the project by double dating students. Thus every student starts off with two partners, as we expect a fairly high attrition rate (due to the language courses being an add-on course for students of Arts, Science, and Engineering). Students are repeatedly trained not only in the technical know how of email and MOO commands, but also the principles of tandem learning. In particular this means training in error correction and using the authentic target language input from their partner to create a future learning resource for their own needs. All four courses now have a project oriented structure, and the year 2 courses (1 course on each side) have the same four project frameworks. Email and MOO work is an essential part of course work and assessment. Because of the different term structure in Germany and Ireland, only two projects are used for assessment. The first of these, initiating a debate, can be particularly well planned and exercised in the MOO environment, while the second, the project web site, will probably more likely use email exchanges. Throughout, however, students are encouraged to use both facilities to improve their written and oral proficiency.

Conclusion

The MOO environment as presented here offers an ideal solution to the drawbacks of the traditional language learning classroom. According to their individual personal constructs, learners are enabled to create their own learning environments, either by actively participating in the object-oriented virtual reality or by redefining their identity as learners through interpersonal contact with the target language culture and its speakers and analysing their new place within this relationship. The double role as learner and expert in an environment characterised by learner autonomy allows them to take part in the immediate and personally meaningful creation of collaborative learning material that is by definition also meaningful for their partners.

Abstract: The Internet infrastructure is presented as an ideal training medium distributing self-directed, just-in-time, information waiting to be transformed into newly-constructed knowledge. This training environment becomes viable when pedagogical strategies supporting learning outcomes are explicitly implemented. In this paper, we present various strategies associated with on-the-job software engineering training over the Intranet. We believe that this particular Internet infrastructure has the possibility of not only developing new individual knowledge skill sets but also creating and identifying new communities of Web-based learners, regardless of domains.

Keywords: pedagogical strategies, Internet Technology, Web-Based Training, Software Engineering Education and Training, Just-in-Time training, Collaborative Training, Learning by Doing.

Introduction

According to [Davis 94], knowledge is doubling every seven years and technical fields that are knowledge dependent are critically affected by this phenomenon. A great part of what students learn in their first year of College is obsolete by the time they graduate [Davis 94]. This justifies not only the incipient existence of continuing education but also the need to design and develop innovative, on-the-job training strategies associated with life-long learning skills. In this context, Internet technology and tools can provide a less costly and more efficient alternative to on-going training and continuous education. We believe that in order to take advantage of this technology one must concurrently adapt existing strategies with new methods of apprenticeship capable of empowering and sustaining the act of learning.

The emergence and ready availability of Internet technology is providing software engineers and educators with new tools and innovative means and ways to communicate and disseminate information as well as develop resourceful, constructive and outcome-driven training strategies. These variables have the potential to either be exploited internally by companies developing their own corporate Intranet or externally within an extranet environment targeted to their client base.

There are many ways of utilizing the Internet's infrastructure to improve the conditions of training and education [Brunner 96, Malay 97]. We list a few, in part:

- Records the level of understanding, prior knowledge and competencies associated with the participating end-users.
- Collectively shares and exchanges one's individual efforts and strategies identified with knowledge acquisition.
- Makes available pertinent resources identified with self-directed and just-in-time learning.

Examples of Internet Technology-Based Environments

At its most basic level, the Internet infrastructure is viewed as a platform that distributes information and supports communication. Given these two services, we can develop an effective intranet/extranet environment for distance software engineering training. [Tab. I] presents an example of this basic training environment.

| HTML Resources          | - Overheads
|                        | - Syllabus
|                        | - Objectives
|                        | - Assigned readings
|                        | - List of work to accomplish
|                        | - Excercises
|                        | - FAQ
| Links to WWW sites     | - Bibliographic References
|                        | - Additional information
|                        | - Other Courses
| Discussion Group       | - Questions/Answers
|                        | - Trainer's Comments
|                        | - Student Ideas
| Electronic Messaging   | - List of available experts to consult
|                        | - Registered students in the course
|                        | - Personalized Questions/Answers
|                        | - Training follow up
|                        | - Corrected Exams
|                        | - Training Overview
|                        | - Personal Information

Table 1. Description of an Online Courseware Environment

This environment allows students to freely browse through different kinds of learning resources used to either achieve a greater understanding of the lesson or receive further information concerning the lesson.

Current plug-ins and middleware extensions facilitate the development of advanced training environments. From a technical perspective, these environments are characterized, in part, by highly interactive and portable learner interfaces and by a gateway that enables a Web browser to access external databases and tools. This technical integration can now lead us to promising learning outcomes supported by a whole range of pedagogical strategies.

As an example, we have developed an advanced learning environment that identifies to object-oriented developers, their training needs. It accomplishes this by classifying the strong and weak areas of their knowledge concerning object-oriented technology. The system addresses questions such as:

- What does a software developer know about an object-oriented environment?
- Which concepts should he/she focus his/her efforts in order to learn effectively and efficiently?
- How does one identify a developer with the best resources in a team in order to accomplish a certain design/development activity?

The GAA [Khuwaja-96] and UKAT [Desmarais-93] tools developed at the Computer Research Institute of Montreal (CRIM) support the environment. UKAT (User Knowledge Assessment Tool) uses a state-of-art user knowledge assessment method to create a user profile of the mastery of a subject domain. GAA is a Web-based learner interface that uses the UKAT to personalize the distribution of resources stored in a database. The various questions used by UKAT are part of the database.
Pedagogical Strategies

Integrating information and resources into an on-line training environment requires an analysis of apprenticeship skills. This analysis helps to define an appropriate training pedagogy [Seffah 97]. Studies have shown that on-line distance training becomes more efficient with end-users engaging in at least one face to face point of contact.

Our opinion is that an Internet-based learning environment must explicitly support a cognitive technology that encourages the student to (1) become a confident individual singularly organizing and retrieving information and data as well as (2) collaborate with other participants in search of common virtual learning outcomes. Cognitive technology (CT) brings together identified cognitive tools with Internet/Intranet Technologies and Tools. We construct cognitive tools to help us negotiate learning transactions to arrive at some kind of meaning and internalized understanding of the proposed content. As mediated devices, cognitive tools also assist the end user in the transfer of knowledge by encouraging and fostering cognitive activity that is the antithesis of rote learning and the passive retention of material. The Web is an ideal medium for this kind of cognitive apprenticeship because it can simultaneously support singular transactions as well as synchronous and asynchronously interactions with other learners. The following principles apply:

- Learning by sharing information and resources
- Synchronous and asynchronous collaborative learning
- Self-directed learning
- Learning by doing
- Self-assessment

Learning by Sharing Information and Resources

It is important to encourage the student to share and compare his/her solutions and problem-solving capabilities with other students. We accomplish this by:

- Presenting the student with contextualized resources and information.
- Extending those resources and information leading to an acquisition of knowledge.
- Communicating this augmented knowledge and understanding with other participants within the course parameters.

As an example, the inclusion of a tree browse applet within our online courseware environment will assist both course developers and students to generate and organize the overall course content as well as add resources.

Synchronous and Asynchronous Collaborative Learning

[Guzdial 96] indicates that collaboration in learning activities can facilitate both successful performance and reflection for learning:

1- Groups can solve more interesting and complex problems than can individual working alone.
2- Students working in groups need to articulate designs, critiques, and arguments to other group members, encouraging the kind of reflection that lead to learning.

We facilitate both synchronous and asynchronous collaboration, since the former lends itself to planning and brainstorming, and the latter lends itself to reporting experiences and off-line reflection.

Self-Directed Learning
Students should be involved not only in structuring their own learning but also sharing the control of their learning activities through discourse and reflection. In this context, we provide each end-user with the opportunity to make decisions concerning the possible re-organization of the curriculum according to his/her own self-paced understanding of the instructional objectives, access to the materials, demonstrations and problems.

Learning by Doing

It is important to integrate several kinds of resources that can support the requisite training needed to accomplish certain tasks. For object-oriented training, pedagogical design patterns [Manns 96] and scaffolded examples [Rosson 96] are examples of such resources. A pedagogical pattern essentially describes an abstract design template from which specific solutions can be generated, so those later designers don't have to start from scratch when they come across this problem again. Scaffolded examples are sample problems of realistic size whose complexity is gradually revealed in steps that leverage and reinforce the intrinsic structure of the problem-solution process. Scaffolding enables learners to build their understandings through a process of successive elaboration and integration.

Self-Assessment

It is important to understand the outcomes before we design and develop self-assessment strategies. A priori, we need to anticipate and identify the end-user's unique and self-paced exploration of the given learning resources and then situate their need for insight, alternatives and new directions by providing embedded questions, and correct, summative self-evaluation instruments. Once a learner profile has been established, we can confidently design the assessment strategies.

The following illustrates one approach to a test/diagnosis mode related to the advanced environment presented in section 2. It provides opportunities for self-assessment through the administration of multiple choice questions, varies quizzes and Likert style questions. The results of the assessment are available via a histogram applet [Fig.1]. When the student double clicks on his/her particular column, a pop-up menu appears on the screen to display a list of a value added resources that will reinforce the students' apprenticeship.

![Figure 1. Presentation of Results of an Assessment Process](image)

Conclusion

The pedagogical strategies that we have identified should seriously be considered by corporations and institutions wishing to implement an online training environment. However, identifying and implementing such strategies is a large and complex undertaking requiring many critical milestones. In this paper, we have described several strategies.

Web-assisted Teaching - A Geomatics Experience and Perspective

Dr. Jie Shan
Department of Technology, University College Gävle, SE-801 76 Gävle, Sweden
Tel. +46-26-648845 Fax. +46-26-648828 E-mail: jsa@mentos.hgs.se

Abstract: This article addresses the experience in the Web-aided geomatics teaching and prospects its potentials. A brief introduction is made to the education background and the environment involved in teaching activities. Experience in Web-aided geomatics teaching is discussed in detail. Creative assignments for publishing geographical information and its 3-D visualization in the Web environment are addressed. Administrative issues, sharing geographical data and establishment of a universal Web site for geomatics education with participation from industrial domains are prospected.

1. Introduction

The advent and world wide proliferation of the Web (World Wide Web) enables teachers and students to be in a common platform to communicate, either on-site, locally or globally, in the whole procedure of education [IET, 1997]. Through the Web, lectures notes, exercises, lab instructions, reference materials and further readings can be made available to students [Stemler, 1997; IET, 1997]. In addition to this communication function, the Web is also served as a powerful and unique tool to improve the quality of demonstrations, explore and explain phenomena on-site and simulate the dynamic process of events [Bergeron and Bailin, 1997; Stemler, 1997]. Moreover, the Web can be used as a development platform for undertaking labs, assignments in various teaching subjects.

This article presents the experience and results of Web-assisted teaching in geomatics courses at the University College Gävle, Sweden, and prospects its further development. Section 2 makes a brief introduction to the background of the geomatics education and its implementation. The experience in teaching is then discussed in detail in Section 3. Two creative assignments for students, namely publishing geographical information and visualizing geospatial data in three dimensional (3-D) mode, both in the Web environment, are addressed. Perspectives on further development for effective Web-aided geomatics education are given in Section 4. The concluding remakes are in Section 5.

2. Background

Geomatics is the science, art and technology to acquire, process, analyze, depict and distribute geographical information which may take various multi-media forms. Currently, under the curriculum for geomatics (surveying, mapping and geographical information system) subject at the University, two courses, namely digital mapping and visualization of geospatial data for undergraduates are designed and given with the assistance of the Web.

In order to make full use of the Web potential, the teaching activity is conducted in the following way. In addition to lecture notes and reading materials, labs and assigned projects in accordance with the courses are also based on the Web. Netscape Communicator™ and VRML (Virtual Reality Modeling Language) are used as application programming interface for the assignments. The publishing of geographical information on certain themes based on clickable maps are conducted with Netscape Communicator™ and Mapedit™. VRML is used for developing 3-D interactive visualization for terrain and urban models. Cosmo Player™, VRwave™ and WorldView™ are chosen as VRML browsers on the Web.
[Fig.1] shows the system configuration for Web-assisted geomatics teaching. Approximately 25 students for each course have the option to use PC with Windows 95 or Sun Sparc Station 20 in two groups. Support from IT (Information Technology) foundations is granted. National and international cooperation with universities are undertaken and expected to strengthen and expand further. The persistent support and encouragement in using IT for multimedia education from the University initiated the implementation of this program. Without the exceptionally good IT equipment and the well-maintained connection, the entire educational program would not have been a success. During the courses, students can access to the Internet through PCs or workstations at any time with his unique account.

3. Experiences

3.1 Distributing teaching materials

The Web is firstly used as an effective way to distribute lecture notes. Students can therefore read them on-line. In particular, the Web provides an innovative way showing and accessing geographic maps, images, as well as dynamic pictures. With this tool, the lecture notes can be organized and prepared in a consistent way. Its aesthetic effect is greatly improved comparing to photocopies of books or overhead transparencies. Highlighted points are easily marked by using different fonts, bolded text and distinct colors. Teaching materials collected in the Web environment can be shown on-site directly via screen projector.

All teaching materials are integrated on one site. Just by clicking links the complete documents are then available to readers. Moreover, references and further readings on the Web are also organized and pointed by meta-pages, that provides students with a wide space of free thinking and an opportunity to extend their knowledge on neighboring subjects.

3.2 A self-learning site

In addition to lecture notes and specified reference materials, senior students use the Web as a tool to acquire current status in geomatics. Web sites for similar courses in other universities in the world are requested to visit where students get seminars, summary of historical developments, research reports as well as lecture notes and tutorials. Through the Web, students are also able to visit various products of well-known firms in geomatics industry. It is shown that this function is extremely helpful when students are asked to design and perform their works independently. Surfing the Web has played an essential role in completing creative assignments. In this way, one can search and acquire related geospatial data, information and development tools, such as free- or share-wares.
3.3 A platform for assignments

The innovative field in geomatics where the Web is being successfully used and still has prosperous potential is depicting, distributing and even manipulating geospatial data through the Web. Two types of creative assignments within the courses are conducted in the Web environment.

One assignment is devoted to publish thematic geographical information based on clickable maps in the Web environment. Students have the freedom to choose their own interests though suggested topics are given by the lecturer. Heretofore, topics for this assignment have covered information about tourism, national mapping coverage, national parks, municipality, distribution of universities offering education in geomatics, distribution of world culture heritages. All products are based on a properly designed clickable map. Detailed information will show up when the highlighted spots on the map are clicked. Hyperlinks may further guide the readers to other remote or local sites for more relevant information. Multimedia and hypermedia functions of the Web make this publication compatible in all aspects with conventional thematic maps. Moreover, Web publication is uniquely characterized by human-computer interactivity which is non-trivial without using a Web browser.

Another assignment is to visualize geospatial data in a 3-D mode on the Web. This includes shaded perspective view of digital terrain model, 3-D city model of the local area. VRML is used as the development tool for this purpose. A panoramic view of the virtual reality is displayed by browsing the Web page. Again, this visualization technology is characterized by human-computer interactivity so that the realistic and immersed effect is reached. There are several available tools to browse the VRML file. VRwave™ is chosen as the browser on Sun Workstation. For PC users, Cosmo Player™ and WorldView™ are used.

Since all the workstations and PCs are network connected, various desktop tools for graphics and image processing and editing can be used together with Web editors without troublesome data transfer and format conversion.

A final Web-based on-site demonstration is arranged for students to report their works in the class.

4. Perspectives

4.1 System administration

In order to make the Web-assisted teaching activity possible and effective, the school should be well equipped with sufficient advanced hardware (Workstation and Pentium PC) and software (Windows 95 or later) platforms and have them well connected to the Internet. Moreover, the system server is expected to work reliably in a wide bandwidth access to the Internet. Only in this way can be ensured the access to the local and global documents, especially to a large amount of graphical data, in marginal waiting time. Regular upgrade of system packages and plug-ins are also essential.

Students should be able to print out lecture notes and primary reading materials through the intranet. An administration mechanism is expected to be operational in order to examine the amount of free output printing from each individual account for each course.

In addition, sufficient input and output devices (especially for graphics and images) will be an indispensible part in the environment for geomatics education.

4.2 Geospatial data source

This is a unique issue in the practice of geomatics education. Only with sufficiently available geospatial data can be effectively operational the Web-based geomatics education. So far, only a few sites can supply limited sample data. The lack of consistent and comprehensive geospatial data thus remains a key issue for future practice. A global and regional co-operation is highly expected to provide sample data which will be mainly used for the education in 3-D visualization of geospatial data in the Web environment. For this end, contribution and coordination from industrial domain are mostly demanded. Existing consortium or the one yet to be formed may have university participants as its members so that a close industry-university cooperation can be established.
4.3 A universal Web site

Though geomatics courses are taught in many universities around the world and some excellent sites for individual courses are available, a universal Web site is expected to be established and maintained. In addition to collecting related Web sites, it will be served as a forum for exchanging education experience, publishing assignment and project reports, distributing test data and results. On this Web site, programs developed with platform-neutral languages and running in the Web environment will provide local or global students with a uniform and standard learning environment. Moreover, this will make possible the real-time distance-learning through running the same programs and operating on the same data set simultaneously. For this end, international societies and organizations in various subjects of geomatics are expected to play a substantial role together with the possible participation from industrial sector.

5. Concluding remarks

The advent and world wide proliferation of the Internet technology offer us an innovative tool in the education of geomatics, either on-site, locally or globally. The Web can be used as a platform for teacher-student communication, the access to outside sites, understanding the recent development in academy and industry. Besides, publishing thematic geographical information and 3-D visualization of geospatial data can also be conducted in the Web environment as creative assignments to the students. Primary experience and results indicate a challenging potential for refreshing existing courses and developing relevant courses. Cooperation between academic and industrial sectors are expected to establish a universal Web site for geomatics education, including exchanging experience, distributing test data, publishing project results and real-time distance-learning.

Abstract: This paper describes how we are exploiting the potential of interactive Web media to support a central part of academic life: the publishing, critiquing, and discussion of documents. We are as interested in supporting school and university students critiquing course texts and publishing their essays, as in professional scholars and researchers engaged in journal peer review and publishing. We question the replication of “papyrocentric” models which do not stop to question whether the new media make possible new forms of document and new modes of working. We then describe the design principles underpinning the environment for reading and critiquing Web documents that the D3E Publishing Toolkit generates, and illustrate its application to an educational multimedia e-journal, and to tutors and students in a distance learning scenario. We conclude by pointing to directions in which future work could develop.

Documents in Academic Life

The emergence of the internet, in particular the World Wide Web, have potentially far reaching implications for academic life, because documents mediate the work that students, tutors and researchers do everyday. This observation is at one level banal and not particularly helpful: documents mediate the established work practices of every organisation. However, taking this simple observation as a point of departure, a detailed understanding of the work that documents support, the contexts in which they are embedded, and the processes that give them their true significance in the communities that read and write them, opens up a spectrum of possible uses for new technologies (cf. [Brown & Duguid, 1996]).

In this paper, we use the term “publishing” in the broadest sense of a student, tutor or researcher making a document publically accessible, in this case, on the Web. Our approach to analysing how documents and publishing can change is best illustrated by examining what are arguably the central activities in academic life, namely, publishing and critiquing documents. The intellectual ‘cut and thrust’ of debate between peers as they contest the ideas in a document is a core skill that we seek to foster in students, and which obviously needs to be recognised and supported within professional scholarly communities. As members of these communities become increasingly distributed in time and space, how is this to be facilitated? In conventional teaching situations, such debate normally occurs amongst students when they are brought together in a moderated tutorial context; this is difficult in distance educational contexts. When the object of discussion is a document, we need more elegant environments than an e-mail list in order to easily refer to different parts of a document, and conduct parallel streams of discussion. In the context of a journal, such debate is also missing between authors, reviewers and peers with the exception of the few journals which publish commentaries and replies (albeit after a long delay, and with poor support for continued discussion following publication).

Our particular focus is therefore on document-centred discourse. In the following sections, we explain the design principles underlying D3E (Digital Document Discourse Environment), and illustrate how it can support students, tutors and researchers in publishing and debating documents. We conclude by considering promising directions for future work.
Paper-Based Print and Scholarly Work

From surveying the current state of the field, our conclusion is that most e-journals serve only to demonstrate the extent to which thinking is still "papyrocentric" (a term coined by Stevan Hamad). Traditional documents are simply disseminated digitally, and traditional activities are facilitated by established technologies such as e-mail and document/journal management systems. The central processes and products of scholarly work have gone unquestioned. This can be ascribed on the one hand to inertia amongst publishers who fear the loss of markets and are unsure of their role in digital publishing, and on the other to inertia in the paper-based academic culture, where traditional print literacy and genres dominate (understandably), literacy with new media (e.g. HTML, interactive and time-based media) is not yet widespread, and the pressure to publish in established journals is intense.

Papyrocentric deployment of interactive media does not seem to us, therefore, very imaginative. However, for the first time, the dominant influence of print on our conceptions of documents, publishing and associated scholarly processes is being seriously challenged by the convergence of the Web and communications tools. In such transitional times as these, constraints previously taken for granted are recognised as merely contingent on paper, and established modes of working are no longer as natural and obvious as they seemed. Such times provide the opportunity for radical and creative reflection on why we do what we do, offering the opportunity to keep the best properties of paper, but to explore alternative scenarios that transcend papyrocentric practices.

Design Principles Underpinning D3E

D3E is based on extensive research into how hypertext systems can support critical reflection and the analysis of arguments in writing and software design. Over a period of about six years, we have surveyed, prototyped and evaluated the usability and effectiveness of systems designed to support the representation and analysis of arguments to justify decisions, and the smooth switching of attention between building an 'artifact' (whether a written document, CAD design, or program), and reflection on it [Buckingham Shum, et al., 1997][Sumner, et al., 1997].

From this work on pre-Web hypermedia systems, we formulated several design principles to guide the development of D3E:

- Avoid over-elaborate discussion structuring schemes.
- Integrate document media with discourse.
- Redesign work practices to emphasise discourse.
- Support the new practices with tools.

Principle A: Avoid over-elaborate schemes for structuring comments and discussions. If users classify their document annotations or contributions to an online discussion, greater computer support can be provided. For instance, one can search for all Theory comments that have Contradictory Evidence, if those categories have been defined and used. Numerous schemes have been proposed for structuring discussions (e.g. [Conklin & Begeman, 1988][Turoff, et al., 1991]). In the systems we have studied, discussion schemes have required users to categorise contributions as issues, positions, comments, pros, and cons. Schemes of this sort, however, run the risk of burdening people with excessive representational overhead by forcing them to categorise their ideas before they are ready to, or the scheme is too restricted to capture the nature of a subtle comment. Studies from a wide range of work contexts show that at least initially, users are often unable or unwilling to structure their ideas in new ways, because the effort is too great for the perceived benefit [Shipman & McCall, 1994][Shipman & Marshall, 1994]. The answer is to allow a user community to evolve a richer scheme from a simple one as they deem it worthwhile (this may be in ways that cannot be predicted by an outsider).

Principle B: Computational tools must tightly integrate documents with comments and discussions about them. Many systems place documents in a different application to where discussions about them take place (we see this with e-mail discussion lists for Web e-journals). This separation hinders users from quickly accessing relevant comments when they are most needed and makes it hard to add contextualised comments. Likewise, tools should tightly integrate the textual parts of documents with any computational parts. Research in design support tools has shown that users need to easily bridge the separation between different representations of the design, and between representations and associated rationale [Fischer, et al., 1991].

Principle C: Work practices must be redesigned so that structured annotations and discussions are integral to the task. Studies show that people often do not contribute to discussions because it is perceived as extra work
over and above what they are already required to do [Grudin, 1996]. Successful approaches have redesigned work practices to make contributing to a discussion integral to the overall task being performed [Terveen, et al., 1993]. Others also advocate ‘seeding’ (providing some initial contents), arguing that people find it easier to contribute to a discussion site with content designed to promote debate, rather than starting from scratch [Fischer, et al., 1994]. In a course setting, this means providing the right kind of motivation to students to participate in group debates, and seeding the discussion area with appropriate structures and questions. In a journal online peer review setting, this means redesigning the review process to require electronic threading of reviews into a shared space, changing the traditional roles of editor and reviewer, and seeding author-reviewer discussions for readers to build on.

**Principle D: Tools are needed to support the new work practices.** Many people may lack the technical skills, time, or inclination to engage in hand-crafting new digital document forms. Support is needed for automating the tedious and error-prone parts of the document creation process and to make it accessible to non-technical participants. Tools should be designed to make a good first approximation and then allow for humans to refine and correct the tools’ output. The challenge is to create tools that are supportive, yet do not hinder the formation of new practices. Our goal is that the D3E Publisher’s Toolkit will enable students, tutors and researchers (as well as professional publishers) to easily publish Web documents in a well-designed discussion environment, without having to worry about the intricacies of HTML.

**Publishing and Critiquing Web Documents Using D3E**

The D3E Project began through the design and publication of the *Journal of Interactive Media in Education* (JIME), which as we describe elsewhere [Sumner & Buckingham Shum, 1998] is a next generation e-journal that supports web-based peer review and interactive media embedded in articles. It became clear that the HTML mark-up effort that this involved had to be partially automated to make the publishing of such complex Web-sites tractable. It also became clear that there are many contexts where documents need to be discussed in different ways, by different populations. This motivated the requirements for a generic publishing toolkit which could be used to generate different kinds of document-centred discussion sites. The concept of a tailorable environment was conceived, with the project’s research goals being to better understand the factors that make discussion and debate about media-rich Web documents intuitive and effective. We are concerned therefore with the whole spectrum of design issues, from Web hypermedia functionality and usability [Buckingham Shum & McKnight, 1997], to the computational, cognitive, and cultural issues that determine the uptake of such novel technologies by professional communities.

The D3E Publisher’s Toolkit is the result, which generates an environment for reading and discussing Web documents. The toolkit provides a simple user interface via which the user (who does not need to know any HTML) fills in a form describing their document. First, one selects the style of publication to be generated (e.g. “Paper for student assignment”) which determines the look and feel of the site, and then provides the relevant details of the document’s title, author, etc. [Figure 1]. On hitting the “Go” button, the toolkit generates the HTML files for the environment whose key features are shown in [Figure 2]. The discussion environment is a tailored version of HyperNews [NCSA], but discussion structures in other Web-based systems could be generated. Figures 1 and 2 illustrate an article being published in JIME.
Figure 1: The D3E Publisher’s Toolkit provides the tutor with a form to select the style of ‘publication’ (a student assignment), and a form for the article.
A Student Assignment Scenario

An assignment on a distance learning course requires students to critique a conference paper which their tutor has placed on the course Web site. Students are required to construct a critique of it from a number of different perspectives. After the submission deadline, the tutor then allows everyone to see each others' critiques. In a follow-up exercise, the students and tutor discuss their

different interpretations. The students then write a summary essay which they publish as a Web document with links back into the group discussions as evidence for their claims.

Let us imagine that the tutor has downloaded a paper from the Web and obtained clearance to use it for a teaching exercise. She has generated an interactive site from the toolkit, as described above. When a student logs in to the Web site, they are provided with a structured area with headings to guide the construction of their critique.

There are general headings which the tutor has defined as important issues to consider:

- Relationships to other articles in this module
- Does this adopt a modern or postmodern perspective?
- Summarise the article for a web designer in 100 words

These are followed by headings for each section in the article, under which section-specific comments can be made (see [Figure 2], points 8 and 9 to see how these are displayed).

After the submission deadline, all students are sent the address of the shared discussion space which has clustered each student’s private annotations under the three discussion headings [Figure 3]. The students can now view and comment on each other’s analyses in the second phase of the assignment. All of the students are automatically subscribed to this discussion, which means they are sent e-mail copies of new comments. They can also submit responses to the Website via e-mail, which students with slower Web connections find particularly useful (standard features of HyperNews). In the final stage, the students compose their summary essays. Most of them do this using their favourite wordprocessor, convert it to HTML, and then make the links to the relevant commentaries that they are using as evidence to back up their arguments.
Students' individual annotations are pooled under each heading:

- Relationship to other articles in this module
- Does this adopt a modern or postmodern perspective?
- Summarise the article for a web designer in 100 words

Students begin to respond to each other's contributions:

Conclusion and Future Work

Given the ubiquity of document-centred work, D3E is also useful in contexts other than academic debate. We see supporting collaborative discussion of documents as important in the broader context of knowledge management in organisations, since documents acquire significance from the debate they provoke [Brown and Duguid, 1996]. D3E is being trialled within the Open University as a structured intranet environment for committee discussion documents. D3E has also been used to publish a national discussion Website to debate the recommendations of a government inquiry into the future of higher education [Dearing, 1997]. Comments and debate are organised on a recommendation-by-recommendation basis, to facilitate the pooling of related material in constructing responses to the inquiry. Elsewhere, we describe D3E's use to mediate discussion following a live webcast, in the build-up to a face-to-face conference [Sumner & Buckingham Shum, 1998].
Future work will address our ability to analyse the usage of D3E generated sites in more detail, development of a client-server version of the toolkit (to help students publish their own documents such as essays, for discussion by peers), richer encoding of Web documents, and the emergence of new genres in scholarly publishing.

The latter two issues are related in an interesting way. It has been argued that in contrast to static, predominantly hierarchical documents, interactive hypertext networks make possible important new genres of writing [Landow, 1992][Kolb, 1997]. By extension, the Web could form the basis for new genres of scholarly writing and argumentation. In our own work, we are extending our analysis from support for discourse about a particular document (as D3E does at present), to support for interpretation of a document in relation to other work [Buckingham Shum & Sumner, 1997]. We are investigating the feasibility of enriching Web documents in ways that support searches for conceptually related documents. Approaches to this problem include HTML metadata [W3C, 1997], and shared, Web-accessible ontologies [Domingue, 1998]. Such a representational scheme could form the basis not only for more powerful Web searching, but for generating graphical views of the research literature [Chen, 1997], scientific argumentation, or concept maps [Gaines & Shaw, 1995].

To conclude, in the rapidly evolving world of the Web, it is a constant challenge to know how to use the technology effectively. We have argued for a strongly user-centred approach to understanding what we want the Web to do for us. We have described how we are interpreting the challenge of designing appropriate support for publishing and critiquing documents, a form of work that dominates academic life. We have summarised the design principles underpinning the environment for publishing, reading and critiquing Web documents that the D3E publishing toolkit generates, and illustrated its application to an educational multimedia e-journal, and for tutors and students in a distance learning scenario.

Acknowledgements
The D3E toolkit and environment are implemented by Malcolm Story and Mike Wright.

Abstract: This paper presents a set of ideas designed to inform the integration of non-spoken audio in environmental education software. These ideas were developed, implemented and tested in the context of an educational project, named "Sounds of Serralves Park". The main goal of this project was to develop a multimedia application where children could learn about sounds in ecological systems. The design of this multimedia application was thought to offer sensory experiences that are not possible in the field, and also to support and complement meaningful explorations of the Serralves Park (Porto, Portugal) soundscapes.

1. Introduction

"Sounds of Serralves Park", the educational project presented in this paper, started in the context of a research focused on the use of ecological sounds to improve the interaction between learners and the software representations of environmental systems. This research made it clear that there is a need for learning environments that offer opportunities to discover, to hear and to interact with sounds in environmental systems. That is why it was decided to develop an educational project where multimedia potentialities were used to support and complement field explorations of soundscapes [Schaffer 1994]. The central aim of this project is the creation of a multimedia application that would support, in an integrated way, the development of sound awareness, the development of sound literacy and the learning of sensory ecology.

Nowadays, sound is widely used to improve edutainment worlds, such as movies, multimedia products and entertainment parks. In all these environments it is possible to find educational and entertainment activities that contribute to the users' engagement and to their ability of being aware of the sounds used. In movies and in entertainment parks public is invited to enjoy the engagement and fun factors of special sound effects and to understand how those effects were created. The number of available documentaries about the making of different films is increasing, and entertainment parks, namely the ones whose themes are movies, are also exploring the added value of enabling visitors to add sounds to images (just like Foleys) and to see the immediate effects.

In environmental education multimedia products, it is possible to find impressive examples of the integration of sound:

- It is relevant to mention Dorling Kindersley's Eyewitness Virtual Reality: BIRD where users can explore sounds in original activities such as listening to bird songs and calls, while learning about their characteristics and multiple ecological functions. These activities also include the observation of drawings, photographs, graphics (presenting sounds' characteristics) and videos.
- Edmark Corporation's Sammy's Science House is an educational application for young children, where the use of sounds contributes to children's engagement: they are funny and consistent with the global
metaphor (a house) and with children's worlds. The sounds are also used to improve user's feedback and to convey information. For instance, in the learning activities of the Weather Machine, non-spoken sounds are very helpful to understand the different elements of weather (such as the wind and rain) and their different intensities, making it easier to solve related problems.

- In Microsoft Oceans, sound effects are used to simulate oceans' soundscapes, contributing to the user's engagement and awareness. This product presents a learning activity that invites users to match different sounds with images of different animals.

Many other environmental multimedia products integrate sounds in the user interface to improve usability and learning, however this brief analysis aims to illustrate different strategies concerning the use of sound in environmental education multimedia interfaces.

The integration of sound dimension in environmental education can contribute to develop environmental sensibility and environmental understanding which are two main goals of environmental education. Consequently, the development of a more careful and critical listening ability [Schaffer 1994] should be an important concern in the design of soundscapes explorations. It is important that learning strategies designed to explore soundscapes include different ways of listening [Chion 1993]: to invite children and educators to identify the sources of sounds, to perceive their characteristics and to learn what a sound means in its environment. It is possible to hear different sounds in different points of an ecosystem (for instance on the ground, on the top of a tree or in the water) or at different parts of the day. Therefore, children and educators should also be invited to notice that there are different listening points [Chion 1992] in an environmental system, which influence the way listeners perceive sounds.

Understanding the importance and functions of ecological sounds is a subject of sensory ecology and ethology. While sensory ecology draws attention to the fascinating questions concerning the way organisms acquire information about their environment, ethology studies animal behavior in their natural environment [Dusenbery 1992]. These two domains are becoming increasingly important sources of contents and strategies for environmental education.

2. Designing Ideas to Catch Sounds in Serralves Park

"To catch sounds in a Park" is the meta-concept used to develop an integrated set of design ideas. These ideas were developed in order to be implemented in a prototype and tested with children in the context of environmental education activities.

2.1. "There's a World of Sounds Out There..." : Exploring Serralves Park to Design a Multimedia Application

Landscapes and their ecological sounds have unique characteristics in the real world. That is why, in the context of environmental education, children should be invited to visit ecosystems, as much as virtual experiences can never substitute real explorations. Multimedia products and audio-visual representations can contribute in an extraordinary way to complement and improve these real explorations, making it easier to discover the different dimensions of ecosystems [Silva and Silva 1995].

In multimedia products, animals can produce sounds whenever the user wants and their intensity is also controllable by the user. Multimedia applications can also make it possible to travel almost instantaneously between sounds and images, following a line of thought, or to catch sounds in the context of interactive learning experiences. These potentialities support better and deeper explorations of ecological systems if multimedia products are designed on the basis of real systems. That is why field investigations should take place at an early stage of the design of multimedia products, and should integrate audio-visual recordings as well as the related knowledge of experts.

The "Sounds of Serralves Park" educational project is, currently, the result of the collaboration between the Environmental Systems Analysis Group and the Serralves Foundation. Serralves Park, one of the main green
areas of Porto (Portugal), has been developing an intensive environmental education program. This program is based on the ecological diversity of this Park and it offers the opportunity to develop the "Sounds of Serralves Park" project in close collaboration with children, educators and environmental experts. This project is specially designed for children from 9 to 13 years old, however educators are also included in the target population. "Sounds of Serralves Park" multimedia application, designed in the context of this project, integrates landscapes and soundscapes from the Central Garden, the Rose Garden, the Pigeon House, the Wood, the Pond and the Farm. The sounds and images, included in the application, resulted from the collaboration with the technical staff of the Serralves Foundation. Sounds, such as the bird chorus and the ones made by visitors' steps on the different grounds, recorded in the Park can be considered soundmarks [Schaffer 1994].

Based on the way that aural and visual dimensions of ecosystems are related in reality, sounds should be linked to images in multimedia products. This will allow children to discover soundscapes, while exploring landscapes: multimedia products should offer the user opportunities to analyze landscapes, to discover potential sources of sounds, to hear sounds of hidden sources and to relate different sounds to their sources in different contexts and situations.

Catching sounds, like any other way of playing with sounds in multimedia products, makes it necessary to make sounds visible. Sounds should have a visual representation (a familiar one is an icon of a loudspeaker) in order to be manipulated by users. The design of icons, symbolizing the sounds and representing the tools to manipulate them, became an important concern of this project.

2.3. "To Catch Sounds, Follow the Line of Your Thought": Designing a Sound-Web

To catch sounds children can walk around in a park, while exploring the ecosystems and looking for potential sound sources. However, a multimedia application can also make it possible for children to travel between sounds following a line of thought, whenever they wish. A sound-web can support navigation between related sounds, the same way an image-web usually supports navigation between images. In this work, it was decided to design and implement a sound-web that allows users to navigate between animal sounds with related ecological functions. The central aim of this idea is to create an integrated and efficient way to discover sounds in the Park.

2.4. "Let's Talk About Sounds!": Contributing to Sound Literacy

An early stage of "Sounds of Serralves Park" project included a program of two meetings with children (one group of 4 and another one of 5 children), informal talks with 30 children, 22 students from teachers training schools and interviews with 5 environmental educators. During this program, participants were invited, using different strategies, to talk about ecological sounds. This experience was useful to confirm that they are not very familiar with many of the words used to refer to the different animal sounds. However, it was clear that talking about ecological sounds is a motivating invitation. It was interesting to verify that the interest in learning about sounds was visible and sometimes verbally expressed. This program confirmed the relevance of designing learning activities based on these topics.

Talking about sounds with children, with ages from 10 to 14 years old, was an impressive experience. Children were invited to different activities, such as to brainstorm about the sounds they would expect to hear in different ecosystems, or to talk about sounds they liked and they didn't like and to imagine a computer application to catch sounds. Based on their imagination and on photographs of ecosystems, they worked enthusiastically to give lots of examples and they represented them in very different and amusing ways, not only using the names of the sounds or of the sounds' sources, but also imitating the sounds, using
onomatopoeic words and drawing their sources and effects. They proved how different strategies and materials could be important in talking about ecological sounds and, consequently, in developing sound literacy.

2.5. "Mr. Sounds Hunter": Learning With Children About Designing With Sounds

When children are asked to give suggestions about designing with sounds they can really surprise us. During the second meeting with children the authors asked the five children, with ages from 10 to 14 years old, to design a multimedia product named "Catching sounds". To perform this activity, that was based on the "Bag of Tricks" approach to design [Druin and Solomon 1996], children could use diverse arts and craft materials. Among the fruitful design ideas, produced by children, it is illustrative to mention:

- In children's drawings, sounds were usually represented with lines drawn near the sound sources. One child came up with the idea of catching sounds with a vacuum cleaner.
- Another child drew a trash can to get rid of undesired sounds, and he explained the idea: "Then, Mr. Sounds Hunter went to get the sound. If he likes it, he lets it go, if he doesn't like it he puts it in the garbage".

During that meeting, and while exploring a mock-up (previously built by the authors with printings of the screens and with post-it), children also offered design ideas related with the development of the "Sounds of Serralves Park" multimedia application. These ideas will be referred in the context of the prototype presentation.

3. Catching Sounds in Serralves Park

3.1. Presenting the Prototype
Figure 2 - Exploring the wood with the headphones tool and the pond with the navigator tool

A prototype of the "Sounds of Serra Ives Park" multimedia application was developed, using Allegiant Supercard 3.0. This process was iterative and partially simultaneous with the development of the presented design ideas: in a first phase the authors implemented a mock-up to be tested during the meetings with children. The tests performed with this mock-up led to the early identification of usability problems [Nielsen 1993] related with the design of the icons, and allowed the integration of children’s suggestions, such as the use of more drawings in the interface and the use of an applause as feedback. It was also suggested the use of a little hand to catch and drag the sounds.

The implemented prototype allows children to travel between different ecosystems of Serra Ives Park and to use a set of tools to explore their sounds, visually presented as a sound waves icon [see Figure 2]:
- To discover and to hear sounds children should use the headphones tool. If they click on the image they will find sounds with visible (e. g. sound of sheep) and with hidden sources (e. g. sounds of insects).
- To explore textual information about sounds and their sources children should use the information tool and click on a sound or on the image of a sound source.
- To navigate between related sounds children can use the navigator tool. Using this tool and clicking on a sound they will find a pull-down menu offering the possibility to travel to sounds with similar ecological sources. For instance, if they click on the sound of the bird chorus the menu will offer them the possibility to travel easily to another bird sound such as a pigeon, a goose or a blackbird.
- To manipulate sounds children can use the catch a sound tool. Using this tool, they can drag, for instance, a sound to the right word (the sound of a goose to the quacking word), or to the trash can if they find a sound in a wrong place (if the cow is singing or the blackbird is cooing).
- The cursor changes its shape whenever children choose a different tool. This characteristic intends to help them to discover its functionality and to remember which tool is being used. for instance To navigate between the ecosystems children can use a mariner's compass card. This navigation is based on the geographical characteristics of the Park.

3.2. Testing With the Users

In order to prepare the tests of the implemented prototype, it was pre-tested in the laboratory with four children with ages from 13 to 14 years old. Afterwards the prototype was tested with 22 children, with ages from 10 to 13 years old, in the context of the environmental education activities of the Serra Ives Foundation. Although these tests were very effective in discovering small interface problems, they were designed to evaluate the potentialities of the use of this prototype in an educational context.

These tests were performed with groups of four children and one teacher. Children worked in pairs (one girl and one boy) and while a pair was visiting the Park and trying to hear and identify sounds, the other one was working with the prototype. These children had very different previous experiences with computers (some of them didn’t know how to use the mouse) but they had already visited the Serralves Park in the context of other educational activities. It is important to present some of the more relevant observations made during these tests:
- Children and teachers declare that they did like to explore the prototype and that it was not difficult to learn how to use it. They liked to use the different tools and to discover its different potentialities. Discovering sounds in the landscape was regarded as an amusing and interesting activity. On the other hand, to catch sounds was considered a new and original activity.
- Virtual and real explorations of Serralves Park contributed to the understanding of local sounds in a complementary way. These two different explorations made it possible to analyze problems such as "Why didn’t you hear the cows and the goats in the Park? They were there, laying down and eating in the field....". The answers to this kind of questions were in the prototype, namely in the textual information about the ecological functions of sounds. It was also possible to analyze why some of the sounds that they could hear in the Park were not included in the prototype.
While traveling between the ecosystems, children seemed to find the use of a map and of the mariner's compass card useful and easy to co-ordinate. This activity integrated different representations, and children were also able to combine it with the navigation between related sounds (using the sound-web).

Children showed different approaches to the prototype, depending on their styles and ages. As examples, it is possible to mention that one group adopted a strategy of trial and error in order to perform the learning activities, while another one read systematically the related information before deciding what to do next. Besides, it was possible to observe that older children read more carefully the textual information about sounds and their sources than the younger ones.

After using the prototype, and when invited to make suggestions to improve it, children referred that the application should offer more sounds, videos and animations. They also expressed the wish to have more games and more levels of complexity. When they finished the exploration of the prototype most of the children asked to use it again and they also asked, specially the groups with the older children, if they could test the final product. Teachers declared that they did like to see children using the prototype and they found that it would be very useful to have this multimedia application in school, and in the Park, to support and complement the field explorations.

4. Conclusion & Future Work

The integration of non-spoken audio in environmental education software should contribute to the understanding of ecological sounds and to the learning of soundscapes. This paper presented a set of ideas developed on the basis of the meta-concept "To Catch Sounds in a Park" to support the design of multimedia applications. On the basis of these design ideas a prototype of a multimedia application was developed and tested in the context of the educational project "Sounds of Serralves Park". Linking the virtual and real explorations of this park and working in close collaboration with the future users were central concerns. One of the main design ideas was related with the possibility of traveling between sounds with related sources and functions and it was implemented in the prototype using a sound-web.

Testing the prototype with the users confirmed its potentialities to improve the learning of soundscapes, since it was possible to take advantage of the different characteristics of virtual and real experiences. Future work will include the development of a multimedia application to be used in environmental education contexts, and that should integrate children's suggestions.

Acknowledgements
The authors gratefully acknowledge the support of PRAXIS/3/3.2/AMB. We would like to acknowledge Professor António Cámara and our colleagues at GASA for suggestions and support. We would like to thank the collaboration of the Serralves Foundation. We would also like to thank the support of the Polytechnic Institute of Porto for recording and digitizing the sounds. And we would like to thank to all the children, students and teachers who made this project possible.
Practical Replacement of Lectures by Hypermedia Courseware

D.B. Skillicorn
Department of Computing and Information Science
Queen's University, Kingston, Canada
skill@qucis.queensu.ca

Abstract: Many applications of technology to learning and teaching have been treated as special projects with unusual resources. Most have failed to make the transition to the mainstream of the organisations in which they are used. We report on an approach that is scalable and cost-effective, both for course construction and delivery. In particular, we report on a first-year university programming course offered without lectures. This course is one of a suite, at all levels, offered in the same general way. The course has been well accepted by both instructors and students, and we have some evidence of improved learning outcomes.

1 Requirements

We describe the development and delivery of a first-year programming course in which lectures have been completely replaced by hypermedia courseware. This course is one of a collection, at all levels of the curriculum, for which this approach has been successfully used [Skillicorn 1996].

We started with the following assumptions:

- Government funding of universities will shrink for the foreseeable future, and therefore applications of technology to learning must concentrate on doing more with less resources.
- Techniques for developing hypermedia courseware must be largely self-funding.
- The ongoing delivery of courses using new technology must actually save money.
- The learning outcomes must be at least as good as conventional (i.e. lecture-based) courses.

Although these assumptions are fairly obvious, many projects applying technology to learning have failed to sufficiently absorb them. For example, many projects assume that more resources will be available: more money for systems, and more money for salaries for courseware developers. It is easy to find mechanisms for funding the development of a single course. Such mechanisms rarely generalise to permit the development of enough courses to make a significant difference to institutions. It is also surprising how often approaches are proposed that have ongoing costs much higher than traditional courses. For example, university-provided PC labs are a substantial, continuing cost, and course delivery that relies on them must find ways to pay this cost.

An attractive way to cost-effectively develop courseware is to do it incrementally. The key is to make sure that the effort and cost put into developing courseware gets repaid almost immediately, freeing up resources to be put into further development. For example, many traditional courses have some material that is already in electronic form; indeed, the use of web pages to distribute assignments and the like is well-established. Courseware development can begin by making this material into an integrated whole. Once some of the basic course material is on-line, lectures can take a more discursive form, since the basic content is available to students via textbooks, and the new on-line material provides the framework and perspective that an individual instructor brings to a course. This provides some reduction in preparation time for the instructor, time which can be used to further develop the course material.

An important extra source of course material is the students themselves. Once a system is in place that captures their interactions, these become a useful resource in themselves. For example, if students can ask questions on-line, with both question and answer publicly available, or can annotate existing course material, then these new documents can become part of the material for subsequent classes. This has the added advantage that material clearly generated by peers is more convincing, since students are compelled to believe that it is accessible to them.

We have used this approach to develop a number of courses: fourth-year courses in advanced computer architecture and in networks and communication, a third-year course in digital logic, and a first-year introductory computing course. Several of these are now offered without lectures, that is all of the course learning and discussion takes place on-line. We concentrate here on the first-year introductory course.
2 Related Work

Surprisingly little work applying technology to learning has been aimed at replacing traditional systems. Most existing work can be classified as:

- Developing multimedia and hypermedia courseware for delivery on CD-ROM. While useful, we view this as replacing textbooks rather than courses.

- **Developing material intended to supplement existing courses.** There are two problems with this: first, it requires extra resources and most universities are unlikely to have them in quantity and, second, it imposes extra workload on students.

- Developing multimedia lecture presentations, often delivered using a computer system in the classroom. While this can be very effective, it is expensive to produce, and limits learning to particular times and places.

- **Web-based courses.** These are closely-related to what we are doing, but suffer from inability to control access well (and thus maintain revenue), and weak facilities for students to create, as well as read, material. Together these limit interaction, since the environment is neither flexible nor private. We regard on-line interaction as critical to compensate for the lack of face-to-face interaction.

The Microcosm project at the University of Southampton [Davis et al. 1993] is a success story. Their system, however, is so open that it is hard to provide guidance about what students must, may, and might interact with. Also the system is not fully-accessible from the Internet, so it cannot be easily used for distance learning.

We are convinced that successful learning using technology must take place in a learning community. It is not sufficient to provide content. Students must encounter the content in the company of others who are also dealing with the same content. Thus the technology base must provide flexibility (different styles, different speeds) within an overall community framework.

3 System and Delivery

We use the Hyperwave [Kappe et al. 1993][Maurer 1996] hypermedia system as our development and delivery system. It provides several enhancements over the Web:

- It uses a hierarchical structure as well as arbitrary links. Thus navigation is easier, since there is always a natural local structure.

- It has full access controls for arbitrary groups of users (in the Unix style), so that courseware can be both read- and write-protected, at the level of individual documents.

- Links are stored separately from documents. This means that dangling links are not displayed (which is both cleaner and helps incremental development), and that users can create links leading from documents that are write-protected from them. This is the basis for annotations, which are a natural way to generate, and structure, discussions based on existing material.

Of course, it also provides all of the same benefits as web delivery: html as the markup language, worldwide accessibility, links to external documents and search engines and so on.

The Hyperwave system provides a web gateway which handles the enhanced features of Hyperwave by inserting buttons in the pages it serves. These buttons provide for identification, annotation, and insertion of new text. Our students use a standard web browser to access the course material.

The course material is accessed in a variety of ways: public sites on campus, workstations in the library, student-owned PCs in campus residence rooms (which are all connected to the university backbone), from home via dial-in lines or cable, and via local Internet service providers. Very few of our first-year students do not own a PC, so very few actually come to campus to access the material. Of course, the material is available at all times, and many of our students access it at unconventional times.

The course material consists of three parts:

1. Administrative material, such as announcements, assignments and their solutions, exercises and their solutions, questions and answers, on-line quizzes used for self-test, and suggestions.
2. The core course content. This is organised in a way that reflects its origins, into 'weekly' units, each of which is further subdivided into three 'lecture' units. This reflects our belief that first-year students need strong cues about the rate of progress they should be making through the material. This core content is mainly textual, but a large number of images are used, and program fragments are ubiquitous.

3. Programming material. The course is based on the programming language Turing. Unfortunately, the Turing system does not provide a command line interface, so it is the one component that we are unable to include seamlessly within the hypermedia system. We suggest that students run the Turing environment in a window next to their web browser, and we make all of the program text mentioned in the courseware available as source files, so that they can experiment with executing and modifying them.

The top level organisation of the course is shown in [Fig. I]. Note the buttons across the top of the page, and the user identification. Hyperwave adds small flags to collections (folders) that are new or updated. This, together with organising most collections in reverse chronological order, makes it easy to check whether something new needs to be looked at.

The detailed arrangement of topics is shown in [Fig. 2]. There are three streams of material: programming concepts, areas of computing that are of interest, and accessible, to first-year students, and a weekly large program example, which connects the two previous streams by illustrating the programming concept applied to the computing topic.

All other aspects of the course are conventional. There are a series of programming assignments, a midterm examination, and a final examination. The instructor has office hours where students can come to ask questions in person. Teaching assistants mark the assignments, and are available at scheduled times for questions and discussion, as well as spending some hours each week in the programming laboratory. A reference book for the Turing programming language is recommended to the students.

The development costs so far have been modest. A half-time curriculum development specialist, a teacher and computer science graduate, was employed for sixteen months. Most of this time was spent developing the first year course, a significant amount of it going towards learning the Hyperwave system and toolset and discovering which specific presentation techniques worked. For example, we originally planned to develop a screen-by-screen presentation in the style of Authorware or Powerpoint, but this was found to be too restrictive, technically and pedagogically. The server for the Hyperwave system is a Sun Sparc5, which easily supports the current 200 student-courses per term now in use. We estimate that we can develop further introductory courses in three to five months of work, and upper-year courses much more rapidly. This magnitude of cost can be repaid in reduced contact hours within the first year or two. Upper-year course have been developed without external funding. The time cost of preparing an initial hypermedia offering is about the same as preparing a conventional lecture course for the first time, and so is readily handled within the usual course load framework.

4 Experiences

We used a number of formal and informal mechanisms to get student feedback. First, there are a number of online paths for feedback: the kind and number of questions, suggestions made, and annotations on the courseware. There is also an on-line social area, which we provided to enhance a sense of community among the students. Their initial assignment was to insert a short description of themselves in this area. Later in the term it provided a place for students to raise issues that were not strictly academic.

We also conducted a series of detailed course assessments. The response rate for these was not high enough to allow for serious statistical analysis (itself a sign that students were not, on the whole, perturbed by this approach), but some interesting trends could be seen.

There were two obvious groups. The first were very appreciative of the any time, anywhere availability of the course material, and the freedom from having to meet at particular times. It is difficult to be sure, because the assessments were anonymous, but from other comments made on the forms, this seemed to be because they led lives that made rigid schedules awkward: because they live further from campus, or simply because they were night owls. Some also appreciated being able to have more than one chance to go over the material.

The second group were initially resentful about the absence of lectures, although they clearly appreciated the properties of the on-line material. Their comments suggested a belief that formal class meetings caused them to be taught, rather than to learn. In other words, they believed that class meetings were places where instructors

Figure 2: Outline of Topics Covered in the Course
did something, and they did not. Replacing lectures completely challenges this belief at its core. Once it was challenged, this group discovered that they could learn, they did, and became supportive of the approach. This belief had not been visible in earlier, hybrid course offerings. It may be that only a few class meetings are sufficient to sustain a belief in teaching rather than learning. Indeed, students may put disproportionate emphasis on the importance of class meetings when they are rare.

We hypothesise that this transfer of responsibility from instructor to student explains the recent results of Schutte [Schutte 1996], who has documented improved learning outcomes using on-line material without lectures. While we have not carried out formal measurements of learning outcomes, it is clear from test results that students learn at least as well using hypermedia instead of lectures.

In the second, full-scale delivery of the course without lectures, the second group of students did not appear to exist. This may reflect growing confidence that the approach was workable, passed on by word of mouth from the previous year’s class. It may also reflect the rapid change in students’ previous experience. At the beginning of the course, very few had never used a web browser to look for something. It may be that a learner-based paradigm for information retrieval is becoming pervasive among those who routinely use personal computers.

Overall, our approach permits cost-effective development of hypermedia courseware over all levels of the undergraduate curriculum; it is practical to deliver to students, both on and off campus; and it attains the same level of learning success as conventional lecture-based courses.

Abstract: In the article the computer tutorial "Higher mathematics" for engineering specialties of universities is represented. The tutorial includes 17 computer programs of educational purpose. The programs of the package allow to solve practically any problem from higher mathematics course. The package is prepared on CD-ROM.

1. Introduction

It is hard to find in Russia a university, an institute, a faculty (humanitarian, natural science, engineering), where the attempts are not undertaken to use modern computer technologies in educational process. Small creative groups (1-3 participants) make a lot of computer tutorials intended for educational purposes. Many unstate organizations create such programs as well.

Representing a new Russian courseware, computer tutorial "Higher mathematics" for engineering specialties, the authors would like to tell about one of the approaches to the problem of "computer in education", which is realized in this tutorial.

The situation with the use of computers in education is paradoxical. On one hand, the computer programs of educational purpose were developed always and everywhere. From the very beginning of computer era, as soon as a working electronic computing device appeared at school, high school, research institute, there was at least one person there (enthusiast, the fanatic, maniac) who started creating computer programs intended for tutoring. On the other hand, in reality computers are used in tutoring very little (except computer science), and, as a rule, it is done by developers themselves or their colleagues. Why? Such self-made programs usually support the study of rather small part of the course, they are strictly limited by a concrete technique of teaching (material presentation), by concrete educational plan, and usually they are badly documented or have no appropriate methodical documentation at all.

The situation with the use of universal mathematical packages, such as Mathematica, MathCad, MapleV, Derive, MatLab etc. in education is similar. These programs are attractive by their high-power graphic and computational capabilities, and by the possibility to make analytical transformations (symbol calculations). The teacher who masters the package of that kind, as a rule, can effectively use it in tutoring. On the base of universal packages special educational programs are created (for example, StudyWorks is created by MathSoft on the base of MathCad), and the tools for creation of educational courses are developed. However, in spite of the fact that the mathematical packages are known long ago and are rather widely spread, it is too early to speak about adequate use of them in educational process. Why? Since these packages initially were developed to support scientific and engineering researches, their interface is badly adapted for educational purpose. So there are problems in mastering a package (the user, the student or the teacher, should learn the interface or command language of a package). The efforts to master the interesting part of the problem (from the point of view of the subject under investigation) are often comparable to energies spent on a solving of technical problems, concerning the method of a problem notation and interpretation of results in a medium of a concrete package.

Though the market of computer programs of educational purpose is extremely poor, the demand for them grows. A few programs available either decide particular problems (teaching English, increase of grammatical correctness, teaching arithmetic etc., i.e. they are oriented mainly on children before 12 years), or have no adequate methodical support. The appearance of tutoring CD-ROMs hasn't changed the situation (as a rule, it is English for kids and teenagers, children's encyclopedias, museums, historical and geographical excursions, fragments of mathematical courses for junior school, teaching games).

For several years the seminar "Computers in mathematical education of engineering specialities" works on
the faculty of higher mathematics in Moscow Power Engineering Institute. A great number of various computer programs of educational purposes in mathematics, physics, mechanics, programs for schools and high schools, both authorship and created on the base of universal packages, were discussed at that seminar. At the same time in Informational Systems Research Institute of Russia the fund of computer tutorials was analyzed. As a result of these discussions and analysis it was possible to work out a constructive approach to a problem.

This approach consists in attempt to unit the existing educational mathematical programs realized by different authors, in a package on a uniform methodical basis in aim to receive a full computer support of higher mathematics course for engineering specialities, i.e. the computer program, which will assist in teaching of this course.

By results of expert examinations and experimental operation 17 educational mathematical programs created in leading Russian universities were selected. Put together, these programs enable to solve practically any problem from the course of higher mathematics for engineering specialities, and the students often escape laborious calculations and get the visual graphic interpretation of results. In Informational Systems Research Institute of Russia selected educational mathematical programs were incorporated in a uniform package. The staff of the institute and the authors of the programs carried out the task using tool system HM-Card (see below).

The package can be useful to the system of education as a whole, since it contains all necessary tools for introduction of the computer in process of teaching of higher mathematics on a complex basis, that will allow to increase efficiency of teaching process.

The package can be useful to the teachers, since it contains only tools for problem solving and the methodical part of its application is completely determined by the teacher. Thus, the package is free from methodical dictatorship of any kind.

The authors hope, that the package will be useful to students, for it contains not only tools for problems solving, but also demonstration programs showing how to solve a problem.

The created package of educational programs can be called a computer tutorial for higher mathematics, the tutorial assisting in mastering the course of higher mathematics with the help of computer.

One of the main properties of an offered package is that it combines works of different authors for complex computer support of the study of mathematical disciplines. The package is open for inclusion of diverse programs assisting the study of mathematical disciplines. Each work of the authors from different schools can be put on a certain "methodical shelf". It will allow students and teachers to choose and to use in the study of the subject such tools that suit them. The package is also open for connection of any universal mathematical package, that enable to create a highly effective medium for study of mathematical disciplines including both educational programs, and universal packages.

2. Structure and Properties of the Courseware

The computer tutorial for engineering specialities is the library of educational mathematical packages and Navigator for the course of "Higher mathematics".

The library consists of computer programs of educational purpose, developed in the leading Russian universities.

Educational mathematical packages "FORMULA", "MATRIX", "ODE — Ordinary Differential Equations" are developed in Moscow Power Engineering Institute (MPEI) on the Department of higher mathematics by collective of authors: Kirilov A.I., Slivina N.A., Chubrov E.V., Demushkin A.S., Morozov K.A.

Labs on computational mathematics is created on the Department of Computational Mathematics in Moscow Institute of Physics and Technology (MIPT). The scientific principal is Ryabenkii V.S. The group of authors: Petrov I.B. (supervisor), Ivanov V.D., Korotkin P.N., Kosarev V.I., Pirogov V.B., Severov D.S., Tormasov A.G., Ustyuzhnikov S.V.

Computer system of control of knowledge in higher mathematics "Ordinary differential equations" is developed in Moscow State University (MSU) at the Department of Differential Equations. The authors: Baula V.G., Lokshin B.J. Rozov N.C., Sushko V.G., Shikin E.V.

Subject-oriented educational package "MATRIX" provides computer support to the study of linear algebra and analytical geometry. In [Fig. 1] the main dialog window of "MATRIX" is represented. The package enables a user to investigate a wide range of exact and approximate algorithms of linear algebra.
Package "FORMULA" is a subject-oriented medium for solving problems in calculus and approximate calculations. The program has broad computational and graphical capabilities. "FORMULA" enables to perform diverse calculations, from arithmetical expression evaluation to special functions and partial sums evaluation, and symbol differentiation of functions of one or several variables. The analytical and graphical capabilities of the package completely cover the needs of classical calculus course. The friendly interface and effective organization of computing procedures allow to illustrate and to investigate rather complicated models. In [Fig. 2] the example of trigonometrical series investigation is shown.

Figure 1: The main dialog window of "MATRIX". The switching of modes is done by one click of the mouse.

Figure 2: The graphic window of "FORMULA". The next harmonics is added by pressing of one key.
The main purpose of the package "ODE" is to help in understanding of qualitative aspects of the theory of differential equations by consideration of many meaningful examples and solution of many problems, which are hard or sometimes impossible for student to solve without computer. The package allows to input and to investigate any differential equation or system of differential equations up to the sixth order inclusively. The package has the friendly and logical interface. [Fig. 3] shows the phase portrait of an autonomous system:

\[ x' = x(x^2 + y^2 - 1)(x^2 + y^2 - 4) - y, \quad y' = (y(x^2 + y^2) + x/3)(-4) + x \]

Figure 3: The graphic window of "ODE". The phase portrait is built by several clicks of the mouse.

The labs in computational mathematics enables to master the known numerical methods traditionally used in solution of scientific and practical problems. The package instills skills of investigation of numerical algorithms properties, helps to understand the boundaries of their preferable applicability. The graphic capabilities of the programs in the package and well thought-out distinct interface, uniform for all the programs, allow to learn characteristic effects arising in a numerical solution of practical problems in clear and visual form.

Besides the course of computational mathematics the labs can be effectively used in the study of calculus, linear algebra, differential equations and equations of mathematical physics.

On [Fig. 4] the screen during the work with the program "Numerical integration" is shown.

The computer system of control of knowledge in higher mathematics "Ordinary differential equations" is a remarkable problem book containing over 300 problems, composed by the noted experts on differential equations, qualified teachers with long-term experience in teaching of differential equations at Moscow state university.
Figure 4: A screen in the package "Numerical integration".

The navigator of the courseware is constructed as a hierarchical menu that permits to move through sections, subsections and topics of the course of higher mathematics for engineering specialties. Besides, the Navigator introduces main functions and technique of work with each educational mathematical package from the library. It helps to understand how to apply a concrete educational mathematical package for solution of the problem from the course of higher mathematics. To reach this goal over hundred examples of solutions of typical problems from standard problem books are included in the Navigator. The examples are executed as demonstrations with detailed explanation of the course of solution. The menu of the lowest level consists of two parts: the list of problems, that can be solved within the framework of the concrete topic, and the title of an educational mathematical package from the library, that helps to solve the problems in the given topic [see Fig. 5]. The navigator allows the student to keep to the studied course, to receive an information about methods of solution of typical problems from demonstrations and to call for a solution of the problem just that educational package, which suits this purpose in the best way.

Figure 5: Navigator. One of the menus of the lowest level.
Navigator helps to receive enough information on the work with a concrete educational mathematical package: to read the author's summary, to start a demonstration, or to take advantage of the built-in help by starting a concrete package. The tutorial is accompanied by four books (user manuals and methodical instructions).

3. The Tool of the Courseware Creation

The navigator of the courseware is realized with the help of multifunctional tool hypermedia system HM-Card. This tool system developed at Technological University of Craz (Austria), is primary oriented on creation of educational computer programs of various types.

4. Perspectives of Use in the Net

The toolkit system HM-Card, by which Navigator is produced, allows to create packed files with an image of software for transfer in the net. The educational software can be located both in the Internet and on the server of a local network of the university. To run the program on a local workstation Netscape Navigator can be used. The demo-version of the tutorial is published on the WWW-server of ISRIR for free access (http://www.tib.ru).

5. Conclusions

The presented computer tutorial is the first courseware of such class in Russia. The authors hope, that it will help the teachers (to prepare lecture and seminar demonstrations and tests, to give lessons in computer class and to develop of new modem courses), and students (to investigate a subject under the direction of the teacher, to work independently or to deepen their knowledge). Note that all the programs are used by the authors for a number of years in real educational process, as well as in scientific researches and methodical work; these programs are used by the students for self-education and in preparation of degree works and, that is very important, in different universities.

The method applied for creation of the computer tutorial in higher mathematics allows to build blocks of uniform computer support of courses of any educational discipline.

The navigator of the computer tutorial in higher mathematics is open for updating; it is possible to expand the list of sections and topics, to include new educational packages, to enter in the menu of the concrete unit some programs with close capabilities. Thus, the courseware can be built up by integrating developments of various universities, high schools and concrete authors. This approach allows to create by common gains an educational software, which is meeting the requirements of significant number of students, and to avoid so-called methodical dictatorship of single school or direction. The students will have an opportunity to select the most suitable tool from several educational resources.

The authors see in pilot-project of the computer tutorial on higher mathematics the probable prototype of the similar projects on other disciplines. The work on upgrading the tutorial goes on.
Competency-based Learning in Business Education

From Knowledge to Skill

Mr. R.H. Slotman MA
Hogeschool van Utrecht
Faculty of Economics and Management
Cetis
P.O. Box 85029
3508 AA Utrecht
The Netherlands
e-mail R.Slotman@cetis.hvu.nl

Abstract: Knowledge is the motor of economic growth. Via knowledge networks knowledge flows to spots where it may be used in new products and services. Higher Business Education plays an important part in this knowledge network by offering direct and practically applicable knowledge in the fields of markets, finance, information supply and organisational forms.

The pressure on Higher Business Education to anticipate new developments is increasing. Current educational systems are insufficiently equipped to anticipate these developments. The project Competency-based learning in business education is aimed at preserving the position of Higher Business Education in the knowledge network and at strengthening it where possible. By means of the Competency-based learning concept a guaranteed link between developments in professional practice and vocational training in economics is possible.

A Vision, a Model, a Project

Competency-based learning: a familiar vision with new perspectives

Competency-based learning as an educational vision aims at a close interaction of vocational education and professional practice. The training has been organised on the basis of two key-questions:

1. Does the knowledge meet the needs of professional practice?
2. Can the knowledge be put to practical use?

Competency-based learning aims at introducing competencies. By that we mean combinations of know-how and abilities as required in practice. An example to make this clear: the issue is not to possess knowledge of marketing and written reporting as separate final products, but to acquire the ability to write a marketing plan that is professionally sound and communicates well. So Competency-based Learning is not new, but based on the traditions of Higher Business Education: education in broad expert knowledge, skills and practical confrontations.

In the Netherlands the concept of competency-based learning has been used by Nijenrode University in the reform of management courses. American training institutes for business administration are also developing educational forms aimed at competency-based learning. Many business courses have been developed on the basis of the principles of competency learning.

At this time the fingerprint of professional practice is not yet sufficiently visible in the training. Education in expert know-
Knowledge, skills on the one hand and practical confrontations (work placements, projects) on the other hand are still offered too rarely. The educational organisation (subject structure, timetable, media) is ill-equipped to provide integrating study activities that offer a high degree of applicability.

The cultivation of professional skills forms the "raison d'être" of Higher Business Education. Competency-based learning is a vision that logically continues the profile of Higher Business Education and that wants to give it strength and sharpness again. In the first place it is nothing more - but also nothing less - than strengthening the own identity of Higher Business Education. It links up with the shortcomings felt by the institutes of Higher Business Education themselves for years and the urgent wishes of representatives from the professional fields.

A second element in vision is the wish that Higher Business Education should present itself more distinctly as a partner in a knowledge network with other educational institutes, businesses and government institutions, so that, by means of intensive interaction, it can play a role in the innovation of the knowledge required in professional practice.

Thirdly, competency-based learning emphasises learning rather than education. Education needs room for a more active study attitude of the student and a better connection to the abilities of the individual student, together with a more counselling role of the lecturer.

Competency-based learning is not a vision that turns everything upside down; on the contrary, it links up effortlessly with existing educational practice and can be expanded according to capacity and need. That does require a clear image of the desired final situation. For that purpose the educational model of Competency-based learning is being developed.

**Competency-based learning:**
**the educational model**

The existing educational model (final attainment levels, curriculum, didactic, media) will be revised in a number of steps. Final attainment levels and curriculum will be tested and adjusted on the basis of the criteria of practical relevance and applicability. Instruction in expert knowledge will be linked direct to application-oriented skills, the number of practical confrontations will be extended. In addition training and learning will be given a more "outward" orientation. New study activities, media and forms of counselling will be developed. Information technology will be an important integrating factor in the new educational model.

**Competency-based learning in business education:**
**the project**

The project of "Competency-based Learning in Business Education" is an initiative of the Faculty of Economics and Management of the Hogeschool van Utrecht. The Cetis expertise centre handles the program management on behalf of the Faculty of Economics and Management.

The project is aimed at further development of the model and the development, realisation and testing of a number of illustrative learning environments surrounding practical confrontations.

The planned project results:
- a blueprint for competency-oriented curricula;
- a training and educational program for management and lecturers;
- three multimedia practical confrontations for courses in the fields of logistics, strategic marketing and business information systems;
- an Internet facility to exchange know-how and experience concerning entrepreneurship;
- a management game.

In addition to the Faculty of Economics and Management of the Hogeschool van Utrecht the following parties participate
in the project:
- Origin Interactive Media Competence Centre;
- Rematch BV, development and exploitation of computer supported management simulations;
- PTT Telecom;
- Instituut voor Commerciële en Strategische Beleidsvorming;
- Jurjen de Vries, Bureau voor Management en Efficiency;
- Uitgeverij Lemma;
- PiMedia, developer and supplier of services in the field of assessment technology;
- Open Universiteit;
- Expertisecentrum Cetis.

The project started in September 1996. The duration of the project has been set at three years. During the project period initiatives will be prepared from within the project to create new development activities and activities aimed at implementation of part results.

The project has been made possible by a subsidy from the HBO (Higher Professional Education) innovation fund. The contribution from the Open University is made within the framework of the Consortium for the Innovation of Higher Education.

Please consult the www-site for information about the project http://www.cetis.hvu.nl/cleo/

Abstract: We have started a project of making remote control system for a telescope in a public observatory in Japan. This one year we have developed a prototype system, although it was only a conceptual primary design in 1996. The system has user-friendly interface on a web page. The web page has two menus, one is a menu of celestial bodies of Messier catalog, the other is a menu of bright stars. Also it has slight motion buttons. A remote client user can put in the celestial position of a target, or select a celestial target by the web home page of the system, and the telescope catches the target. The main purpose of this system is to show real time images to remote students for education. If this system is used from high schools in western countries such as Europe or U.S.A., the students can see real time images of celestial bodies and celestial phenomena in the school hours. If this system is used from southern countries such as Australia, the students can see northern celestial bodies that is never seen from those countries. Therefore this system will contribute science education internationally. We are developing this system now. In this paper, we describe prototype system and experiments. Also, this paper suggests CANES (Computer Assisted Navigation and Explanation System), which is under development.
the total number of them is around two hundreds. Around fifty observatories among them have telescopes of more than 0.5-m, and four of them have telescopes of more than 1.0-m. Misato observatory in Wakayama prefecture in Japan has 1.05-m telescope, that is the largest one among Japanese public telescopes. On the other hand, only two public observatories in Japan connected to Internet by digital leased lines. Misato observatory is the first one among those two observatories. Misato observatory and Wakayama University have already been cooperating to try some new attempts for education by Internet and video conference tool[Watanabe et. al.1996a, 96b].

In these environments, we have started the new project to make remote control system of the telescope by using WWW for educational use. In this project, we prepare three servers, web server, telescope server, CU-SeeMe server. A Remote client student accesses the web server, and gets home page of remote telescope project. The student can select a celestial target in a pop up menu, or can put in the celestial position of a target. Then the web server transfers the position to the telescope server. Then the telescope server moves the telescope to the direction of the target. A CCD video camera is set on the telescope. After getting real time image of the target by the CCD video camera through the telescope, the image is transferred to CU-SeeMe server. It transfers the real time image to the client student.

Many remote control systems have been developed for astronomers to make observation easier, but those telescopes can be controlled only by LAN. Therefore they are not adaptive to public use [Richimond et. al. 1993, Colgate et. al. 1982, Smith et. al. 1990, Perlmutter et. al. 1990, Tosti et. al. 1996]. The purpose of these systems is to reduce astronomers' load. Astronomers can drive the telescope from remote room with comfortable environment. In the supernova search, for instance, astronomers only have to put in some job schedule of getting images of the sky by CCD camera, then the telescope system executes the job automatically.

On the other hand, a few remote telescope systems began to be made for educational use. Especially, Mar J.Cox and John E. F. Baruch in University of Bradford have developed excellent system called robotic telescope that can be used on WWW[Cox et. al. 1994]. Their system attaches greater importance to technology of full-remote control, but the image of celestial bodies are not real time image. The requests from client users are stored in a queue, and the system makes a schedule to take CCD image of the requests. After taking CCD images at clear night, the images are put on the web page of the robotic telescope. So the images are still images. We think that to provide real time image is much more exciting for client students compared with still image, to enhance their interests of astronomy.

A part of our system is similar to their system in the architecture of remote control with WWW, but our
Figure 2: The architecture of the remote control system of the telescope

System provides real-time images. The web user interface of our system supports slight movement buttons of telescope that enables to control telescope interactively. This kind of user interface on the web for remote telescope is the first one in all over the world.

In this paper, we describe a prototype system of our remote telescope project, architecture of our remote control system. Until now, the second version of the web interface and the program of telescope server are completed. Therefore client student can control the telescope from all over the world through Internet by web user interface, although we still have a problem of time lag between sending request and starting to move the telescope.

When Japan is at night, foreign countries such as USA, or Europe is in the daytime. Therefore those who live in the countries can see real-time image of celestial bodies at the daytime. This remote telescope system can be used at schools to teach science, and can be used in the planetariums for visitors in the daytime in the foreign countries [Fig.1]. This global idea is proposed by some projects of remote telescope for education use, such as the robotic telescope project mentioned before and HOU (Hands On Universe) project[1]. Also, from southern countries such as Australia and South Africa, they can see the real-time images of celestial bodies in northern sky, which is never seen from those countries. So this project will contribute science education internationally.

In this paper, we finally describe how to apply the remote control system to education. Also, we expect that students will be interested in not only astronomy and science but also Internet, WWW and computer science. Robotic telescope project, HOU project and TIE (Telescope In Education) project[2] also make some science program combining astronomy and engineering. We also think that it is possible to make original combined curriculum of astronomy and computer science with this remote telescope in Japan.

2. System Architecture and Mechanism of Moving Telescope

[Fig.2] shows the architecture of the remote control system of the telescope. The user interface is made by web page with HTML on the web server. It has some blank to put in celestial position of the target [Fig.3], and

Figure 6: An experimental demonstration of moving telescope and a scene of class room on CU-SeeMe
pop up menus to select a target [Fig.4]. A student selects a target, or puts in the position of the target that he/she wants to see. The position is put in by equatorial coordinates. Then the position is transferred to the web server, and a CGI (Common Gateway Interface) program in the web server gets the position and put it in a temporary file. The web server is SUN Sparc workstation.

A telescope server always monitors the temporary file by NFS mount, and if new values are put in it, the telescope server reads them. The telescope server is personal computer with Linux. It calculates the sidereal time, by the Japan standard time, latitude and longitude of the observatory. Then the telescope server transforms the position of the target on equatorial coordinates into horizontal coordinates. If the altitude of the target is more than 20 degrees, the object can be seen in the sky clearly. If the altitude is less than 20 degrees, the object is seen low in the sky or cannot be seen because it is under horizon. Even if the target is seen lower in the sky, it is dangerous to move telescope towards such a target, since there is possibility that the telescope crashes into objects in the dome. In these cases, the telescope server cancels the student's request.

If the target is seen in the sky at the safe direction for the telescope, the telescope server calculates the difference between the position of the target and the current direction of the telescope. Then the telescope server sends necessary serial signals to the control module of the telescope. Finally the telescope is moved toward the direction of the target.

The web user interface also has slight movement buttons that moves the telescope to north, south, east, and west directions in a range decided by the student [Fig.5]. This type of user interface of telescope control system on the web is first one in all over the world. The buttons makes the system interactive. For instance, when a student is observing a large celestial body such as the moon or Andromeda galaxy, he can see only a part of it because field of view is too small to see whole of it. In such a case, the student can move the field of view by the slight movement buttons. Also, we have our original idea of CANES (Computer Assisted Navigation and Explanation System) described in chapter 5. The slight movement buttons are very useful with GANES.

3. Catching Real Time Image by CCD Video Camera

A CCD video camera is set on the eyepiece of the telescope. If the target is very bright one, such as the moon, Jupiter, or Saturn, the CCD video camera is enough to get the real time image. If the target is not bright one, such as a galaxy, nebula, and cluster of stars, an image intensifier is necessary between the eyepiece and the CCD video camera. By this composition, real time images of famous galaxies, nebulae, and clusters of stars in Messier catalogue can be provided.

On the other hand, wide view video camera is prepared for providing real time image of movement of the telescope. It catches the real time image of which the telescope is moving according to the student's request.

Both images of CCD video camera and wide view video camera are sent to CU-SeeMe server through a video selector. At the first, wide view video camera catches real time image of movement of the telescope, and it is sent to the client student. After the telescope caught a target, the real time image is changed into the target image by video selector. Both real time images are sent to the student by CU-SeeMe.

4. Experimental Observation
