This study examined gender differences in the correlates of different types of nonsocial play behaviors. Seventy-seven kindergarten children (38 males, 39 females) were observed during free play. Behaviors were categorized according to three subtypes of nonsocial play: reticent, solitary-passive, and solitary-active. Additional measures included an interview, assessment of academic achievement, parental ratings of child temperament, teachers' ratings of children's behavior problems, social competence, and academic skills. Findings from regression analyses indicated that a lack of social play for males, but not for females, was associated with indices of maladjustment. In particular, solitary-passive play was associated with positive outcomes for females, but not for males. In contrast, reticent play was a predictor of maladjustment for both genders. Findings indicate potentially different meanings in the various forms of nonsocial play behaviors for young boys and girls. Contains 17 references. (Author/HTH)
Nonsocial Play in the Kindergarten Classroom: Gender Differences in Relations With Adjustment

Carleton University
Ottawa, Ontario, Canada

Abstract

The goal of this study was to examine gender differences in the correlates of different types of nonsocial play behaviors. Seventy-seven Kindergarten children (38 males, 39 females) were observed during free play. Additional measures included an interview, assessment of academic achievement, parental ratings of child temperament, teachers ratings of children's behavior problems, social competence, and academic skills. Results from regression analyses indicated that a lack of social play for males, but not for females, was associated with indices of maladjustment. In particular, solitary-passive play was associated with positive outcomes for females, but not for males. In contrast, reticent play was a predictor of maladjustment for both genders. These results indicate potentially different meanings in the various forms of nonsocial play behaviors for young boys and girls.

Poster presented at the biennial meeting of the Society for Research in Child Development, Albuquerque, New Mexico, April 1999.
Nonsocial play in childhood is a complex, heterogeneous construct. To begin with, children may play alone for many different reasons (Rubin, 1982). Moreover, not all forms of nonsocial play appear to be risk factors for adjustment problems.

**Subtypes of Nonsocial Play**

Three subtypes of nonsocial play behaviors have been identified, each with their own "underlining psychological mechanisms" (Coplan & Rubin, 1998).

**Reticent** behavior consists of onlooking and unoccupied behavior (Coplan, Rubin, Fox, Calkins, & Stewart, 1994). This type of behavior appears to be reflective of anxiety, fear and internalizing problems both in a familiar environment (e.g., Coplan & Rubin, 1998) and in a novel setting (Coplan et al., 1994).

**Solitary-passive** behavior consists of quiet, exploratory and constructive behavior while playing alone (Rubin, 1982). Children who frequently display solitary-passive behavior seem to prefer solitude to socializing with their peers (Rubin & Asendorpf, 1993), perhaps being more object-oriented rather than people-oriented (Jennings, 1975). However, these children may not have a problem when they want to interact with others (Asendorpf, 1993). Solitary-passive play in early childhood has not been associated with concurrent indices of maladaptation. Moreover, this behavior tends to be positively reinforced by peers, parents and teachers, as well as being associated with peer acceptance.

**Solitary-active** behavior involves solitary-dramatic play and solitary-functional play. This behavioral type has been associated with more aggressive and immature forms of behavior as well as peer rejection (Rubin & Mills, 1988). While this behavior is highly salient to the peer group, it occurs rather infrequently during free play (approximately 3% of the time), making it rather difficult to study (Coplan et al., 1994). Thus, solitary-active play was not the main focus of this study.

**Gender Differences**

There has been little research exploring gender differences in the frequency of nonsocial play. Overall, researchers have not reported any significant gender differences in the frequency of occurrence of these types of play behaviors (e.g., Rubin, 1982; Coplan et al., 1994; Coplan & Rubin, 1998).

There is some evidence to suggest that shyness, inhibition and social withdrawal may have different "implications" for boys and girls. It has been argued that shyness in girls is more likely to be rewarded and accepted by parents, whereas shyness in boys is more likely to be discouraged (Engfer, 1993). As well, there is some evidence to suggest that as compared to withdrawn girls, withdrawn boys seem to have more difficulties (Rubin, Chen, & Hymel, 1993).

**Present Study**

To date, there has been no research with respect to gender differences in the adjustment outcomes of nonsocial play in early childhood. Thus, the primary goal of the current study was
to examine gender differences in the relation between nonsocial play forms and indices of adjustment (both social and academic) in the familiar setting of the Kindergarten classroom.

**Method**

**Subjects**
The participants in this study were 77 Kindergarten children (38 males, 39 females, $M_{age} = 66.16$ months, $SD = 4.11$ months) attending public Kindergarten classes in 7 schools in a mid-sized city in Ontario, Canada. The sample was ethnically and socioeconomically diverse.

**Procedure/Measures**

**Parental ratings.** Four months into the school year, parents completed the Colorado Child Temperament Inventory (CCTI, Buss & Plomin, 1984; Rowe & Plomin, 1977). For the purposes of this study, we were particularly interested in parental ratings of shyness (e.g., “child takes a long time to warm up to strangers”, “child tends to be shy”).

**Observations of children’s free-play behaviors.** Six months into the school year, children’s behaviors during periods of free play were observed. Behaviors were coded over a three- to four-week period using an adapted version of the Play Observation Scale (POS, Rubin, 1989). Each child was observed for 10-second intervals for up to 4-5 minutes per day, on at least three separate occasions. In total, each child was observed for 12 minutes, thus receiving 72 codes of data.

For each 10-second interval, the child’s predominate free-play behavior was recorded. Some of the possible time-sampled codes were: reticent play (e.g., unoccupied, onlooker), solitary-passive play (e.g., construction and exploratory play) and social play (e.g., group play/peer conversation).

**Academic achievement.** Children’s academic achievement was assessed individually with a series of questions designed to examine early academic skill (e.g., basic concepts, literacy and numeracy skills). The protocol included 28 items (correct/incorrect) derived from the primary battery of the Metropolitan Readiness Test (MRT, Nurss & McGauvran, 1988). Academic achievement was only available for 67 children. Cronbach’s alpha for this scale was .88. A single aggregate score representing academic achievement was created.

**Teacher ratings.** Near the end of the school year, teachers rated children’s behavior problems and social competence using the Preschool Behavior Questionnaire (PBQ, Behar & Stringfield, 1974). The two-factor solution was employed (internalizing problems and externalizing problems) (e.g., Hoge, Meginbir, Khan, & Weatherall, 1985; Moller & Rubin, 1988). Also, items pertaining to social competence were added (Tremblay, Vitaro, Gagnon, Piché, & Royer, 1992).
Teachers provided a measure of children’s performance and skill improvements over the school year (academic skills). The teachers rated the children on their improvements on academic skills (e.g., understanding language, reading, and math) on a 5-point likert scale. The child’s scores for each of these items were aggregated. Cronbach’s alpha for this scale was .94.

Results and Discussion

Preliminary Analyses

Preliminary analyses concerned gender differences in the frequency of nonsocial and social play forms. Supporting past research (e.g., Coplan & Rubin, 1998), results from t-tests indicated no significant differences (see Table 1).

Table 1

Mean Frequency Ratings (and Standard Deviations) of Nonsocial and Social Play Forms for Males and Females

Results also indicated no significant correlations between nonsocial or social play forms, and both parental education and child age. As such, these variables were not controlled for statistically in later analyses.

Social Play

Regression analyses were conducted to assess the main effects and interactions between gender and social play in the prediction of social (internalizing behavior, social competence) and academic adjustment (academic skills, academic achievement). Results revealed a similar pattern of results for 3 measures of adjustment. No significant main effects were found; however, significant gender by social play interactions were revealed for internalizing problems ($R^2_{change} = .06$, $F(1, 73) = 4.79$, $p < .05$), and a trend for social competence ($R^2_{change} = .04$, $F(1, 73) = 2.95$, $p < .09$) and academic achievement ($R^2_{change} = .05$, $F(1, 63) = 3.39$, $p < .07$). The interactions were explored by re-computing the regression analyses separately for males and females. Results are summarized in Figure 1.
Thus, it seems that a lack of social play was a predictor of maladjustment for males only. Boys who engage in less social play had more internalizing problems, as well as lower social competence and academic achievement. For girls, no associations were found. The next set of analyses examined whether certain nonsocial play forms (reticent and solitary-passive play) might differentially be associated with maladjustment for males or females.

**Reticent Behavior**
Regression analyses revealed that significant main effects were found for social competence ($\beta = -.28; t = -2.55, p < .05$), academic skills ($\beta = -.22; t = -1.95, p < .05$) and a trend for academic achievement ($\beta = -.24; t = -1.75, p < .09$). Results are summarized in Figure 2.
Figure 2. Summary of Main Effects for Reticent Behavior.

Note: Numbers represent standardized Beta's
* = p < .05
+ = p < .10

Thus, reticent behavior was associated with maladjustment in Kindergarten for both boys and girls. Children who displayed reticent behavior were less socially competent and had lower academic skills and academic achievement. These results are not surprising, given the fact that children who display reticent behavior tend to demonstrate anxiety and fear even when they are in a familiar context. This may impact upon their ability to acquire (and demonstrate) academic skills.

Solitary-Passive Behavior
Results from regression analyses revealed no significant main effects of gender or solitary-passive behavior in the prediction of Kindergarten adjustment. However, significant gender by solitary-passive play interactions were revealed for internalizing problems ($R^2_{\text{change}} = .05, F(1, 73) = 3.84, p < .05$), academic achievement ($R^2_{\text{change}} = .08, F(1, 63) = 5.64, p < .05$), and a trend for social competence ($R^2_{\text{change}} = .04, F(1, 73) = 3.45, p < .06$) and academic skills ($R^2_{\text{change}} = .04, F(1, 73) = 3.37, p < .07$). The interactions were explored by re-computing the regression analyses separately for males and females. Results are summarized in Figure 3.

These results suggest that solitary-passive play is associated with positive outcomes for females and negative outcomes for males. That is, for females, solitary-passive play is associated with a lack of internalizing problems, greater social competence, academic skills, and academic achievement. This is consistent with the position that solitary-passive play in young children is not associated with maladaptive outcomes (e.g., Coplan et al., 1994; Rubin, 1982). However, for males, solitary-passive play was associated with lower social competence and academic achievement.
Figure 3. Summary of Interactions for Solitary-Passive Behavior.

Males

\[ \begin{align*} &-0.25 \\
&0.10 \\
&0.26 \\
&0.24 \end{align*} \]

Note: Numbers represent standardized Beta’s

\[ * = p < .05 \]
**Shyness and Nonsocial Play**

The final set of analyses concerned the temperamental correlates of reticent and solitary-passive play for males and females. In predicting shyness, a significant main effect of reticent behavior ($\beta = .23; t = 2.04, p < .05$) was found. Thus, shyness was associated with reticent behavior for both males and females.

However, for solitary-passive behavior, there were no significant main effects, but a significant gender by solitary-passive play interaction was found ($R^2_{\text{change}} = .06; F(1, 73) = 5.05, p < .05$). Exploring the interaction, it was found that for males, solitary-passive play was positively associated with temperamental shyness while for females, solitary-passive play was negatively associated with temperamental shyness. Results are summarized in Figure 4.

**Figure 4.** Summary of Interaction for Shyness and Solitary-Passive Behavior.

**Males**

\[ \text{shyness} \rightarrow \text{solitary-passive} \rightarrow .17 \]

**Females**

\[ \text{shyness} \rightarrow -.32^* \]

Note: Numbers represent standardized Beta's

$^* = p < .05$

**Implications**

Results from the present study demonstrate that there are gender differences in the correlates of different types of play behaviors (social, reticent and solitary-passive play) in young children. In general, our results indicate that a lack of social play may be more detrimental to boys than girls in terms of adjustment to Kindergarten.

Moreover, certain kinds of nonsocial play forms may have different meanings for young boys than for young girls. Whereas reticent behavior was found to be associated with negative outcomes regardless of gender, solitary-passive play was associated with positive outcomes for females and negative outcomes for males. Thus, gender appears to be an important variable to consider when examining the relation between nonsocial play forms and adjustment outcomes. Future research is required to further elucidate these findings and their implications for intervention programs.

Dear Colleague:

It has come to our attention that you will be giving a presentation at the 1999 Biennial Meeting of the Society for Research in Child Development to be held in Albuquerque, New Mexico, on April 15-18th. We would like you to consider submitting your presentation, or any other recently written education-related papers or reports, for possible inclusion in the ERIC database.

As you may know, ERIC (the Educational Resources Information Center) is a federally-sponsored information system for the field of education. Its main product is the ERIC database, the world’s largest source of education information. The Clearinghouse on Elementary and Early Childhood Education is one of sixteen subject-specialized clearinghouses making up the ERIC system. We collect and disseminate information relating to all aspects of children’s development, care, and education.

Ideally, your paper should be at least eight pages long and not have been published elsewhere at the time of submission. Announcement in ERIC does not prevent you from publishing your paper elsewhere because you still retain complete copyright. The reproduction release is simply ERIC’s way of stating the level of availability you want for your material. Your paper will be reviewed and we will let you know within six weeks if it has been accepted.

Please complete the reproduction release on the back of this letter, and return it with an abstract and two copies of your presentation to BOOTH #19 or to ERIC/EECE. If you have any questions, please contact me by email at (ksmith5@uiuc.edu) or by phone at (800) 583-4135. I look forward to hearing from you soon.

Best wishes,

Karen E. Smith
Acquisitions Coordinator
