NCATE/ISTE standards (ISTE, 1998) require that students have a working knowledge of telecommunications and its use in the classroom. The State of Illinois and NCATE standards recommend more field based training such as Professional Development Schools (PDS) for preservice teachers. Although Illinois State continues to increase the number of PDS sites, increased field placement is difficult given the numbers of elementary education majors (over 2,000). This research examines how telementoring can provide introductory contact with K-12 classrooms as well as improve telecommunication skills.

Telementoring is defined as mentoring a group of novices through telecommunications by practitioners (Wrighton, 1993). Telementoring in this project is defined as mentoring preservice teachers through Internet by practicing teachers.

This is a follow-up study to the pilot study conducted fall 1997. A survey of supporting literature is presented in that article (Brehm, 1998). Based on students' and teachers' suggestions from the pilot study, modifications were made in the recruitment of mentors, building community, and the types of mentoring activities planned. Community between preservice teachers and mentors was built through pairing of a teacher with two students, an introductory e-mail exchange, the development of a collaborative project, and a mentor visit to the campus classroom.

After the initial introductory e-mail exchange, pairs identified a topic for a thematic unit or a literature focus unit that the classroom teacher was currently teaching or developing for the future. On-line activities continued throughout the semester related to the chosen unit. They also participated in the netWorkPlace (nWP) discussion area.

Methodology
Participants
Twenty-three preservice teachers in a language arts methods class and 13 inservice teachers representing either school districts participated in the research. The language arts methods class is taken in a block with three other methods classes usually during the junior year. Four weeks into the semester, students go out into local schools for four weeks full time. They then return to the classroom for the second half of the semester.

All participating teachers had been enrolled or were currently enrolled in graduate classes taught by the author. Eight teachers chose a $100 stipend from a HECA grant to participate, one chose one hour university credit, and four chose mentoring as a project in a doctoral class in which they were enrolled.

All student and mentor teachers had access to e-mail. Five mentor teachers from one school had access only through a school address on one computer located in the school library. Two of these teachers obtained individual e-mail addresses during the semester. The remaining eight teachers had convenient access from their classroom or home computers.

Data
Data were collected using questionnaires, interviews, e-mail exchanges, and netWorkPlace interactions. Questionnaires with Likert ratings and open-ended questions were administered to students at
the end of the class. They also completed outside of class an anonymous summary of their thoughts on the mentoring project. All thirteen participating teachers completed questionnaires and the researcher interviewed eleven.

The mean for each Likert question was calculated. Open ended questions and interviews were read and categories determined from the content. Categories were developed independently from students and teacher data. Categories were then described and frequencies in each reported.

Procedure

Teachers were assigned two preservice teachers who were enrolled in a Language Arts methods class. They communicated through e-mail and participated in a Web discussion. The discussion software used was netWorkPlace developed by NCSA at the University of Illinois. This software was chosen because it is organized in a building metaphor, which is easy to navigate and use.

Two students were assigned to each mentor by the author who matched student grade level requests as closely as possible. Due to the number of volunteer mentors, three mentors had only one student. Two weeks into Spring Semester 1998, students send get acquainted e-mail messages and their mentors responded. This was designed to begin building community between mentor teacher and his/her students. Students also ask for a list of several units that the teachers taught. Students choose a unit for which they wanted to develop a lesson plan. The student and the mentor determined goals for the unit together. Due to the time shortage, most mentors just supplied goals. Students spent weeks five through eight full time in local schools (clinicals). After Spring Break, they returned to the campus classroom to complete the semester. Each student located Web sites that fit with the teacher’s unit and e-mailed those sites to his/her mentor teacher. Each student or student pair developed a lesson plan to fit the mentor’s classroom. The mentor teachers provided feedback on the lesson plans, which were then turned into the instructor for grading.

Results

The data are reported beginning with the general evaluation of the project, proceeding with individual parts of the project, and concluding with suggestions from both the students and teachers. Results from the Likert scale questions are reported on a scale of one to five with one being the best rating. Data summaries are reported in the percent of responses of the group.

At the end of the semester, students were asking to rate the components of the class on a five point Likert scale anonymous questionnaire with one as the most useful. Twenty-one students of the 23 enrolled in the class, completed the questionnaire. Some of the components including the mentoring parts are shown in Table I. Students rated all parts of the mentoring project and instructor presentations about average. Clinical experience consisting of four weeks in a school was rated as the most valuable part of the class.

Table 1: Student numeric ratings of class instruction including mentoring activities on a questionnaire.

Students were also asked to reflect on the mentoring process including what they liked and disliked and suggestions for future projects. These reflections were written outside of class and were anonymous although some students choose to include their name. The overall ratings of the project fell into four categories of responses. The four categories shown in Table 2 emerged from the data. Figure 1 explains each category and lists sample student comments for each category.
Table 2: Student overall evaluation of Telementoring Project from self-reported reflections.

Sample responses characterized as enthusiastic are as follows:
- Beneficial
- Enjoyed
- Good idea - I learned a lot.

Responses characterized as good were generally positive but had a few frustrations as follows:
- Good idea but some [corks] to be worked out
- Overall mentor experience worked pretty well

Fair responses liked the idea but didn't gain much from the mentoring as follows:
- Great idea but not much feedback so not useful
- Needs a lot of revision

Poor responses were totally negative about the project as follows:
- Waste of time
- Did not like. Did not gain anything

Figure 1: Explanation of categories of student satisfaction with the mentoring process

Teachers completed an anonymous open-ended questionnaire on the telementoring project. Most choose to include their name on the questionnaire.

Seven teachers (53.8%) reported that both students had positive attitudes and were enthusiastic, two reported (15.4%) one student was enthusiastic but the other student did not correspond as often and was less involved. One reported (7.7%) that she didn't feel that her student "put much time or effort into her project". Three (23.1%) did not report student attitudes.

Teachers were asked whether or not they would be interested in mentor another semester. Eight (65%) responded that they would, four (30.8%) responded possibly, and one (7.7%) did not respond. The ones who responded "possibly" cited time and the actual presence of a preservice teacher from another university in the classroom. One said that her "junior block student from another university brought gifts and she missed that payback and the personal contact with the students that she was mentoring". One, who responded "yes", said that she would continue if there were some kind of compensation for the time that she invested. Of the eight who answered "yes", seven continued mentored during the fall semester 1998. The four possible and the one no response answers were from mentors who had access only through the school library.

On-line Interactions

The on-line interactions discussed in this section are nWP, e-mail, lesson plan activity, and building a virtual community. Students and teachers both reported good feeling about netWorkPlace (nWP). A student described nWP as a "Place to share ideas". Seven students made good comments while no bad comments were recorded. Five students mentioned that they liked the variety of ideas and perspectives on nWP. The following two quotes summarize student comments: "nWP provided many perspectives that the instructor alone could not provide" and "It was neat to see different ways that people answered my question". Two students who reported limited e-mail feedback from mentors were included in the group that made positive comments about nWP.

Table 3: Mentor teacher participation in netWorkPlace.
Eleven teachers (84.6%) reported positive comments such as “loved reading responses”. Four (30.1%) reported spending extended amounts of time reading messages such as, “Got hooked when I accessed the site [netWorkPlace discussion] and began to read several items”. Two teachers (15.4%) responded that they liked being able to access parts of the discussion that interested them rather than having to read all of the comments. Six (46.2%) reported using ideas posted on nWP in their classroom. Four teachers (30.8%) reported time as a factor limiting participation. The median of 3.5 interactions per teacher is more representative than the mean of 4.4 since one teacher participated thirteen times.

Students participated only as required except for two.

All teachers and students used e-mail to communicate and complete the requirements for the project. Five students (23.8%) reported using e-mail to discuss professional topics and ask questions not pertaining to this class. The five teachers (38.5%) who had limited computer access reported using it only as required, five (38.5%) reported using it more than required, and three (23.1%) did not report frequency of use.

During the revision stage, mentors reviewed student lesson plans. Six students (28.6%) reported receiving good professional feedback, two (9.5%) reported not much feedback, and 13 (61.9%) did not comment on feedback. Four students said that it was difficult to write a lesson plan for a classroom and students that they didn’t know. Most teachers were enthusiastic about the lesson plans and the fresh ideas that they presented. Six students reported that they actually wanted to teach their lesson in the mentor’s classroom.

Five teachers reported using the Web sites in their classrooms. One reported that her students couldn’t find Web sites on the topic so she provided them. Students had received training on searching the Web as part of their class. The author assisted two students in defining keywords and choosing search tools to find appropriate web sites.

The initial e-mail exchanges and unit collaboration were designed to build community between students and mentors. NWP provided a place for sharing for the entire virtual community. Bringing the mentors to campus to present with their students at the conclusion of the semester was designed to be the culminating activity for the semester. Six students (28.6%) wanted to meet or at least see a picture of their mentor at the beginning of the semester. Three mentors (23.1%) voiced the same desire to “put a face with a name”. Two students (9.5%) suggested an alternate means of communications such as the phone. One student (4.5%) liked the mentoring idea but just wanted to work in person with her mentor.

Barriers

Seven teachers (53.8%) reported time to be the biggest barrier to successful participation in the telementoring project. “Time prevented participation as much as I might have liked.” Teachers from one school, who had access only after school from the school library, five (38.5%) reported that access was a problem.

Initially in class students complained about the length of time that it took to receive a response through e-mail. They wanted an immediate response. By the time that evaluations were completed at the end of the semester, only two students (9.5%) cited response time delays as a problem.

A few technical problems did occur. Some problems such as changed e-mail addresses and typing errors occurred at the beginning of the project. The author called two mentors to verify e-mail addresses. The library aide at the school with only one e-mail address initially failed to distribute e-mail messages to mentors. This was discovered and corrected after a call from the author. One school district had temporary problems with their e-mail system. By two weeks into the project, all e-mail addresses were corrected and all contacts had been made.

Suggestions

The largest number of suggestions from both teachers and students was a call for stricter guidelines for lesson plans. Seven students (33.3%) and eight mentors (61.5%) suggested that more structure and guidance was needed to develop, revise, and evaluate the lesson plan. An example of teacher comments: “I needed to know specific expectations. The syllabus was not enough. I didn’t know my part.”
A student suggested that students and mentors be given a packet with an description of the lesson plan project and a rubric by which it would be graded.

Two students suggested that they be able to choose their own mentor so that their interests and grade level would more closely match. No other student suggestions occurred more than once.

Three mentors suggested the addition of chat room to allow real time interaction and quick responses to student questions and concerns. Two suggested that students be given a choice of options for their project such as creating a web page, WebQuest, or writing a lesson plan.

Discussion and Recommendations

This discussion is meant to both reflect on the data and to provide guidelines for people planning a mentoring project. In both telementoring projects that the author has conducted, there has been a disparity in overall ratings between numeric ratings using a Likert scale and self reported benefits in a narrative. Both reporting forms are anonymous allowing the same level of input without consequences. One possible explanation is the student perception that too much time was spent on technology or that students do not see the connection with language arts. The semester following this research, a former student stopped the author on campus to tell her how beneficial the telementoring was for her and that she was still e-mailing her mentor. She said that she didn’t realize at the time how much she had benefited.

On-line Interactions

The four on-line interactions discussed in this section are nWP, e-mail, lesson plan activity, and building a virtual community. During both open discussions of a group of mentors at the end of the project, they emphasized how beneficial nWP was for them. One teacher commented that she couldn’t tell who were students and who were teachers. Several other teachers agreed but suggested that comments from both were beneficial. Two teachers suggested on the questionnaires that the mentoring process be more of a learning experience for both groups rather than the mentor on the high end and the student on the low end. These findings support collegial rather than teacher/student relationships.

The author has found that the closer the content from a discussion area is tied to class work, the more beneficial it is for students. The instructor needs to monitor the discussion closely and include information from it at relevant points in class and encourage discussion of differing opinions that are posted. Students were urged to use information from nWP in presentations and written assignments such as the final examination. Used in these ways, it serves as another current resource for the class and as a connection between the real world of teaching and classroom theory.

E-mail must be easily accessible for both students and mentors. The problems of just one address per school have been described in this paper. A suggested requirement for all mentors is that they have private e-mail addresses and convenient access to their accounts.

Because of the almost overwhelming number of e-mail messages received by the instructor in this type of project, it is important to organize incoming message from the beginning. Create mailboxes or folders for each activity within the project. After each message is read and a reply is send, file the message in the appropriate place so the it can be retrieved as necessary or used for research data at a future date. Create a filter so that all messages from a project or class initially go into a folder for that class. Instruct the participants to include the class number or other identifying information as part of the Subject line so each message can be filtered into the proper mailbox.

Acknowledge all assignments promptly. E-mail is not perceived to be as reliable as the Post Office and people do not feel as secure using it. Encourage students using Eudora to choose the return receipt option. An automatic receipt relieves student anxiety and removes some of the load from the instructor.

When either a mentor or a student claim to have sent information that the other did not receive, the author suggests that both people send the instructor or moderator a ‘carbon copy of the next several exchanges. This is to make sure that the messages did arrive and to give credit to the student. In the author’s experience, this excuse occurs most often when assignments are late. This simple tactic removes the instructor from the need to determine who is right and alerts students that it is not a viable excuse.

The lesson plan was the most problematic activity of the project. A description of the lesson plan assignment with due dates was in the syllabus given to the students, e-mailed to the mentors, and posted on
the class web site. Although the anatomy of a lesson plan was discussed in class, the students were not
given a specific form since the preferred form varies among instructors and classroom teachers. Mentors
were instructed to give feedback as to how the lesson would work in their classroom. As reported in the
data section, more detailed instructions and a rubric are suggested to make on-line activities go smoothly.

The author initially suggested that the mentors participate in the evaluation of the lesson plan in
addition to providing feedback for the students. They responded that they did not want to be involved in the
grading of the students. In most cases, the lesson plan was a good one and the mentors gave constructive
feedback. In a few cases, the lesson plan was hastily written and not well developed or inappropriate for the
classroom. Some mentors reported when interviewed that they were hesitant to give negative feedback to
the student even though they felt that it was deserved. This placed the instructor in the awkward position of
grading down a lesson plan that the mentoring teacher had said was acceptable. Another problem was that a
few mentors gave very little feedback.

This lesson plan experience exemplifies the need for extra structure in distance education projects.
The ideal approach is for the students, mentors, and the instructor to develop a rubric for assessing the
lesson plan perhaps using nWP or a similar discussion or chat area. A sample rubric could be posted on the
class Web site as a starting point. Time presents a problem in collaborative distance projects. Regardless of
how it is developed, there needs to be a rubric to evaluate the lesson plan or other on-line assignments.

Utilizing the class Web page as a location for detailed information on assignments, a link to the
discussion area, and e-mail to the instructor facilitates access. Students accessing the discussion group from
the campus labs must carry a disk or enter the address of the discussion area since bookmarks or favorites
cannot be saved on lab computers. With class Web site access, the student then needs to remember only
one address to access all parts of the project.

A feeling of belonging to a virtual community is necessary for maximum satisfaction. Several
ways have been presented in this paper. Suggestions from participants indicate that the face-to-face meeting
should be at the beginning rather than the end of the project. An alternative might be the posting (if the site
is closed to the public) or exchanging of digital pictures at the beginning of the project.

Implications for Future Study

Several issues arose from this research that need further study. Students report that some teachers
are better mentor that others. What are the characteristics of a good telementor? The experience with the
lesson plans points to the following question: Should the coordinator of the project be the instructor or a
moderator not responsible for the evaluation of the students?

Mentor teacher attitudes were excellent but students reported less satisfaction with the mentoring
process. How can the mentoring be structured to create less stress for students and improve their
perceptions of the project?

The pilot project was only a discussion on nWP. While this project involved more interactions and
connections between students and their mentors it was perceived by some students as focusing too heavily
on technology. The question that follows is: What is the optimum amount of interaction for a project and
what technological components are the most effective?

Abstract: This paper reports on the effectiveness of using on-line second language/culture virtual seminars to maximize the contribution of international teachers, researchers and resources to an understanding of the multiple perspectives inherent in gaining an appreciation for intercultural communication. Observations and reflections made by students on questionnaires and in interviews in pre-service, in-service second language methodology courses and a graduate seminar on Narrative as Inquiry on Intercultural Communication attest to the potential of online courses to overcome some of the limitations of traditional seminars in promoting second language acquisition and an appreciation of intercultural communication.

Introduction

The globalization of information technology permits new approaches to second language/culture teacher preparation as well as to in-servicing and graduate program specializations. The rapid growth of national internet networks such as CANARIE in Canada, CA*netII in the PRC, TANet in Taiwan, SingAren in Singapore and their integration into larger networks such as APAN in the Asia-Pacific has made the emergence of virtual pre-service, in-service and graduate courses and virtual graduate programs for language/culture teachers around the globe a virtual reality. Yet the creation of highly interactive pre-service, in-service and graduate courses has not been fully realized and to date there are no highly interactive graduate seminars on intercultural communication using WebCT technology. Therefore, a test of the potential for a highly interactive on-line graduate seminar in a challenging area of intellectual pursuit on intercultural narratives is an ambitious yet needed goal to set. Consequently this interactive graduate seminar was created using extensive resources and URLs which are coded and organized to maximize students exposure to multiple perspectives when considering Narrative as Inquiry and Intercultural Communication in the Asia-Pacific. A piloting of this prototype was made so that students could compare the online experience with conventional seminar sessions on Narrative as Inquiry and Intercultural Narratives. As in previous studies of pre-service and in-service second language methodology courses (Carey & Crittenden, 1998), dedicated students report that the on-line course provides far greater opportunities for exposure to and a great depth of analysis of resources. In addition, the organization of these online resources provides multiple perspectives on theory, research articles and paradigm biases that are difficult to attain in a conventional graduate seminar. Finally, the networking of in-service teachers and graduate students with education researchers and teachers from around the globe as a result of this virtual seminar demonstrates the potential of these technological tools to enhance and supplement conventional professional pre-service, in-service graduate seminars.

The majority of the world’s students are attending school in a second or other language (Carey, 1996) in part due to the rapid global spread of English and other international languages. Thus there is a need for language planning in education (Carey, 1997) to ensure that students from these countries can master an international language to a level that their academic reading comprehension and writing production will permit them to contribute to academic research and publication, (Carey, 1998) at the university level. The internet provides a useful tool for providing academic material and courses to help achieve these ends. For the past few years I have been developing on-line supplements to regular lecture courses (Carey & Crittenden, 1998). The first critical stage of this sequence was the development of the Modern Languages Website (http://www.mled.lane.educ.ubc.ca) for second language/culture research and teaching. This website was developed in 1996 and is used extensively as a resource and supplement to the regular graduate courses that I teach. It has also been an invaluable aid in encouraging student teachers around the globe to become web-wise and to feed their enthusiasm for more resources and further connectivity. It continues also to be used by teachers and researchers around the world and receives from 200-800 hits a day. The evolution of the on-line courses
proceeded from using list-serves and the WWW as supplements to conventional classes to the second stage of offering the first “wired classroom” course in our Faculty in 1997. This first on-line course was a second language methodology course for teachers. Because this course was divided between course components that were on-line in the wired classroom, on-line components in the faculty computer lab and traditional lectures it was possible to consider how these different components were best integrated, how each component complemented the others and how students compared and evaluated these components. The students in these initial courses were quite mixed in their familiarity to the WWW and extensive tutorials and instructional time in the computer lab was also made a component of this courses. These language teachers, who were seeking to upgrade their knowledge of second language teaching methodology and educational technology were enthusiastic about the innovations in the course (Carey & Crittenden, 1998) and particularly found some features such as the asynchronous posting features of the bulletin boards highly useful.

The asynchronous bulletin board provided the impetus to consider a more complete exploitation of this resource because it represented the core of a virtual class seminar. I therefore sought to develop this component in a graduate on-line course using WebCT which would maximize interactivity in a challenging subject area. The goal was to create an on-line graduate seminar that was both more challenging and more fulfilling for students than a conventional seminar. Because many of us have memories of highly dynamic exchanges in graduate seminars and these often animated exchanges are the life-blood of learning, I thought it would be critical to determine if a virtual graduate seminar could create this type of lively exchanges that are so conducive to learning and to perhaps extend such a course to a group of graduate students who came from diverse origins in the Asia-Pacific. It was reasoned that those rare moments of lively and motivated exchanges that occur in a traditional seminar could be greatly increased in a virtual seminar that allowed for much greater opportunities for individual exchanges that was not bound by time and space considerations and therefore would create possibilities for a more equitable participation across culture, gender and ESL proficiency levels.

International pre-service, in-service and Graduate Students as Resources

The international pre-service, in-service and graduate students who enroll in my courses constitute a rich resource for adding multiple perspectives in approaching intercultural issues from diverse intercultural backgrounds. In addition, they offer feedback for evaluating the authenticity of published research articles on Asia-Pacific language/cultures through their critiques and research topics development. To fully appreciate this rich source of information and its contribution to the seminar’s benefit, it is advantageous to encourage each of these students to search out, evaluate and elaborate course-relevant websites and other www resources that are originating from their home culture/s. To effect this I sought to maximize the links to diverse researchers in universities around the globe that would treat the particular topics of the course. However, I also wanted to offer an extremely rich variety of resources on any of these topics across cultures. Therefore, a number of lists of specialized websites have been developed for each of the dedicated topics within the course. For example, on a given theorist such as Foucault, there are a variety of biographies, critiques and explications of his works and these are written for students with different levels of prior knowledge. This allows students from different cultural and educational backgrounds to progress through the multiple perspectives on Foucault’s works at different levels of academic difficulty.

This provides students not only with multiple perspectives and multiply encoded representations of theorists works associated with different contexts, but also provides a rich choice through which to develop their academic vocabulary and reading comprehension skills as well as their academic writing for different audiences. This is an important aspect of the course because for almost all of these international students English is their second language and by providing students with such a diversity of interesting materials, there are added benefits of improving their academic reading comprehension. In addition, because students were encouraged to write extensively each day on the bulletin board, it was thought this would greatly increase their academic vocabulary acquisition and writing ability. Finally, and most importantly, the course is designed to maximize the interchange between student and professor and between students from diverse cultural perspectives. This most vital aspect of a conventional graduate seminar was maximized through several measures in this virtual seminar. Again, it was reasoned that the diversity of cultural backgrounds and viewpoints was a highly valued asset.

There are numerous reasons for the advantages of the asynchronous bulletin board over a regular seminar for promoting discussion. First, many students including ESL students are reticent about speaking out in conventional graduate seminars due to their lack of confidence about the material, their lack of time to formulate
their question, their insecurity in their second language, the realization that they are taking up precious seminar time and a host of other reasons that limit their seminar participation. Similarly, there are occasional students who love to hear themselves speak, think their ideas are the most profound, ask questions which have been extensively dealt with in the previous seminar that they missed and feel it is only right that they monopolize conventional seminar time. In addition, there are inherent severe time limits in a conventional seminar and a lack of opportunity to formulate or express questions in this limited class time. Moreover, the important questions for students usually occur after the seminar when students are mulling over the class notes and readings and when there is no-one to discuss these burning issues with. This on-line seminar sought to overcome these limitations of a conventional seminar and to preserve and to expand the essential and critically important component of a traditional seminar by providing extensive opportunities for student and professor to exchange perspectives on questions of vital interest to the students who come from diverse backgrounds.

The particular reasons for choosing to develop this specific highly interactive on-line graduate seminar was to fully develop the utility of an on-line course using WebCT technology options and to simultaneously demonstrate that an on-line seminar should be able to equal or exceed the dynamic nature of learning that can occur in a highly interactive graduate seminar. The key prerequisites to a successful graduate seminar is to provide the students the opportunity to become actively involved in debate on issues that are of critical importance to them. At their best, graduate seminars include discussion between rival viewpoints that can become animated and involve student affect and ego involvement. It was hoped that this on-line seminar would augment the opportunities for such critical learning situations. The key point and challenge in developing this graduate seminar was to fully exploit the potential for a highly interactive course that empowers students by providing them with the autonomy, the individualization, the self-paced flexibility and the greatly expanded scope of resources that should make it possible to exceed the effectiveness of a traditional seminar. To date, there is no other graduate seminar using WebCT technology that is as highly interactive in the dynamic sense that this course is designed to be. Too often, the great potential of on-line courses are obviated by course authors and developers who think in traditional terms of conventional courses and thereby creating "shovel on" courses that represent traditional courses loaded onto an on-line shell. In addition, I sought to maximize the resources that were immediately available for the students. Too often, in traditional graduate courses, the resources are limited for cost reasons to a particular text or set of course readings. In this course, I sought to organize an extremely rich and organized set of readings that students could download. This would allow students to gain multiple perspectives on any particular theory or works of a particular researcher on a theoretical viewpoint. This requirement also enabled students to have access to readings that were at various levels of expertise on a given topic to match their individual existing schemas or prior knowledge on this topic. Such an individualized and flexible approach should also encourage students to acquire a much greater breadth and depth of comprehension of any theory, research project or paradigm bias. Consequently, they should be in a much better position to have greater comprehension of a theoretical viewpoint on narrative inquiry or to competently challenge the interpretation of research results.

Similarly, I wanted these international graduate students who come from diverse countries to be able to explore the research and theory from other countries and universities while at the same time, where possible, acting as authoritative resource people in the seminar for their particular country and background when appropriate to the other students. This further encouraged me to maximize the on-line journal articles which provide an excellent opportunity for both ESL and native speakers to develop their academic reading comprehension and their academic writing for academic journals by increasing their interest in the diversity of topics. It was also reasoned that students would spend more time exploring diverse on-line academic journals than making a major trip to the library as required in a conventional course. Moreover, I thought, by requiring students to post each day their academic writing on discussions and critiques of assignments for the professor and fellow students that this would promote a higher level of writing and discussion than would occur in a regular seminar. In addition, because students would have the time to compose their messages and to research further the articles or arguments that they were querying before posting, it was reasoned that students could benefit more than they would in an conventional seminar. Furthermore, because students would not be as pressured by time constraints, they might have time to pose more questions and offer more comments of a higher quality that there would not be the time for in a regular seminar.

In general, there are several reasons for various components in the course to be more conductive to higher levels of discussion and critique, for students to learn more about academic composition and journal writing and for students to have a greater opportunity generally to learn more on the importance of academic writing. Finally, for the professor, who is often too concerned with covering additional material in the seminar
and unable to deal with each student sufficiently, the on-line seminar sought to offer the opportunity for answering and developing each student's question in a more responsible and extensive sequence.

What is critical in these interactive courses is for the graduate students to take ownership of the resources that they are introduced to and to delve into those resources that are most motivating to the individual student and appropriate to their level of prior knowledge and interest. To this end students are provided with information on regional networks such as APAN and are given extensive experience at locating individual specialists from around the globe and then encouraged to network with them directly on their websites and e-mail. We now know that students do tend to be more creative in utilizing on-line activities when that work is done in their home computer environment and this is part of taking ownership of their interactive seminar. Their preference in working in their home environment may be in part due to the fact that students in their own environment and context are more accustomed to assimilating information in their idiosyncratic manner that is more retrievable and related to their daily lifestyle. Thus, students are repeatedly encouraged to take ownership of the course.

Enhanced Interactivity

Using the WebCT package allows each student to asynchronously post a question, report, critique or first version of a research proposal or term paper on the bulletin board which can then be read by the professor or any student. The students have adequate time to post intelligent well formulated questions and this important process of formulating the question and composing it in appropriately nuanced terminology is a critical process to acquiring academic composition skills. Students are also encouraged to post relevant e-mail that they may have received from significant researchers from around the globe and that may buttress the students claims or point of view. Moreover, the professor has adequate time to answer and critique the question and cite appropriate websites, resources and commentary without cutting into the limited time of a conventional seminar to answer questions that may be of limited interest to other students. Students can also answer all questions and offer diverse resources and websites that they may have uncovered from their own work and interests. In this sense, there is a multiplexing effect of the current availability of resources and students are empowered to be peer and collegial seminar members. There is therefore the potential to develop a sense of "community of scholars" and a greater sense of student participation in their on-line seminar. Because the seminar can become quite student centered, the occasional professor may feel threatened by having to share the podium but can at least entertain the consoling thought that no individual professor can have the multiple perspectives and resources that such an international student body provided with such unlimited resources may be able to contribute.

Student Seminar Participation Evaluation.

An additional advantage of the bulletin board and chat lines feature of the WebCT package is that each student can be required to make a specific number of comments each day on questions posed by the professor and/or students. This is a major advantage over a conventional seminar where grading the students participation is often too subjective and prone to non-accountability. Using the WebCT approach, at any time during the course, it is possible to have a print-out of each student's seminar participation in answering questions on readings and resources, and critiquing initial versions of students term papers and quizzes. Consequently, it is possible to more defensibly and accountably grade the quality and quantity of each student's participation in each of the on-line discussion components of the course. Therefore, it is possible to greatly encourage and augment the level of all students participation by increasing the proportion of the seminar grade that is dedicated to student participation in the seminar. This is not possible in a conventional seminar since there is no record of student participation and assigned grades for participation are often indefensible. This can further lead to a lack of students motivation to participate in the conventional seminar since their grade is primarily on their term paper. Moreover, students do not have equal opportunity in a conventional seminar to participate for the diverse reasons stated above. To ensure student seminar participation in this online seminar, students are also required to post the first version of their term paper, research proposal or other seminar assignment on the bulletin board. Each student can then be required to critique and suggest revisions and additional resources for the proposal or paper. The opportunity for promoting collaboration and cooperation between pairs and groups of students who are interested in particular research topics is therefore greatly increased over that in a conventional seminar. Again, it is important to realize that the wealth of expertise that international students bring to the discussion of
language/cultural issues in the Asia-Pacific is a major asset that can be shared by involving the students in such peer evaluation and collaborative and cooperative research proposal development. In addition, students can post questions, critiques, and outstanding website URLs they have found for themselves and their colleagues, on the asynchronous bulletin board. This allows the professor and students to respond to any of the above whenever they have the time, interest or additional resources to contribute to the ongoing discussion.

**Live F/F seminars**

It is of course possible to supplement this on-line course with one or more live face to face seminars for select interest groups or all of the seminar students when opportunity exists. It is also possible to use the WebCT online course as a supplement to a conventional face to face seminar. I have piloted such a course and for certain interest groups it is possible to develop a seminar with both alternative modes of delivery. Moreover, it is possible to offer an entire program towards a virtual M.A. degree by on-line courses or to simply offer a single on-line course as an option in a conventional Masters program.

**Off-Shore Students**

One of the major advantages of the WebCT on-line seminar is that graduate students who are working anywhere around the globe can be enrolled in the seminar. This is another aspect of the seminar that can be appropriately utilized to access the resources that such international students offer in diverse countries. At present, there are professors in diverse universities throughout Asia who would like to enroll in such a course while they are continuing to do their research in their respective countries. Such graduate students can also offer current insights into development in their countries. As the speed of change increases in the Asia-Pacific arena such current resources are fundamental to understanding the unfolding changes in the languages, literatures and cultures in these countries. Having other professors in these countries as online students or as online team teachers can greatly enrich the seminar delivery and discussion.

**Conclusions**

Global interconnectivity provides in-service, pre-service and graduate teachers with access to far richer professional contact for the study of second languages/cultures and their intercultural and interlingual variants. In the quarter century that I have been teaching, this is the most significant innovation that I have experienced to improve the quality and depth of student involvement in seminars while promoting the students improvement in academic reading comprehension and academic writing production. Due to the rapid global spread of English as the language of academic, economic and international communication, ESL competence has become a major factor of education at the tertiary level for international students. With the growth of the potential for international students to register in virtual courses and graduate programs such online seminars allow the expertise from graduate students around the globe to be shared with other graduate students and to permit a much higher attainment of collaborative and cooperative study and research. The enhanced resources that online courses provide should translate into higher academic standards. The Web CT highly interactive on-line graduate seminar allows for the enhancement of the traditional graduate seminar which is the primary building block of highly specialized graduate research and theses. It provides a means to expand on the critical interaction in graduate seminars that promotes motivated debate and critical thinking on the multiple perspective that such culturally diverse students bring to the discussion of research and theory. The format of the seminar encouraged the promotion of intercultural perspectives while also raising critical and multiple perspectives on such fundamental dualisms as that between positivism and narrative inquiry. Global interconnectivity promises a much higher level of appreciation of the intricacies of studying the multiple perspectives provided interculturalism and the implication for pedagogy of second language/cultures.

Technology Training in Foreign Language Teacher Education: The University of Colorado's ATLAS Project

Brian Lewis, German, University of Colorado-Boulder, U.S.A., Brian.Lewis@Colorado.EDU

Obdulia Castro, Spanish, University of Colorado-Boulder, U.S.A., Obdulia.Castro@Colorado.EDU

Kuan-Yi Rose Chang, Anderson Language Technology Center, University of Colorado-Boulder, U.S.A., Kuan-Yi.Chang@Colorado.EDU

Abstract: The paper describes the present use of computer technology in foreign language teaching and discusses the knowledge and skills in technology required of foreign language faculty and of graduate students in foreign languages entering the job market, focusing especially on the Foreign Language Education component of an on-going project funded by the Alliance for Technology, Learning and Society (ATLAS) at the University of Colorado in Boulder. This project aims to develop interactive lessons for language courses using the World Wide Web and CD-ROMs. With consultation with faculty, graduate assistants in six languages are designing and developing interactive Web lessons. The training of these graduate students will be a major focus of this article.

The Present Use of Technology in Foreign Language Teaching

The changes taking place in foreign language teaching today are not to be found in the goals of instruction or in the methods used to achieve these goals. At the present time, communication in a foreign language is the primary goal, as it has been for a decade or more, and the methods of instruction that promote communication are most prevalent. It is rather in the increasing use of computer technology to support foreign language learning that change is most apparent.

Computers have not made the inroads into foreign language teaching (or into the humanities in general) that they have made into the natural sciences and engineering, but significant changes are clearly underway. In probably all colleges and universities, language laboratories with their audio tapes and tape recorders have been at least partially replaced or are supplemented by computer laboratories. Audio tape is giving way to digital audio. The lab technician who maintained the tape recorders is being replaced by the computer expert. The nature of the technology is changing, and more of it is used.

How does technology support the learning of communication skills in a foreign language? The use of multimedia and the World Wide Web is increasing greatly. The benefit of the World Wide Web for foreign language learning is that it provides, in a quantity and variety never available before, an easily accessible source of authentic cultural materials from the countries in which the target languages are spoken. The use of e-mail to communicate with an instructor, other students, or students in a foreign country is a valuable communicative experience.

What do foreign language teachers in particular need to know about technology? It is necessary here to distinguish between the use and development of computer-based language learning resources. It is certain that in the years ahead all foreign language teachers will be expected to know how to make use of this technology in their classrooms and to be aware of the pedagogical implications of its use. They will need to know how to integrate it into their courses, how to use it to reach the goals they have for their students.

Technology Training for Foreign Language Teachers
The increasing use of technology in language teaching necessitates a change in the education of foreign language teachers. This paper is concerned particularly with the training of graduate students and future secondary school teachers in the uses of computer technology for instruction. A related, important issue, the in-service training of faculty and secondary school teachers will only be touched upon here.

Students now leaving colleges and universities to teach at the secondary or tertiary level clearly need to have skills and knowledge in this area. A large percentage of college job listings describe knowledge of the use of technology as required or desirable. Graduate students entering the job market and faculty seeking positions are at a disadvantage if they do not have some knowledge of technology.

Training in the use of technology for graduate students who are about to look for their first job has become an essential part of their education, but the means of providing them with this training are now only in the process of being put into place. A number of different training options are available. Courses on the methodology of teaching foreign languages incorporate some technology training, depending on the expertise of instructors of these courses and the availability and use of guest speakers. Workshops and training sessions may be given. At the University of Colorado in Boulder a new technology course for foreign language teaching titled “Multimedia Applications in Second/Foreign Language Education” has been introduced. An innovative use by the Anderson Language Technology Center (ALTEC) of graduate student liaisons with the foreign language departments has provided experience for these students in the area of technology.

Involvement in projects that focus on the development of language learning materials has proved to be a valuable source of training for both graduate students and faculty. A project funded in 1996 by the University of Colorado used the Libra program, a HyperCard-like authoring program, for the development of multimedia foreign language lessons with videodiscs. One of the benefits of this work was the realization that participation in a project of this kind could serve as a means of training graduate students and faculty in the use of technology. The experiences obtained by several graduate students with the Libra project played an important role in their acquisition of their first full-time position. Our present project for the development of interactive World Wide Web language lessons, which was funded by the University of Colorado at Boulder's ATLAS initiative, will be the focus of the rest of this paper.

The University of Colorado's ATLAS Project

At the University of Colorado at Boulder a new campus wide initiative, the Alliance for Teaching, Learning, and Society (ATLAS) has been created to promote excellence in teaching, curriculum, research, and educational outreach through the integration of information and communication technology into the classroom and learning environment. ATLAS supports all university programs that combine technology, arts and media. It also promotes projects that explore the impact of technology in society. All of these goals are present in our project "Foreign Languages at a Distance: The Next Step in Interactive Language Learning" which was funded by ATLAS for the academic year 1998-1999.

With grant support from the ATLAS initiative a group of foreign language faculty and the Anderson Language Technology Center (ALTEC) at the University of Colorado at Boulder are working together with graduate students to design foreign language interactive lessons in the World Wide Web. This project to create interactive language lessons on the Web has brought together four different language departments (East Asian Languages, French and Italian, Germanic and Slavic Languages, and Spanish and Portuguese), and graduate students and participating faculty from six different languages (Chinese, French, German, Italian, Japanese, and Spanish), under the umbrella of the Anderson Language Technology Center (ALTEC). Each department has designed their language-specific pages to accommodate their curricular needs. Some of the pages concentrate on reading, others on listening comprehension and cultural activities, others on developing level-appropriate language exercises on the Web. The overall goal of this project is to make these on-line materials part of the regular curriculum. This will add breath and variety to language
activities and will increase the length of exposure to actual language use. When fully implemented the results of this project will directly impact approximately 5000 students in lower division language courses.

As part of the ATLAS initiative goals, at the same time as we are creating this new learning resources for our students, we are carefully studying the effects the use of this technology will have on actual learning. We have already conducted surveys on language attitude, and we are developing evaluation measures to ascertain both the quantitative and qualitative effects that the use of this new technology will have on our students language development.

Part of the problem presented by the introduction of new methods and technologies to the learning process in general, and to foreign language learning in particular, is the need to familiarize the instructors with them. The foreign language profession is so tied up with the need to conduct widely accepted research and publish, to teach, and to help with departmental administrative needs, that little, if any, time at all, is left to be dedicated to the learning of a completely new field which requires extensive training. This is problematic enough, but to this we have to add the lack of recognition the time dedicated to the development of new technology learning tools is receiving nowadays at the time rank and tenure decisions are made. Highly qualified and motivated instructors are seeing the need to develop new ways of teaching with technology, but they see their future as faculty members compromised by the lack of time to do it all if their work on development of technology-based teaching materials is not given the proper weight in their rank and tenure evaluations.

One way in which we are trying to even the field is to offer this technology training to our future teachers before they leave the university. One very important goal of this project is to use the development of new teaching materials as a way to introduce our student-teachers to the technical knowledge needed to use technology in their teaching, as well as to the evaluation process needed to design pedagogically sound teaching materials. Through the participation of faculty members together with graduate students we are narrowing the gap between these two populations and technology. It is hoped this training will make them better teachers as they make decisions on what to teach, how to teach it, and how to evaluate if learning took place.

The selection of the initial participating members was conducted at two levels. All faculty members, and some graduate assistants self-identified themselves through their previous interest in this subject. We have to mention that the amount of faculty members interested in this field is at this time limited, not only because of lack of motivation, but because of time constraints. In some departments the graduate assistants were selected from a good number of interested students. The selection was based on interest, experience, and/or how at ease the interested students felt with technology. Consideration was also given to how far away from entering the job market these students were. If we had students in the last stages of their careers without enough experience with technology in foreign language teaching, they were considered first. We look at technology in foreign language teaching as a way to give graduate students an edge when entering a highly competitive job market.

We have seen how a project which integrates the use of technology with foreign language learning, student-teacher training, and research on the effects of teaching with technology can be incorporated into foreign language departments through collaboration and communication at different levels. We have learned that departments and universities need to allocate more resources to technology training and assistance for their faculty, students, and staff. If we want our faculty members to develop pedagogically sound ways in which to teach with technology, they should be provided with the time and recognition needed to produce effective teaching tools which will affect the quality of education significantly.
Evaluating Software and its Effectiveness in Literacy Development in the High Needs Learner

Jane A. Chisholm
School of Education
Acadia University
Wolfville, Nova Scotia, Canada
E-mail: 005008c@acadiau.ca

Abstract: The purpose of the project was to assess software programs that have been designed to assist in literacy development of students. When assessing the software programs, one of the main foci concentrated on the usability of these programs by students who were identified as high-needs in literacy development. Other foci include ......
The two software programs assessed were, “WiggleWorks” by Scholastics and “Reading Blasters Jr”, by Davidson.

Introduction

Norris (1994) notes, “that the one common thread in successful educational programs for the at-risk is individual attention.”(p.12) With class sizes staying at considerably high numbers, the means by which the teacher can provide these individualized programs must be addressed. With technology becoming very commonplace in today’s schools, teachers should have the opportunity to assess those software programs that may be used to design individualized programs for their students. This is particularly important for those students who require a more highly structured individualized program. Classroom learning environments according to Norris (1994), must be flexible and suited to each student’s needs and abilities. Teachers should assume the role of facilitator and guide with the knowledge that each student is an individual with a unique learning style. Self-paced instruction and concentration on basic skills, with an emphasis on thinking and coping skills, appears to be particularly effective. (p.12)

As a teacher of the Reading Recovery Program, (Marie Clay, 1972), I have had the opportunity to work with those children, at the Grade 1 level, who were well behind their peers in developing appropriate reading skills. The program is designed so that at-risk children, who show difficulty in acquiring those reading skills that are necessary to make them independent readers, receive one half-hour of intense one-on-one assistance from the Reading Recovery teacher to enable them to become independent readers. Because of the prescriptive and restrictive structure of the Reading Recovery program, students were required to keep on task so that each component of the program could be completed within a half-hour framework. In reflecting upon the techniques that were used in the Reading Recovery program, I began to think about the possibility of using computers as a tool for assisting the at-risk reader. As part of my work with my Reading Recovery students, I was able to explore the use of the computer in a component of the program called, “Roaming Around the Known”. Roaming around the known provides the student and teacher with the opportunity to explore freely and creatively, the process of reading and writing text. I used two educational software programs at that time and they were, “WiggleWorks” by Scholastics and “Reading Blasters Jr.” by Davidson. The students enjoyed the opportunity to work with these programs and expressed disappointment when our “Roaming Around the Known” sessions ended. With this experience in mind, I wanted to explore the possibility for teachers to use software programs within their own classrooms in addressing the needs of students who were at-risk in developing the reading skills required to grow as an independent reader.

At-risk students quite often feel a lack of personal control of their destiny due to experiential, physical, mental or language disabilities and are found to respond well to educational programs that empower them to take control of their learning. With the ever-increasing possibility of computer use in our schools it is important to ask whether or not this technology might assist teachers in facilitating at-risk students to take control over their learning and develop effective literacy strategies? Based on my initial observations I would have to reply in the affirmative. Computer technology has improved a great deal over
the past ten years and many programs have been designed so that the user can become a part of the software program. This interaction between child and program acts as a motivational tool for the child. If software programs have been appropriately selected they should provide individualized instruction that addresses the unique needs of the intended audience. Individualized instruction, according to Norris (1994), “[b]y far has been the single most effective one for teaching at-risk students.” (p.12)

How does one set about evaluating a software program?

When selecting software to be used for instructional purposes, it is important that teachers have a clear understanding of what it is they want to use the program for, is aware the varying levels of independent learning their students are at. Programs must be compatible with the curriculum area in which they are intended to be used in. Additionally, the programs should be compatible with computers that exist within the schools. In assessing software programs, there are many varieties of check lists available for teachers to use. Of course the best evaluations of software can take place if teachers have actively used the programs themselves keeping in mind the abilities of the students in their class. When trying to establish guidelines for this project, I found that those developed by Marjorie Simic (1990) best suited my needs.

1. Computer instruction in reading should focus on meaning and stress reading comprehension.
2. Computer instruction in reading should foster active involvement and stimulate thinking.
3. Computer instruction in reading should support and extend students' knowledge of text structures.
4. Computer instruction in reading should make use of content from a wide range of subject areas.
5. Computer instruction in reading should link reading and writing. (ERIC.)

Matthews (1996) notes that “Crucial question(s) (are) to determine if the text is narrated...(or)...if the text is superimposed over the illustrations? Can the narration be turned off(?)... Do the illustrations...enhance...or...distract the reader? Does the program offer textbook version?” (p.12)

The above guidelines by Simic and questions by Matthews provided the framework for the evaluation techniques used in assessing the software programs that were used in this project.

Procedures
I wonder if you should use I rather than the teacher?

Prior to implementation of the project, I had an opportunity to work with the programs so that an understanding of the program and its applications could be acquired. In addition it is felt that, the programs, just like any other teaching tool that is being used by the classroom teacher, should be examined closely to insure that they are acceptable and potentially lend themselves to meeting the needs of the students selected to use them.

Students of both groups were instructed on how to access the programs they were using. Thus, two sessions of one-half hour each were set aside for this purpose. Upon completion of the two sessions, the students were then encouraged to work independently with the programs seeking the assistance of the teacher only if it was absolutely necessary. The teacher acted as an observer, never straying, far from those students who were working at the computers. Sessions usually took place during a writing period so that the exercise would lend itself to being a part of the Language Arts program.

At the end of the three week period, students were asked what they liked and did not like about the program they were working with. It was felt that this was a major component of the assessment process because the goal is to select programs that encourage success while developing independent learning skills in students. During that three week period, students who were selected to take part in the project were encouraged to help other students become familiar with the software programs. This was done to boost the participants self-esteem and to include others in the class who may have felt left out.

Findings
In summing up the findings of the project, an analysis of each of the software programs assessed will be addressed separately.

WiggleWorks

The first to be discussed is the software program by Scholastics entitled “WiggleWorks”. This program was used by the three Group A students in the grade one-two classroom. The following describes the positive characteristics and applications of the program.

The students who used the program really enjoyed the bright colorful graphics which were used to encourage interaction between the student and the program. Students found that the colorful illustrations in the texts were very appealing. The teacher did not find that either the colorful graphics or illustrations distracted the children as they worked with the programs. When reading the text components, the children were observed as being as intent on listening to the story as they were in looking at the pictures.

The students did have the option having stories narrated by the computer or narration could be turned off by either the teacher or the student. This option allows the student to read the story on their own. In addition text can be selected by the student, in the form of individual words, or phrases so that feedback could immediately be obtained if a child was uncertain they had read the text correctly. This is a definite asset for software programs to possess when the teacher is trying to encourage independence in the developing reader.

The magnetic board component of the program allows children to construct words on their own. They may select words from the story they have just read and practice spelling those or perhaps use them to construct new words. A procedure that is similar to that of the Reading Recovery Program called “Making and Breaking”. Children are able to create their own dictionary containing words that they are familiar with and perhaps will retrieve at a later time when creating there own stories.

Children are able to record their own stories by two methods. They may chose from a voice recorded method or can use the keyboard to type their own stories. For those students who feel more comfortable using a “mouse”, an on-screen keyboard can be accessed for their use.

Students are able to create their own stories that include illustrations generated by themselves. This application encourages a feeling of ownership and the children were anxious to share their finished projects with other students in the class.

The icons on the screen are considered to be user friendly, however it was and is necessary for the teacher to insure that students understand what applications are relevant to each one. Some children will feel relatively comfortable with the use of these icons after a brief introduction but, students who are recognized as high-needs may require more assistance so that they do not become discouraged. However, “WiggleWorks” definitely was motivational in that the students remained on-task for most of the sessions.

The file manager programs were found to be excellent. The teacher was able to log-on and access any child’s folder. This was found to be a wonderful tool to assess a child’s progress and to specialize a child’s session on the computer. This information could be printed so that the teacher could have access to a hard copy of the child’s progress.

Any program that includes tapes or books as a part of their software package is a plus and “WiggleWorks” included both. As well, lesson plans were included for the teacher to use as a guide.

The program was definitely designed as an affective tool that could be used as a part of an early elementary classroom’s Language Arts program. The program is flexible and could be used effectively by the teacher who is seeking a program that could lend itself to a cross curricular -approach. In addition, this program could be used successfully in designing a language curriculum to meet the needs of the high-needs learner.

There are very few disadvantages to this program. However, it is felt that note should be made of these. First, if schools are not equipped with labs or mobile computers, the use of this program within the classroom would have to be planned around other activities that are taking place at the same time. To gain the full benefits of the program, it is necessary that the children are able to have the sound turned on. Headphones are an option but can act as a distraction if the child involved in the program learns better by speaking their thoughts out loud. The teacher needs to consider the learning environment of both the students using the program and those who are not.

An additional drawback was for those students who liked to include a great deal of text on their storybook pages. There is a limitation of eight lines of text per page. For the average grade one student in the beginning, the eight line limitation would not be a factor. However, as students of this level become
more proficient with their writing skills, some level of frustration may be experienced as they try to limit what they want to write.

Reading Blasters Jr.

Group B, consisted of two grade two students who were identified as being high-needs students by their classroom teacher. Further assessment was done using the Diagnostic Survey used in the Reading Recovery Program. These students were identified as being able to read at an early to middle grade one level. These students were also receiving resource twice a week. It was decided that because of the special needs of these two students that they would participate in the project, using the “Reading Blasters Jr.” program. This program is designed to assist students in developing early reading skills.

The program provides a phonetic approach for those students who require practice in the development of reading skills. The program introduces the students to those easy-to-hear consonants as initial letters in words. The new words that are introduced in each level of the program are similar in structure and usually have word endings that are common.

The goal of the students, as they move through this program is to obtain a new status level as crew members aboard the Reading Blaster’s rocket ship. The participants visit planets where they are asked to complete a specific task. As the child progresses through the levels in the program, the approach to each task remains the same but what is required to be done changes as the program moves from teaching about word beginnings, to word endings and changes that take place within words.

The program is user friendly and could be operated by the students with relative ease. Students can access the program by clicking on the appropriate icon and than logging into the program by clicking on their own name.

The program begins by describing what the user will be required to accomplish before moving on to the next level. An explanation of what is to be expected of the child is given at the beginning of each level. A visual guide is provided so that the student can visualize the route he/she will be taking.

The students enjoyed the colorful graphics and developed somewhat of a relationship with the characters that appeared consistently throughout the exercises. The program does have some hidden features that are useful as entertainment tools but soon became boring to the user because they were repetitive. This would not necessarily be a problem because the child would not be encouraged to waste their time exploring as opposed to staying on task.

As students completed each level, they were awarded with a certificate congratulating them on their progress. The certificate could be retrieved by clicking on the mailbox. While in the mailbox, the child has the option of completing a letter that has the major components already in place. This does encourage use of the keyboard and does provide some writing to be done. This type of format would be appropriate for the high-needs learner as it provides an outline for them to follow, however, this type of application does not encourage a great deal of creative writing to take place.

The last component of each level is a visit to the planet of the Story Heads. Here the child has an opportunity to practice listening skills and sorting skills. Once they have successfully sorted out the sequence of the story, they can then go on to read the story. The child has the option of listening to the story while it is read by a narrator or read the story on their own. If the child chooses to read on their own, the program does provide assistance for the child if they wish to confirm the pronunciation of a word.

It was agreed that this program would be beneficial for those students who required practice in developing word skills. The teacher would be required to be familiar with this program so that curriculum activities could be designed to compliment the use of this program. An added feature of the program is that it comes with a complete guide and black-line masters that can be used as supplementary material to the program.

As with the first group, students of Group B were encouraged to demonstrate to other classmates how the program worked. Students of this group were eager to do this activity because they became the teacher and leader of the instructional process.

Conclusions

As with any instructional tool that a teacher selects to use as a part of their curriculum, it is important for them to assess the value of that tool. Does it lend itself to the curriculum that is being taught?
Will the instructional tool meet the needs of those students who will be using it? Does it encourage independent learning to take place? When acquiring software programs for the classroom, it is very important that the teacher takes the time to use the program themselves because they know best what is required within their classrooms.

It was found that students can provide valuable input if given the opportunity to take part in the evaluation of software programs. Students are very honest and will demonstrate through words and actions their likes and dislikes. The observant teacher will recognize if a child is enthusiastic or frustrated while working with programs and should seek out what it is the child likes or dislikes about a program.

When software programs have been selected to be used by those students who have been identified as high-needs learners, it is important that the students are instructed on the operational procedures of the program and that teachers constantly monitor the progress of those students as they learn with computer assisted programs. These students need to feel a sense of empowerment in their educational development and technology has provided another tool that can be used by educators in the development of such independence. Further, students need to be able to work with developmentally appropriate material and develop useful strategies to enhance their literacy learning. In words of Ellis (1974, "(T)hinking about the computer’s role in education does not mean thinking about computers; it means thinking about education." (p.42)

Abstract: This descriptive study investigates the uses of SMART Board in foreign language classes. The paper first discusses how SMART Board can facilitate the teaching process. The second part is dedicated to a more detailed analysis of the various uses of SMART Board from the point of view of the student. Finally, the weaknesses of this tool will be identified. The study may show the potential value of this tool in foreign language acquisition.

Introduction

Cary Academy is a new independent school situated in a booming area of North Carolina called The Research Triangle. In this 6-12 school, teaching and learning are based on the use of technology. Each foreign language classroom is equipped with one networked computer for every student, and several SMART Boards were introduced in the classroom during the first operational year (997-98).

This paper describes and analyzes the use of SMART Board in foreign language classrooms. We will first discuss SMART Board from a teaching point of view - how SMART Board can facilitate the teaching of a foreign language. We will then look closer at the activities using SMART Board from a student's perspective -- how those activities may encourage and facilitate the learning process of a foreign language. And finally, the weaknesses of this tool will also be identified.

We will start by giving some information on SMART Board itself.

I - The Features of SMART Board

SMART Board is an interactive electronic whiteboard. This board is connected to a computer and to a projector that displays the image of a computer screen. SMART board works through a piece of software that allows the users to use SMART Board for different purposes. To enhance the board you first need to start the software and then to orient the board. Once that is done, you are ready to begin...

By projecting the computer screen onto the SMART Board the user can control all Windows applications using his finger on the board just as he would use a desktop mouse. He only needs to press the board's surface to open and close files, explore web sites on the Internet etc.
As with a regular white board, the user can take notes on SMART Board. These can be printed and/or saved like any another document.

Those are the two main features of the board. Let's see now what kind of activities Smart Board offers to foreign language instruction.

II - Activities involving SMART Board in the Foreign Language Classes

We will now analyze the activities proposed in our foreign language classes from two different points of view: that of the teacher, and that of the student.

A- Activities Which Support Teaching

SMART Board supports the teaching process of foreign languages in three main ways: 1) it helps the presentation of new linguistic and cultural elements, 2) it supports interaction with the class and 3) it promotes the teacher's organizational skills.

1) Activities Supporting the Presentation of New Linguistic and Cultural Elements

SMART Board is basically a support on which the teacher can project what he displays on his screen. The prime use of SMART Board in the foreign language classroom is to present new linguistic and cultural elements.

SMART Board allows teachers to prepare and then to present a lesson (grammar, for instance) on a Notebook document. One advantage of such a presentation on SMART Board is that the instructor can make use of the varied writing features to overwrite, underline, highlight or circle the elements he wants the students to focus on. Another advantage is that the document is typed and therefore very readable. It can also be saved and displayed at any time again.

The writing features of SMART Board also make a difference when presenting authentic documents (web sites). It enables the teacher to explore the document in depth, rather than staying at a simple presentation level. BACON/ FINNEMANN (1990) and ALLEN, BERNHARDT/ BERRY, DEMEL (1988) suggested in their studies the positive influence of authentic documents in language learning. With SMART Board the instructor can not only project a web site, he also can overwrite it to emphasize linguistic elements (vocabulary, idioms, structures etc) and specific cultural elements. SMART Board also facilitates navigation of the site. The finger-driven navigation has a tremendous advantage for foreign language classes in that it supports interaction within the classroom.

2) Activities Supporting Interaction with Students

A projection onto SMART Board is very different from a classic projection: it allows the teacher to navigate from the board. The instructor does not have to go to his computer, turn his back to the class, and be more focused on the technology than on the learning process of the students. This point is very important when using SMART Board to teach and is crucial in foreign language classes. Every foreign language teacher knows how difficult it is to have a relaxed conversation with students in the target language. The projection makes it easier to start a conversation on a topic since it allows a group to watch a document at the same time and focus on the same point of the classroom. The merit of SMART Board is that it enhances conversation: when the teacher is navigating the document from the board, he faces and interacts with the class. It allows the instructor to focus on the students' language production and conversations, not on technical issues.
SMART Board also supports communication when it is combined with a wireless keyboard. The teacher sits with the students, reading a text or having a conversation. Suddenly, new vocabulary is needed or appears in the conversation. Instead of breaking the conversation by standing up, going to the board and writing the new word, the teacher can type it with the wireless keyboard onto the SMART Board Notebook. The students do not have to worry about the vocabulary right away. At the end of the activity, the teacher can reinforce those new words by underlining, highlighting or circling important linguistic aspects (articles or prepositions) or conjugations. This document can then be printed for the students and saved for the teacher.

3) Activities Supporting Teacher Organization

Keeping track of vocabulary introduced in class is a major organizational issue in foreign language teaching, especially in more advanced classes. The feature of SMART Board that allows the teacher to save the notes written on the board during the class supports this process tremendously. It helps teachers to remember those words and promotes their reinforcement: the teacher knows exactly the new elements he has introduced and is better able to work on reinforcing each of them.

B - Activities supporting the Learning Process

1) Activities Supporting Oral Skills

PENNINGTON (1996, 10) noticed "that the computer can sometimes encourage a form of 'anti-social' behavior that amounts to working in isolation from others". A common criticism of computer use, this is especially relevant in the context of foreign language classes because we are supposed to interact as much as possible in the target language. The introduction of the projector associated with SMART Board brings this problem into a new perspective. Presented to the whole class, a web document enhances oral interaction in the classroom and opinions or ideas will be exchanged. As suggested for group activities using the computer (Abraham and Liou 1991; Chapelle, Jamieson and Park 1996), SMART Board brings people together and encourages communication.

Besides the fact that the whole class may interact regarding a particular web site, there also exists the possibility of assigning a student to navigate a site on SMART Board. The other students must guide him by giving directions according the assignment related to the specific page. Every interaction takes place in the target language.

It is also possible to have students present projects on SMART Board. They are able to present and speak about the subject without having to concentrate on the mouse. Pictures and text are shown without delay with a simple finger touch on the board to support what they have to say. This places oral production in the target language in the foreground.

2) Activities Supporting the Cognitive Process

SMART Board supports and enhances the learning process in many ways.

One basic feature of SMART Board is the possibility of overwriting any projected document. This allows the students to know exactly what they need to focus on. It helps them to not get lost and to always know exactly what the teacher wants them to select from the document. If the teacher wants to emphasize any particular structure used on a web page, he can underline it with different colors. The various overwriting possibilities presented by SMART Board (colored underline, highlighting, circling) help the students to organize the new concepts. It is a valuable visual learning tool.

SMART Board does not just support learning. According to PAPERT, we generally think that "in the presence of computer, cultures might change and with them people's ways of learning and thinking." (PAPERT 1987, 23). More specifically, Pennington (1996, 3) pointed out that the computer has the potential to change the processes involved in foreign language learning. SMART Board may have this potential too. Used to accomplish certain activities, SMART Board may enhance new kinds of learning processes. We
specifically refer here to activities requiring the use of two windows. These kinds of activities use a first window displaying an original web page in the target language, and a second window showing the teacher's instructions on this web document (what the student has to look for or to discover on the site etc.). Studies are required to support this hypothesis.

Writing a paper on French Guyana does not require the same skills as preparing a web based presentation on the same subject. We already have paper and books to write and read extensive texts. To simply reproduce a text on a web document does not make any sense at all. The web has to bring some new features to the content. One of the unique features of a web document is that it is non-linear: the use of links allows a text to have different levels.

A presentation supported by SMART Board requires the student to prepare his project according to the features of the tool that will support it. In an electronic context, this means to use links. Creating links to present a paper requires the student to organize his ideas and the content of what he has to say. It requires him to have a paper structured in different parts. The organization required by this type of presentation may encourage him to make a learning habit out of this discipline. As Chapelle and Jamieson (1996) suggested, “It seems that the type of metacognitive strategies Oxford (1990) defines - e.g., organizing, setting goals and objectives, planning for a language task - would be essential for learners working in CALL environments”.

Another activity supported by SMART Board is the correction a paper by the whole class. Students can look at the papers of other students, giving them an opportunity to look at their own paper with another perspective. It may help failing students to understand better what the teacher is expecting. It is also a nice way to reward good papers.

Beside the direct or indirect general feedback that every student gets, correcting a paper on SMART Board gives everyone the possibility of working on improving language skills. Students may look for spelling mistakes, correcting them by overwriting the paper projected on the Board. This kind of correction helps students to get an eye for the language. Trying to figure out what is correct or incorrect in a language requires the students to be more aware of linguistic elements. This type of activity has impacts not only the person who produces the work but also on the group working at its improvement.

3) Activities Supporting Students' Motivation and Emulation

Students like to work on SMART Board! They are all excited about this board that you just need to touch to use. They especially love to write with their fingers, so even activities like quizzes are fun on the electronic board! They ask to be quizzed, only for the fun of writing on the board. This magic board brings true excitement in the classroom.

Many studies show how much this excitement and positive attitude is important for learning. From a hormonal point of view, the learning process cannot be started without a student's positive attitude. Vester (1994, 73) affirms that the emotional and psychological state of the student, via hormonal activity, is crucial. He explains it this way: a “negative hormonal state” provoked by stress, fear, pain ... provokes the production of the ‘stress’ hormone (adrenaline) which blocks the synapses activities and the ionic exchanges necessary to the mental process cannot take place. That students have to be in a “positive hormonal situation” to be able to learn. Using SMART Board gives them a positive attitude.

C - Some Problematic Aspects

The problems encountered with SMART Board are not specific to foreign language teaching but are more general problems. The technical issues we underline in this part may be specific to the use of SMART Board in an educational setting.

The first that issue teachers need to be aware of is that the orientation of the board is crucial to be able to use SMART Board properly. This has to be done carefully and nothing can be moved from at all in order to get
an optimal reaction of SMART Board when using the fingertips. Nobody should touch the projector or the cart that contains the projector. If you use a portable board, you must make sure that you have blocked the wheels. If the orientation has not been done properly or if someone has moved one of the elements involved in the projection onto SMART Board, you will waste your class time.

Another technical aspect is related to the pens of SMART Board. The place where the pens lay is electronically connected to the system so that it can recognize when a pen has been taken. This means that if you forget to put back a pen to its place, the board will interpret that you want to write with that pen, and whatever you do on the board will be written there. You will be unable to navigate if all the pens and erasers are not covering their electronic fields.

Another small issue relevant in an educational setting, especially when interacting with young students, is the quality of writing. When students are learning a language, they often cannot connect the new words to their sound system. It is important that the students be able to see a very clear spelling of the new words.

**Conclusion**

This analysis of SMART Board in the foreign language classroom has underlined the gains and possible problem sources for classroom use.

Our impression is that SMART Board is a very innovative and powerful support for language acquisition. First of all, it provides a bridge that allows using the features of computers without breaking communication, -- it even supports it. Secondly, it may enhance new kinds of learning processes, for instance when working with two windows.

On the practical side, SMART Board offers a very interesting option for bringing the Internet into every FL class. The Internet, and the access it provides to authentic documents, is the biggest revolution in foreign language teaching/learning in the last few years. SMART Board brings this interactive feature into the classroom without involving the cost of having one online computer for every student in the classroom.

David's Story: How Technology Helped a Severely Disabled Learner Read and Write

Margaret H. Hill
University of Houston-Clear Lake, USA
hillp@uhcl.cl.uh.edu

Liz C. Stephens
Southwest Texas State University, USA
lcs@tenet.edu

Abstract: This case study describes how one autistic learner became a co-researcher with university literacy instructors to investigate how hypermedia can help him develop language and literacy skills. Researchers learned that fast paced behavioral games were a detriment to learning language processes whereas books on tapes, schematic mapping software, and simulations helped the learner increase reading and writing competencies. The learner’s scores doubled every six months in reading and writing.

How Can Hypermedia Help Autistic Learners?

Autism and what specifically was identified by Leo Kanner (1943) and Hans Asperger (1944) is a syndrome which has led educational specialists searching for a variety of instructional strategies to help the autistic learner acquire literacy. Due to the insular nature of this syndrome, language development and the subsequent learning of reading and writing are problematic. Language is acquired through a complex multiplicity of social stimuli. Yet, the very nature of the autistic individual prevents this necessary social interaction and the response mechanisms needed to produce language and literacy. The autistic learner, according to Kanner (1943) is alone, obsesses on sameness and has a literal mind. In this case study, literacy researchers hypothesized that a hypermedia platform might be a suitable mechanism for stimulating the development of language growth in one autistic learner (Rouet & Levonen, 1996; Spiro, Feltovich, Jacobson, & Coulson 1991; Spiro, Coulson, Feltovich, & Anderson, 1988).

Hypermedia provides a platform which can be conducive to language growth for autistic learners. It is nonbiased, can be highly repetitive, is based upon pattern generations, and provides multiple links to senses through visual, tactile, and auditory senses. It is interactive, infinitely patient yet provides pathways for multiple ways of knowing and learning. Spiro, Feltovich, Jacobson, and Coulson (1991) claimed that “revisiting the same materials at different times, in rearranged contexts, for different purposes and from different conceptual perspectives is essential for attaining the goals of advanced knowledge acquisition”(p.28). Spiro et al contend that hypertext provides a platform for cognitive flexibility and therefore allows the learner to create his own learning pathways. In addition, the flexible branching and multiplicity of information platforms provides the autistic learner avenues of learning that were heretofore not available. Multiple options such as larger print, audio and visual simulations, rebus symbols, live motion examples and multiple branching options all enhance the learner as new vocabulary and concepts link to the existing schema. In this study, one autistic learner’s pathways to learning literacy are described. Past studies (Heimann, Nelson, Tjus, & Gillberg, 1995; Mykelbust, 1995; O’Conner & Hermelin, 1994; Proco, 1989; Prizant, 1996) of autistic learners describe and document the autistic learner’s acquisition of word recognition alone. However, no studies systematically explain the acquisition of processes involved in reading comprehension, of retellings, and of story and information writing. This is the story of one autistic learner’s journey into hypermedia and increased literacy acquisition.

Stumbling Blocks to Literacy and Why Hypermedia May Free this Roadblock

Reading and writing is a social phenomena based initially on the development of the speaking and listening processes already acquired through social interactions—talking and listening to others. However, if these connections are never firmly acquired as they are not in the autistic learner, then how
can reading and writing proceed? Reading is the recognition of a writer's message—it is listening to that writer's voice. Writing is the connection in writing to an abstract audience—to those unknown or known audiences. In addition, the abstract symbol system of writing and reading adds an additional confounding variable. Because autistic learners are inward and do not connect socially, it is very difficult for them to learn to read and write (Frith, 1989; Myklebust, 1995; Prizant, 1996; Sigman, Yirmiya, Capps, 1995). However, if they can begin to connect their wonderings to information that is available over hypermedia which is presented with a multiplicity of presentations both audio and visual, then how can this literacy acquisition occur? Most of the writing produced over the internet is information—not narrative story. Fact laden information is presented without feelings and abstract beliefs and thus, might be a more connective process for autistic learners. The autistic learner according to researchers (Grandin, 1995; Happe & Frith, 1995; and Harris, 1995; Tager-Flusberg, 1996) might be able to read and comprehend hypermedia and internet platforms far more effectively than reading books and stories. Thus, hypermedia and internet learning may be an avenue that is a perfect platform for the autistic learner who is grounded in repetitiveness, rigidity, and singlemindedness.

The Study

A year of data were collected from video taping, journal notes, interviews with teachers and the parents, test scores and student artifacts of reading and writing samples. David, an eleven year old boy, came to our office every week for one to two hour sessions. The purpose of the study was to explore his literacy growth through a hypermedia environment. He was asked to be the scientist along with us and together we explored software that would help him grow in literacy and learn important information also. Thus, David became a co-investigator with us and was very aware that we were investigating software that would enable him to advance his knowledge in many fields of learning.

Initially, he brought in software that he had at home. These were games that he played. He proudly showed us the components of each game and how he played the game. He was never able with these platforms to tell us the main purpose, to predict, or explain what concepts he had gained. These games were all behavioral in nature; to David, trial and error was the main strategy; and it never seemed to bother him if he won or not. However, we did notice that he used the characters' names of his "game" software as he wrote his initial stories on Story Weaver (MECC). As a result, these first stories were very disjointed with names attached to actions that did not make sense.

However, they did make an impression on him. It is interesting to note that David's first stories used characters and actions that he learned from these game formats but he was never able to make real sense of them as he was later able to do from retellings of CDROM talking books. For example, he drew a picture of a stage and actors and then wrote, "Spy Fox saved Mr. Othery with his toothbrush. He had a steel door and his toothbrush was on the steel door on the handle. Then those bad crabs were coming after him." With much of the game platform, David viewed the isolated parts, but never connected the whole.

My reflections from my journal were as follows.

With this software, David, responds but seemingly without thinking why. He also doesn't seem to have a strategy as he tries one avenue, and then another. The episodes of these software pieces are very short, very reactive, and not enduring. For example, David takes the red car through a series of adventures where he must choose one pathway or another. Depending upon his decision for pathways, his car ends in a ditch or on a road to another adventure. Quick actions and reactions are necessary. As I sat and asked him questions, David was never able to tell me what he was really doing, what was the point of this game, or how it was played. He had many isolated reactions and comments, 'Look!', 'Oh!' 'Get him!' That was it. There was never an explanation on David's part. He never questioned why or tried to compare it to something in his own life or other learning. However, through all this, he was engaged.

However, due to the rapid sound byte platform of these games, once we shifted to more informational text, to talking books on CDROM and to writing and creating stories, these platforms were slow for David. At first he didn't have the attention span to sit and create a story, to read through a book,
or to discuss what he was learning and the connections that it had to his life. Initially, his reactions were only one or two words, his attention was very short, and his follow through and connections to other learning were non-existent. However, we persisted.

**Talking Books on CDROM**

The first books that we introduced to David were folk tales. We chose these because folk tales are formulaic, relate a story which has a moral or main point that is blatant and characters are flat and stereotypic. David is also trying to sort out what is true and what is not true. And so the exaggerations used in folk tales are blatant enough that David began to understand the exaggerations as being untrue.

When reading through Pecos Bill, Paul Bunyan and Johnny Appleseed David’s first reads were quick and with no discussion. He only wanted to listen to the sound reading. We had to scaffold heavily to get him to retell any of the story. He chose a small part to retell and used only one sentence.

Examples:

- “bout a boy who falls out of a wagon.” (Pecos Bill)
- “It’s a big man.” (Paul Bunyan)
- “Johnny planted seeds.” (Johnny Appleseed)

**Building Schema**

At this point, we introduced the software piece called *Inspiration* which allows children to build schema of story through pictures, words, and sentences. Then it will transform the map into a linear outline form if asked. However, this schematic platform greatly helped David to begin to understand how a story can develop.

David’s first map of Johnny Appleseed had the following words and pictures: Johnny, appleseed, traveled, planted, house. He drew a picture of Johnny, the seed, the house and trees. Compare this to three months later (May) when he wrote the following with *Inspiration* and illustrated it. “Paul Bunyan. When he was a baby he was so big that he had a cradle that rocked him by floating on the water. When the cradle rocked it made big waves. The waves crashed onto the land and into houses. People were angry.” During the reading of this story David asked us to write the following words: houses, waves, grew, baby, cradle, rocked. These were the words that he incorporated into his story. It should be noted that David’s handwriting is very labored and difficult to read. Thus, through writing on the computer, David is better able to read and write his own words.

During the first four months, we worked with talking books on CDROM, with *StoryWeaver*, and with *Inspiration*. During the fall semester, we continued those platforms, but a new CDROM which became extremely successful with David. Edmark has published thematic areas which allows students a virtual reality of oceans, pyramids, rainforest, and neighborhoods. Because of the perseverance of the autistic learner, David has become obsessed with mummies, pyramids, and treasures. Thus, the software, in addition, to books (Aliki, 1979) with explicit diagrams of pyramids, drawings, writings expanded his study and readings of ancient Egypt.

In addition, to reading, writing, and investigating the Egyptian culture, David has also begun to investigate his own feelings and ask questions. “How is his God different from the Egyptian gods?” “What will happen to him when he dies?” “Will he be a mummy, too?” Of particular interest to him were the beliefs of passing into heaven or hell. In Egypt he learned that the two biggest sins were to build a dam and to harm or kill a person. David talked about the things that bad boys did and the things that good boys did in comparison. He has very literal reasoning regarding these rules. However, through comparisons, he is learning that different people do believe different things and that is acceptable. They are just different from him.

David’s mother is a wonderful mother and tries to contextual all David’s learning for him. She also believes in the importance of experiences that can help David learn. She provides trips and visits to special events. Along with these activities, she builds learning environments for David like collecting artifacts, books, pictures, and brochures. Each time David comes into our office, he brings something to talk about. Last summer the family went to Galveston and collected shells. David’s mother helped him classify his shells and mount them in a special box with labels. He brought these to me and we digitized the pictures and created a story through *Inspiration*.

**David at Galveston**
Last summer David went to the beach in Galveston. David collected many shells. Some were very little and some were big. Some were pink, some were gray and some were white. Some still had animals in them. David likes to collect shells.

These stories are language experience stories for him and provide practice each time for reading and writing. He takes them home and reads them to his father and mother. He also takes them to school to read them to his class.

**Assessment Results**

In addition to the stories that David reads and writes each time, the Woodcock Johnson Reading Mastery Test was administered in February and May to help us see the growth that he made when he is compared to a norming group. Because the norm group comparisons are meaningless (they only tell us that he is below his age norming group) we will instead look at raw data for qualitative differences.

The pretest word identification (words in isolation) David’s score grew from 26 to 31. However, word comprehension and passage comprehension nearly doubled. Word comprehension grew from 12 to 20 and passage comprehension grew from 10 to 18. David learned that words make sense and so he always looks first for meaning before he attacks a passage. These scores also indicate how important contextual learning is for his literacy growth. Words in isolation mean very little to him. The interesting subtest was the word attack subtest which is a test of pronunciation of nonwords. In both the pre and post tests his score remained zero. On the pretest he listened and when the explanation told him that these were not really words, he responded, “I can’t read those. They are not words.” (He definitely is smarter than we are!) On the post test he took each word and tried to make a real word out of it because he know that reading and words always make sense. The words he chose were orthographic similarities. (din as desert; ig as log; dat as did; tay as tie). David is secure with about a 200 word high frequency count, however. And his use of rhyme is improving with the constant work of onset and rime each time as he builds a word family word wall.

Probably the most significant growth has been with his writing. At the first of the year, he was unable to develop any story structure at all. His stories were only words. Now, he is able to think in terms of cause and effect and outcomes. He summarizes and paraphrases. His stories are coherent and full of meaning although lacking in rich detail.

**Discussion**

For this study we've drawn upon the theoretical structure of Piaget, Vygotsky, and Werner. From Piaget we know that scheme is what is repeatable and generalizable. The hypermedia platform offers David unlimited repetition, the schema to build a structure for story and information through main ideas and details, and the links to areas that he knows and wants to know more about. Through simulations of pictures, sound voice, and motion, David is shown representations that are real to him. Vygotskian theory would indicate that hypermedia represents a platform that can scaffold learning within his zone of proximal development as well as linking multiple ways of representing thought connections. Werner would argue that hypermedia represents the ability to represent shifting points of view and concrete relatedness that will enable the autistic learner to come at learning through multiple symbolic representations.

**Conclusions**

David’s literacy learning with the hypermedia platform grew in many dimensions. He became able to tell a story from beginning to end. Before he only would tell specific events or facts that were meaningful to him. Now he will write a story which has a focus. Before, there were many disconnected sentences with unrelated ideas even within a sentence. However, the most dramatic shift has been with David’s attention to literacy growth. Initially, David would only tell me words to write. Now he chooses his words from the story he reads. He asks many questions. We talk and make connections to what he already knows. He builds ideas, examples, and connections based upon his learning. He uses the computer to gather information, to store information, to organize information, and then to write his own reflections and responses. Hypermedia is the perfect platform for his literacy growth because of the multidimensional way he can represent his own thoughts and language. Through Hypermedia David can learn and build literacy links far beyond those that are provided with only paper, pencil and books.
Through David's explorations into Hypermedia, he controls the construction of meaning in ill-structured domains by guiding himself through nonlinear, multidimensional explorations of language and learning.

Communication Apprehension, Writing Apprehension, Introversion, and Computer-Mediated Communication Technology Use in Education: A Call for Research

Michael D. Rapp
Department of Curriculum & Instruction, The University of Houston, USA, mdrapp@bayou.uh.edu

Abstract: This paper highlights the need for research that considers communication apprehension, writing apprehension, and introversion together with computer-mediated communication (CMC) technology use in the classroom. Brief overviews of the educationally-relevant aspects of communication apprehension, writing apprehension, and introversion in regards to CMC technology use in the classroom are presented. Finally, speculations on future lines of research are considered and a call is made for further scholarly inquiry.

Anxiety is a natural part of being human and rapid scientific and technological advances over the past few decades have served to increase the rate of exposure of individuals to anxiety eliciting situations (Carlson & Wright, 1993). Indeed, ever since Time Magazine named the computer "Man of the Year" in 1983, there has been an increasing drive for teachers to integrate computer technology in the classroom and scholars turned immediately to investigating anxiety associated with computer use. Currently, a search through an educational or psychological scholarly database can produce over a hundred articles on computer anxiety.

Recently, computer-mediated communication (CMC) technologies such as e-mail, electronic discussion groups, and videconferencing have begun to be included in educational curriculums. As these technologies are based on the computer, computer anxiety is surely to be relevant; however, investigation into computer anxiety may only provide part of the apprehension picture (Reinsch, 1985). The use of CMC technologies is characterized by the act of communicating and thus consideration of oral and writing apprehensions is especially relevant. Therefore, in order to gain the fullest understanding of apprehension as it relates to CMC technologies in education, aversion to the task of communicating must also be researched.

This paper seeks to address the dearth of scholarly inquiry that considers communication apprehension and writing apprehension in regards to CMC technology use in education by making a call for research in this area. General overviews of the research literature relevant in educational contexts on each of the apprehensions and introversion will be presented. Next, directions for future CMC apprehension research will be discussed.

Literature Review

Communication Apprehension

Communication apprehension has its share of varied labels, such as reticence, shyness, social anxiety, unwillingness to communicate, and pre-disposition to verbal behavior (see Daly, Caughlin, & Stafford, 1997 for references). McCroskey (1978) defines it as "an individual's level of fear or anxiety associated with either real or anticipated [oral] communication with another persons or persons" (p. 192). In essence, highly communication apprehensive individuals engage in less oral communication than low communication apprehensives (McCroskey, 1978). The current construct is more a trait anxiety than a situation-based anxiety in that it is a "relatively enduring, personality-type orientation...across a wide variety of contexts" (McCroskey, 1982, p. 147). Although a portion of the anxiety is genetically based, reinforcement issues (e.g. operant conditioning, learned helplessness), and modeling effects form the bulk of the basis for the development of communication apprehension (Daly et al., 1997).

Communication apprehension has several educational correlates. For instance, communication apprehension is positively associated with classroom apprehension (Olaniran & Roach, 1994), text anxiety (Scott, Wheless, Yates, & Randolph, 1977), and preferences for large lecture classes over small ones (McCroskey & Anderson, 1976). It is negatively related to performance on oral exams (Bettini & Robinson, 1990), motivation to study (Frymier, 1993), and positive attitudes toward school and instructional activities (Hurt & Preiss, 1978;
McCroskey & Sheahan, 1978; Scott & Wheeless, 1977b). High communication apprehension is related to a tendency for students to wait until after class to ask a question of a teacher, not raising one's hand in class, waiting for someone else to answer a question, and not borrowing notes from another student (Neer, 1990). Additionally, highly apprehensive students perceive teachers as less animated, less likely to leave impressions, less dramatic, and less friendly than low apprehensives (Anderson, 1979). Furthermore, Richmond (1997) observes that no only do quiet students learn less in school, they also tend to be absent on presentation days; sit along the sides or the rear of the classroom; quiet younger students may assert they cannot read to avoid reading aloud in class; and in group discussions quiet students will withdraw as much as possible, contribute less, make irrelevant comments, and profess agreement with the group regardless of their actual feelings.

Nevertheless, research has generally not investigated the effect of communication apprehension on actual CMC technology use in the classroom. However, research does suggest that communication apprehension does affect media use. Carlson & Wright (1993) did find a small positive relationship between communication apprehension and fear of the computer itself. Scott & Rockwell (1997) found that communication apprehension is negatively correlated with reported likelihood to use CMC technologies and strongest with those involving a high oral component. Additionally, in unpublished research, Rapp (1998) found that communication apprehension was a weak predictor of choice among CMC technologies that varied as oral or written. With communication apprehension affecting so many educational variables, it is a great weakness in the research literature that the effect of communication apprehension on CMC technology use in the classroom is not well known.

**Writing Apprehension**

Klopf & Cambra's (1979) research underlies the importance of examining writing apprehension as a construct separate from communication apprehension because communication apprehensive individuals are not necessarily apprehensive about writing and vice versa. Daly (1977) defines writing apprehension as a learned response by an individual to either approach or avoid writing encounters. Behaviors displayed by writers, the attitudes expressed about writing, and the actual written products can all reflect writing apprehension (Faigley, Daly, & Witte, 1981). Highly apprehensive writers learn to expect negative evaluations of their writing and can potentially find writing punishing (Faigley et al., 1981). Low expectations drive the highly apprehensive writer to avoid writing, which results in less practice in writing, which in turn results in lower evaluations of writing compared to low writing apprehensive individuals (Daly, 1977). Those low in apprehension, on the other hand, are confident in their writing skills and often enjoy writing (Faigley et al., 1981).

Research also indicates that highly writing apprehensive individuals write messages of less words, less sentences, less qualifications, and of less quality than messages written by low writing apprehensive individuals (Daly, 1977). Also, highly writing apprehensive individuals use significantly less intense language than those low in writing apprehension (Daly & Miller, 1975a). Writing apprehension has also been shown to be inversely related to measures of self-concept, self-esteem, and self-competence (Daly, 1976 as cited in Daly, 1977; McCroskey, Daly, Richmond, & Falcone, 1977).

Writing apprehensives tend to be the individuals who consistently fail to turn in compositions, who do not attend class when writing is required, and who seldom voluntarily enroll in classes in which writing is pervasive (Daly & Miller, 1975c). Daly provides evidence that not only do highly apprehensive writers write differently than low apprehensives, but that high apprehensives additionally fail to demonstrate as strong a working knowledge of writing skills as low apprehensives (Daly, 1978). Indeed, an inverse correlation exists between the construct and reported SAT-verbal scores (Daly & Miller, 1975b). Writing apprehension has also been shown to affect student satisfaction in writing courses, expectations of success in writing courses, and enjoyment of outside-of-class projects (Daly & Miller, 1975b; Scott & Wheeless, 1977a). Additionally, teachers may need to use different instructional materials for highly apprehensive writers given their different performance in writing than low apprehensives (Faigley et al., 1981).

The connection between writing apprehension and the use of CMC technologies is not clear. Very few studies have investigated the relationship between writing apprehension and CMC technologies, especially in the classroom. Moreover, the studies that do exist have produced conflicting results. Harris and Grandgenett (1992) found that writing apprehensive individuals were less likely to log on to a computer-mediated communication system than those low in apprehension. Mabrito's (1991) research suggests that CMC technology can prove to be an equalizing force to bring highly writing apprehensive individuals to the same participation level in evaluating writing as low writing apprehensive individuals. Yet, another study found that highly writing apprehensive individuals were less likely to communicate in teacher-student interactions in a computer-mediated collaborative writing environment than low writing apprehensive individuals (Hartman et al., 1991). Feenberg (1987) reports that
users in a text-based CMC conferencing system may feel very anxious about how communications written by them are received and evaluated, but at the same time will approach receiving messages from others with extreme casualness. However, a recent study found that writing apprehension was not correlated at all to likelihood to use CMC technologies (Scott & Rockwell, 1997). Rapp's (1998) research is also consistent with the finding that writing apprehension does not affect CMC technology choice, message length, or communication process satisfaction. These seemingly contradicting results highlight the need for a greater understanding of the relationship between writing apprehension and CMC technology use.

Interaction of Apprehensions

Studies that investigate interactions among apprehensions are rare in the research literature. Dobos (1995) did investigate communication apprehension, writing apprehension, and computer anxiety together, but did not explore the effects of the interactions among the different types of apprehension. Scott & Rockwell (1997) concluded that the combination of the apprehensions better predicted the use of some communication technologies, but not for all of them and Rapp's (1998) study is consistent with this finding.

One of the chief limitations of the interaction studies that have investigated apprehensions and CMC technology use is that they have concentrated on technologies that are primarily oral or written. Many recent technologies, on the other hand, increasingly blend oral and written elements. Indeed, group decision support systems and other collaborative CMC interactive environments often have oral (e.g., videoconferencing) and written communication (e.g., computer conferencing or electronic whiteboards) occurring simultaneously. As these technologies begin to make their way into schools, it will be necessary to have an understanding of the interaction effects, if any, among apprehensions in regards to such blended CMC technology use.

Introversion

Although introversion is not per se a communication construct, it is clearly related to communication apprehension and many researchers investigate the construct with communication apprehension (McCroskey, 1997). Introverts tend to exhibit the communication characteristics of being quiet, reflective, introspective, reserved, and subtle, whereas extroverts tend to be outgoing, sociable, lively, talkative, expressive, and enthusiastic (Jung, 1921/1971). Low communication apprehension is commonly associated with the extrovert (Meyers, McCallum, & Domingue, 1993; Richmond, McCroskey, & McCroskey, 1989). However, writing apprehension and introversion have not been investigated together in the research literature. Some research indicates little correlation between writing apprehension and other personality-type individual differences (Daly, 1977). Straus (1996) found that participation in CMC is associated with extroversion; however, other research has found that introverts and extroverts do not vary in regards to their CMC technology use (Russ, Daft, & Lengel, 1990). Also, introversion may be a predictor of CMC technology choice, but more so for technologies with a high oral component than for those with a high written component (Rapp, 1998). Thus, as introversion is often expressed by communicative behaviors and given the limited understanding of its effect on CMC technologies, investigation into introversion's relationship to communication apprehension, writing apprehension, and CMC technology use in the classroom is a salient line of research.

Speculation on Implications

Although the understanding of the effect of communication apprehension and writing apprehension on CMC technology use in the classroom is limited, it is still exciting to speculate on some potential implications of the current research. Scott & Rockwell's (1997) research revealed low to moderate negative correlations between communication apprehension and likelihood to use some CMC technologies. Likewise, Rapp (1998) found communication apprehension to be a weak predictor of CMC technology use. The presence of the computer in these instances may provide some explanation as to why the association is not as strong as one might expect. The behavior of talking through the computer may reduce the user's perceived relevancy of communication apprehension. That is, the task of interacting with the computer may take precedence over perceptions of using an oral communications channel. The act of communicating orally in a computer-mediated environment may serve to make communication seem less direct, thus reducing the effect of communication apprehension. If this is indeed the case, it is interesting to wonder why this may be so. Perhaps novelty perceptions are overriding the expected relevancy of communication apprehension. Communicative interaction that would not normally take place may be
encouraged by perceptions of novelty in regards to new CMC technologies, such as videoconferencing. Teachers could use such an effect to increase the interaction of communication apprehensive students in their classrooms and it also might increase positive attitudes toward school and learning. It must be stressed that this is speculation and by no means is it demonstrated in the research literature. However, it does highlight the greater understanding that investigation into communication apprehension and CMC technology use in the classroom can bring to the field of education.

Moreover, the preliminary findings regarding writing apprehension and CMC technology use are especially engaging. If writing apprehension is indeed shown not to be related to CMC technology use, this paradox will assuredly spur much research. As with communication apprehension, a user's perceptions of the computer may alter the individual's perceived level of writing apprehension. Generally, a keyboard is the primary mechanism by which text is entered into a computer. However, the keyboard is also used for a great deal of tasks that would not immediately be labeled as writing. If the keyboard is considered by users to simply be an interface to the computer rather than as being analogous to a pen or pencil, the user's level of writing apprehension may become less salient. Additionally, if writing apprehension is not related to CMC technology use, educators can use this to great advantage. The implication is that if a text-based CMC system is used (e.g. group decision support system or collaborative writing software), students communicating via the CMC technology will be on roughly equal footing as far as an apprehension toward communicating is concerned. Writing apprehension may not then hinder participation, thus increasing the likelihood of efficient and valuable contributions to the discussion. Also, teachers would be able to judge an absence of communication as more of an indication of less grasp of the material than a reluctance to communicate due to an anxiety of writing. These tantalizing speculations indicate the immediate need for a greater understanding of writing apprehension's relationship to CMC technology use in the classroom.

Furthermore, the construct of introversion may also aid in giving understanding to the relationship between apprehensions and CMC technology use in educational contexts. Consideration of the differences between introverted and extroverted behaviors may begin to provide some explanation to the conflicting findings of several of the studies that took introversion into account when investigating CMC technology use. Those high in extroversion would logically be expected to engage in and desire more social activities than introverts. Therefore, extroverts may be more likely to engage in CMC technologies that they perceive to meet an acceptable degree of sociability. Oral-based CMC technologies would probably fit this criteria, but not written-based CMC technologies because CMC technologies with a high written component are characterized by a less temporally adjacent response, thus potentially limiting the degree of perceptions of sociability by extroverts. For teachers, this could imply that using CMC technologies with high written components may make interaction differences prompted by introversion-extroversion less of a factor than if oral-based CMC technologies were to be used. Again, whether this is the case is not known, but researchers should not exclude introversion from investigation into the relationship between apprehensions and CMC technology use in education.

This paper has provided a brief overview of the relationship of communication apprehension, writing apprehension, and introversion to CMC technologies in educational contexts. Additionally, a few speculations designed to highlight the limitations of the current research were put forth and discussed. As technology and especially CMC technologies become more and more pervasive in educational institutions, the need for a strong theoretical and practical understanding of the relationship between apprehensions and CMC technologies in education is paramount. The potential rewards for learning, classroom interaction, and teaching necessarily demand scholars' attention to this exciting area.

TECHNO-POETRY: ENHANCING POETRY WRITING IN METHODS COURSES THROUGH TECHNOLOGY

Sherron Killingsworth Roberts, University of Central Florida and Denise Schmidt, Iowa State University

This paper describes the outcome of an innovative mentoring program at Iowa State University that paired technology faculty with methods faculty to form partnerships that modeled technology integration for K-6 preservice teachers. As a result of the partnership within a reading/language arts course, both faculty members concluded that even topics in seemingly juxtaposition such as poetry and technology could provide successful models of integration. While many have made worthy technological applications within poetry instruction, most of these applications are related to incorporating visual presentations with poetry such as laserdisk technology and multimedia projects or they use electronic postings, teleconferencing, and distance education to revise and edit poetry. These applications treat technology as an addition rather than a true partner that reaches into the actual writing of poetry. Conversely, this paper describes the creation of some useful applications for enhancing poetry writing through technology for elementary students.
Everyday Learning with the Tools of Tomorrow: Exploring Web Based Literacy Projects through the Eyes of a Third-Grade Classroom

Abstract: This paper details the integration of technology tools into a third-grade web based literacy project. The project included 13 students at the beginning of the school year possessing a wide range of technology exposure and reading experience levels. The students were provided an opportunity to work in small groups, reading works by a selected children's author, researching biographical data and exploring the writer's style and use of conventions of literary works such as characterization, plot and setting. Included in the project were authentic purposes for writing; research on the web and traditional sources; cooperative and collaborative learning opportunities and planning, designing and creating finished products in a multi-media presentation.

Introduction

Today's student will be entering a work world which holds differing expectations from those of the past. This modern work world will require them to know more than how to navigate technology tools to achieve a desired and predetermined effect. They will use technology as a tool to express and share their knowledge and findings. Use of the traditional linear curriculum model assumes that students will enter the learning arena at a specified point with a benchmarked knowledge base and a prescribed set of skills, proceed through a set course, and emerge at the other end "educated". This model, which evolved from the industrial age, is becoming obsolete as we progress further into the age of information. It must be replaced by a model which addresses real world expectations, allowing students to learn through an integrated approach with opportunities to work collaboratively and cooperatively as well as individually. The new model of education must include practical, authentic use of technology as a tool for research and presentation. However, according to Owston (1997), we cannot expect the use of technology tools to revolutionize education on their own. Instead, the key to the impact of technology, and in particular to the use of the Web, is how effectively it is used in the classroom.

Foundation: Tools

Today's children, in many cases, continue to be taught with yesterday's tools, a method that could leave them unprepared for our rapidly evolving technological society. An emphasis on learning predetermined content in isolation would more effectively be replaced by an emphasis on learning to think and learning to learn. Haymore, Sandholtz, Ringstaff and Dwyer (1997) identify this as a phenomenon in American schools spawned by accountability systems that relied heavily on raising standardized test scores. These programs for change became commonplace in the 1980s and seem to be on the rise once again. Today, leaders in our nation measure our children against each other and against the children of other nations with norm-referenced scores. As society clamors for higher test scores, schools become more adept at turning students into "better test-takers, but at a terrible cost" (p. 12). Their ability to perform complex tasks suffers as the emphasis in the classroom shifts to "drill and practice of the kinds of skills and disjointed facts" (p. 12) targeted in standardized and norm-referenced tests. With this in mind,
we must not lose sight of the fact that today's students must be able to think critically about the information presented to them, analyze, dissect and discover new ways to apply the information and use it as a stepping stone to further learning. Furthermore, they must be exposed to the many technological advances which will advance their endeavors--advances such as the Internet and presentation tools. Rather than being taught about technology, they must learn to use technology in everyday learning. The emphasis must shift from instruction in how to use technology tools, to instruction that uses technology as a tool. In the former model, technology is an object of study. It is operation based and important to understanding the tool, but the learning is superficial. In the latter, technology tools are the means to an end--they are incorporated with learning in a fashion similar to utilizing a chalkboard, pencil and encyclopedia. The learning that takes place incorporates complex thinking skills such as analysis and synthesis because it is application based, more advanced and thus more complicated.

Foundation: Environment

Classroom environments have a large part to play in how technology is incorporated in the curriculum. A traditional direct instruction model, which was thought to be effective in delivering predetermined content in isolation, does not prepare students totally for a society that requires a great deal of synergy and non-linear productivity. Our classrooms must, therefore, reflect this modern model of society. To do this, we must realize a shift in our traditional concept of the classroom and foster A.C.T.I.V.E. (Grabe & Grabe, 1998) environments with opportunities for Active and Cooperative learning. Grabe and Grabe adopted the acronym A.C.T.I.V.E. to describe the ideal setting for a technology-rich classroom. This environment is Active, Cooperative, Theme-Based, Integrated, Versatile and Effective. An Active and Cooperative environment reflects the shift from competitive learning to cooperative learning which allows children to draw on peers as resources and as sounding boards for formulating, defining and defending new learning. According to Crook (1998), these learning situations are most successful when three criteria are met: (1) an existing "communal purpose," (2) an ample supply of resources and (3) previously established interpersonal relationships (p. 241). Grabe and Grabe (1998) maintain that the learning must be Theme-Based to allow critical connections to the real world. These theme-based projects must be Integrated across the subjects to teach skills in meaningful contexts rather than in isolation. The environment must be Versatile to accommodate many skill levels and interests. Finally, Evaluation must be based on progress, products and effort (p. 23). A teacher and student designed rubric such as the one implemented in this project meets the evaluation criteria necessary for this type of environment.

Shifting Roles

A change in environment will necessarily require a change in roles. Haymore, et al (1997) assert the premise that roles must reflect the modern workplace "where problems are solved through conversation, inquiry, trial and error, and constant comparison of one approximate solution against another." (p. 13). In this type of environment, teachers will step down from the podium to relinquish their role as "lecturer" in favor of the role of "coach". There will be a shift from teachers as "lesson planners" to teachers as "instructional designers". As such, teachers will focus on selecting activities and providing materials. The teacher will introduce the activity and assign a task set in a meaningful context with clear goals. The teacher's goal is to facilitate the students' work by making connections between observations made by the students and associated principles or theories. The teacher will interact with students in a variety of situations: whole-group, small group and one-on-one. Overall, there will be a shift from large group direct instruction to small group instruction, which addresses the particular needs of targeted students. Students will become active participants, constructing knowledge and taking a decision-making role in their education. In this new role, there is a shift in the child's acquisition of knowledge from primarily verbal content to an integration of visual and auditory elements. The student is no longer a passive learner taking in all that is delivered and reflecting that same learning in much the way it was delivered. In this modern model, the traditional "cookie-cutter" students are transformed into active learners who are inquirers and members of a production team, each with an important, often unique role in the total learning experience of class members.

Scaffolding

When children are given support to explore how technology works, they are encouraged to realize their technological potential. They become cognizant of their ability to impact technological products and to express
themselves through technological tools (Stables, 1997). The WebQuest as developed by Bernie Dodge (1997b) is an excellent scaffolding tool for young technologists with an emerging role as active participants and decision-makers. "A WebQuest is an inquiry-oriented activity in which most or all of the information used by the learner is drawn from the web" (Dodge, 1998). This information may be supplemented with traditional information sources (e.g., trade books, encyclopedia, dictionary). It is designed to assist the learner in focusing on and using the information provided by the quest rather than looking for the information. This information is in the form of links to web pages which have been previewed by the teacher or WebQuest designer to ensure their relevance and value to the task at hand. The links take the learner to the targeted information, thus relieving him or her of the burden of searching and sorting through the myriad of information available on the web. This method is all the more attractive and effective when considering the very real possibility that children will be sorting through information which is objectionable or of little value. The WebQuest is a way of narrowing the available resources in much the way a teacher would narrow library holdings by previewing relevant resources and reserving them for the class.

"The WebQuest is designed to support learners' thinking at the levels of analysis, synthesis, and evaluation" (Dodge, 1998). This is accomplished by offering opportunities which allow the learners to make choices and take control of their project while providing enough scaffolding to ensure success and a sense of direction. In a longer term WebQuest, students might be required to use many higher level thinking skills as they: compare similarities and differences, classify by attribute, induce or deduce by inferring generalizations, analyze errors, construct support (proof), abstract key ideas, and analyze differing perspectives (Dodge, 1997a). These are all skills to consider and build in when developing the "process" portion of the WebQuest.

WebQuests may be short- or long-term projects. In a short-term project, the instructional goal is knowledge acquisition and integration. "At the end . . . a learner will have grappled with a significant amount of new information and made sense of it" (Dodge, 1997a). This type of WebQuest is designed for completion in one to three class periods. The instructional goal of a longer term WebQuest is to extend and refine knowledge. "After completing a longer term WebQuest, a learner would have analyzed a body of knowledge deeply, transformed it in some way, and demonstrated an understanding of the material by creating something that others can respond to, on-line or off." (Dodge, 1997a). This type of WebQuest will typically take between one week and a month in a classroom setting. The WebQuest used for these third-grade students, WebQuest: Amnesia, was a longer term WebQuest.

A typical WebQuest is found on a web page, but with newer versions of word processing software which support web links, a web page is not essential to the task. A WebQuest includes an introduction that explains what the WebQuest is about, orients the learners as to what information will be presented, and clearly describes the steps to be taken. The WebQuest includes information that will let the learner know the exact process needed in order to accomplish the task. Additionally, learning advice and information resources in the form of links should be provided as well as resources not found on the web. Evaluation of the students' work should be able to measure the results of the WebQuest. A rubric devised by the teacher in the design phase of the WebQuest or a rubric devised by the teacher and learners in a collaborative context are authentic methods of evaluation. The WebQuest concludes with a method of sharing the learners' product as evidence of the learning gained by the students. This closure activity serves to remind the learners about the learning that took place and encourage extension of the experience into other domains. Sharing the product may be accomplished in a multi-media presentation to peers and adults and can be loaded on the web page.

**Action: Literacy Project**

El-Hindi (1998) asserts that today, literacy is more than reading and writing, it includes the ability to "make sense of and navigate through several forms of information including images, sounds, animation, and ongoing discussion groups" (p. 694). This literacy project focused on El-Hindi's definition and incorporated the use of a WebQuest. It was conducted with a third-grade class of 13 students in a suburban "Chapter One" (as determined by low income) elementary school. These students included one child identified as "gifted," three children served by the school's speech therapy program, one child being tested for learning disabilities and one identified with Attention Deficit Disorder. Of these students, there were three African American, five boys and eight girls.

The introduction to the WebQuest stated that a favorite children's author was stricken with amnesia and the task before the learners was to help the author regain his or her memory (Foster, 1998). Children formed groups that
varied in size from two to four members and selected an author from the choices provided on the WebQuest. The first task was to select job roles and set tasks for the week. Next, the students brainstormed possible avenues that would help their author to regain his or her lost memory. Strategies employed by the student groups included researching biographical information and reading the author's work to determine the writer's style. Additionally, the group constructed a synopsis of each story focusing on plot, theme, characterization and literary elements.

Children learned to use the links on the WebQuest page to research their author's biographical data and the books he or she wrote. They wrote letters to the school librarian and the teacher to enlist their aid in gathering trade books. They accessed the computerized card catalog in the library to locate and secure resources. They created advertising fliers to describe their mission and in the process learned many computer skills including retrieving an image from the web and using word processing software. These fliers were then loaded on the web page with the WebQuest. As the students collected data, they began to design HyperStudio cards as evidence of their learning. An example card was then used in a group critique session allowing the children to consider elements such as color, contrast, content and effectiveness. Throughout the project, the students kept a daily learning log describing their accomplishments, problems and solutions and plans for the next day. Some of their log entries were in the form of e-mail messages to Dr. Snider, see [Figure 1]. By e-mailing Dr. Snider, the students were afforded an opportunity for authentic electronic communication and were provided with another expert source of support. All four groups were able to create a HyperStudio card for their author. As a class, they decided to keep this project as an ongoing experience, adding to and refining their cards with specified deadlines for various elements of their products. The HyperStudio stacks were loaded on the WebQuest: Amnesia page and shared with other classes in the school.

An important part of the evaluation process calls for the instructors to reflect on the effectiveness of the project and use this to plan future WebQuests. As part of the evaluation process, the instructors considered lessons learned in this first attempt at a WebQuest. Prior knowledge of the specific multi-media program used in this project emerged as the primary area of concern. These children had never been exposed to HyperStudio and needed an opportunity to play with the tool as a way of familiarizing and fulfilling a desire to explore. Although this aspect had not been built into the project by design, the children took advantage of the student-directed environment to undertake these explorations. These explorations, at first, seemed to be time-consuming, off-task behavior; however, they proved valuable to the children's understanding of the tools and built foundational skills which were utilized and further developed as the project unfolded.

**Figure 1:** Authentic purposes for writing were included in the project. Children kept Dr. Snider apprised of their progress. (The student's original composition was retained.)

Due to the children's unfamiliarity with the tools and the fact that this was a beginning effort in the use of the web as a scaffold for constructing student projects, expectations were somewhat flexible. Therefore, rather than following WebQuest design steps exactly as designed, the instructors did not initially establish a rubric for the children. Instead, students were given an opportunity to use HyperStudio and generate the initial card prior to establishing a rubric for the product. This allowed the children to familiarize themselves with the options and limitations of the software and gave them a more informed understanding of the scope of the WebQuest project. This greater understanding then allowed them to be active participants in generating a rubric with reasonable expectations, see [Figure 2].
Figure 2: Learners actively participated in developing a rubric with reasonable expectations.

In order to help students remain focused on the project goals and minimize time wasted on narrow objectives and off-task behaviors, deadlines were imposed for various written assignments. These assignments were in addition to the HyperStudio cards, (e.g.: summaries, character and story webs, a log of titles with their main ideas). Daily learning log entries helped the students structure their goals and reflect on their progress. These entries also provided evidence of understanding and pointed to possible teaching points which needed to be addressed either individually or in a group setting. Additionally, weekly teacher-student group conferences permitted guidance and further scaffolding by a “more experienced other” and helped the teacher to establish a timeline for completion of the specific tasks inherent in the project.

In addition to supporting developing technology skills, encouraging the use of various multi-media programs, and helping students to set project goals and evaluate a finished project, designers should consider the roles of student and teacher and how these can be facilitated most effectively. Reflection on the scaffolding provided to the children in the form of links and supplemental sources as well as the clarity and effectiveness of the goals presented in the WebQuest is paramount. All of these factors should be considered in order for an evaluation of the WebQuest to be an effective tool for planning future projects.

Next Steps

Teachers and curriculum materials designers may want to further explore web-based literacy projects by researching examples of WebQuests (see Dodge 1997). Many fine examples can be found by accessing this web page and following the links attached to this page.

Once the designer has exposure to examples and an understanding of the goals and various elements of a good WebQuest, a unit of study should be identified. When choosing goals for the project, special attention should be given to aligning the WebQuest with established curriculum scope and sequence guidelines. Student interest can also be used as a determining factor in the formulation of a unit of study. Additionally, the designer will need to locate the necessary software and hardware to ensure that the WebQuest is feasible. Finally, the designer will use search engines to locate and collect relevant websites for use in the project. By following these next steps and keeping in mind the lessons learned through this first attempt at a WebQuest, teachers can help their students walk further down the path of the information age equipped with the tools necessary for today and provide a foundation for the crucial skills needed for tomorrow.

Using Semantic Networking Tools to Teach Reading

Dr. Denise Staudt
Department of Education
University of the Incarnate Word
United States

Abstract: Active thinking and learning supports the interactive view of reading comprehension where the role of the reader's background in understanding the text is acknowledged. In this view, teachers can build on students' existing schemata to support comprehension. This paper presents a successful method for teaching reading comprehension through the use of Inspiration, a semantic networking program.

Introduction

Every year thousands of children fail to learn how to read or they read at such an inadequate level that they are functionally illiterate. The inability to read is detrimental to children in today's modern society as it hinders their intellectual and educational growth. Children who do not read well in the first, second, and third grades are likely to struggle with reading throughout their lives.

The problems associated with having limited reading skills in the United States have been well documented. Children who have difficulty learning to read do less well in other subjects, have lower self esteem, pose greater discipline problems in school, and are less likely to complete a high school education. For adults, limited reading ability is correlated with unemployment, crime and lack of civic awareness, poor health and other problems.

On August, 27, 1996, President Clinton announced The "America Reads" Challenge, a major initiative to ensure that all children can read independently and well by third grade. However, nationally 40 percent of fourth graders do not meet the basic level on the National Assessment of Educational Progress (Read Well and Independently, 1997).

Innovative programs in reading, as well as other content areas, are demonstrating that technology can facilitate new ways of teaching reading and learning challenging content. Computers have provided many opportunities to enrich instructional activities in reading. The best use of technology for a reading program is through software that promotes interactivity and builds on the premise that reading is a constructivist activity.

The constructivist view of literacy emphasizes that learners actively create meaning. Reading becomes a meaning making and meaning using process. Meaning is constructed through the interaction of the student and the text. This view acknowledges the role of the reader's background in understanding the text (Burns, Roe, & Elimore, 1996). The proficient reader validates comprehension by decoding important text and by using prior knowledge.
These readers build mental models or diagrams as they read. The comprehension process involves the reader in the active construction of meaning by making connections between what is known and what is new. This meaning making specifically engages learners in relating ideas to what they already know (Barchers, 1998).

Concept mapping is a reading strategy that requires learners to draw visual maps of concepts connected to each other via lines. Taking the form of graphic organizers, concept maps give students information relative to the content material encountered and to support the knowledge-building process (Brozo & Simpson, 1995). Graphic organizers are a diagram or scheme for showing relationships among words and concepts. In a graphic organizer, a superordinate concept is identified with coordinate concepts and subordinate concepts arranged in an appropriate hierarchy. There are a number of paper-and-pencil methods for representing these maps that depict semantic structure among concepts (Barchers, 1998).

Active thinking and learning supports the interactive view of reading comprehension where the role of the reader’s background in understanding the text is acknowledged. In this view, teachers can build on students’ existing schemata to support comprehension. Students select the information to be learned, commit information into memory, make connections among ideas, and integrate new ideas with existing knowledge (Barchers, 1998).

However, recently several computer-based concept mapping tools or semantic networking tools have become available. Semantic networking programs are computer-based visualizing tools for developing representations of the semantic networks in memory. These tools enable learners to identify the important ideas or concepts and interrelate those ideas in multidimensional networks of concepts by labeling the relationships between the ideas (Jonassen, Peck, & Wilson, 1999).

Inspiration for Windows has become available as a powerful mind tool for organizing and integrating ideas. It is one of the most foremost visual thinking and learning tools available. In Inspiration, students can create a picture of their ideas or concepts in the form of a diagram. Thinking and learning becomes an active rather than passive process (Inspiration User Manual, 1997).

In Inspiration, many kinds of visual diagrams such as concept maps, idea maps, webs, storyboards, and outlines, can be created. It has two views or environments: Diagram view and Outline view. As students work, they can keep track of their ideas.

As part of a strategy to teach elementary preservice teachers how to teach reading comprehension to children, I have integrated Inspiration into assignments for a field-based initial reading course. I have found that this software offers new opportunities for children and teachers to be creative and to invent new means of expression, and to tackle more interesting and complex readings. This presentation will show how elementary preservice teachers are using this software to design reading lessons for students and how they integrate the software into their lessons.

Abstract: Computer Managed Reading Programs have become more common in the primary grades nationally. Reading instructors can use these programs to track curricular, and extra-curricular reading activity, track individual student progress, and compile group performance data for a wide range of children's literature. This article considers the benefits and potential pitfalls of CMRPs from a pragmatic and psychological standpoint. The effective use of CMRPs can provide lasting benefits, both from a cognitive-developmental and a motivational theoretical perspective.

What is a CMRP?

Computer Managed Reading Programs, hereafter referred to as CMRPs, refer to a family of software that is available to elementary school teachers which assists them in the tracking of students' reading progress of both in-class and extra-curricular reading materials. A commonly used CMRP is Accelerated Reader. This and similar programs provide multiple-choice comprehension tests that students take upon completing a piece of literature. Test items assess both literal and inferential comprehension. The software supports inclusion into the curriculum of hundreds of examples of quality children's literature. The software also tracks children's progress and the progress of the class as a whole. Students who are falling behind predetermined norms can also be tracked and flagged by most programs. CMRPs also provide instructors with the option of expanding the literature base and adding teacher-made comprehension tests.

Uses and Benefits of CMRPs

School districts across the country are purchasing computer managed reading programs. There are tremendous benefits in instruction and assessment when these programs are properly implemented. What follows is a discussion of the psychoeducational benefits of the addition of CMRPs to the regular classroom.

Instructional Benefits

Research by Stanovich and Cunningham (1992) has demonstrated that when children read texts beyond what is required by the curriculum, the results are long-standing cognitive gains. CMRPs provide teachers with easy access to individual silent reading comprehension of those books that students read beyond the curriculum. This integral part of a child's reading development is often difficult to assess and is accomplished by the student taking a short computer-administered comprehension test given by the CMRP. CMRPs are useful for other types of reading as well. Instructors
can use these programs to assess listening and guided reading comprehension. An instructor may also wish to program the CMRP with tests from curricular-based materials. Whether an instructor only tracks silent reading comprehension or wishes to track a large variety of reading comprehension-based activities, a well designed CMRP will track and compile a variety of data.

CMRPs are designed to give the instructors compiled and individual student data that can aid in the design of the curriculum and better meet individual student needs. Class composite reading level averages, individual book lists, and comprehension scores are several pieces of information that are at the fingertips of an instructor using a CMRP.

Though a CMRP is easy to operate and data is readily available, there is an important element that must be considered for it to be successful in the classroom. An instructor must first determine the reading ability level of the student and her/his zone of proximal development. The Zone of Proximal Development (Vygotsky, 1986) is a concept central to Vygotsky's socio-cultural theory of cognitive development. It refers to the difference in performance at any task between what a child can do while working independently vs. what a child can do with the assistance of a competent peer or adult. Texts presented at the upper end of the zone of proximal development are challenging to the child but are still within grasp.

Reading materials should be selected for each child within her/his zone of proximal development, preferably at the upper end. CMRPs can help identify, based on a student's past performance, texts that are developmentally appropriate and optimally challenging. CMPRs provide teachers with information on texts difficulty and student comprehension performance. Children will score at ceiling (100%) on materials that are at the low end of their zone of proximal development. Texts that result in comprehension scores between 50% and 80% are at the high end of a student's zone and thus are optimally challenging for the reader. Students can then be presented with texts at this difficulty level until comprehension performance is as ceiling.

Better Student Monitoring: Resulting Motivational Benefits

CMRPs make it extremely easy for the teacher to keep abreast of a large number of indicators of students' progress with a minimum of effort. Furthermore, these program make it easy for instructors to take into account the type of language comprehension, whether independent reading, reading with a peer, or listening comprehension. More advanced readers require more independent reading than beginners. Again, CMRPs allow for the tracking of all types of reading outcomes.

A CMRP is useful in monitoring a broad range of ability levels. Most elementary classrooms contain a broad range of ability levels, especially with the emphasis today on inclusion. A classroom instructor can tailor lessons to fit the needs of various clusters of students; the CMRP can be used to monitor each of these groups. Therefore, the students benefit from instruction customized to their needs, and the instructor benefits from the greater ease of assessment. The data generated by the CMRP can help identify students' independent and instructional reading levels without the need of administering a time-consuming individual reading assessment.

An understanding of student motivation and factors affecting it is crucial for the teacher. Students in the regular classroom can usually be classified as having either performance goals or learning goals (Brophy, 1987; Dweck, 1986). Students with performance goals seek to outperform their peers and can have excellent grades, regardless of actual achievement. When an emphasis is placed on competition in the classroom or preparing students for standardized tests, performance goals tend to emerge in students. Learning goals, on the other hand, involve students wishing to learn for its own sake. This intrinsic motivation is encouraged by the teacher who emphasizes learning as its own reward and adopts a mastery orientation. Clearly, the learning goal orientation is in the students best interest.

CMRPs can help determine reading motivation and can track student achievement toward individual and classroom goals. In programs such as Accelerated Reader, developmental ratings are assigned to each book as well as point values based on the developmental rating and book length. One is typically assigned to first grade books while ten corresponds to books at the high school level. Students earn points based on the percentage correct on the comprehension test multiplied by the point value of the book. For instance, if a student achieves 80% (.8) correct on a 5 point book, the points earned would be 4. Thus, students are reinforced for attempting more difficult books. It is important for instructors to consider book difficulty along with comprehension scores. Students, when given a choice, who consistently choose easier books are more likely to have a performance orientation. Those consistently choosing more challenging book tend to have a learning orientation. Teachers can encourage learning goals by discouraging competition between students.
Implementation in the Classroom: Potential Pitfalls.

There are factors that limit the benefits of CMRPs. Improper implementation of a CMRP is as good as not having one at all. For instance, instructors must stay current in tracking data. Recent data, that may show a child is struggling, will not surface in a report of a child's yearly compiled record because previous high scores will "drown out" more recent low scores. Fortunately, more advanced CMRPs will track a variety of data and highlight any extreme changes in performance.

Access to computers may also pose a problem. One or two computers in a classroom may not be enough to make optimal use of a CMRP. If a classroom is under-equipped, students may face long delays between finishing a book and being tested on it. According to information processing theory, long delays between when a text is read (encoding) and when a test is taken (retrieval) is problematic. The longer this interval is, the greater the chance that memory decay or interference will result in inaccurate comprehension assessment (Rayner & Pollatsek, 1989).

Sharon Klay, a Cook County (Illinois) elementary teacher experienced in the use of CMRPs, adds that "not only does a classroom have to be well equipped with computer hardware, support staff is often needed to iron out the logistics." Students need to be trained in fundamental computer skills, e.g., how to log on to the CMRP. Sharon added that "I rely on whatever support I can get to help orchestrate all the tests my second graders take." A class of thirty students needing two tests a day can spell disaster given insufficient hardware. When students are reading books that can be completed in one sitting, such as a well illustrated story book, a bottle neck of students needing to take tests on the computer can develop. Longer and more challenging books can avoid this problem given an insufficient number of computers in the classroom.

Conclusion

Instructors should determine what they want their CMRP to do for them, not to them. For a CMRP to be implemented properly, the instructor must identify the needs of the students relative to the amount of available resources (e.g., hardware). A realistic schedule can be devised to make maximum use of these resources. Classrooms that are under-equipped should not rely on the CMRP to monitor all of the students' reading. Rules such as 'one test a day' can help. In addition, for the best results the instructor should inculcate in students an attitude such that taking the tests does not involve a contest between students or a privilege. Rather, all students should have equal access to the machine and comparison's with a student's past performance should be emphasized. This will promote a learning goal orientation.

Constructivist Uses of Technology for Second Language Learning

Abstract: This article suggests the potential power of constructivist uses of technology to support second language learning using examples from sheltered instruction. It argues that the fields of learning technology and second language teaching share similar theoretical orientations and students would benefit from cross-disciplinary efforts to tie language acquisition theory and practice to the use of technology.

Teachers of English as a Second Language (ESL) recognize the need to teach language within the context of meaningful content learning. Sheltered Instruction combines the best of communicative language teaching with challenging content learning. It requires a variety of scaffolding strategies including modeling, bridging, contextualization, schema building, metacognitive development and text re-presentations that support second language learning (Walqui-van Lier, 1992). Technology has the potential to uniquely support each of these strategies. Yet few resources are available which help teachers of English Language Learners (ELL) to tie constructivist uses of technology to current second language acquisition theory even though both fields are grounded in the same evolving theories of learning. This article attempts to connect second language acquisition theories to constructivist technology uses in order to help Teachers of English to Speakers of Other Languages (TESOL) to improve their practice.

Theoretical Framework

We define sheltered instruction as grade-level instruction in academic classes for non-native students who have intermediate level English skills and who are literate in their own language. We also feel the sheltered instructional strategies suggested in this paper could be applied to any instruction that utilizes special techniques designed to assist non-native English speakers to more readily understand the subject matter. Our aim is to tie cognitive and social constructivist teaching/learning approaches for English Language Learners to technology learning environments.
Bruner (1986) proposed that much of what students learn depends on how they structure knowledge about themselves and their environment. Their ability to interact with their environment is influenced by the organization of that environment. Bruner advocated that educators provide instructional supports by scaffolding their teaching in ways that assist students' mental organization and development of schema. Constructivist uses of technology are grounded not only in cognitive constructivism with its roots in the work of Piaget and Bruner, but also in social constructivism. Willis, Stephens, and Matthew (1996) suggest the differences between these two theoretical perspectives. “Social constructivism spotlights the role of language as a tool used to spur forward intellectual growth; cognitive constructivism explores how language is processed at different stages of natural human development“.

While the sheltered instructional approaches that will be discussed include an appreciation for each student’s internal mental processing, we are also concerned with language learning as it is influenced by socially and culturally-mediated activity. Vygotsky (1962) suggested many years ago how the learning community affects each individual’s knowledge construction. He also made us aware of the importance of tools in influencing cognitive development. As technology tools evolve to become more flexible and powerful understanding the affordances of these tools is essential. (See Norman (1993) for more discussion.)

Constructivist theory has also evolved to include models of constructivism based on the notion of situated cognition which centers on the role authentic experiences play in helping learners construct their own meaning. Traditionally, much of education has separated knowing from doing. Knowledge has been treated as independent of the situations in which it is learned and used (Lave, 1988). Situated learning occurs when students work on authentic tasks in real world settings (Brown, Collins, & Duguid, 1989). Designing opportunities for students to learn deeply depends on recognition of the interconnectedness of tools, authentic activity, and the culture of practice (Norton & Wiburg, 1998).

Connecting Language Teaching Praxis and Technology Use

Sheltered instruction draws upon many approaches including theme-based, task-based, and content-based instruction. In this paper we have focused specifically on the various scaffolding techniques which can be used to support language learning and then tied them to uses of technology which may make these strategies more powerful. The topics covered include

- Modeling through the use of teacher-demonstrated products and processes
- Bridging connections between a student’s personal experience and/or prior knowledge and new material through open-ended and anticipatory computer activities.
- Schema building using computer tools that help build graphical organizers
- Contextualizing through the use of hypermedia resources
- Re-presentation by taking one form of printed material and transforming it through presentation tools
Meta-cognitive development as a result of thinking about technology-based manipulation of language.

Modeling

The teacher demonstrates a task or shows an example of a final product as a whole class activity. For example, the students might be shown a hypermedia stack on the planets and the example of a card about one planet filled out with answers to specific questions such as the size of the planet; distance from the sun; density; etc. Students would then be asked to fill out the information on another planet in the same way. Many kinds of writing process software, such as The Writing Process by Scholastic, or The Student Writing Center (The Learning Company) provide examples of different types of writing and then guide the student through a series of computer-generated prompts to create a similar type of writing, such as a business letter, poem, or exercise in comparisons.

Bridging

A bridging activity establishes a connection between a student's personal feelings and/or prior knowledge and the theme of the new material. This helps make the material relevant to the student's life. Using an overhead projector and a word processing program in the one-computer classroom, the teacher can put up a variety of writing prompts related to the topic that will be discussed. These prompts can be anticipatory charts such as ones that encourage students to list what they know/want to know or agree/disagree about. A unit on world geography might be introduced with an interactive map program such as those available on the Internet. In the process of showing the program the teacher could ask the students to talk about where they came from and/or where their relatives or friends came from. The new maps available on the web can allow the teacher to zoom in and show locations very close to the students' present or previous homes.

Schema Building

Teachers can help students develop clusters of meaning that are interconnected through schema building. When words are introduced in meaningful context it is easier to learn language. The National Council of Teachers of Mathematics in their Standards suggests introducing mathematical concepts using well-grounded big ideas rather than isolated facts and bits of information. Schema building is supported by the use of computer-based drawing and idea development programs such as Inspiration. Students can develop and complete hierarchical concept and language charts, vocabulary trees, matrix diagrams and tables, and outlines of main ideas. For example when studying language students can begin to understand levels of language by visually constructing a class and specific example tree. Furniture is a class, a rocking chair is a type of furniture;
grandpa's blue rocker is a specific example. Computer software now makes it easy for a student to add pictures to each of these levels on a chart.

Contextualization

Contextualization provides contexts that make textbook and formal academic language more understandable. Manipulatives, pictures, and realia create a context that gives clues to the meaning of the material. The teacher or other students can also provide verbal contexts to make new language more comprehensible. A great example is new software programs such as Storybook Weaver that show vocabulary in context. One can build story scenes by selecting from groups of animals, people, buildings or scenery. Using multimedia authoring tools students can also contextualize new content and vocabulary by creating products such as stories or interactive scenes.

Metacognitive

Metacognitive development occurs as students reflect on their own thinking and learning processes. Three important parts to metacognition process include:

1) Planning a task and deciding appropriate strategy
2) Monitoring performance of task
3) Evaluating accomplishments of the task

Students will have opportunities to engage in all three of these steps as they think about technology-based manipulation of language to accomplish tasks and/or solve problems. A common strategy for helping students gain comprehension in the reading classroom is to use Reciprocal Teaching (). Students read one passage together. Student A reads a section aloud; Student B asks A two "thinking questions" (not simple fact questions). Student A responds and the two discuss the answers. Student A gives the text to student B, and the same procedure is repeated with student B doing the reading and A asking the questions. Using a computer authoring or word processing program students can take content and develop questions on that content for other students. The other students can open the developed program and add their answers to the document. You can have several students answering the questions on the same computer at a center in the classroom.

Using electronic portfolio program or simple word processed journals, students can record their information and periodically re-evaluate their progress using the documents they developed to help them measure their growth. Using a video camera as students explain what they are doing or what they have learned is another example of how technology can support metacognition especially as the students get opportunities to view and re-view their performances.

Text Re-presentation

Text re-presentation is a common strategy for helping students learn language. Students work with text to present it in some form other than the original version. For example, they might change a poem into a narrative; act out parts of a story; or write a dialog after watching a short skit. Using technology students can easily take printed material and transform it through the use of presentation tools or authoring programs. They might also take historical or personal autobiographical events and re-present them on a computer-generated time line or map.
Conclusion

We began this paper by suggesting that the fields of educational technology and Teaching English to Speakers of Other Languages share a similar foundation in terms of constructivist learning theory. We further suggested that the implementation of new theories of language acquisition in ESL classrooms can be uniquely supported by the use of technology tools including computer application programs, the Internet, and multimedia authoring programs. It is hoped that the specific examples provided for using technology to support sheltered instruction will help stimulate discussion, research and innovative practice in the use of technology to assist English Language Learners.

RESEARCH
Survey of Pre- and In-Service Educators' Ethical Attitudes

Beverly Abbey, Ph.D.
Secondary and Higher Education
Texas A&M University - Commerce
United States
Bev_Abbey@tamu-commerce.edu

Abstract: This paper presents initial results of a survey in progress of attitudes and opinions related to the ethical use of information technology in education. Respondents were graduate and undergraduate students enrolled in educational technology courses and gifted high school students enrolled in an internship program. The survey covered areas related to general computer issues, personal ethical actions, and educational uses of technology.

Introduction

Interest in public actions and attitudes toward the ethical use of information technology has been heightened due to the growth of and access to the World Wide Web. More people are directly involved with the creation, distribution, and consumption of electronic information than was ever previously thought possible. Due to the abstract nature of electronic information, responsibility for appropriate and fair use of information rests primarily with the individual. Recent information from an ethical organization cites surveys that report that 57% of public-school parents said that courses on values and ethical behavior should be taught by schools and of 1,000 Americans, 26 percent ranked "teaching children values and discipline" as most important to address in education today. It was listed ahead of all other issues, including "keeping drugs away from school" (24.9 percent), "setting higher achievement standards that students must meet (12.6 percent), "ensuring that schools are safe" (12.0 percent), and improving teacher quality (11.4 percent) (Global ethics, 1998).

Teacher educators and universities in general are in a unique position in that they are dealing with an audience that is in a greater state of flux than that of other social institutions. Education itself is being redefined as a result of the impact of information tools. Faculty are re-examining their internal value systems at the same time as they are responding to the task of guiding the next generation. Teacher educators have a responsibility to analyze and reflect upon their own information ethics while making students aware of appropriate behaviors for the access and use of electronic information.

The scope of ethical conflicts that occur at a educational institution fall into three main classifications: right of the individual versus the greater good of an organization or society; contradictory needs and varying interests of educational subcultures; and the intellectual role of the institution in encouraging open examination and questioning of social and moral issues (Smith, 1996). One of the implied roles of public school personnel is to present models of behaviors for students to adopt. Their actions in managing ethical conflicts reflect the ethics of the community and sometimes professional guidelines set by a few professional organizations.

Ethics governs conflicts between personal desires and social responsibility and obligations (Abbey, 1997). As a personalized code of conduct, one's ethics provides guidelines on how to act when confronted with a situation not covered by formal sanctions or religious dogma (Forcht, 1991). The standards of right and wrong behavior set for oneself are based upon peer, family and religious influences, past experiences, and one's unique value systems. What are the behaviors exhibited by educators? What are the attitudes and opinions of educators concerning the ethical and acceptable uses of computers and information?

The purpose of this study was to identify in-service and pre-service educators' attitudes and opinions regarding the appropriate use of computer and electronic information technologies.

Methodology
The survey was administered during the Fall 1998 semester to 218 students attending a regional university. Subjects were 55 graduate students enrolled in four Master’s level Educational Technology courses and 123 undergraduates enrolled in six Educational Technology classes. The questionnaire was also administered to 40 students enrolled in a career internship program for high school gifted and high achieving students.

A survey instrument was developed using items created by the author and items modified from several other survey instruments. Information from the following areas was requested:

Demographic Information - included age, gender, employment category, major, approximate grade point average, experience with computers, and economic status and background;

Respondent’s Personal Opinions Concerning Ethical Use of Computers - 61 statements covered various types of computer related abuse, misuse, questionable actions, and appropriate uses in three broad areas of general computer issues, personal actions, and educational computer uses.

Items related to three of Mason’s (1991) four categories of ethical problems were addressed: privacy, accessibility, and property. Problems of accessibility deal with security concerns, equity, and resource allocation and abuses. Problems with the murky issue of electronic intellectual property rights and concepts of “fair use” are of major concern. Items also included issues of responsibility and management concerning procedures and mechanisms to control ethical infringements.

Respondents were asked to reflect his/her personal opinions by rating the questions or situations on a Likert scale. The Likert scale included choices of Strongly Disagree (1), Disagree (2), Agree (3), and Strongly Agree (4). The usual fifth option “No Opinion” was not offered in order to force a choice. A section on Personal Actions included slightly different choice options (Never, Sometimes, Often, Almost always). Four other items presented a three (Very rare - Occasionally - Very Common) or five choices scale (Very likely to Very unlikely or Excellent to Poor). Three of the items presented descriptive statements from which respondents could choose. It was assured that all scale options were presented in the same order - low/negative to high/positive. Individual questionnaires were not coded to assure anonymity, however, instruments were grouped in order to compare responses.

Analysis

Data was analyzed to look at relationships among demographic variables and ethical conflicts regarding privacy issues, intellectual property right issues, issues of access rights and privileges, and social responsibility and management issues.

Specific questions addressed relationships between and among:

- age and gender and privacy concerns, accessibility, and property rights,
- employment location and categories and privacy, accessibility, and property rights,
- content major and privacy concerns, accessibility, and property rights,
- grade point average and privacy concerns, accessibility, and property rights,
- computer experience and privacy concerns, accessibility, and property rights,
- work experience and privacy concerns, accessibility, and property rights,
- economic background and privacy concerns, accessibility, and property rights,
- and personal income and privacy concerns, accessibility, and property rights.

Additional questions dealt with the same personal variables and exposure to faculty attitudes, rights of management and authority, and procedures for control of ethical infringement.

Summary

Self-reporting surveys are often influenced by the subjects’ perception of desired social behaviors (Ferrell & Ferguson, 1993). More than other professionals, teachers and pre-service teachers may be expected to respond
with what is perceived to be most socially acceptable rather than what is actually true for the respondent. However, the data collected through this survey presents information unavailable elsewhere.

Few resources were found that were directly related to ethics in education. It was necessary to extrapolate from works on information ethics (Dejoie et al, 1991; Oz, 1994), and the Internet (Smith, 1996, Dartmouth University, 1996). It was disappointing to find so little literature regarding educational ethics. This situation would appear to warrant further research and dissemination.

Many researchers and organizations examine behaviors and set standards specific to their discipline or interests e.g., bioethics, computer ethics, medical ethics, legal ethics, business ethics, etc. However, the field of education is rarely, if ever, identified as one of those disciplines whose practitioners examine or determine codes of behavior and/or ethical situations specific to the area. Professional organizations in education are actively promoting the tenet of "professionalism", yet few appear to be establishing unique professional ethical standards.

Bibliography

This study investigated the conditions, processes and consequences of instructional computer use by teachers in three elementary schools and compared and contrasted these across sites. A cross-case analysis grounded in symbolic interactionism and an interpretivist research methodology was conducted. Results indicate that teachers' beliefs and thinking about technology is socially constructed within local contexts and that teachers' beliefs and prior experiences influence instructional computer use. The processes teachers engage when using technology in classroom instruction varied greatly, however, they resulted in similar consequences. This study raises significant questions about educational technology policies, teacher education and professional development models.

Introduction
Increasingly, administrators and teachers are told that technology holds the key to educational improvement and change. Policymakers assume that technology is the silver bullet that will revolutionize education. The federal government and state governments are redirecting billions of dollars into technology for classrooms with little understanding about how this technology is received and used by teachers working in actual classrooms. Policymakers imagine technology and learning as a black box. They assume that simply adding technology into classrooms will lead to improved student learning. In that black box, the instructional practices and professional development needs of teachers are ignored. It is imperative to understand the relationship between technology and teachers' instructional practices in order to understand the impact of technology on student learning. Previous research has not adequately conceptualized this relationship. This is a qualitative case study that investigated the "typical" use of technology by teachers in three elementary schools under the conditions in which they teach. The purpose of the study was twofold: (1) to investigate the conditions, processes and consequences of teachers' instructional computer use in numerous elementary classrooms within three schools and (2) to compare and contrast the effects of these conditions, processes and consequences across the three selected sites.

A Qualitative, Cross-site Approach
Research on educational technology is replete with surveys which analyze teachers' attitudes toward instructional computer use (Loyd & Gressard, 1984), report teachers' self-efficacy using various educational technology (Deltcourt & Kinzie, 1993; Olivier & Shapiro, 1993), report instructional practices (Becker, 1991), determine factors influencing instructional computer use (Becker, 1994; Maricinkiewicz, 1994) and categorize teachers according to instructional computer uses (Evans-Andris, 1995; Hadley & Sheingold, 1993). More recent studies analyze how teachers use of computers may change their basic instructional philosophy and practice (Becker, 1998; Dexter & Anderson, 1998). These studies are valuable to the field and provide much useful knowledge. However, most research designs have employed data which relies on teachers' self-reports rather than direct observations of instructional practices. More knowledge about how teachers think about and engage technology in practice is necessary to make the most advantageous use of technological resources in classroom teaching.

Case studies related to educational technologies are becoming increasingly popular in the field. Several case studies have examined teacher education programs considered exemplary in technology integration (Strudler and Wetzel, 1998; Persichitte, 1998). Other case studies have examined technology-rich K-12 classrooms (Dwyer, 1994) and K-12 schools engaged in technology-supported reform efforts (Means,
These case studies have been useful in understanding how technology influences the teaching process. However, they have focused primarily on single sites and have examined schools and classrooms considered exemplary in their use of technology. This qualitative, multiple case study of technology and teaching practice is distinctive in at least two ways. The schools selected for this study are average or typical elementary schools with regard to technology use. That is, these schools have not been identified as exemplary in computer use nor can they be considered advanced in terms of technology resources. In addition, three elementary schools from two districts were selected to enable a cross case analysis of the impact of technology on teaching at the sites.

Paradigm and Conceptual Framework
Since we were interested in administrators' and teachers' definitions and interpretations about technology and classroom practice, this study employed a symbolic interactionist (Blumer, 1969) conceptual framework and an interpretivist research methodology (Erickson, 1986). According to symbolic interactionist theory, teachers and principals redefine and reinterpret messages about technology that they receive. They then act according to their own definitions of the situation (Blumer, 1986; Smith, Noble, Cabay, Heinecke, Junker & Saffron, 1994). The conditional matrix (Strauss & Corbin, 1990), a form of symbolic interactionism, conceptualizes social actions as a connection between conditions, processes, and consequences. The conditional matrix was used in this study to identify the conditions, process and consequences of technology use in classrooms.

The following issues, identified by Schofield (1995), have also guided our conceptual framework: (1) teachers' beliefs about the appropriate use of technology (2) teachers' beliefs about the goal of using technology (to change practice or make practice more efficient), (3) barriers that are a function of traditional classroom practice and culture (e.g. reliance on lecture and rote software), (4) school and school district level factors (e.g. teacher training and testing), and (5) teacher attitudes toward computers (e.g. computer phobia, notions of classroom authority and technical support).

Methods and Data Sources
Specifically, we employed an interpretivist research strategy (Erickson, 1986) and a multiple case study design (Miles and Huberman, 1986). This design is based on the rationale that understanding complex processes such as classroom computer use requires multiple site visits over an extended period of time. We sought careful grounding in local cases as a prelude to a cross-case analysis. Using multiple cases provides an interpretive context for each case developed.

Case Selection
Three elementary schools were chosen for the study. This number was chosen due to the resources available to support researchers in the field. Average technology using schools were selected for this study. An urban, a rural and a suburban elementary school were selected not in order to increase the external generalizability of the study but rather to improve the internal validity of each case study. This strategy prevents researchers from overlooking some aspects of cases deemed not salient. Seeing multiple cases in parallel can alert researchers to such oversights. Only elementary schools were chosen in order to make the cross-case analysis more meaningful.

Each researcher developed a detailed case study of technology and teaching at her site. Consistency across researcher perspectives was maintained in several ways. First, a common design for data collection and common definitions were developed by the team. Second, the theoretical framework focused attention on common issues at the sites. Third, bi-monthly meetings were held to address issues and concerns and to share preliminary findings. Fourth, a project manager monitored the quality of data collection and analyses procedures. Finally, all members of the team read each case study and reactions were incorporated into the final cross-case analysis.

Data Collection
The unit of analysis for this study was defined as individual teachers within the school. Once the sites were selected, researchers negotiated access to the classrooms of five teachers at each site. Access was
negotiated with the school principal and participating teachers, and five teachers were selected based on the resource constraints of the project.

Data for each case study was gathered over a seven month period via classroom observations, teacher and principal interviews and document collection. Researchers took the role of observers rather than participants. Protocols for the observations and interviews were developed both from the conceptual framework and from initial data collection. Researchers took detailed observation fieldnotes and tape recorded interviews. Fieldnotes were developed into detailed observation write-ups and interviews were transcribed. Data and write-ups were submitted to the research coordinator and were reviewed for detail and thickness of description.

Data Analysis

Within Site Data Analysis

Data analysis was conducted using the techniques of analytic induction as specified by Erickson (1986). In the first step of analysis empirical assertions related to the research questions were generated. Researchers coded data based on emergent themes and categories as they developed in the course of investigation. The researchers initially employed sensitizing concepts according to conceptual categories derived from literature related to teachers' instructional computer use (Becker, 1991; Vockell & Sweeney, 1993; Means, 1998), conditions related to instructional computer use (Willis, 1993; Marckinkiewicz, 1994; Means, 1998), processes related to instructional computer use (Hadley & Sheingold, 1993; Hawkins, 1996), and consequences related to instructional computer use (US Department of Education, 1995; OTA, 1995; Glennan & Melmed, 1996; Means, 1998). Other emergent conceptual categories such as the role of technology in context of teaching, the meaning of technology to teachers, and the relationship of technology to the curriculum, pedagogy, and school organization were used to frame data analysis.

The second phase of analysis consisted of establishing warrants for the assertions generated through a rigorous and systematic search for confirming and disconfirming evidence in the data record. Assertions or statements about the use of technology by teachers, inductively derived, were developed and revised. Finally, vignettes or other empirical exemplars were provided to support the assertions.

Cross-site Data Analysis

Each researcher created her own case record and submitted data to the project coordinator for cross case analysis. Data was entered into a computer-assisted qualitative data analysis software package, Folioviews, for management and analysis. From the individual cases and team meetings, we then developed a cross-site matrix to compare sites and reduce the amount of information presented without losing the grounding and authenticity provided by each case (Smith et. al, 1994). We employed the conditional matrix (Strauss and Corbin, 1990) from our conceptual framework of symbolic interactionism to construct the categories for the cross-site analytic matrix. These categories were conditions of technology use, processes of technology use and consequences of technology use.

Results

Results indicate that teacher technology use in conventional settings varies significantly from results of previous studies conducted in technology-rich environments. Teachers’ beliefs and thinking about technology is socially constructed within local contexts. These local contexts included the role of the principal, peer relations and resource support. Teachers’ beliefs and prior experiences influenced their instructional computer use. The processes teachers engage when using technology in classroom instruction varied among classrooms and sites. However, these processes resulted in similar consequences concerning instructional activity. This study raises significant questions about educational technology policies and their impact on classroom practices. It also raises questions concerning teacher education and professional development models and their role in effective technology use in classrooms. Technology infusion is contingent upon environmental factors. In Virginia the newly implemented “Standards of Learning,” and parental/ public views of the importance of technology have had an impact on the push for technology in the schools. However beyond meeting access needs, Virginia is recognizing new disparities arising in the use of technology toward engaging student learning. These disparities stem from leadership within the schools and the appropriateness and accessibility of training provided for teachers.
Educational Significance

Because of distinctive features of design and focus, this study is significant to the field in several ways. It provides information about how typical schools are using technology in instruction. It also provides insight into how schools approach computer use differently depending on unique contexts. Finally, the results of this study open up the black box between policy and practice. As educational technology budgets continue to grow, this study highlights the need for policy makers, when making allocation decisions, to consider instructional processes within school cultures. This study provides relevant information to guide policy development in this area.

Abstract: There is a great need for increased competency at technology integration by public school teachers. Among the best ways to encourage assimilation of those skills by pre-service teachers is to model the effective use of technology in both college and clinical classrooms. Four hundred-eleven pre-service teachers were surveyed to determine to what degree were their professors' and supervising teachers' modeling the use of technology. The only technology that was used consistently was wordprocessing. Differences among the various major professors modeling of technology skills were also found.

Introduction

The recent growth of computer use and web-based technology is changing the way our society functions (Jerald, 1998). These tools are influencing the way we think about, access, and use information. In an effort to prepare students for the information age, public schools are increasing access to these tools by putting more hardware and software in schools; connecting schools to the internet; and providing cable and satellite capabilities (Zehr, 1997; Zehr, 1998). However, having access to technology tools is only part of the answer. Teachers must become more knowledgeable about technology, and be able to integrate them into their teaching and student learning. Districts throughout the country are making efforts to increase the use of technology through staff development activities and providing on-going building and district technology support. However, this training must begin with pre-service teacher education (Wetzel, Zambo, Buss, & Arbaugh, 1996).

Pre-service teachers will be the teachers of the 21st century. As such, they must develop the necessary technology knowledge and skills to prepare the next generation of students. If they do not, they will perpetuate the lack of technology expertise that is characteristically the norm of the current generation of teachers. Not acquiring these skills during their pre-service program will cost schools districts greater hardships because they will ultimately have to bear the financial responsibility for expensive staff development activities. The bright side is that in a nationwide study of recent pre-service graduates, the majority felt that they were well prepared to use technology in their teaching (Colon, Willis, Willis, & Austin, 1995).

Technology mentoring must become an essential component of the pre-service development of the potential teacher. Content knowledge and skill development about one's discipline is essential; however, good technology mentoring is only achieved through role modeling, on-going evaluation, constructive criticism, and coaching (Wright & Wright, 1987). Pre-service teachers should be afforded these mentoring elements in their content, methods, and professional education courses; through their classroom observations and experiences; and during their student teaching experiences. It is through these experiences that university professors and supervising teachers help pre-service teachers become knowledgeable about content and methods. However, are these mentors arming their proteges' with the necessary technology tools and skills for the information age (Niederhauser, 1996; Wetzel et al., 1996)?
Research Question

This research reports the findings of a two-year study designed to discover if professors and supervising teachers were modeling technology skills for pre-service teachers, what technologies were used, and were they integrating technology tools and skills into their teaching? The question that guided this research was "What was the impact of faculty in acquiring and motivating technology skills used by pre-service teachers?"

Methodology

Instrumentation

To investigate the ways student teachers assimilated and applied technology in their newly chosen profession, a survey of student teachers was conducted. Questions investigated their perceptions of:

- Technology utilization of 12 different technologies by their supervising teacher during student teaching. The 12 technologies that were surveyed were wordprocessing (WP), spreadsheet (SS), database (DB), desktop publishing, electronic presentations (e.g., PowerPoint), the Worldwide Web, email, Galileo (a statewide research database), videodisc, satellite TV (including videotape derivatives), GSAMS (a statewide 2-way audio/video distance learning technology), and Channel 1. Utilization was classified as "Not at all," "At least once," "Weekly," and "Daily."
- Modeling of technology skills by undergraduate teacher program instructors in three different areas:
  - Core classes
  - Professional Education classes
  - Specialized Content for Teaching classes.

These areas were rated on a four (4) point Likert scale (None, A little, A moderate amount, A great deal).

The Core Curriculum is required in all bachelors degree programs and is usually completed during the freshman and sophomore years. The courses total 90 quarter hours and cover areas such as Humanities and Fine Arts, Mathematics and Natural Sciences, Social Sciences, Health and Physical Education, and lower division courses appropriate to the major.

Professional Education courses in the B.S.Ed. curriculum are those which contain the particular knowledge and skill development involved in teaching. Courses in this area typically cover teaching methods, curriculum, learning and motivation, special needs students, and student teaching. This segment usually requires 40 - 45 quarter hours.

Specialized Content for Teaching is the portion of the B.S.Ed. program that prepares the pre-service teacher in the content they will teach in the classroom. In the secondary and P-12 programs, it is equivalent to a major in the teaching field. Fifty to sixty quarter hours are typically required.

The complete survey in PDF format is available at <http://www2.gasou.edu/eltr/tech/rcarlson/stsurvey.pdf>.

To facilitate the analysis, the use of 12 different technologies by faculty was treated as a summative scaled variable - that is, the individual scores for each of the 12 responses were summed to arrive at an overall technology use score. Reliabilities using Chronbach's Coefficient Alpha ranged from 0.89 to 0.91, an indication of very high score reliability.

Subjects

The subjects for this study were graduating seniors from a midsize southern university who completed a survey instrument at the end of their student teaching experience. A total of 444 students participated in the practicum experience during the Spring quarter 1997 through the Spring quarter 1998. Four hundred ten (410) surveys were returned for a 92% return rate. The fact that the survey was included along with the course materials, helped to motivate the return of the surveys.

Table 1: Sample Demographic Characteristics.

A total of 410 student teachers, predominantly white and female (Table 1), responded to the survey. Early childhood educators were the largest group followed by secondary educators. Special, middle grades, and other educators were about evenly represented. Other educators were classified as those who did not fit into one of the listed categories, such as business, health and physical education, music, and art. Ethnic groups other than white and black were eliminated from further analysis because of their small representation. Age ranged from 20 to 57 years with a median at 23 years and a mode of 22 years.

Table 2: Technology Modeling by Supervising Teachers.

A major factor in the use of technology is the behavior of those near them who are in instructional or supervisory roles. When student teachers were asked about the use of technology by their supervising teachers, very few indicated that technology was used frequently. Of the 12 identified technologies, only 50% or more of the supervising teachers (Table 2) used wordprocessing at least weekly. On the other hand, more than two-thirds of the student teachers reported that their supervising teacher never used any of the technologies except for wordprocessing.

Table 3: Technology Modeling by Undergraduate Professors.

The student teachers should have been influenced by the way their professors used technology in the classroom. Innovative, motivational uses of technology in the undergraduate teacher education program may motivate the teachers to use it in their own instructional setting. Table 3 shows the average ratings for teachers encountered in teacher preparation programs. Students were asked to rate the average and the best of their professors in core, professional education, and specialized content for teaching classes. Wordprocessing was used to the greatest extent by these professors, followed by internet (WWW and email) usage. Videodiscs, Television, GSAMS, and Channel 1 had the lowest usage.

Table 4: Significant Differences by Group for Technology Modeling by Undergraduate Professors.

ANOVA's were accomplished to compare student ratings of professor technology use between groups. The dependent variables were scores that were the sum of all the 12 technologies. Chronbach's Alpha reliabilities of these scores ranged from .89 to .91. Table 4 summarizes the comparisons by groups.

There were no statistical differences between males and females or among the ethnic categories. There were differences among the identified majors, however the statistical model was significant only once - in the case of the professors who used technology to the greatest extent. Table 5 shows the total scores adjusted for the effects of the other factors for the various majors.

Table 5: Deviation from the Grand Mean by Group for Technology Modeling by Undergraduate Professors.

In every case, students majoring in Exceptional Childhood Education rated technology use by their professors higher than those majoring in other disciplines did. Similarly, students classified as "other" rated their professors lower than those in other disciplines.

In the case of professors in professional education classes who used technology to the greatest extent, students majoring in Exceptional Childhood and Secondary Education rated their professors above average, while those classified as "other" rated their professors well below the average.

To test the hypothesis that there were differences among the way students rated the professors, a repeated measures ANOVA was accomplished. Pillais, Hotelings, and Wilkes tests showed significance (F=2.28, df= 5, p=0.47). Within group variables were the six professor groupings and the between group variables were ethnicity, gender, and major. The within factor significance was p=0.33 (F=2.44, df=5). The professional education professors who used technology to the greatest extent averaged a significantly higher mean score than any of the other professors.

Discussion

This study confirms previous research which showed that the only classroom technology that educators are comfortable using is wordprocessing (Wetzel, 1993). This was the only technology used at least once per week by 50% of the supervising teachers. The next highest technology type was Channel 1, used at least weekly by only 22% of the supervising teachers. Access to technology may have limited supervising teachers from using technology to a greater extent than they did. Similarly, student teachers rated the modeling of technology by their professors at least 3 on a 4-point scale only for wordprocessing. The closest next technology was internet related and was one-half point lower on average.

Most technology is underutilized; therefore, student teachers have little opportunity to see it modeled in their college classroom setting by their university professors or in their practicum setting by their supervising teachers. If student teachers are not shown how to use technology they should not be expected to integrate it into their lessons. This encourages the continued underuse of tools that have great potential to help students learn.
When asked to rate their university professors on modeling technology use, student teachers rated their professional educational professors highest, followed by specialized content professors, and lastly core professors. This is somewhat concerning in that core and content area teachers may be underutilizing important teaching tools. When looking at technology modeling by major, students studying Exceptional Childhood Education rated all of their professors higher than any of the other majors. Conversely, other majors rated their professors lowest. Looking at the rating of the Core professors which should be equally rated, one finds that Exceptional Childhood Education majors rated these professors high and other majors rated these professors the lowest. However, these ratings showed no statistical difference. The only statistical difference was for the professional education professors who used technology to the greatest extent.

**Recommendations and Conclusion**

Although Colleges of Education should continue to emphasize the use of technology as a teaching tool in all of their pre-service educational programs, it should be understood that it must be a university-wide mandate. It is imperative that technology modeling and use also take place in core and specialized content area courses. To achieve this, professors must have technology access not only in their offices, but also in their classrooms. They must also have technology support when needed. Colleges should also provide on-going, small group or one-to-one staff development activities for professors.

When considering student teacher placement, the technology awareness of the supervising teacher and his/her colleagues should be one criterion for selection. Another should be the level of access the student teacher will have during the experience.

Supervising teachers must begin to view student teachers as a technology resource because of their familiarity and comfort level with the technology. For instance, when preparing lessons, make it the student teacher’s responsibility to integrate one or more technologies.

Finally, colleges of education and/or individual departments should sponsor activities where student teachers and their supervising teachers demonstrate and celebrate the integration of technology into teaching and learning. Besides providing an opportunity for student teachers and supervising teachers to “show-off,” it would also be an opportunity for professors to see innovative ways to integrate technology into their teaching; thereby raising their learning curve.

Preservice versus Inservice Educators' Attitudes Toward Information Technology

Rhonda Christensen

Abstract: This paper compares and contrasts attitudes of preservice teachers to those of inservice teachers and administrators. In the first section we describe categories of preservice and inservice educators from which data has been gathered, while the second section addresses data collection and instrumentation. The third section includes findings and their implications for the field of teacher education.

Categories of Preservice and Inservice Educators

Two categories of preservice teachers are examined:

a) those taking university coursework on campus, and
b) those involved in student teaching in classrooms.

Two categories of inservice teachers are singled out as well:

a) classroom teachers in general, and
b) teachers who are mentors of student teachers.

Data Samples and Instrumentation

Data Samples

Findings for this paper are based on three sets of data gathered during 1995-98:

Set 1: 1995-96 data gathered from 138 K-12 teachers in a large South Texas school district, contrasted with data from 19 interns (student teachers) from the same district and during the same time frame;

Set 2: 1997-98 pre-post data gathered from 29 preservice educators enrolled in university coursework prior to student teaching; and

Instrumentation
All preservice and inservice educators completed some version of the Teachers Attitudes Toward Information Technology Questionnaire (TAC) or the Teacher's Attitudes Toward Information Technology Questionnaire. These instruments measure from 7-16 psychological constructs such as computer anxiety, classroom productivity, and teacher productivity. They have previously been shown to be reliable measurement instruments (Christensen & Knezek, in press; Knezek & Christensen, 1998). A Stages of Adoption of Technology questionnaire based on work done by Russell (1995) was administered to most of the subjects to determine their perceived stage of technology integration. Six stages are included in this instrument: (1) Awareness, (2) Learning the Process, (3) Understanding and application of the process, (4) Familiarity and confidence, (5) Adaptation to other contexts, and (6) Creative application to new contexts.

Findings and their Implications for Teacher Education

Analysis of the 1995-96 data (Set 1) indicates that many of the distinctions between preservice and inservice educators may be due to a generation gap. For example, the 1995-96 interns believed that reading is difficult, relative to the perceptions of their inservice peers. Also the 1995-96 interns reported a preference for working on a computer over reading, writing, or even watching TV, while the inservice teachers had a more even distribution of preferences among these four alternatives. In many other attributes, such as computer importance or enjoyment, inservice educators with no prior exposure to information technology tend to acquire attitudes similar to those possessed by preservice educators, after meaningful information technology inservice training has taken place.

The general trend in this data appears to be that preservice teachers are entering the profession relatively comfortable with technology, compared to their inservice peers. This corroborates recent observations by the authors that first year teachers can often skip the beginning 6-8 hours of standard information technology awareness training, because they generally come into the profession with these skills. Such trends imply that a "buddy system" in which new teachers instruct veterans on information technology skills, while experienced teachers instruct novices on classroom management and teaching techniques, might serve to benefit both groups.

Data Set 2 from preservice teachers enrolled in an elective computers in the classroom course prior to student teaching included a pre- and posttest of their attitudes. The course focuses on how to integrate computers into the classroom rather than how to use them for productivity.

A paired t-test was performed on the preservice teacher data. As shown in Table 1, both Multimedia and Stages were significantly changed from pre to post (p<.001). Students moved up an average of one stage on the Stages of adoption of technology measure. The pretest mean was 4.36 while the posttest mean was 5.23.

Table 1: Paired t-test and sign test from university students in the teacher education program

Results of a nonparametric sign test showing how many students' attitudes increased, decreased or tied from pre- to posttest administration are listed in Table 1. With the exception of Productivity for teachers, all Semantic Differential subscales (see Appendix) showed an increase in attitudes during the course of the semester.

Table 2 contains a comparison of attitudes toward: a) E-mail for teachers, b) the World Wide Web (WWW), c) Multimedia, d) Computer Productivity for teachers, and d) Computers in the Classroom for several groups of educators including preservice and inservice teachers. The preservice teachers began their fifteen week course of study well above the mean attitude for teachers in general, but lower than the highest inservice teachers. By the end of the course, the preservice educators were higher than the inservice teachers on all scales for which comparative data was available.

Table 2: Comparison of preservice teacher pre-post attitudes to typical and highly positive inservice teacher attitudes

Many of the variables studied were highly positively correlated with stages of adoption for the pretest but insignificantly correlated by the post test. This may indicate that only students in a high stage of adoption at the beginning of the course were able to see the value of information technology for their future students, but by the end of the course most students (preservice teachers) saw the value of computers in the classroom regardless of the stage in which they resided. For example, the item “For my students, using computers in the classroom is valuable” was highly correlated with stage of adoption for the pretest (.5156*) but not significant for the posttest (.2099). This type of information, combined with the fact that students in the class advanced an average of one stage from the beginning to the end of the semester, led to the conjecture that even students in lower stages of adoption came to perceive the potential value of computers for their students, by the end of the course. Further research is needed to confirm or refute this hypothesis.

Masters Students Developing Research Proposals and Published Articles

Caroline M. Crawford
Instructional Technology
School of Education
University of Houston – Clear Lake
crawfordcl@cl.uh.edu

Abstract: Masters-level students within the specialization area of Instructional Technology have a disconcertingly succinct speaking ability; however, such speaking abilities may not necessarily lend themselves towards the written word. Masters-level students, especially with backgrounds in the area of teacher education, offer wide ranges of abilities within numerous areas of skill. Such skills can range from strengths within the areas of training, public speaking, instructional design, curriculum development, instructional development, research and statistical calculations; however, the same students that display such awesome strengths within their repertoire of abilities may have areas that can be further developed. One of the areas of further development is within the arena of developing written research proposals and publishable articles; writing literature reviews, thoughts, experiences and research in publishable formats so as to advance the literature of instructional technology is an area that may be wrought with difficulties.

Introduction

Masters-level students come from numerous walks of life and have several hats, which they wear throughout the day. One of these hats is the student hat; this hat requires that the students not only process vast amounts of information, synthesize this information into coherent and presentable bits of information and display public speaking abilities, but the students also must define themselves as persons with distinct abilities within the area of penmanship. Masters students are expected to write numerous reports throughout their time as students, taking into account that the primary audience will be the instructor of record. However, what is the result when the students are no longer writing to merely the instructor, but to a much wider audience?

The instructor is, of course, a primary audience to all students reaching to attain the honor of a masters degree; but when the students begin to delve into writing journal articles, theses, grants and reports, what type of disconcerting elements are felt by the student? Each person that writes at a scholarly level must work through their own sense of inability and insecurity, and most authors do indeed feel that sense of frightened anticipation as to whether their work, over which they have slaved and into which they have put their heart and soul, will be accepted and admired by peers. It is no different for masters students merely beginning their soulful journey into the ranks of the scholarly. Now students must not merely read, analyze and spout thoughts written by persons to whom they have held as superior through out many years of study; now these same students must decide upon a topic of interest, analyze the available research, and delve into the construction of their own thoughts, beliefs, scholarly voice and strategies for the development of scholarly research. To some students this is not a difficult task; however, to most students this is a frightening point at which not only their years of schooling are at issue but also their personal desire to be accepted as a part of the scholarly community.

All researchers began their scholarly career with very little understanding of numerous issues such as the formatting, reference guidelines, writing voice, and level of work that are deemed to be acceptable and expected within the scholarly community. The difficulties surrounding the progress of masters students from writers to scholarly writers and researchers are ones which must be overcome. Masters students have found certain difficulties through out this process; specifically, the students have found themselves in a
quandry concerning such basic issues as understanding the process through which one must travel to obtain relevant research and information upon the subject matter in question, obtaining previous research upon their subject matter, analyzing the obtainable research, formatting issues, reference guidelines and overcoming their basic, undeniable fear of submitting their scholarly endeavors to a wider audience.

**Subject Matter**

The first area of concern in introducing the topic of scholarly research to many students seems to be the focus upon one specific area or topic to research. I found this to be particularly difficult until switching the idea of a topic to the development of a proposal paper that could turn into the first two chapters, introduction chapter and review of related literature chapter, of a masters thesis. This shift seemed to focus the students upon an experience that they could use towards their degree program, and not merely another staid attempt to complete a paper in order to please the instructor. Instead, the students focused upon topics that they found to be intriguing and ones that could indeed develop into reviews of literature for a thesis paper.

The students in this specific course were soon to be graduating and were interested in developing a paper that could coincide with another course, Research Design and Development, in which they either were enrolled or would be enrolled within the next semester or two. Luckily, the introduction and review of related literature sections that we were to develop were areas that would not be necessarily covered in the Research Design and Development course. The students were very interested in working the two courses into one complete product, which made the course much more enjoyable in nature. Due to the desire of the students to accomplish one task for two courses, the students maintained a desire to accomplish the designated procedures.

The first hurdle was for the students to choose a subject matter. This was a difficult task for most students because they had so many intriguing research ideas; however, once the students focused upon a topic, they were interested in beginning their research process. Unfortunately, one or two students decided upon topics that had little or no research specifically related to their subject matter and were very disconcerted by this fact. Although numerous discussions were held upon the difficulty of locating research directly related to their topics, the students were still quite distracted, confused and worried about this matter. Instead of choosing areas of research at a secondary level upon the topics in question, an example being to research business profit margins and growth ratios along with the growth of World Wide Web usage instead of corporations doing business on the World Wide Web, the students were uncomfortable with this shift and instead chose another topic to research. Once the students changed research area topics and began to find research upon their specific areas, the students felt more comfortable with their progress and caught up to their fellow students in obtaining research at a rapid rate; in some instances surpassing their classmates.

**Research**

Researching topics was a new experience for most students. Although the World Wide Web was an area which offered a wealth of information and, in some cases research, the students found it a learning experience to delve into the library to locate their research articles that would be of primary importance within their final products. The experience of working through the process of locating relevant research, discerning which articles would be of use in the students' work, and obtaining copies of the articles were learning experiences which were difficult but nonetheless important to work through.

The students found interlibrary loan to be most appealing throughout the course. Each time the students could locate an article that was not located in the university library, the students learned that the university library would not only obtain the article for them (i.e., less legwork for the students) but would also copy the article and send it to the designated address (i.e., free of any direct copying charges to the student). From discussions with the students, it became something of a game to the students throughout the course to see who could locate the most articles that were available through interlibrary loan and the time it would take to obtain the articles. By the end of the course, the students clearly understood the benefits of the university library and the services the library offers.
Relevant Research

The students located numerous articles upon their topic matter through out the process, but some articles did not specifically pertain to the topic that the student specifically desired to discuss; some of the research did not fit into the schema that the students were developing. Although the students did find the material interesting to read, and tried their hardest to include the material in their papers due to the work the search entailed, the students did discover that some research was not meant to be included in their final product due to the relevancy of the research. Although this was a difficult realization, the students did use the nonrelevant research’s references to locate other relevant research through a webbing process. The webbing process consists of using reference lists to locate other research that would be useful to the development of the subject matter.

Subject Matter Research

Subject matter branched off into related areas for each student. Depending upon the topic each student chose and began to focus upon a proposal format, the students soon realized that other, related areas of research, would also need to be included in the review of related literature. For example, a student that was interested in designing and developing a product that would then be tested through an experimental research design would need to not only include the main subject area that the product would be focused upon (for example, Biology and the use of technological Biology programs in a high school classroom situation) but also include instructional design theory, instructional design models, instructional development theory, instructional development models, student-centered software programs, teacher-centered software programs as well as several other possible subject areas. If the students found this idea to be difficult to perceive, fellow students as well as instructor dialogue offered opportunities to build schemas of understanding and outlines to implement an understandable outline model.

A secondary opportunity for students to observe the branching of subject matter within their chosen research topic was located within the research articles. A majority of students located at least one article that closely aligned their developing topic. These articles acted as guides to the students concerning possible areas into which the students could expand their research inquiries. Not only did students have opportunities to expand their research areas while locating and reading through the research, but the students also developed skills analyzing the relevant research they located.

Analyzing Research

Being a newcomer to the university, I was surprised at the depth to which the masters students could not only read research but could analyze the research results and discussion sections. The majority of students were currently taking a Research Design and Development course which would offer a schematic landscape through which an understanding of research results and discussion would arise, but I was amazed at the clarity the students offered concerning the results of the research they located. Knowing that the students were at the masters level and most likely somewhat unfamiliar with the research in the field of information technology, and most likely research articles in general, I was quite amazed at the comprehensibility the students brought to this area of the course. Very little guidance was required for the majority of students due to their level of understanding.

Formatting Issues

The students were unfamiliar with the format that the developing papers should undertake. This was something of a difficulty through out the course, although handouts and samples were made available. Students were advised to purchase Publication Manual of the American Psychological Association (American Psychological Association 1994) through which they would follow standard guidelines to complete their project. Although the students did try to follow the guidelines, difficulty arose due to the
unfamiliarity of the guidelines. Due to this difficulty, published theses were distributed for viewing during one of the classes, as well as an online example was made available to the students for perusal. Although the dispersal of the published theses were said to be advantageous to the students, the availability of the online example was felt to be more useful due to the specific questions that arose throughout the course.

Reference Guidelines

Similar difficulties to the formatting issues were felt throughout the course due to the unfamiliarity of the students with the *Publication Manual of the American Psychological Association* (American Psychological Association 1994) pertaining to the bibliography format. Each reference was included, whether obtained from research journals, World Wide Web, e-mails or other forms of information dispersal. Although sample reference guidelines were presented in handout format as well as available online, the students continued to have difficulties with the formatting throughout the course. However, on a positive note, the students diligently worked towards perfecting their bibliography sections and did, in fact, present a faultless final product.

Fear Factor

The most difficult part of the course for the students was overcoming the fear of publishing their work, either in thesis format or submitting an article to a research journal for possible publication. The students had a considerably high, real fear of presenting their work in a public forum. Discussions occurred between students, between students and instructor on a small group level, and as a large group of students stating their concerns and receiving positive feedback from the instructor and other students in the course. Once most students realized that they were, in fact, not alone and were actually joined by the other class members in their concerns, the fear factor dissipated and turned into something of an exciting venture. From observing the conversations and exchange of understanding between students, the students themselves supported each other’s efforts and offered encouragement whenever possible. A community of positive support and encouragement arose out of the concerns and fear issues that previously plagued the students at the beginning of the course. Seemingly, such a disconcerting experience brought the classmates closer together and developed a closer bond due to the shared feelings of being in this together.

Feedback

One of the topics the students felt most strongly about while in the course and at the conclusion of the course was the significant feedback that was offered by the instructor. Students were expected to turn in drafts of their work to the instructor so that the students could obtain developmental feedback as well as allow the instructor to check for difficulties or areas of concern throughout the course. The instructor made a concerted effort to mark the drafts with an infamous green ink pen so that the students could have solid, significant feedback on areas of strength as well as of concern. From student feedback, this is the area that the students felt to be the most helpful in not only developing their work, but also in feeling secure that they were meeting the course objectives.

Publishing Articles

The students were each expected to develop a thesis paper product as a part of the course. A second expectation was that the students would take the paper they were developing for their thesis paper product and develop it into a scholarly article. The students were required to work through the process of obtaining publication guidelines for journal articles, submit abstracts of their literature review to not only journals but also conferences, and develop an article that could be published in a scholarly journal. Perhaps the most significant part of the course for the instructor was hearing from the students that their work was accepted to be submitted to a scholarly journal and to be presented at educational
conferences. The pride and surprise in the students’ voices and facial expressions was quite clear and offered the instructor a strong sense of accomplishment and pride in the students’ efforts.

Conclusions

In summary, the student experiences are a microcosm of experiences felt by each scholar when they write their first scholarly work. All researchers began their scholarly career with very little understanding of numerous issues such as the formatting, reference guidelines, writing voice, and level of work that are deemed to be acceptable and expected within the scholarly community. The difficulties surrounding the progress of masters students from writers to scholarly writers and researchers are ones which must be overcome. Masters students have found certain difficulties throughout this process; specifically, the students have found themselves in a quandry concerning such basic issues as understanding the process through which one must travel to obtain relevant research and information upon the subject matter in question, obtaining previous research upon their subject matter, analyzing the obtainable research, formatting issues, reference guidelines and overcoming their basic, undeniable fear of submitting their scholarly endeavors to a wider audience. However, masters students seemingly gain tremendous understanding and positive experiences from the support and guidance of a course surrounding such efforts.

Abstract: This paper reports on the findings of a college of education technology survey that 
investigated faculty knowledge, levels of use, types of use, and perceptions of the importance 
of technology in teacher education. Data suggest faculty knowledge of and skill with using 
technology do not necessarily transfer to use of technology in teaching despite the fact that 
93.1% of the faculty rated technology in teacher education as "very important" or "important." 
Time to learn new software and equipment access remain constraining factors to application 
of technology in teaching. Tenured/tenure-track faculty and affiliate faculty needs and 
concerns should be addressed as efforts to integrate technology in teacher education programs 
continue.

Introduction

Colleges of education have a pivotal role in preparing teachers who are able to teach with technology. 
In Teachers and Technology: Making the Connection (U.S. Congress, 1995) education graduates reported 
feeling inadequately prepared to teach with technology. This is not a surprising situation, given that in most 
colleges of education, "technology is not central to the teacher preparation experience" (p. 165). Willis and 
Mehlinger (1996) summarized the topic of technology in preservice education: "Most preservice teachers know 
very little about effective use of technology in education and leaders believe there is a pressing need to increase 
substantially the amount and quality of instruction teachers receive about technology" (p. 978). Thomas (1992) 
argued that technology must become “an essential part of America’s teacher preparation programs” if it is to be 
an integral part of K-12 education (p. 9).

In order to assure that teacher preparation programs adequately address technology competencies for 
preservice teachers, two key elements need to be examined: faculty knowledge about technology and faculty 
use of technology in teaching. NCATE’s 1995 Standards, Procedures, and Policies for the Accreditation of 
Professional Education Units included a new indicator under faculty qualifications which states that “faculty 
are knowledgeable about current practice related to the use of computers and technology and integrate them in 
their teaching and scholarship” (p. 24).

The Study

This study investigated how technology was being used by faculty in one college of education (COE). 
The following six research questions were addressed:

1. What are the current levels of faculty knowledge and skills regarding specific types of technology?
2. Which technologies do faculty use in preparing for and in teaching classes?
3. What level of importance do faculty give to technology in teacher education?
4. What factors inhibit faculty use of technology in teaching?
5. What are the primary concerns of faculty in using technology in teacher education?
6. What assistance do faculty perceive is needed to facilitate integration of technology in their teaching?

A survey (available online at http://www.nevada.edu/~strudler/survey.html) was designed by the principle investigator with assistance from a research specialist in the university’s Center for Survey Research. Drawing from research by Spotts and Bowman (1995), Vagle (1995), and Wetzel (1993) current issues regarding college/university faculty use of technology were included in the survey. Two faculty members with expertise in survey research reviewed it, and the survey was tested for item clarity with doctoral students in a seminar class. Two additional faculty members with expertise in educational technology reviewed the survey and the final version was examined and approved by the survey research specialist. In January 1997, the survey was distributed to full-time, tenured/tenure-track faculty (n = 66) and to affiliate faculty including part-time faculty and lecturers who were not in tenure track positions (n = 80). The number of completed surveys returned was 87 for an overall return rate of 59.6%.

Descriptive statistics provided data concerning faculty knowledge, skill, and use of technology in preparing for and in teaching class. Data were analyzed with mean, median, and mode calculated for appropriate items, and tables and graphs were constructed for visual comparison of information gleaned from selected survey items.

Faculty concerns about the integration of technology in teacher education were elicited through an open-ended item, “When you think about the integration of technology into teacher education, what are your concerns?” Responses were categorized based on the Stages of Concern (SoC) model (Hall & Hord, 1987). SoC describes seven levels ranging from 0 to 6: (a) Awareness = 0, (b) Informational = 1, (c) Personal = 2, (d) Management = 3, (e) Consequence = 4, (f) Collaboration = 5, and (g) Refocusing = 6. The SoC model was designed to help analyze concerns experienced by teachers as an innovation is being adopted, thereby increasing the likelihood of providing appropriate assistance or reassurance to alleviate those concerns. On the survey, some COE faculty responses reflected concerns that corresponded to more than one stage and they were coded into multiple categories. Each coding was counted as a separate response, making the total number of responses (n = 99) greater than the number of faculty (n = 87). Rating reliability was established by having a peer also code the responses and agreement was 94.0%.

After rating the importance of technology in teacher education, faculty were asked to expand on reasons for their ratings in an open-ended survey item. Categories were created for coding the responses and intercoder reliability was 90.8%. Responses sometimes fit more than one category and were coded accordingly, therefore, the totals for expanded reasons (n = 108) were greater than the number of participants (n = 87).

Findings

Results of the survey provided data to describe the overall use of technology by COE faculty. Of particular interest in this study were faculty knowledge, skill levels, and use of computer-based technologies in preparing for and in teaching classes. Means for ratings of skill levels for using various computer-based technologies (i.e., word processing, computer spreadsheets, statistical computing, e-mail, educational software, presentation software, Internet/World Wide Web, and multimedia) as reported by faculty were only slightly lower than means for their ratings of knowledge levels about those technologies (see Fig. 1). Faculty selected from a Likert-type scale: a) No Knowledge = 1, b) Very Little Knowledge = 2, c) Some Knowledge = 3, and d) Extensive Knowledge = 4.

Faculty rated their knowledge and skill levels highest with word processing and e-mail, and indicated these two technologies were used most frequently in preparing for class. However, the frequency of use of word processing or e-mail in teaching class was lower. Means for each of the other technologies reflected little use in teaching as displayed in Fig. 2. Frequency choices on the Likert-type scale were a) Not at all = 1, b) Once during Semester = 2, c) Monthly = 3, and d) Weekly = 4.

Survey data separated by tenured/tenure-track faculty and affiliate faculty showed use of technology in teaching was infrequent for both groups. At least 70% of the affiliate faculty and 50% of tenured/tenure-track faculty indicated no use of the various technologies in teaching with the exception of educational software which was used by nearly two-thirds of the tenured/tenure-track faculty.
When asked about the importance of technology in teacher education, both tenured/tenure-track faculty and affiliate faculty responses were similar. Survey data suggest that faculty (n = 87) believed technology integration in teacher education was important, with nearly two-thirds of the faculty selecting "Very important" (see Fig. 3).
Many responses of survey participants supported the importance of technology in teacher education with statements reflecting the idea that technology is a part of the modern world or important to the future. A greater percent of affiliate faculty responses related the importance of technology in teacher education to being a part of the modern world or important to the future. The category of “other” included responses that did not explain the importance rating such as “It is important and I need to do it” (see Tab. 1).

Table 1: Frequency of expanded reasons for importance of technology in teacher education.

Survey respondents were asked to select the primary factor that inhibited their use of technology in teaching. “Time to learn new programs” was the overwhelming factor selected by 44.0% of tenured/tenure-track faculty and by 24.3% of affiliate faculty. “Obtaining equipment for use during instruction” was selected as the primary factor by 18% of tenured/tenure-track faculty and by 27.0% of affiliate faculty (see Tab. 2).

</table>

Table 2: Frequency of factors inhibiting faculty use of technology in teaching.

A survey item regarding preferred arrangements for learning new things about technology is summarized in Tab. 3. “One-on-one assistance” was ranked as the first choice by both faculty groups, with 50.6% of the total respondents indicating a preference for that arrangement. The relationship between preference for one-on-one assistance and frequency of technology use in teaching was explored. Of respondents indicating no use of the various technologies in teaching (i.e., word processing, computer spreadsheets, statistical computing, e-mail, educational software, presentation software, Internet/World Wide Web, and multimedia), 60% or greater also selected one-on-one assistance as preferred.
Table 3: Frequency of preferred arrangement for learning new things about technology.

Faculty concerns about integrating technology in teacher education were coded using the SoC model (Hall & Hord, 1987) and then grouped into three main levels, (a) awareness, (b) management, and (c) impact. Statements showing little concern or involvement with technology in teacher education were coded as awareness, and blank responses were included in this stage. The awareness level accounted for 33.3% of faculty concerns when awareness concerns (20.2%) were combined with informational concerns (1.0%) and personal concerns such as fears about failures or personal ability (12.1%). Management level concerns refer to issues about resources, access, efficiency, organizing, managing, scheduling, and time demands. Survey results showed 33.3% of faculty concerns were management level. Concerns grouped at the impact level look beyond personal concerns and equipment. Impact level concerns include consequence, collaboration, and refocusing stages. Of the faculty responses, 24.2% were consequence concerns, no responses reflected collaboration concerns, and 9.1% were refocusing concerns. Responses grouped at the impact level represented 33.3% of faculty concerns (see Tab. 4).

Table 4: Frequency of responses categorized by stages of concern.

Conclusion

In analyzing survey data, it is clear that faculty believe technology in teacher education is important. Faculty also indicated high confidence levels in their technology knowledge and skills, yet they are not implementing use of technology in their teaching. Rogers (1995) contends that “knowing about an innovation is often quite different from using a new idea” (p. 167).

Time and equipment concerns, frequently cited as factors that inhibit use of technology in education (Barron & Goldman, 1994; Carr, Novak, & Berger, 1992; U.S. Congress, 1995; Wetzel, 1993), constrain COE faculty use of technology in teaching. In considering the time issue, benefits of learning new software need to be perceived as compelling enough to balance the time costs. With NCATE unit standards as the basis, expectations for faculty use of technology in teaching should be conveyed and modeled by the administration and evidence of use should be required and rewarded in yearly evaluations.
In some cases, faculty do not know how to implement technology to enhance instruction or to help accomplish course goals. Affiliate faculty indicated a higher preference for workshops than did tenured/tenure-track faculty who would rather figure things out alone. Both faculty groups indicated a strong preference for one-on-one assistance when learning new things about technology. This type of technology support requires individuals with technical expertise and strong interpersonal skills (Strudler, 1995-96). Knowledge of software, and of strategies for teaching with technology are important also.

Efforts to integrate technology in this COE focused on tenured/tenure-track faculty, with workshops and support more readily available to them than to affiliate faculty. It cannot be assumed that the needs of tenured/tenure-track faculty and affiliate faculty are the same. Despite the fact that affiliate faculty are teaching increasing numbers of college courses, they struggle with obtaining equipment and lack of knowledge about available resources in the COE. The importance of working with affiliate faculty, assessing needs, disseminating information about technology resources, and providing professional development opportunities is evident. Since many colleges of education depend on affiliate faculty to deliver some of their courses, ongoing support for their technology use in teaching is essential for integration of technology throughout teacher education programs.

A Deeper Psychology of Technology:
A Case Study of a Girl and her eMate

Richard E. Ferdig, Michigan State Univ., USA
Steve Weiland, Michigan State Univ., USA

A Need for a Deeper Psychology

In an article entitled, "The Learning Effectiveness of Educational Technology: A Call for Further Research," Jones and Paolucci make the claim that "a missing component of justifying the expansion of technology in educational delivery is the establishment of research agendas using formal research methodologies" (Jones & Paolucci, 1998). The evidence to support their claim comes from a three-year study of 8 major refereed educational technology journals. The survey shows that only about 18% of all technology research completed addressed an evaluation of learning outcomes. A majority of the articles revolved around technology applications, development, or implementation.

Jones and Paolucci's article, as well as their survey, points to a current trend in educational technology research programs—that of focusing solely on the cognitive domain in the relationship between technology and learning. This is not to suggest that measuring learning outcomes of technology use is an unnecessary or fruitless endeavor, only one with inevitable limits. There is a plain, one might say urgent need for a more complete approach to research on technology integration.

The problem with this trend in educational technology (often situated in educational psychology programs) is the disappearance of research addressing the affective domain of technology use. The statistics in the survey point to an almost extinct population of articles relating to affect. There have been a number of articles which have attempted to break out of the cognitive domain by asking questions about perceptions, attitudes, and motivation in using technology (Lepper and Hodell, 1992; Cordova and Lepper, 1996). Many others have ventured into the affective domain only in so far as it helps to explain cognitive gains. Although these studies are leading the way for creating a new set of research tools, we must continue to focus on gaining a more complete psychology of technology.

Clifford Geertz (1973) argues that we need “thick descriptions” in order to better represent and understand human experience. And in his famous essay “Deep Play” (1973), he supplies a timely metaphor for a new field like educational technology. Applying this metaphor of “depth” to educational technology essentially means opening it up to all of the tools available to us as psychologists rather than technologists. There are a number of psychological questions that, although normally associated with developmental psychology and psychoanalysis, may prove fruitful in our discussion of a “deeper” educational technology. Questions include the role of emotions through technology, mediating relationships with technology, and sense and meaning-making through technology. Many of these questions fall outside of the realm of the cognitive domain.
This paper argues that the limits of current tools in educational technology research may obscure for researchers and (perhaps more importantly) teachers what is happening in the classroom. It may also deny them the necessary tools to explain phenomena they encounter in the classroom and in the lives and minds of the subjects of their studies. Research is also presented as an example in which a broader and deeper view of educational technology affords a more complete understanding of technology integration. The paper concludes with suggestions for achieving depth and completeness in educational technology research. It is hoped that this revised perspective towards technology and education will aid researchers and teachers in their understanding of technology innovation implementation.

Computers in an area elementary school

In the summer of 1997, a team of graduate students and faculty of a large, public Midwestern university began a project to implement technology into special education and inclusion classrooms at a local elementary school (Author, 1998). As part of the project, the team decided to purchase an eMate for each of the three classrooms in the study. (An eMate is an Apple product, a grandchild of the popular Newton series.) There were two main reasons for the purchase. First, special education children can sometimes have a hard time typing on the computer. It was felt that if they had an opportunity to write on the screen, a technology the eMate affords, they may be more motivated to practice spelling, write stories, and read works to their colleagues and teacher. Second, the eMate is fun to use. The team thought it would be interesting to see how the children reacted to new and exciting technologies in the classroom.

Shortly after the eMates were introduced, a team member had a conversation with one of the students. Sarah, labeled by the school psychologist as “Educable Mentally Impaired (EMI),” was a fourth grader at the school who had bonded with her computer. She used the eMate whenever she was required to complete a spelling test on a computer (she also had the choice of one of the “bigger” computers). The eMate was also utilized to write stories when Sarah had free time. From a cognitive perspective, Sarah made tremendous improvements over the course of the year. Her reading test scores as well as her general classroom scores improved. The original research questions were aimed at discovering how much of this improvement was associated with technology use. However, there was much more to Sarah’s story than mere test score improvements.

Sarah and her computer “Brian” became friends. The bonding could best be described as an intense, human-like experience. Not only did she talk to the computer (and assure the team members that it talked back), but she also named him and took care of daily needs such as its feeding. The integration project was supposed to help special education children with the development of literacy skills. The eMate was going to assist in that goal by helping children learn to type, write stories, and spell better. The initial research questions that were situated in a cognitive domain, however, had nothing to offer the research or the researchers when presented with a young girl hugging a computer.

At first, the teacher and the team member considered the situation nothing more than an interesting phenomenon. However, Sarah’s relationship with the eMate became
more striking when she began using it to mediate relationships both in and out of school. In the classroom, she was one of the only girls in the resource room. She did not get along with many of the boys, complained often about the lack of girls, and yet decided to have her computer "be a boy." "Sarah needs to control things" her teacher commented. "This may be her way of controlling the situation with the boys in the class.'

School was not the only environment in which Sarah mediated with the eMate. At a party during the school year, her aunt was murdered. She told us that she could not tell Brian about the death because "it would cry." She spent much of the next few weeks after the death without Brian. It took her quite a while to learn how to tell "it" what had happened.

Sarah was a poor student and was going through some pretty difficult times. However, she was not only able to maintain her composure, but she was even able to better herself as a student and as a person (both her teacher and her mother commented on her improved behavior). The only major change between the first semester and the second was the introduction of the eMate. How did the relationship between the eMate and Sarah facilitate this growth?

Initially, some of the team members wondered whether this type of situation was similar to a child having an imaginary friend or a doll. The eMate was a safe tool for Sarah. All of the students knew the importance that the teacher and visitors from the university had placed on technology. Her classmates, peers, and instructors would treat her with more leniency with a technology in the classroom than they would with something she brought into the classroom on her own. But, how did this differ from the actual psychological use of a blanket, doll, or imaginary friend? Trying to further understand these happenings, we turned to psychology and the influential British developmentalist D.W. Winnicott (1896-1971).

In his widely cited "Playing & Reality", Winnicott (1971) suggests that infants, children, and even adults make use of "transitional objects." Transitional objects are objects or phenomena that are related both to external and internal reality. "This intermediate area of experience, unchallenged in respect of its belonging to inner or external (shared) reality, constitutes the greater part of the infant's experience, and throughout life is retained in the intense experience that belongs to the arts and to religion and to imaginative living, and to creative scientific work" (Winnicott, 1971). Sarah used the eMate as a transitional object between her internal reality and the reality that existed in the classroom and at home.

Viewing the eMate as merely a computer used for spelling tests, even if it was important in her obtaining higher reading scores, one would have missed the "thicker description" of what was really happening and thus a more probing psychological account. This application from Winnicott is but a small sign of the potential uses of psychological ideas in the study of educational technology. Both the teacher and the research team were better able to understand the cognitive gains Sarah had made by uncovering the affective uses of her eMate. Furthermore, they were able to better plan future educational activities understanding what Sarah was bringing with her to the learning event.

However, stopping at the point of reinforcing or better understanding cognitive gains may mean missing a more complete picture of the study. Coming to terms with how Sarah was using the eMate also helped the teachers and researchers better
comprehend her emotional development and how to foster her emotional and social growth in the classroom. As the teacher said, "I now better understand how to reach Sarah." Drawing on the experiences in the social life of the classroom, the teacher was also better able to help the parent grasp the social and emotional mediations her daughter was making at home.

**Finding the Right Words**

Contemporary educational technology research has argued for more systematic and ambitious studies of the effects of technology implementation into the classroom. However, the major trend within this field of research has been to focus solely on the cognitive domain of the relationship between technology and pedagogy. Research is missing reflecting other domains of inquiry, and thus, we do not have the accounts we need of the emotional and social development of students new to educational technology.

This paper presents a case study in which a student used a technology to mediate control within her school and home life. Initial research questions focused on a cognitive change and addressed improvements in reading scores. However, it is the return to a deeper psychological vocabulary that provides more complete insight into the cognitive and other gains made by a student. Further, it presents the researchers, the teacher, and the parent with a set of tools to scaffold the development of the child on multiple levels: social, cognitive, developmental, and affective.

The task of technology-focused, educational psychologists and teachers, then, is not only to establish more structured research and teaching agendas, but also to expand the terminology within those inquiries. For instance, object relations theory states that the individual's psychological life is created in and developed through relations with others (Stevens, 1998). How might Sarah's story be perceived realizing that the eMate helped her mediate relations with her friends, peers, and family? Narrative psychology, contends that meaning is made of one's life through the stories told and re-told about the events and experiences in their life (Bruner, 1996). How has Sarah's story changed as a result of the relationship with the technology? Finally, cultural psychology says that the tools a person learns to mediate with are both enabled and constrained by the society and culture of which they are apart (Cole, 1996). What were the different views that the researchers and the student had of what the artifact was meant for?

We return to Jones and Paolucci's initial petition for more invention in educational technology research. Thus, this paper will offer a retelling of Sarah's story, using the complementary approaches offered by Bruner, Cole, and Stevens. Valuable ideas, terms, and concepts in psychology and other disciplines can then be coordinated with what cognitive psychology supplies to the kind of situation of which Sarah is representative. For it is only through this integration that we will have a more multi-layered and complete understanding of pedagogy and technology.
Muffled Voices: Teachers' Concerns Regarding Technological Change

Abstract: Successful integration of technology is seldom serendipitous. Successful infusion of technology is dependent on the thoughtful plans, strategies, and provisions developed by knowledgeable educators to meet the needs of their students. Advances in technology and its increasing availability in K-12 schools make it incumbent upon administrators and teachers to make use of today's technology-related learning tools. This paper presents teachers' accounts about their efforts and vexations regarding integrating technology into classroom practice. Unfortunately, many teachers feel their voices have not been heard by the organizational culture. The authors give voice to teachers' concerns regarding issues such as training, arrangements for facilities, security policies, management strategies, and procedures for technical support. Additionally, the paper focuses on pertinent issues and considerations resulting from actual situations experienced by classroom teachers and administrators in their attempts to infuse technology in their schools.

Not long ago, most administrators and teachers could easily ignore the computer revolution and disregard the technological advances that had drastically impacted and changed business and industry. However, the infusion of technology into educational settings has now been identified as a national priority, and many states, supported by the United States Congress, the President, and state legislatures are mandating the use of computer related technologies. Although critics argue that schools are rushing to jump on the latest education bandwagon, it appears evident that educational environments cannot survive without implementing electronic media and instructional technologies. Indeed, today's schools are in a period of transformation.

Technology Demands Change in Schools

Peter F. Drucker (1995), one of the most respected management thinkers of our time, stated "It is a safe prediction that in the next fifty years, schools and universities will change more and more drastically than they have since they assumed their present form more than three hundred years ago, when they reorganized themselves around the printed book" (pg. 79). These changes are being driven by a number of forces which include recent innovative technology such as multimedia microcomputers, DVDs, CD-ROMs, interactive distance learning and virtual reality capabilities; by the demands of federal/state politicians and business leaders; and certainly, by the demands of our present day knowledge-based society. Increasingly, parents, boards of education, and district and state education departments expect administrators and teachers to make use of today's computer-related learning tools.

Millions of dollars have recently been allocated on federal, state, and local levels to equip schools with technologies which will change their very structure. Today's technological changes are not simply limited to the delivery of instruction. That is, the advent of standalone microcomputers has placed the
power of technology directly in the hands of educators, and the image of technology has shifted from replacing teachers to supplementing and enhancing teacher-based instruction (Roblyer, Edwards, & Havriluk, 1997). This paradigm shift holds important implications for educators, for although no one can be sure what the future will bring given the complexity of technological advancements, administrators can assuredly predict that they will be responsible for developing sound technology strategies and shared leadership plans with teachers to integrate technology related tools into the curriculum.

Administrators and Teachers As Technology Leaders

According to the seminal Rand Corporation Change Agent Study, administrators must evidence support for technology, or technology innovations will be ignored by teachers (McLaughlin & Berman, 1977). Therefore, if educators are to succeed with the increasingly complex task of technology deployment, they must ensure that technological change has a broad base of support and that leadership is a shared endeavor. "Success with technology is rarely serendipitous. Certain clear factors profoundly affect whether technology helps education take a leap forward or a pratfall" (Roblyer, Edwards & Havriluk, 1997, 28).

It could be argued that most teachers and administrators are struggling to understand their respective roles and responsibilities in an attempt to justify the expensive and time-consuming task of integrating technology into today's classrooms. This is not surprising since the educational institution as a whole clearly has not understood nor addressed many of the external forces that have driven the development of new technologies. It is a given that educators are in a difficult position to serve as technology leaders for their schools; however, for administrators the human dynamics of integrating technology impose one clear imperative: they must listen and respond to teachers' concerns about the technological venture. Based on our experiences, interactions, and informal interviews with teachers, the following recurrent themes appear to be central to teachers efforts and vexations regarding integrating technology into classroom practice. A primary purpose of this paper is to give voice to teachers concerns.

Training for Teachers and Administrators

Experts in the field of technology acknowledge that technology involvement can pose an intimidating challenge under the best of circumstances. Most teachers and administrators feel threatened by this challenge because it represents a journey into the unknown, and they know that they are inadequately prepared. "If technology is to be widely used, teachers and administrators need training. Training to use technology must be a part of every entry-level teacher's preparation and should continue throughout a teacher's career so that he or she can keep abreast of developing technologies" (National Governors' Association, 1991). The teacher's role is a critical factor in the use of computers in the classroom (Office of Technology Assessment (OTA), 1995). As Hebenstreit noted:

It has been said that computers can improve education if they are used at the right place, at the right time, with the right amount and in the right way, but to meet all these conditions teachers have to be trained to use the computer that way. The mere presence of computers in schools does not guarantee that education will be improved.... (1992, p.59).

Administrators must be advocates of educators' training due to the fact that teacher training in the use of computers is absolutely essential. Without endorsement by teacher practitioners, the utilization of computers in education will not occur (Hebenstreit, 1992). In the nationwide OTA (Office of Technology Assessment) study of the use of technology in education, lack of training and limited knowledge about computers were the most commonly cited reasons for non use of computers (Office of Technology Assessment, 1995). Recent studies continue to report that properly trained teachers make the difference between success or failure of technology integration efforts (Siegel, 1995).

A school-site technology lead teacher explains, "Teacher do not want to get training because they are so angry about the way computers have been shoved in their classrooms. They have not been involved in the planning process, and no one has even asked teachers if they wanted computers! Computers are being dumped in classrooms without even tables to put them on." A high school English teacher stated that
most teachers in his building are still struggling with the basic skills needed to operate the computers. He refers to these educators as "teachers with two hands on the mouse." They can not "drag and click" let alone use software programs for instruction.

Unfortunately, many school systems have spent their technology budgets largely for the purchase of hardware and software. Teachers have been instructed to "learn on your own," after attending one-shot inservice sessions. Teachers are frustrated because learning computer skills requires the ability to absorb so many different concepts and also requires a great deal of time to practice and experiment before they feel confident enough to involve their students. One veteran teacher explains, "Years ago most teachers would not show movies in their classrooms because they did not know how to thread the movie projector. The situation with computers is just the same; however, the financial investment is much greater."

Research indicates that most school districts spend less than a quarter of their computer budgets on training (Bruder, 1993). Therefore, the rate of hardware and software acquisition has continuously out-paced the rate of computer-related professional development. Perhaps rethinking budget priorities for professional development is long overdue.

Teachers are being told to create a school environment that integrates new technologies requiring radical changes in their teaching strategies (Collins, 1991), and yet, teachers justifiably complain that their districts will not provide the training, money or resources necessary to initiate such sweeping changes. The teachers' complaints range from "the district will not purchase user manuals or training programs because they are too expensive" -- to being told to "purchase needed software with their own money because they can get an educator's discount." Teachers have also been directed to request whatever they need for technology implementation... but remember that these purchase requests have to come out of the regular instructional budget." This administrative double speak has served to thwart teachers' efforts while all the talk about the Information Superhighway falls increasingly on deaf ears. The point is clearly stated by teachers when they contend "[They] will not be responsible for implementing technology without first being well trained and provided with the necessary resources."

School Facilities

Although schools may not presently be able to attain ideal facilities for technology equipment, each school should identify the physical facilities needed in a technology plan so that educators can develop a list of priorities that will help them obtain these needed arrangements. The question most teachers (especially elementary) are asking is "Now that we have them, where do we put them?" One first grade teacher stated:

"I'm not going to give up my reading circle space just so the administration can unload computers in my room. The rule in my school now is five computers in every classroom. It would make better sense to have one computer in each room and set up a computer lab for the entire school to use. Someone better tell me, too, where to store all the manipulatives we have purchased for the children. There simply is not enough space to fit everything."

The classroom of yesterday, although adequate for housing thirty students in five straight rows, is inadequate for containing those same thirty students who now require computer workstations in order to perform the gamut of today's technological tasks. Spatial arrangements for equipment and traffic flow, furniture placement, and power outlet sources have become a concern for teachers in most schools. For example, in older buildings where conduit is not available, wires on the floor are invitations for student and teacher injuries. Stuffing students and equipment into small rooms also increases the chance of equipment breakage, greater discipline problems, and frayed nerves on the part of teachers and students due to the lack of individual space. Teachers are very concerned about these physical facility issues as well as issues related to security.

Security Requirements

Many teachers resent the all-encompassing warnings several administrators have made such as "You're responsible for stolen equipment, vandalism, viruses, and equipment breakage." Some teachers have felt so threatened by these statements that they deliberately resist using technology equipment. They
believe it is unfair to place such undue responsibilities and burdens on them. Teachers recognize that computer viruses are as widespread as the common cold and that protecting equipment from being stolen or damaged is a common problem in most school districts. Teachers acknowledge that this is a shared concern for a school system, but they contend that administrators should bear the major burden of this responsibility. Teachers have stated "School boards and administrators should know that these things will happen - we just do not want the finger of blame pointed at us when it does." Administrators are in the position to establish requisite procedures and policies that address these security issues. Security precautions can be a costly expense; however, they are usually more cost effective than replacing stolen or vandalized equipment. Sadly, just as home security systems have become essential, school security systems appear to be imperative.

Management for the Acquisition of Supplies

Teachers are increasingly concerned about the availability of consumable technology supplies (e.g., toner, ink cartridges, videotapes, diskettes) as well as the lack of available technology accessories (mouse pads, copy holders, diskette containers, computer covers, printer stands, switch boxes). Running out of sticks of chalk in yesterday's classroom was one thing (you could always find broken pieces); however, running out of toner completely shuts down the technological operation in today's school. A media specialist shares this account:

Our school houses a $4,500 laser printer; however the toner for the machine is kept at the central administration building. Whenever the laser printer runs out of toner, it takes three days to get a cartridge from the administrative office. Teachers have learned to remove the depleted cartridge from the machine and shake it in hopes of printing a few more copies, but that only works for about two more times. The bottom line is 'tough luck' if you need anything printed. What upsets the teachers is that they have been told by the administration to work around the problem. It is really frustrating for teachers when they are in the middle of a project or tests need to be printed!

This situation is not limited solely to printing demands. A similar story about another supply, VHS tapes, is related by a media specialist from a rural school system:

Our school system owns a satellite dish... so the teachers requested that the feed be taped for use in the classroom. The joke is that our school has state of the art video recording equipment but blank video tapes were not purchased to record programs. The reason the administrator gave us was that video tapes were too expensive for the school to buy. So, he suggested that if teachers wanted this service, they would have to purchase VHS tapes with their own money.

Administrators must anticipate and make budgetary provisions for continual expenditures of consumable technology supplies. Indeed, making these projections is difficult because baseline purchasing data on new technologies is non-existent or incomplete. However, there is one sure point to remember - as the integration of technology increases within the school, the amount of consumable supplies and accessories necessary to sustain this effort also increases proportionally. It is recommended that administrators establish permanent line items for technology expenses in the school's budget rather than lumping these expenditures under yesterday's instructional budget umbrella. Budgeting an adequate amount of money for consumable and accessory technology needs is just part of the total cost for technology implementation. Another major administrative financial pratfall is allocating money for the maintenance of technology.

Maintenance Needs

Because of the sophisticated nature of today's computer and technology systems, educators cannot be expected to solve complicated equipment malfunctions and maintenance problems. One of the cardinal rules technology specialists stress is "Do not tamper with the control panels on the computer, unless you fully know what you are doing." Recklessly clicking commands, changing passwords, and altering subscriber number codes are sure ways to guarantee greater functioning foul-ups. Intentionally hammering on the tops of computer platforms, forcing disks in hard drives, and attempting "to fix" computers without proper training or tools are proven ways to ensure hardware damage. One library specialist shared an
account about a teacher lab coordinator who attempted to repair a cracked plastic casing on a dot matrix printer by using super glue. Unfortunately, "He not only glued the crack in the plastic cover of the printer, the glue seeped into the interior of the machine and froze the printers gears. If this mistake was not great enough, the administrator had the dot matrix printer repaired, and the cost of fixing this outdated printer almost exceeded the cost of purchasing a new, upgraded ink jet printer."

Many of these problems can be avoided if administrators develop proactive policies to prevent such disasters. Administrators should not falsely assume that there will be few technology-related problems, nor that equipment malfunctions can be solved by their faculty or staff. School districts must develop maintenance contracts with outside agencies or set up an in-system department and hire special technology personnel. The overwhelming majority of teachers simply do not possess the technical skills necessary to guarantee that technological equipment will be operative.

Selecting one maintenance option over another (out-sourced versus in-system) is a difficult administrative decision, and teachers report that there are problems and limitations with both methods. For example, an educator who teaches in an out-sourced system explains:

Our maintenance contract provides for technical support one day per week. There are six buildings in my district, including the administration building, and each and every week at least one of the schools loses out. The tech rep always attends to the needs of the administration building first, so they never experience a one or two week delay. The administrative office fails to realize how angry and disappointed the teachers are at the non-serviced buildings.

Teachers also dislike filling out technical support requests on triplicate forms, being told to schedule appointments with tech reps (as though they can schedule the breakdowns of their computers), and being warned not to talk to tech reps when they are servicing equipment in the building, because the reps are getting paid by the hour. Some schools have tried alleviating some of these problems by designating one teacher per building to act as a technical liaison with the contracted company. This arrangement has been fraught with difficulties, too.

Teachers who serve as technical liaisons find themselves in the unenviable position of providing troubleshooting and stopgap maintenance for their colleagues. They complain because generally they are not reimbursed for this service, oftentimes tech reps do not return their calls in a timely fashion, and they are frustrated with trying to maintain current information about so many different computer hardware systems and software. One special education teacher who also serves as a technical liaison comments, "I rarely ever get through a day without a student coming up to my room bearing a request from a fellow teacher for immediate help with a computer problem. These interruptions are troubling given I teach developmentally handicapped and learning disabled students, and there is no way I can leave my classroom unattended even for a few minutes. Teachers just have to wait until the end of the day for my assistance, and that does not help them when their computer has frozen."

Teachers have also attempted to alleviate some of these technical problems on their own by contacting the technical support division of the computer and/or software company. Dial 1-800-(computer) Help! is a frequent byword in many schools. However, teachers report that being placed on hold when they make these calls or being asked to read what is on the computer screen can cause considerable difficulties when the school's phone is located in the principal's office and their computer is on the third floor of the school building. Teachers exclaim, "School systems lack basic technology equipment such as portable phones!" These procedures appear to most teachers to be poorly considered and uncoordinated approaches for technology maintenance.

Some school districts choose to hire their own technicians and establish internal offices to manage technology maintenance needs and support services. However, as both teachers and technicians relate, this technical support measure is not a panacea either. Teachers lament that "the salary of a technician is often much higher (usually double) that of a teachers salary, and that technology specialists know nothing about the instructional needs of educators." Many school systems also report that the turnover in technical support personnel is high and that it is difficult to hire persons who possess both technical competency and interpersonal skills, and who also prefer working in a school rather than a business environment.

**Conclusion**

The implementation of technology into today's schools requires both administrators and teachers to be technology leaders. However, studies show that most administrators are not promoting the integration
of technology into the school curriculum (Waxman & Huang, 1993). If administrators are to lead their schools forward, they must address teachers' concerns which are central to integrating technology into classroom practice. Issues such as training in technology, arrangements for facilities, space for technology equipment, security policies to guard technology investments, management strategies for the acquisition of technology supplies and accessories, and procedures for technical maintenance and teacher assistance are some of the major factors that impact the failure or success of technology implementation.

The ability of teachers to integrate technology into instruction is directly tied to the organizational environment and educational culture in which they work. Thoughtful administrators realize that the daily challenges of teaching work against technology implementation (time, training, resources, technical support). Administrators certainly can help teachers if they are willing to listen to teachers concerns about technology implementation, and provide innovative shared leadership to circumvent the constraints of the educational system. Just as the proper use of technology requires significant changes in how teachers teach, the successful implementation of technology into schools requires administrators to make significant changes in how they support their faculties.

A Qualitative and Quantitative Evaluation
Innovative Use of Internet Based Collaboration

San Marcos, Texas, USA
elearn@Deanie.org

Abstract
The descriptive study has two phases. The first phase describes the mechanism for on-line collaboration. The second phase quantifies collaborative interaction. The coding design was partially based on ProjectH, a research study from 1992-1994 involving a large number of collaborators from several countries who worked together to study world wide collaborations on the net. Sheizaf Rafaeli, Hebrew University of Jerusalem, Israel and Fay Sudweeks, Key Centre of Design Computing, University of Sydney, Australia coordinated ProjectH. This current study looks in depth at the interaction of ten graduate students who communicated through the German based system, Basic Support for Collaborative Workstation, (BSCW) during one month, September, 1998. E-mail messages from Internet based students were also coded. Final observations were made regarding student interactions throughout the course.

Introduction
The German National Computer Research Centre provided the collaboration system used in this study as a public service. The system is called "Basic Support for Collaborative Work" (BSCW). Version 2 of the BSCW Shared Workspace System has won first prize in the European Software Innovation Prize 1996. The BSCW system enables collaboration by providing shared workspaces over the Internet. The BSCW supports document uploading, event notification, group management and much more. To access a workspace only a standard Web browser is needed. A shared workspace allows storage and retrieval of documents and sharing information within a group, which is defined by the user. This functionality is integrated with an event mechanism, as an e-mail web report or icon based link, to provide each user with an awareness of the activities of others within the workspace. On-going innovations continue to make this system highly supportive of educational collaboration. The BSCW developments have been partially funded by the European Union through the Coop WWW project and the CESAR project of the EU's Telematics Applications Programme. Partners of these projects contribute to the development of the system. BSCW is maintained and developed by the BSCW project group at German National Research Center for Information Technology (GMD) and the Institute for Applied Information Technology (FIT). FIT is a research unit of GMD, Germany's national research center for information technology and has a staff of about 70 researchers.

Evaluation Questions
The BSCW is complex and many different types of questions could be explored. This study focused on these six:

1. How many students from the Internet class participated in the BSCW system?
2. Do some students use the system more frequently than others do in a one-month period?
3. What were the e-mail variations?
4. What were the basic problems students had related to the BSCW system?
5. Were students satisfied with the course?
6. By the end of the course, what were the variations of participation in the BSCW system?
Data was analyzed according to five units of analysis: daily reports from the BSCW administrative system, individual e-mail messages, department student satisfaction ratings, a student survey and a focus group with the small San Antonio learning pod.

Description of the BSCW system

Figure 1. illustrates a collaborative workstation composed of folders that are the actual work areas of the system. There is a "Catch Up" button to find out what was missed since the last visit. The "Add Member" button allows you to invite others to your workspace. Documents of many different types can be added to the system. i.e. Word, Excel, Power Point, HTML and others. The "folder button" allows new workspace. "Add Article" allows exchange of information as a bulletin board system. The faces link to all the members of the workspace. While in the member's section, it is possible to send group e-mail to everyone or selected individuals in the group.

Each individual has a workstation identified by personal name at the top. Shared folders, containing information, become the collaborative "workstation" for the group. This group chose the name, "1998 Internet Think Tank". There are many sub folders within the group. The first folder contains articles as bulletin board threads, which were provided by the professor. Threads included: Confused...please help; Have an idea; Disappointments and Frustrations; Want an answer; and Did you really like something? These phrases triggered varied responses from the students. Archived information was provided in a separate folder for students to use as background information.

Not all information has to be within the BSCW system, URL links can provide different types of information for access. The professor and students can add an unlimited number of links to related sites. The emphasis at the beginning of the course was to provide personal connections among students; therefore, students used a simplistic program for homepage development. Two basic sites, were used for developing these easy home pages: Free Yellow (http://freeyellow.com) and "The Express Page" (http://www.expage.com/). The media web site is the basic course manager for students. It includes fourteen different information sites including links to the course syllabus, course due dates, grading information, directions for getting on the BSCW, and tutorials. Any information stored in the BSCW is password protected and only members can access the information. However, the Web page with all related course information can be publicly accessed. (http://WWW.SWT.Edu/~df12/media/media.htm )

The students and the professor can all view the same documents at different times from their personal computer and see the remarks provided by different individuals. These comments provide feedback to the individual student, as well as, help other students with ideas and suggestions to improve their own work. The products are criterion referenced with acceptance or non-acceptance according to pre-stated criteria, so there is no grade competition for this portion of the course.
As soon as students create a new document and upload it to the BSCW, other students and the professor can simultaneously assess it for review. Individuals are sent an e-mail report for all the new events which have occurred during the last 24-hour period. Figure 3, depicts how the professor and students all know when and where new hyperlinked activity can be found.

Reliability

Reliability standards were based on ProjectH methodology. Reliability assesses the degree to which variations in data represent real phenomena rather than variations in the measurement process. Two raters for the same data helped establish reproducibility of the results. Independence among coders was maintained. To ensure autonomy, coders were discouraged from discussing coding problems with each other. There was agreement of ratings between...
the coders for BSCW activity. However, there was wide variability in the coding of e-mail categories; thus the
experienced senior ProjectH researcher did the final coding of the e-mail. Difficulty in coding e-mail messages was
due to the complexity and length of messages.

Group Process

This Internet section evolved as a request from six San Antonio students who wanted to take the traditional San
Marcos classroom HHR 5332 Media course as an Internet based course. The group evolved from students who were
enrolled in a traditional class with Dr. French in San Antonio, which was augmented with self-directed Internet
based features. Two students who were not part of this original class became a part of the San Antonio group
through word of mouth. Later other students from San Marcos and Austin heard about the course and asked to join.
The guidelines for being in the first graduate Internet based media class included: 1.) Having had Dr. French as a
professor in another class, which provided self-directed learning skills and mastering on-line modules concepts, 2.)
Willingness to work collaboratively, 3.) Commitment to make the process work or 4.) Permission of the professor.

The San Antonio learning pod met as a group with the professor once before the class started in San Antonio. It
appeared that the group would have sufficient skills within the pod to help each other meet class goals. As the
semester progressed, one student, who was to act as a key leader dropped the course due to work and personal
responsibilities. Two students worked primarily independently. One of these students who worked independently
helped other students through telephone calls. Three students who I will refer to as the small pod (SP) became The
remaining students who were not part of the SP group worked though the BSCW, e-mail, attended optional class
lectures, and participated in optional open labs. This class expanded into a total of ten students.

Use of the BSCW System

During the first month of September, 80% of the students were participating. After the class was over, a focus
evaluation session was held, and the SP group revealed that they had found a "backdoor" (using a URL to by-pass
the sign-in section) to the BSCW system and tended to view the information as a group rather than log-on as three
separate individuals. It is impossible to determine their activity in the BSCW. Their final projects were submitted as
 hard copy or on disk; thus, the SP group found a way to avoid the BSCW for about 75% of the course. Two of the
SP group had major computer problems, which affected their early attempts and attitudes toward integration with the
system.

Frequency of Use by Individual Student

Eighty percent of the students participated in different types of events such as reading, creating, deleting, renaming,
replacing and changing descriptions. The range of "events read" was 18-59, with a mean of 25. Seventy percent of
the students participated in the system by "creating events". The range was 2-15 with a mean of 6. Four percent
"deleted items" from the system. The range was 2-10 with a mean of 6. Ten percent "renamed documents" with a
range of 1-2. Thirty percent "replaced documents" with a range of 2-4 and a mean of 3. Forty percent "changed
descriptions" of the documents by entering comments, which related to a document in the system as a form of peer
review and support. The range was 1-9 with a mean of 5. Twenty percent of the students were recorded as not
contributing or participating in the BSCW.

Analysis of e-mails sent to the professor in September

All but one student sent e-mail to the professor the first month. A total of sixty-three messages were received. The
number of messages received from individuals ranged from 1 to 20. Eighteen messages indicated confusion or
frustration. Most of the messages were a mixture of questions and sharing of information. Two students had the
professor in a different course at the same time and tended to share information in person. One student had a
complex problem related to the BSCW and posted a question to the BSCW listserv. A range of professionals
responded in two days and the problem was solved with this outside assistance. One response was from Rice
University while the others were mostly from Germany.
Peer student survey

One student became frustrated with small problems related to the BSCW and conducted an on-line survey of the Internet students. He identified several problems and solutions, three of which are as follows:

1. The Netscape Navigator is the only browser that worked consistently within the BSCW workspaces. Other brands of browsers such as Microsoft's Explorer did not function well within the BSCW spaces, and in many cases would not allow access to all of the system's capabilities. Problems were also encountered with older versions of Netscape; therefore he recommend downloading the most current version from the Netscape home pages. The student's finding could be confounded by use of an older version of Explorer. There is no difference in performance between latest level versions of each browser.

2. Microsoft Office 97 or Microsoft Word and Microsoft PowerPoint are recommended to insure compatibility.

3. Some of the students did not have adequate hardware (CPU, storage, RAM) to access the BSCW and upload documents. He recommended discouraging students from signing up for Internet courses unless they have adequate equipment or frequent access to equipment resources. Current minimum equipment recommendations are: a Pentium 100 MHZ CPU, 32 megabytes RAM, and a 33.3 baud modem.

4. Students were confused about exact Internet specifications. For maximum effectiveness it is recommended that each student have access to the Internet through his or her own Internet Service Provider or SWT's Internet services.

Course Satisfaction

The Department of Health Service and Research anonymous student rating system was utilized. This tool consists of a three section 24 sentence instrument with agreement levels of 1-5. Each section is broken into an "overall" agreement statement. Course satisfaction was high as indicated by the following ratings:

1. Quality of Instruction (1.5),
2. Instructor method of measuring progress (2.5), and
3. Interaction with students (1.3).

Focus Group

The concept of collaborating over the Internet is new to most students and requires guidance and nurturing of students' attempts to interact with the system. By the end of the course, five students regularly wrote supportive statements to each other and interacted freely with each other. Two of the students contributed to the system but did not interact directly on the system other than as required. They did not write supportive statements to each other nor participate in the discussion groups. The three students in the small learning pod in San Antonio became a very close team and were highly successful in completing projects. However, they tended to avoid the BSCW for a variety of reasons. The group was lead by a student who was a lawyer and liked to solve her own problems even if this meant "driving to Canada for what is available in Mexico." One of these students told me that they knew that they would eventually get to right spot. This group was very reluctant to use other peers or the professor for support. They felt they had "used up" their amount of the professor time in the first part of the course. All three students held professional positions outside the course and liked to finish student projects into the early morning hours.

The process described by the SP group is supported by previous research findings. French (1995) has found that students can change their manner of learning. Qualitative and quantitative data for these behaviors have been collected over several years. In the fall of 1991, a t-test was employed to test paired differences on pre- and post-test scores for a group of 17 upper level undergraduates enrolled in a training class. The instrument used a Likert-type scale to measure beliefs about self-directed learning versus traditional learning. Significant differences were found in pre and post beliefs about self-directed learning (alpha .001). These results indicate that while most students enter university classes with primarily linearly based backgrounds, they can master new behaviors to facilitate restructured learning. On-going qualitative analysis with graduate focus groups has revealed that difficulties related to mastering new patterns of learning revolves around four key barriers:
1. Asking peers for help. Former educational programming implies that asking for help may be a form of "cheating." The SP group wasted many hours by not seeking more support.

2. Changing learning style. After a course is completed, most of my students have indicated they enjoyed self-directed learning and looked forward to other courses which used this style of teaching. However, other students have felt that teachers are "paid to teach" and thus, the teacher should be in front of class "teaching" the students. While the SP group liked the self-directed learning process because it allowed the three of them not to have to drive to San Marcos, they could have expedited their learning by not repeating the same mistakes.

3. Developing failing resilience. Some students become very frustrated with enduring temporary lack of success in mastering new skills, particularly high technology skills. Just the opposite seemed true for the SP group. One member of the SP group said that she had learned when to "quit;" while the others kept going and going. It is very rare for students to endure repeated failure. Having a lawyer in the group may or may not have affected this group's process.

4. Personal reward for success rather than the teacher's reward of the student. Many students have difficulty identifying and accepting intrinsic recognition apart from external rewards from the faculty or other outside influences. Basically, it appears that many students use the standard of "what is on the test" to determine what is most important to learn. The opposite was true for the SP group as they were rewarded by the joy of learning.

Conclusion

Both teachers and learners have to adapt to new styles of teaching and learning to meet future learning needs. Dr. Steve Bett (1994) has noted that colleges need to help students cope with the new learning environments and emerging conditions in a productive manner. He stresses that there needs to be more emphasis on process, how to learn, retool, update, communicate, and less on content. Bett noted that teaching can be content rich but the emphasis should be on process. He further points out that "it is no longer cost effective to focus just on the 'facts' which are true today but may take on new meanings tomorrow." (p.1)

Abstract: Educational research has long been conducted at a distance; both mail and telephone have successfully been used in survey research. The development of the Internet offers yet another medium over which research can be conducted. This study discusses the use of electronic mail as a vehicle for conducting educational research. It focuses particularly on the way in which electronic mail can be used to engage in reflective dialogues, which yield deep, qualitative data. The research methodology is presented along with examples of the dialogue that emerged from the semi-structured interview protocol that was used.

Introduction

Educational research has traditionally been conducted by undertaking studies of educational statistics, surveying those involved in educational practice, or more recently, conducting ethnographic studies of the practice occurring at one or a variety of sites. Many studies are conducted at a distance; written surveys, for example, are mailed to a number of people or institutions within a defined region; others are interviewed by phone to obtain more complete information than can be obtained in a written survey. Surveys though are limited by the questions asked, and often don't offer the researcher or the respondent the opportunity to review the response in order to restructure the question or refine the answer.

The development of the Internet offers another medium through which to conduct educational research. The very factors that make Electronic Mail (E-mail) a favored mode of communications, the fact that E-mail is asynchronous and text-based, lends itself to exchanges that are timely and thoughtful. In this paper we describe a project in which E-mail was used as a medium of educational research, and the quality of data that emerged from that process. The project is described, with an emphasis on the methodology, and examples of the data are presented. The viability of text-based E-mail as a research tool, the process of finding participants, and gathering sufficiently detailed information from the participants is also discussed.

Survey Research

The use of online survey research is relatively new. Hiltz and Turoff (1978) discussed the possible use of computer-mediated communication as an opinion research tool, especially using predictive data gathering techniques such as Delphi. Honey and McMillan (1994) used online technology to interview subjects who had participated in an earlier national telecommunications survey (Honey & Henriquez, 1993). All but two participants completed open-ended questionnaires using the Internet. James, Wotring and Forrest (1993) found that online surveys are "fast, relatively inexpensive and allow users to request feedback that can clarify misunderstandings about the instrument" (p. 52). Thach (1995) analyzed the use of E-mail to conduct survey research and found it to be cheaper, easier to edit, faster to administer, simpler to invite participants, a higher response rate, more candid answers, and a potentially quicker response time with a wider area of coverage. The speed of electronic transmission allows messages to be transmitted worldwide in a matter of minutes as opposed to traditional mail which may take months to...
reach a country outside the U.S. This allows for quick data collection from a variety of populations, which might otherwise not be utilized.

E-mail is particularly well suited as a vehicle for conducting personal interviews when space and time do not connect the researcher and subject. Personal interviews are the most effective way of obtaining the cooperation of the interviewee, and allow for the most flexibility in asking questions, probing for answers, and building rapport (Katz, 1993). E-mail interviews can be viewed as a dialogue between individuals that can easily and inexpensively be transformed into usable data, making them a highly valuable tool for conducting research (Thach, 1995). Online technology overcomes the barriers imposed by space, time, and location (Harasim, 1993). Foster (1994) listed various advantages of the online interview format, including: it is relatively inexpensive; interviews can be sent many places at the same time; it is asynchronous, meaning respondents can answer when it is convenient; respondents can choose to participate or not; the responses return in a form which is already readable for analysis; the data is easily transferred from a mail program to a program for analysis; and very little transcription is necessary. He did caution, though, that online interview protocols must be more self-explanatory and explicit than those conducted in face to face or telephone interviews. Foster also discussed the problems of using listserv sites as locations for posting an interview protocol, while Sudamlis (1992) stated that participants in online research are often self-selecting individuals who subscribe to listservs.

E-Mail and Reflective Conversation

E-mail has been discussed as a useful tool for teaching and learning. Used as a tool for online communication, E-mail has been credited with helping teachers move to more constructivist teaching practices than previously held (Heflich, 1998). An important aspect of this movement is the extent to which E-mail can stimulate discourse that leads to reflection by the participants. E-mail discussion groups have been used in preservice teacher education to help develop reflective thought (McIntyre & Tlusty, 1995) and the moral development of preservice teachers (Harrington, 1992).

Central to all of these efforts is the significance of the protected conversational space that is offered by E-mail. Online conversation has previously been characterized as reflective (Heflich, 1997). Reflective conversation is an exchange of ideas in which the expression and receipt of ideas leads to the construction of new understanding of their own experience among the participants. Bamberger (1991) has described such an exchange as "conceptual chaining" in which ideas are articulated, exchanged, recreated and re-exchanged as they move from person to person in a conversation. The reflective aspect of such a chain is the way in which individuals capture the ideas that are seemingly forming in the air and construct their own meaning from them as the reflectively integrate them with previously held knowledge.

Feldman (1995) has described the use of conversation as a research tool in the teaching of action research courses. Conversation for Feldman (1995) counts as a reflective, meaning-making process because it represents an exchange of ideas that lead to understanding. Conversations can become a tool for critical inquiry when the goal of the conversational exchange is to share and develop knowledge and promote understanding among the participants.

Conversation offers us an opportunity to reflect-on-action, as it allows us to discuss and process into our intuitive knowledge base (Iran-Nejad, 1994) things that have previously occurred. It can also involve reflection-in-action as we dynamically engage in conceptual chaining (Bamberger, 1991) in the midst of an ongoing dialogue. In either case, conversation serves as a vehicle for stimulating reflective thought and may lead to both personal and professional growth.

Reflective thought has long been considered an important aspect of professional growth. Argyris and Schon (1974) identified the contradiction between one's espoused theory, one's expressed beliefs, and one's theory-in-use, beliefs made evident by one's activity. Growth for Argyris and Schon (1974) was recognized as the dissonance between one's espoused theory and theory-in-use and taking steps to align them. Osterman and Kottkamp (1993) discuss the role of inquiry as an element of professional growth. It is inquiry among individuals that helps expose the contradictions between beliefs and practices of teachers. Feldman et al. (1996) argue that teachers in a reflective stance examine their own practice exposing and questioning tacit assumptions about their teaching. This allows them to reflectively evaluate past practices and seek alternatives.
Project Description

The project for which email studies were used was designed to evaluate the attitudes of educators who participate in online discussion groups regarding the impact that online technology has had on their practice as educators, and on the learning of their students. The project was concerned with understanding whether online technology is another educational fad, or whether it contributes to changes in educational practice from didactic to constructivist methodologies. Also examined was the assessment of the impact of Computer-Mediated Communication (CMC) on constructivist teaching and learning using the trends identified by Collins (1991). The questions the research attempted to answer were:

1. Are teachers with more access online technology in their classrooms more likely to exhibit the practices of a constructivist teacher identified by Collins (1991) than those who are isolated users of computer technology in their classrooms?
2. Which structural or sociocultural elements of school support the use of online computer technology in a constructivist manner?

Subjects

One assumption of the study was that educators with experience using online computer technology will possess insights into the changes that exposure to online resources will have on classroom instruction and the relationship between student and teacher. It was believed that this population would have ideas concerning the role of technology in the long-term restructuring of teaching and learning. The goal was to reach the typical case of an online educator. A typical case may be located by first developing the criteria that define the case and then seeking those who possess the defining characteristics (Lecompte et al., 1995). The typical case in this study is an educator whose commitment to using online technology is made evident by his/her participation in online educational discussion groups. In order to locate the desired population, notices describing the study were posted on a variety of listserv discussion groups geared toward educators. Thirty-five people responded to the posting. Of these 35, 24 respondents agreed to participate in the study. Efforts to reestablish contact with the original 24 respondents met with mixed success, so a second round of notices was posted. Twenty-five respondents ultimately expressed interest in participating in the study representing schools in 16 states and 6 countries. They represented schools that had already adopted the use of the Internet, and were experimenting with its use; and schools that were in the process of adopting the Internet. Fifteen of the educators came from that schools were primarily elementary; ten were from secondary or K-12 schools.

Materials

An interview protocol was developed for use in a written interview exchange, which allows for in-depth exploration of the contextual considerations involved in decisions to implement online technology, and integrate it into the curriculum. The use of a semi-structured interview protocol enables data collection to proceed in a conversational fashion. In an semi-structured interview the reflective element of the conversation leads to new thoughts on the part of the researcher and subject, leading to the construction of new meanings (Klave, 1990, cited in Miles & Huberman, 1995). Questions asked can follow the thematic outline, but be specifically addressed to the situation and concerns previously expressed by the subject.

Data Collection and Analysis

The interview protocol was used as a guide for questioning the respondents. Interview questions were sent by E-mail to each participant, one at a time. The respondent answered the question by E-mail before the next one was sent. This exchange of messages allowed the interview to adopt a conversational tone. Messages containing subsequent questions contained reference to the previous response. In this way the researcher and the respondents developed a rapport that allowed for a thoughtful, reflective exchange of
questions and answers. Once begun, the E-Mail exchanges lasted for a period of weeks. The researcher interpreted the data collected, then sent his interpretations back to the participants to be certain he understood their replies. Once agreement was reached, the responses were analyzed.

The data collected were qualitative, textual quotes as they appeared in the E-mail exchanges between the researcher and the participants. They were downloaded into Microsoft Word 6.0, where they were saved into separate text files of questions and answers for each participant. These files were then reformatted for compatibility with The Ethnographer 4.0, a qualitative data analysis program. Data analysis was conducted according to the guidelines of the Constant Comparative Method (CCM) (Glaser & Strauss, 1967). The goal of CCM is the emergence of theory from data, derived through repeated review of the data, each time examining it for common themes.

Results

The results of this study demonstrated several things, concerning both the objectives of the study and the methodology. This paper is mainly concerned with the results of the methodology. The results indicated that E-mail is a viable method for obtaining reflective data from participants. The participants in the study provided a large quantity of very thoughtful responses because it led them to think creatively about their practice. Reflective conversations have been recognized as stimulating professional growth among the participants (Feldman, 1995; Fine & Riggs, 1994; Lincoln, 1992). Conversation itself has been acknowledged as a mechanism for fostering reflective practice (Feldman, 1995; Osterman & Kottkemp, 1993; Schon, 1987); and online technology, used as CMC has been successfully used in organized professional development (Schrum, 1992), in reflective seminars at the university level (Harrington, 1992), and as an unanticipated consequence of online usage by professionals (Lincoln, 1992). This study appears to be the first example of an online research project fostering professional growth through interviews that resulted in reflective conversations.

Riel (1990, 1993, 1994) and Schrum (1992) discussed the positive impact of online communication on teaching and learning as an opportunity for professional growth. A number of study participants wrote about their interactions with others online. They valued online educational discussion groups and the relationships they develop with others who participate in them. Participants in this study cite online communications with others as one of the most valuable aspects of CMC. Some participants commented that the interview/discussions gave them the opportunity to explore ideas and reflect upon their practice as educators. The extent to which the interviews served as reflective conversations that led to professional growth, in the course of which the participants reorganized their own knowledge can be seen in the comments of one of the study participants to one of the interview questions.

Question: What do you see as the future of education when you consider the impact of online technology? What sort of impact will it have on teaching and learning? What will be the role of a teacher? What will the life of a student involve? How will these represent a change from what exists today?

Answer: I am concerned about the isolation that computer use often entails. It does not seem to me, as I watch my classes work, that the use of online technology has fostered working together. I am concerned that much that has been developed in terms of authority systems over the past 100 years (selection media, reviewing for library materials, refereeing for academic journals, and the like) does not lend itself to a system of universal access and information such as the Internet. Obviously this has its good side, but I don’t see much emphasis on teaching students to evaluate the information they get as I do teaching them to "access" it. I’m concerned, too, about the emphasis on the pictures over the word. The web is more popular than gophers because of the ability to use pictures, etc., but I fit it much slower, actually, as an information source. But I read. My students look at the pictures and move on. It’s almost impossible for me to imagine the future of education, technology changes so fast and we are obviously just at the beginning of online tool development and online information systems.

Quite clearly this person had the opportunity to reflect on the question given the conversational space created by both the asynchronous nature of E-mail and the conversational methodology of sending one question at a time. The rapport developed between the researcher and the subject during the interview...
process allowed the interview to become a rich source of data that fully explored the beliefs of educators. E-Mail which overcomes the limits of time and space seems to hold great promise for educational research.

Preservice Teachers' Perceived Effectiveness of Technology Resources: A Cross-National Study

Abstract: This study investigated cross-nationally preservice teachers' perceptions of the effectiveness of computers and technology in improving education. Among all participants, 180 students each from the United States and Taiwan were randomly selected. A survey instrument that identifies types and amounts of technology resources generally found in elementary, middle, and high schools was used. The results indicate that preservice teachers in both places valued a computer lab in each school and computers in each classroom higher than interactive video equipment or calculators. They also thought that these technology resources were more important and useful for students in high schools than in elementary or middle schools. Preservice teachers in the United States, however, had more positive perceptions of the effectiveness of technology resources in improving education than their counterparts from Taiwan. Findings of this study and their educational implications are discussed in the paper.

Cross-national or cross-cultural studies of computers in education have gained considerable attention during the past decade. This may attribute to the feasibility of this type of approach in (a) testing the generalizability of attitudes toward computers originated in one country to others, (b) broadening the perspective of researchers and thus helping to strengthen our sensibility for idiosyncratic features of our own educational system, (c) contributing to a better understanding of the relative influence of some significant variables on educational computing, and (d) looking for universal variables and relationship between variables that are cross-culturally valid (Wubbels, 1993).

There have been a number of research paradigms in cross-national inquiries of educational computing and technology. The questions pursued, however, tend to center on (a) assessing computer use in education at elementary and secondary schools (Pelgrum & Plomp, 1993), (b) comparing college students' computer attitudes with respect to gender difference, confidence, and anxiety (Leutner & Weinsier, 1994; Marakis, 1992; Marcoulides & Wang, 1990; Sensales & Greenfield, 1995), and (c) examining preservice teachers' attitudes toward computers (Liao, 1995; Paprzycki, Vidakovic, & Ubermanowicz, 1995). Very little research, however, has specifically investigated and compared cross-nationally preservice teachers' perceptions of the effectiveness of computers and technology in improving education.

It is very important to examine preservice teachers' perceptions since research studies have found that teacher perceptions of computer and technology are closely related to their computer use (Brownell, Brownell, & Zirkler, 1993; Huang, 1994; Huang, Waxman, & Padron, 1995; Huang & Padron, 1997; Liao, 1993) and that teachers who were aware of ways computer could help do their job better (Sheingold & Hadley, 1990). Investigation of prospective teachers' perceptions of computers in education in the United States and in Taiwan may help to reveal how much these teachers knew about computer and technology resources as well as to accomplish some of the objectives Wubbels (1993) stated. Therefore, the purpose of this study is to compare perceptions of the effectiveness of computer and technology resources in improving education between preservice teachers in the United States and Taiwan.
Methods

Subjects

The participants in the study were undergraduate education students from a southern state of the United States and northern Taiwan. Among all participants, 180 students from each place were randomly selected for study. Among the 360 sample subjects, 21% were male and 79% were female. Over 72% of them were between the ages of 18 and 25, 21% were between 26 and 35, and 7% were older than 35. Nearly 6% of them had never used a computer, and over 41% had used computer(s) for more than two years. However, the two groups of prospective teachers varied greatly in the compositions of their demographic variables. There were more males than females among preservice teachers from Taiwan than from the United States, whereas preservice teachers from the United States were older in age and had longer experience working with computers than their counterparts from Taiwan.

A computer course has been mandated as a teaching certification requirement in the southern state of the United States, and a "computer literacy" course was offered at the undergraduate level. In Taiwan, most colleges have offered introductory computer courses as prerequisites. The content of these courses contains the basic concept, operation of computers as well as software.

Instrument

The instrument used in this study is the Educational Technology Survey (Waxman, Huang, & Padron, 1992). This survey identifies types and amounts of technology resources that were generally found in elementary, middle, and high schools. It measures the extent to which the subject thinks that computer and technology resources will change schools and improve education of all students. All the 15 items are on a 5-point Likert-type rating, including "Very Effective," "Effective," "No Effect," "Ineffective," and "Very Ineffective" for improving students' education. In addition, there is a category for subjects to indicate that they are "Not Familiar" with the technology. A brief section on these prospective teachers' background was also included in the instrument.

The survey instrument was translated into Chinese for the use of sample subjects in Taiwan. Verification of the content validity of the Chinese version was done by reversing translation of it into English by English teachers who had not seen the English version. The result shows that there is no need for revision. The survey instrument has been found to be reliable and valid in prior studies (Padron, 1993). For the present study, the alpha reliability coefficient is .81 for the subjects in the U.S., and .90 for the subjects in Taiwan. This suggests that the instrument is reliable in measuring perceptions of these prospective teachers from both places.

Procedures and Analysis

The survey instrument was administered at the beginning of the academic year to the preservice teachers by experienced researchers in both nations. Preservice teachers responded anonymously. Frequency distributions displayed the percentage of preservice teachers' ratings on each resource item. A series of chi-square test was conducted to determine whether there were significant differences between preservice teachers from the United States and Taiwan in their perceived effectiveness of technology resources in improving education.

Results

The frequency distributions show that, in general, preservice teachers from both places thought that technology resources were effective rather than ineffective in improving education for all students. Over 60% of preservice teachers in the United States perceived that (a) a computer lab in each elementary, middle and high school, and (b) several computers for each elementary, middle and high school classroom would be "Very Effective" in enhancing education. Over 60% of preservice teachers in Taiwan thought that these two types of
computer resources were either "Effective" or "Very Effective." Less than 10% of preservice teachers from both places responded "Ineffective" or "Very Ineffective" for any type of technology resources, except the responses from preservice teachers in the U. S. on the Calculators in elementary or middle schools item.

Table 1 reports the chi-square results. The results from chi-square analyses reveal that there were significant differences between the two groups of preservice teachers in their perceived effectiveness of all types of technology resources in improving education. More preservice teachers in the United States than in Taiwan viewed that (a) a computer lab in each elementary, middle, and high school ($p < .001$), (b) several computers (4 to 5) for each elementary, middle, and high school classroom ($p < .001$), and (c) one computer for each elementary, middle, and high school classroom ($p < .01$) were "Very Effective," whereas more preservice teachers from Taiwan viewed these computer resources at all schools "Effective" rather than "Very Effective."

The Chi-square results also reveal that the two groups differed significantly in their perceived effectiveness of other technology resources. Again, more preservice teachers in the United States than in Taiwan indicated that calculators in elementary, middle, and high schools were "Very Effective" in bringing change and improving education, whereas more preservice teachers in Taiwan than in the U. S. indicated that calculators in elementary, middle, and high schools were "Effective." The chi-square values for the effectiveness of calculators are significant at $p < .001$ for all schools. Furthermore, preservice teachers from both places thought calculators as being "Very Effective" for high school rather than for elementary and middle schools.

</table>

Note. VE = Very Effective, E = Effective, NE = No Effect, I = Ineffective, VI = Very Ineffective, NF = Not Familiar
*p < .01. **p < .001
Preservice teachers in both places generally perceived greater effectiveness of interactive video equipment in high schools than in elementary and middle schools. More preservice teachers in the United States than their counterparts from Taiwan thought that interactive video equipment in each high school was "Very Effective" and in each elementary and middle school was "Effective" (p < .001). Furthermore, over 50% of preservice teachers in Taiwan thought that interactive video equipment was "Effective" only in high schools, but had "No Effect" on educational improvement in elementary and middle schools.

Discussion

Findings of this study reveal that there were certain common characteristics among preserve teachers in the United States and Taiwan. In general, preserve teachers in both places valued computer and technology resources highly. However, they valued a computer lab in each school and computers in each classroom higher than interactive video equipment and calculators. Furthermore, they all agreed that these technology resources were more important and useful for students in high schools than in elementary or middle schools.

Nonetheless, there were significant differences between the two groups of preservice teachers. Preserve teachers in the United States had more positive perceptions of the effectiveness of technology resources in bringing change and improving education than their counterparts from Taiwan. More of them responded "Very Effective" on most of the computer and technology resources. On the other hand, more preservice teachers in Taiwan responded that they were not familiar with computer and technology. Preserve teachers in Taiwan were also more conservative in their belief of the effectiveness of computer and technology in enhancing teaching and learning processes. An examination of their computer background reveals that preservice teachers in Taiwan generally have less experience in working with computers and other types of technology resources than their counterparts in the United States. This may partially explain the disparities found in this study, since prior experience in computer has been reported as the major factor in determining prospective teachers' perception of computers (Brownell, Brownell, & Zirkler, 1993; Huang & Padron, 1997). Increasing computer experience corresponded to more positive attitudes toward computers (Liao, 1995). Another plausible explanation for the significant disparities may include difference in social and cultural concepts. Preserve teachers in Taiwan may rely more on intrinsic efforts like individual's hard working and educational aspiration rather than external resources for educational improvement. Future research needs to investigate various factors related to differences in perceptions of computer and technology among preservice teachers of different places and cultures.

Findings of this study have several educational implications. First, it contributes to the knowledge base of the common belief of preservice teachers between countries and how they differ from each other in terms of their perceived effectiveness of technology. Second, the study identifies the technology areas that preservice teachers are less familiar, i.e., interactive video, and calls for teacher education program to address such needs. Third, it invites further investigation of the impact of some variables such as social value and cultural heritage on preservice teachers' perceptions of computer and technology in educational improvement. Teacher educators, however, should keep in mind that to make computers and other technological resources effective for educational improvement, preservice teachers must have competency in utilizing these resources. Indeed, the added value which telemedia may bring to education processes is strictly linked to how it is used (Trentin, 1996). Teacher educator may get help from research studies that provided strategies and suggestions to enhance preservice teachers' use and appreciation of computers and other technological resources (Handler, 1992, 1993; Petrakis, 1992; Stephen & Ryan, 1992; Tearle & Davis, 1995).

Abstract: This paper provides an overview of a pilot study conducted in Northeast Ohio. The study considered the questions; 1) Are the technologies available in schools supportive of the classroom goals of teachers and students? and 2) What reasons influence the use of technologies in their learning activities? The present study attempts to examine what learning activities are applied across a variety of subject areas, how technology assists students' learning activities, and why technology is/isn't used in the typical learning activities. The study documented the typical learning activities and potential role for technology within the classroom learning environment of the effective middle school teacher. Learning activities such as data collection, data analysis, visual/written communications, and design were employed as core categories for analysis of technology use, non-use, and potential.

After two decades of personal computing in the schools it is easy to overlook the fact that many teachers' experiences with technology fall short of the successful and exciting experiences reported by researchers (Ambron and Hooper, 1990). What is reported; the individual instances of success, innovative technologies, and well funded development projects provide a stimulating look at what can occur when circumstances are optimal. Unfortunately teachers work in less than optimal conditions. The occupational world of most teachers is quite different from that of an educational technology researcher. Classroom teachers do not design the software, hardware or technologies they use. They have minimal control over instructional time, preparation time, or the teaching content mandated by their district. In regard to technology support, the classroom teacher has comparatively little daily assistance with technology.

For the average teacher the use of technology has not been an empowering experience. Consequently, the level of technology use has remained relatively low. There is concern that the quantity of technology needs to increase (Morrison, Lowther, and DeMeulle, 1999). Criteria identified in recent technology surveys suggest that emphasis is placed on the quantity of technology available in schools rather than the purpose of the intended technology use. From the standpoint of the students, the end users of the technology, or the teachers, the facilitators of learning, the process is the reverse of what is expected. The critical variable of interest is student learning. Technology offers one tool for accomplishing this learning. Using level as the primary variable ignores the goals of the teachers and the needs of the students. Quantity alone disregards the context of the learning activity and discounts whether technology supports classroom instruction.

Agreement with the position that the quantity of technology in schools needs to increase is dependent on assumptions regarding the design of the technologies provided teachers. A key assumption is that the technology identified in surveys was designed for use by teachers and students. This is not the case for much of the technology hardware available in schools.
Two questions merit considerations; 1. Are the technologies available in schools supportive of the classroom goals of teachers and students? and 2. What reasons influence the use of technologies in their learning activities? These are complex questions but they can be considered in light of studies of how people work in technology intensive workplaces. Holtzblatt and Jones, (1993) have pointed out that well designed technologies that take into account the reality of what people do on the job can boost productivity, enhance job satisfaction, and give workers a clear sense of what needs to be accomplished in their workplace. The essential point is that technological tools that are insensitive to the work being performed lead to the negative consequence of reduced productivity. The argument for teacher and student use of technology hinges in part on how well available technology represents and supports what teachers and students do. A sizable amount of software has been developed for the classroom including tutorials, drill and practice software, and educational games. These applications are designed to deliver instruction by complementing or replacing the teacher. Underrepresented in the software designed for school use category are tools for increasing productivity. Much of the tool/productivity software such as the word processors databases, spreadsheets, and graphics were designed for an industrial or business audience. Both the context and the content of classroom teaching are markedly different from that of industry.

Those of us in teacher preparation who work in the field of educational technology recognize technology as an outstanding resource. It provides opportunities for learning, tools for productivity, and a medium for creativity. However, many teachers still perceive technology to be confusing, complex and cumbersome. Despite the proliferation of graphic user interfaces, teachers report that productivity software is not intuitive and that the software fails to address the needs of their classroom situation. Productivity software is essentially re-purposed for classroom use. Consequently, teachers are hesitant to implement the technology with their students since the audiences are dissimilar. As an example, elementary teachers participating in an inservice technology workshop indicated a preference for using The Writing Center, a writing and publishing tool designed for classroom use over Microsoft Word despite the expanded feature set offered in Word and pressure by their administrators to use the more powerful software (P. Comstock, personal communication, June 16, 1998).

Review of Literature

Morton (1996) points out that "while the real world uses computers to move forward, schools often use them in a misguided efforts to support 19th-century instructional practices." In the beginning period of computer education teacher s learned BASIC as an introduction to technology use in classrooms. They couldn't use their training in their classroom. After that period, teacher education programs for technology use in schools focused on general terms such as computer literacy that emphasizes productivity tools like word processing, database, spreadsheet, and communications in a broad spectrum of activities. However, the general computer literacy skills ignored the integration of technology into regular activities in various subject matters. Guidelines for teachers were needed on how to integrate computers in various subjects (Yaghi, 1996).

In 1997 National School Technology and Readiness (STaR) Assessment conducted a survey on technology presence, use, and integration in typical American schools. STaR Assessment was based on data collected from nearly 80,000 public schools as well as supplementary data. According to the STaR report, only less than 3% of classrooms have fully integrated technology into the curriculum while 59% American schools have no technology or inadequate technology in their schools. 12% of schools are using technology yet still not devoting adequate time and resources to quality content, and the remaining 26% are still considering technology an "extra" (National STaR Assessment, 1997).

The Tennessee State Department of Education examined the teachers' perceptions about the use of technology. According to the findings, technology was viewed as a beneficial tool for classroom teaching. But the negative comments were on issues of inappropriate use, lack of teacher training and support, piecemeal and unintegrated use, too few computers for too many students, lack of an integrated infrastructure, and lack of a systems approach (Lewis, 1996).
Niederhauser (1994) examined how teachers' best beliefs about the effectiveness of using computers in instruction, the amount, frequency, and type of CAI teachers engaged in, frequency of use, subject area for software used, and the types of technology training they had received. The finding was that some teachers considered technologies as tools that students use in collecting, analyzing, and presenting information, while others viewed them as transmission tools that can be used to present information, give immediate reinforcement, and track student progress.

From a study by the Office of Educational Research and Improvement (OERI) in Education Reform Program, the researchers found that only a minority of classrooms where the school environment already provided adequate levels of technology access, technical assistance and supported time for learning about technology integrate technology for learning activities. To integrate technology in the classroom they suggested: 1) help in planning for technology uses and acquisitions, 2) training in how to use new hardware and software, 3) demonstrations and advice on how to incorporate technology into instruction, 4) On-demand help when software problems or hardware failures arise, and 5) low-level system maintenance. The researchers have argued that the critical transformation for classrooms is the shift from teaching discrete skills and information within specific subject areas to centering instruction around authentic, challenging tasks (Means and Olson, 1995).

On the other hand, the emphasis on technology in American schools has focused on quantity of technology rather than the use of technology in the classrooms (Jurema, 1996). Some argue that simply having more technology does not persuade teachers to use it into their classroom teaching and that teachers adopt a technology when that technology helps them do better what they are currently doing (Marcinkiewicz, 1994: Cuban, 1989).

Purpose of Study

The goal of this preliminary study was to establish a baseline on what technologies are most useful for students, what technologies fit appropriately and effortlessly into classroom learning. The study considered the questions; 1) Are the technologies available in schools supportive of the classroom goals of teachers and students? and 2) What reasons influence the use of technologies in their learning activities? This preliminary study examined technology use from an activity-oriented view. This viewpoint guided our research focus: 1) What are the typical activities that students do in the classroom. 2) How can technology assist students' learning activities? 3) Why isn't technology used in the typical learning activities? The long-term goal of the study is to suggest an idea for teacher preparation programs that can assist in the design and integration of technology.

Methods

Within the field of software design there exists an organizing structure for initiating an analysis of user needs (Kuhn, 1996). The structure is a design approach that employs an activity-oriented view assessed from the perspective of the user audience. This pilot study initiated an examination of technology use from an activity-oriented view. Middle school teachers and students were targeted as the user audience. Central to the goal of identifying learning activities was to understand the middle school teachers and the tasks they wish to achieve with their students. A secondary goal was to identify existing technology based tools that might serve the teachers and students with these learning activities. The process of determining typical learning activities and enhancing some of those activities with technology began by surveying teachers.

The phenomena of learning in a middle school setting occur across a wide range of conditions. Agreed upon descriptions of classroom activities are elusive. A survey was developed to obtain a baseline of learning activities that span the curriculum. The survey was distributed to ten middle school principals representing urban and suburban school districts in Northeast Ohio. The principals were instructed to select two teachers to participate in the survey. The criteria were provided to the principals for teacher
selection. The teacher was to have at least three years of teaching experience, the students of this teacher should consistently perform at or above expectation, and the teacher should also have a history that included parental requests to have students placed in his or her class. Expertise in technology was absent from the selection criteria. The selected teacher completed an anonymous survey composed of three sections and returned it to their principal.

The first section consisted of six questions that contributed background information on the respondent. Included in this section were questions on teaching experience, grade level, subjects taught, technology expertise, student expertise in technology, and the type of technology available to the teacher.

The second section provided a list of nineteen possible learning activities along with a five-point scale indicating the anticipated frequency of the learning activity. Traditional and technology based methods for implementing the activity were listed below the learning activity. The teachers were directed to rate all items that applied. The nineteen activities represented a range of learning activities including; writing, collecting data, organizing data, analyzing data, presenting information, discussions, reviewing instruction, and developing projects. Ideas for the learning activities were based on sample activities included in assignments submitted by teachers enrolled in an instructional development course during the past ten years.

The third section of the survey included eight questions pertaining to students use of computer based tools. These statements were also scored using the five-point scale. In addition, the teachers were asked to select the reason(s) for the score. Twenty-four reasons were provided. The teachers were encouraged to select all reasons that applied or to choose "Other" and explain this choice. The respondents were informed that this was a pilot survey and that comments were welcomed.

Results

Eighteen of the twenty surveys were returned for examination. Three surveys were not returned in time to be included in the results. Participants indicated minimal difficulty completing the survey. All of the surveys were coded to insure confidentiality.

Section One of the survey provided background information on the participants. The pool of respondents represented all levels of teaching experience from less than 4 years to over 20 years. The teachers taught in grades 5 through 8. The scope of subjects included Language Arts, Mathematics, Science, Social Studies, Foreign Language and Computers with many teachers responsible for more than one content area. The rating of teacher skill in the use of technology ranged from novice through expert with a mean score of 2.94. However, the mean score was not reflective of the population. A bimodal distribution emerged with 40% of the teachers rating themselves as somewhat experienced and 35% rating them as advanced. The average rating of students' skill with technology was 1.89, just below "Somewhat experienced."

The technology available to the teachers varied considerably. This was true within schools as well as between them. All respondents indicated the availability of minimally a computer in the classroom or access to a computer lab. In addition all but two respondents indicated the availability of a monitor and videocassette player. Calculators were not listed as technology equipment in Section One. Some respondents added calculators to the "Other" category of this section. Based on responses provided in Section Two on learning activities, 15 of 18 respondent's classes had access to calculators. The three classes that did not use calculators were taught by Language Arts teachers.

Section Two of the survey was included to ascertain what learning activities are commonly implemented in the classroom and to discover what if any technologies the teachers employ with the learning activities. Seventeen of nineteen learning activities had an average score for one or more method of implementation near or above 4.0 signifying that the activity occurred at least occasionally in the classroom. Two activities; Writing Correspondence 3.06 And Drawing Maps 3.06 failed to rate at a meaningful level. In retrospect, both activities could have been incorporated into other learning activity categories.
As expected, traditional methods of implementation averaged higher than technology based methods. The singular near exception was the use of calculators for analyzing data. Respondents rated calculator use at 3.78 to a manual computation rating of 3.83.

Section Three focused on student use of computer based instructional tools such as word processors, databases, draw and paint programs, the Internet, Spreadsheets, E-Mail, Presentation software, and calculators. Two tools; word processors and calculators recorded average student use ratings of 3.28 and 3.72 respectively. The average score for the other tools was 1.98. Common problems cited for low use of the eight tools included; Not enough equipment, I lack training, Time consuming, and Not useful. Common reasons cited for use of the tools included; Students have skills to use, Useful, and Equipment is available.

Conclusion

This study provided a snapshot of the middle school teachers who participated in the survey. The teacher sample was diverse but the sample size was small. The bimodal distribution of technology skills reported by the teachers may not be indicative of the general middle school teacher population.

The teacher responses confirmed that the learning activities listed in the survey were representative of the learning activities that occur in middle school classrooms. As such, the activities offer a starting point for examining an activity-oriented view of middle school teachers and students as technology users. In particular, it advances a framework for further examination of the original questions.

Regarding question one: Are the technologies available in schools supportive of the classroom goals of teachers and students? Two tools, word processors and calculators were occasionally used in many of the learning activities such as writing or data analysis. In addition, the frequency of activities involving data collection, data analysis and project development imply that other existing tools such as graphics programs, spreadsheets, and Internet access may be recommended for classroom use.

Regarding question two: What reasons influence the use of technologies in their learning activities? Several variables proved revealing. Lack of equipment was identified as a key reason for student non-use of tools. Limits on available equipment influenced teacher's ability to incorporate computer tools in the learning activities. This issue was compounded by a belief reported in Section One of the survey that students lacked the skills to use the tools. Consequently, it is difficult to confirm whether the technologies currently available are well suited or if access to equipment is the problem. The argument that they may not be well suited is supported indirectly as 14 out of 20 respondents reported that they either had access to many computers in their class, a computer lab or both.

Other variables may be influencing student use of computer tools, only 5 teacher responses out of a possible 144 responses indicated that a specified computer tool was selected because it was “Easy to Use.” One can hypothesize that even when technology was the method of implementation it was not perceived to be easy to implement. Fifteen percent of the responses indicated that the reason for student use of computer tools was that it was useful. Two opposing interpretations of this low result are: 1) the teachers do not perceive technology as useful in supporting a learning activity independent of their ability to use the tool or 2) lack of equipment and problems such as lack of skill by students and teachers, or difficulty with use discouraged the teachers from identifying the tools useful.

As a pilot, this study generated more questions than it answered. As expected the technology skills of the middle school teachers span a wide continuum. The survey Section Two responses suggest that the learning activities listed reflect some of the common learning activities that middle school teachers implement with their students and Section Three suggests that reasons for use and non use of technology are varied. In this preliminary phase of the study, emphasis was placed on reframing the question of why the level of technology use is low away from a traditional view to a more teacher-centered view of
technology. Clearly, a more extensive follow-up study is required to establish the factors that influence the use of technology and to determine if current tools are supportive of the classroom goals of teachers and students.

Abstract: A survey was mailed to all deans of education across a five-state region in February 1998. The inquiry focused on the status of particular indicators of technology integration such as infrastructure, financial support, staff development, use of technology, Colleges/Schools/Departments of Education.

Another survey was mailed to districts that had more than 50% of their enrollment classified as economically disadvantaged along with high student enrollment. Technology coordinators were asked to complete a questionnaire that focused on their technology training experiences and present needs.

In general colleges of education reported an increased level of support for technology but still felt the support for technology at their institutions was meager. This paper describes the differences in technical support, financial support, access to staff development and current use of technology at selected institutions, the expressed needs of current practitioners in the field, and how the two may better fit the needs of the field.

Introduction
Projections in the United States show that two million new teachers will be needed in the next ten years. It is also well documented that the current rate of technological change is phenomenal. Computing power keeps improving (following Moore’s law of doubling processing power every 18 months), as well as rapid advances in telecommunications technologies and expansion of the Internet.

Traditionally, our schools have looked to institutions of higher education to provide leadership in new ways of doing things. Today, institutions of higher education hold great responsibility to provide leadership for the infusion of technology into our schools and to model appropriate use of the technology in their own teaching situations. How are institutions of higher education measuring up to the challenge?

Purpose of the Study

Recently, the National Council for Accreditation of Teacher Education (NCATE) called for increased focus on technology in teacher education programs, citing the need for technology to move from the periphery of teacher preparation to the center of teacher preparation. Recognizing that “some schools of education are in the vanguard of introducing technology into teacher preparation,” Wise reports that “…most schools of education have not yet fully integrated technology into their teacher preparation programs (1997, p.v). With this call from NCATE for “vigorous action” to integrate technology into preservice teacher education programs, the purpose of this study was to examine teacher education programs at both public and private institutions of higher education in the South Central region to:

• Determine how and to what degree training instructional technology is being incorporated into those programs in order to establish baseline data for the region
• Determine status of technology support provided by the institution

The study also sought to identify current needs felt by technology practitioners to better inform changes in the current system.

Technology at Institutions of Higher Education

• A mailout survey entitled, Technology and the Preservice Teacher Education Program: A Survey of Colleges, Schools, and Departments of Education was distributed to all the deans of the Colleges of Education across a five state region (Kansas, Missouri, Nebraska, Oklahoma, Texas) in February 1998 requesting their participation in completing a questionnaire. Responses ranged from small private institutions of higher education to large state sponsored institutions of higher education and included both public and private institutions of higher education. The inquiry focused particular indicators of technology integration in their Colleges/Schools/Departments of Education. Survey questions were grouped around seven major topics:

• Group 1 Institutional information/general technology course information
• Group 2 Status of technology support
• Group 3 Technology skills of preservice teachers
• Group 4 Hardware technologies faculty members use in teaching methods courses
• Group 5 Hardware technologies preservice teachers required to use in courses
• Group 6 Software faculty members use in delivery of methods courses
• Group 7 Software preservice teachers required to use in methods courses

Conclusion
In general Colleges of Education reported an increased level of support for technology but still felt that support for technology at their institutions was meager. In addition, this increased level of support meant many things to different people. For example, one university saw the installation of computer labs for faculty use as support while another university already equipped with computer labs saw technical assistance and training given to faculty as increased support. Access to and use of the Internet by both faculty and students, along with administrative support and encouragement for the use of technology were rated as adequate.

Colleges of Education were asked about technology skills that might be important to teacher education majors and were asked to respond to their (the university) perception of the adequacy of general skills training currently received by preservice teachers. Institutions of higher education felt that preservice teacher skills were adequate in their ability to operate a computer system to use software and good use tools that were directly related to their own professional use such as productivity tools along with databases, word processing, and spreadsheets. Other skills were reported as being meager.

In response to the queries regarding university faculty members using certain hardware technologies and software technologies, the majority of responses indicated a low level of use by faculty. The exceptions to this were in the use of the VCR in instruction and the use of word processing, spreadsheets and presentation software where responses were in the middle to high range.

In response to information regarding preservice teachers being required to use certain hardware and software technologies, the majority of responses again were within the low category. The exceptions to this were the preservice teacher use of the computer and interactive video disc, along with the use of word processing, presentation software and web browsers where responses were in the middle to high range. A complete report and breakout of responses can be found on the South Central Regional Technology in Education Consortium-Texas website. http://www.coe.tamu.edu/~texas/

**Current Technology Needs by Teachers and Coordinators in the Field**

Another survey was mailed to 400 school districts in Texas that had more than 50% of their enrollment participating in a free or reduced lunch program combined with high student enrollment. Responses ranged from small rural to large urban districts, some having enrollments in excess of 200,000 students. The survey sought to identify technology-training needs of current teachers in the field and to then provide information to institutions of higher education to guide them in designing technology courses.

In general, nearly forty percent of the technology coordinators positioned themselves on the lower half of the training/experience scale, the majority of the respondents marked limited or fair training or experience in technology use. Sixty percent were positioned on the upper half of the scale. The majority of those respondents ranged from adequate to significant training or experience in technology use. Of those, only fifteen percent claimed to have advanced experience or an advanced degree in technology use. Of the one hundred and sixty-three respondents, only three indicated that they had earned a Masters Degree in Educational Technology.

In response to the number of preservice hours of technology training, the coordinators claimed one hundred and ninety hours. In response to the number of inservice hours of technology training, the coordinators claimed two hundred eighty-one hours.

The courses of most interest and need to the respondents were:
- Integrating the Internet into the Classroom
- Technology Integration into the Classroom Curriculum
- Multimedia Development
- K-12 Distance Learning
- Basic/Intermediate Web-Construction
- Technology Planning
A complete report and breakout of responses can be found on the South Central Regional Technology in Education Consortium-Texas website at http://www.coe.tamu.edu/-texas/.

Conclusion

In closing, there is an imbalance between the institutions of higher education and their ability to provide substantial preservice training in cutting edge technologies. This study found that there were many "islands of excellence," but for the most part, the needs of teachers in the field were for staff development and training in technical areas of educational technology that institutions of higher education were not yet able to provide. The institutions of higher education themselves were coping with issues related to training their staff, accessing equipment for their faculty and infusing technology more into their teaching situations. Higher Education is still internally focused on their needs and is not yet able to really focus on preservice teacher education program technology needs. But right now, what can institutions of higher education do to move their organizations to be more "user friendly" towards technology? Let us consider the following courses of action:

- Colleges of Education can make sure that the technology infrastructure and associated support services follow a performance support model. Support should be provided to those first requesting it. A reward structure should be made available for faculty willing to make positive changes.
- The technology infrastructure and technology infusion program should be given a top priority and considered "mission critical."
- Staffing patterns should be adjusted to support the work to be done.
- Fiscal, facility, and human resources should be reallocated to support mission critical.
- The technology should be distributed only as widely as it can be supported. This support must come in the form of ongoing staff development and training for staff at all levels and ongoing, just-in-time technical support.

A Comparison of an All Web-Based Class to a Traditional Class

Edward R. Jones, Ph.D.
Computer & Mathematical Sciences Division
Texas A&M Univ. Corpus Christi
United States
ejones@stat.tamucc.edu

Abstract: A study at California State University at Northridge, (Schutte, 1997) and (Schutte, 1998), reported that students in a virtual classroom scored 20% higher than students in a traditional classroom (p<0.001). This paper describes the results of an investigation into the demographic and performance differences between students in an all web-based class in introductory statistics to students in a traditional classroom setting. It also presents some conclusions, recommendations and raises some questions requiring further study.

Introduction

A study at California State University at Northridge, (Schutte, 1997), (Black, 1997) & (Schutte, 1998), reported that students in a virtual classroom scored 20% higher than students in a traditional classroom (p<0.001). Professors at the University of Kentucky, reported a decrease in the failure rate of freshmen chemistry students using their web-based practice quizzes, (see Kiser & Toreki, 1997). Their work suggests that a web-based course could improve student retention and performance, at least in undergraduate mathematics and science courses.

Schutte speculates that the reason for the higher performance of his students in the web-based class is increased group interaction among students in a web-based class. Although he did not present data to support this finding, he concluded:

"The number one residual finding of my study is that students placed in a virtual environment, performing the same work as classroom-based students, are more likely to engage others for help and understanding (not to be confused with collaboration or group tasking, as is done in Neal's review) than are students placed in a face-to-face environment where constant contact is the norm."

(Schutte, J. G. 1998)

Ed Neal and others have criticized the research design and methodology of Schutte. Neal writes:

"Unfortunately, Schutte's research design and methodology are so flawed that the results of the study are uninterpretable."

(Neal, E. 1998)

(Schutte, 1998), counters the criticism of Neal and others. It appears that much of the criticism and debate may be precipitated by a general lack of rigorous, well-designed studies of web-based learning. The primary purpose of this study was to attempt to replicate the results reported by Schutte and to investigate the advantages and disadvantages of a web-based class. The major objectives can be summarized as:

1. To evaluate the performance differences between students in an all web-based class and those in a traditional classroom setting when students are allowed to select the course they prefer,
2. To evaluate the hypothesis that the background of students who prefer to enroll in an all web-based course is not different from those who prefer to enroll in a traditional class, and
3. To identify what advantages, if any, the technology used in a web-based class enhances the learning objectives of an introductory statistics course.
Methodology

Since, the experiment described by Schutte detailed a remarkable claim of success by the virtual classroom, a similar, but larger, study has been conducted at Texas A&M University Corpus Christi with a similar protocol. During the Fall of 1997, 89 students enrolled into two sections of an introductory statistics course, one taught in a traditional classroom and the other taught entirely via the Internet.

Similar to the Schutte study, this was an undergraduate statistics class. Likewise, the web-based class used the same general means employed by Schutte – lecture notes, on-line quizzes, a discussion listserver, email and biweekly live web classes (chat sessions). (Schutte, 1998) reported that his server crashed 14 times during the semester. In this study, the server was only off-line for 4 hours during a scheduled power outage. In addition, the lecture notes over the more difficult material were served as a PowerPoint lecture with synchronized audio; Real Audio compressed to server over a 28.8k modem connection (visit http://stat.tamucc.edu/m2342/chap12/xrchart/ for an example lecture).

However, unlike the Schutte study, the students were not randomly divided between the classes. Instead, students registered for the class of their choosing during normal registration. This was done since:

1. an objective of this study was to evaluate differences in demographics between students who prefer to enroll in a web-based class and those that do not, and
2. it was felt that it would be unfair to force students into the web-based class since it required some familiarity with the use of a web-browser and convenient access to the Internet.

To account for the non-random assignment of students to these classes, the overall university GPA of all students was recorded and all students completed test A/4F distributed by the Mathematical Association of America on college-level algebra, the only prerequisite for the course. This same test is administered every semester to incoming freshman, providing a large database of information about the average scores on this test and how they correlate with student performance in introductory statistics and other mathematics courses.

In addition, both classes ran concurrently for 15 weeks and were taught by the same instructor. Both covered the same content, had the same homework assignments, used the same text, Elementary Statistics by (Triola, 1997), and followed the same syllabus (visit http://stat.tamucc.edu/classes/m2342.html for the syllabus). Grades were based upon the same three written in-class, multiple-choice examinations administered at weeks 5, 10 and 15. The week 15 exam was the final exam which was a 2.5 hour comprehensive examination. Both classes took these examinations under the same conditions, and student names were obscured during grading to minimize testing bias.

The primary dependent variables under analysis were:

1. Student demographics - age, GPA, completed hours, and pretest scores
2. Scores on the three, in-class, multiple-choice in-class examinations
3. Student withdrawal and passing rates

Student demographics (1) were compared using the Wilcoxon test. Examination scores (2) were compared using the repeated measures analysis of covariance. This analysis was conducted both with and without the use of the covariates - GPA and algebra pretest. Withdrawal rates (3) were compared using Fisher's exact test. All calculations were done using the Statistical Package for the Social Sciences, SPSS version 8.0 (visit http://www.spss.com for a description), and all were conducted using a significance level of 0.05.

Comparison of Student Demographics

As (Table 1) indicates, the students who enrolled in the all web-based class were somewhat more mature students. The web-based class was statistically significantly older than the traditional class (p<0.001).
Likewise, they had a higher GPA and had completed more university hours. However, the differences in GPA and university hours for enrolling students were not statistically significant. Interestingly, although the students in the web-based class had an average GPA about 7% higher than the traditional class, their algebra pretest scores were only about 2% higher.

<tr>
<td>Wilcoxon p-value</td>
<td></td>
<td>0.891</td>
<td>0.081</td>
<td>0.079</td>
</tr>
</tbody>
</table>

Table 1: A comparison of demographics for enrolling students.

Comparison of Examination Scores

The following figure depicts the average scores between the two classes for the three major examinations. On average, the web-based class did score higher than the traditional class. Notice, however, that the difference between the two classes appears to narrow as the semester proceeded.

<table>
<thead>
<tr>
<th>Source</th>
<th>Df H</th>
<th>Df E</th>
<th>F-test</th>
<th>p-value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Exams</td>
<td>2</td>
<td>66</td>
<td>7.99</td>
<td>&lt;0.001</td>
</tr>
<tr>

<td>0.009</td>
</tr>
<tr>
<td>Exams by Classes</td>
<td>2</td>
<td>66</td>
<td>1.28</td>
<td>0.289</td>
</tr>
</tbody>
</table>

Table 2: Repeated measures analysis of variance (ANOVA) of examination scores.

The repeated measures ANOVA, (see Table 2), of the examination scores indicates that the difference in examination scores is statistically significant (p=0.009). However, these differences can be explained by the higher average GPA and pretest scores of the web-based class.

(Table 3) gives the same analysis using the pretest scores and student GPA as covariates. A graphical display of the least squares means from the adjusted analysis are displayed in (Figure 2) and (Figure 3). When the algebra pretest score is taken into account, the differences between the two classes narrowed to only 3% for the final examination, and the difference is no longer statistically significant (p=0.096). This is in spite of the fact that the difference in pretest scores among students finishing the course is not statistically significant (p=0.812), (see Table 5).

The difference between the two classes is even smaller when student GPA is taken into account (p=0.390), (see Figure 3). However, among students who completed the course, the web-based class did have a higher mean GPA (p=0.016), (see Table 5). Note that not only does the difference in adjusted scores
narrow as the semester proceeded, by the final exam, the average adjusted score for the traditional class was higher than the web-based class.

Figure 3: Average examination scores, after adjusting for student grade point average (GPA)
Comparison of Withdrawal Rates

At Texas A&M University Corpus Christi, students are allowed to withdraw from any course up to the last day of class without the instructors approval and without receiving a grade for the course on their transcript. It is not unusual to have a student who is passing a course withdraw from the course in the final weeks of the semester because of unforeseen personal circumstances or because they needed an "A" in the course to get into a medical school or a highly selective graduate program. Additionally, this course is a service course to science majors. That is, everyone taking this course is doing so because it is a required course outside the core courses of their particular major. This creates an environment with a higher than desired student-withdrawal rate and a lower than desired passing rate.

<table>
<thead>
<tr>

<td>68.7</td>
</tr>
<tr>
<td>Wilcoxon p-value</td>
<td></td>
<td>0.812</td>
<td>0.016</td>
<td>0.344</td>
</tr>
</tbody>
</table>

Table 5: A comparison of student demographics for students completing course using the Wilcoxon test.

The above table, (Table 5), describes that analysis of the demographics for students completing the course. Notice that although the average pretest scores and average university hours completed are still not statistically significantly different between the classes (p=0.892 & p=0.344 respectively), the average GPA of students completing the web-based class was about 11% higher than the traditional class (p=0.016).

Summary and Conclusions

(Schutte, 1997) reported that the students in his web-based class scored 20% higher than his traditional class. In this study, the difference between average scores on the final exam is only 6 points higher in the web-based class. Similar to the Schutte study, no statistically significant differences in GPA were seen among the students enrolling in the two sections (p=0.081). There was an even smaller difference between pretest scores (p=0.891). However, when the examination scores are adjusted for either the pretest scores or student GPA, differences in the average examination scores are no longer statistically significantly different (p=0.379 & p=0.390 respectively). Hence one would conclude that the higher average GPA of the students completing the web-based class could explain the 6% difference in the average score on the final exam.

This raises the question of why this study did not replicate the results of Schutte. It is unlikely that the lack of complete randomization in this study accounts for the different results since the students in the web-based class had better preparation, as measured by their pretest scores, GPA and number of completed university hours. This would have predicted an even larger advantage for the web-based class than that reported by Schutte.
Schutte also claims that students in a web-based class are more likely to "engage others for help and understanding.” This was not seen in this study. In fact, every attempt to organize the web-based class around a team project and introduce them to one another was strongly resisted. Students complained that the reason they enrolled in the web-based class was for schedule flexibility and that it was too hard to coordinate schedules between students to meet as a team. Likewise participation in the class discussions on the listserv and the voluntary weekly live web-classes was poor. On average, only 15%-20% of students attended the live web-classes, although they were loyal and enthusiastic toward these classes.

It could be that the students in Schutte’s classes were more motivated since his course was probably not a service course. Likewise, his students may have been younger and less involved raising families and working. In this study, the average age of the students completing the web-based class was 30.7. On average they were enrolled in 11.8 semester hours and were employed 22.3 hours per week. It can also be speculated that Schutte’s teaching style may be more suited to a web-based class than a traditional class.

The major conclusion of this study is that the results reported by (Schutte, 1997) do not appear to be reproducible, at least with our student population. This also points to the need for further careful research into the best teaching methodology for web-based classes. It is unlikely that a simple translation of a course from a traditional classroom format to an all web-based class will improve or degrade student learning performance.

However, at Texas A&M Univ. Corpus Christi, we are continuing to offer web-based classes since they offer an alternative learning format that seems to be increasingly popular with a segment of our student population. Like many universities, we will continue to explore new teaching methodology for web-based classes.

Abstract:

Iowa Consortium for Assessment of Learning with Technology (ICALT) grew out of a shared interest in assessing student learning from classroom technology experiences. The group was initially started by a group of Area Education Agency (AEA) technology coordinators who shared an interest in technology planning. From the starting point of implementing and assessing technology planning in Iowa schools, the focus of the group became what some have called the big question: How does technology use in classrooms affect student learning? The purpose of this paper is to discuss the vision of ICALT, and the process of exploring the big question the group has initiated.

Clearly, technology is a part of a complex educational system, and it is impossible to separate the effects of technology use from the effects of other crucial pieces of the learning and teaching process (for example, the teacher, the curriculum, or additional materials). An assessment model will, however, help educators better define the specific purpose and role for using technology in the learning process. One of the barriers to assessing effects of technology use in Iowa schools has been that there is no cohesive set of goals for this use. Hardware has been purchased and some teachers have been trained, and now it is time to emphasize specific content-related goals for the use of technology in learning and teaching. Obviously, without emphasis on specific goals for technology use, it is almost impossible to measure what is occurring with student learning.

The Iowa Consortium for Assessment of Learning with Technology (ICALT) grew out of a shared interest in assessing student learning from classroom technology experiences. ICALT is a consortium of educators who are involved in leading Iowa in technology learning and teaching. Its membership includes AEA and LEA technology specialists, Department of Education personnel, Star Schools personnel, representatives from the Urban Eight, university professors working in technology and assessment, classroom teachers, and school administrators.

ICALT's mission is to design and implement a plan to assess the effects of technology use in Iowa classrooms on student learning. Its vision is to assist Iowa educators in implementing an approach to student assessment that provides useful feedback to students, teachers, families, community members, educators, legislators, and other interested parties on the effects of technology use in learning and teaching. The data from ICALT assessments will be used to continually modify and improve the classroom applications of technology to ensure that technology is being used to create experiences and outcomes that maximize its potential to improve and expand student learning. One of the outcomes of the ICALT assessment system will be to assist educators in determining appropriate goals for technology use in classrooms.
ICALT members believe that the current national standards efforts in specific content areas are closely aligned with areas where technology can be most useful in classrooms (for example, problem solving, project-based learning, emphasis on communication of results, and student projects). Thus ICALT has decided to use the National Council of Teachers of Mathematics (NCTM) standards as a starting point and to design an assessment system based on the use of technology to help facilitate the implementation of one of the NCTM standards. This will be a beginning model for more assessment efforts that will focus on technology use in other subject areas.

A graphic model has been developed to summarize ICALT's approach to assessment. The graphic illustrates that the model falls under the umbrella of school improvement and that within school improvement, particular standards should be selected by schools as targets for the impact of their work with technology. The graphic also illustrates ICALT's belief that using technology involves issues of both development and systems in the school. The development area includes both curriculum and professional development and the systems area includes resources, teacher beliefs and behaviors, and administrative support. The intersection of the two areas defines the school climate with respect to use of technology in learning and teaching. Assessment of learning with technology needs to address all the inputs into the system and reporting should be used to inform school improvement efforts. Finally, research should be used for decision making in all areas defined in the model.

With observations and focus groups with middle school students and teachers, both participants responded to what they have learned by emphasizing the problem solving, the collaboration, and the connections to real life. With the technology-rich learning environment, students and teachers were able to change the way they were doing things to include a richer learning beyond rote learning. One student wrote on her exam that she wanted to explain to her teacher what she was thinking when she completed the math problem. The energy radiating from the learning environment encouraged ICALT members to delve further into exploring the big question: How does technology use in classrooms affect student learning?
Abstract: This study followed 16 graduate students enrolled in a Reading/Language Arts Master's program through a semester of tutoring young readers. Because the literature suggests that students benefit from guidance in reflection, this study explored the effects of a guided reflection experience for graduate students. As participants explored ways to connect assessment and instruction in a clinical setting, they interacted with class peers and course instructors using electronic mail. E-mail offered participants a non-threatening forum to explore questions and concerns, successes, and perceived failures. Three interventions were implemented to guide participants in reflection about their teaching interactions. Data analysis consisted of triangulation of participant's e-mail interactions, observations of their teaching experiences, and analysis of specific written interactions. A majority of e-mail messages focused on requesting suggestions or ideas for upcoming lessons and discussing client problems. Additionally, several barriers to e-mail communications were identified by the subjects.

Significance

"Learning" has long been accepted as involving two aspects: first, the experience and second, one's reflection upon that experience. The idea that "you really don't understand what you know until you begin to examine it" (Whitford, Schlechty, & Shelor, 1987, p. 164) has become widely accepted in adult education circles, especially those dealing with teacher education. Beginning with Schon's (1983) work on the reflective practitioner, the teacher education literature has featured numerous calls for teachers to reflect upon their teaching as a way to take control of one's professional development and teaching success (cf. Ash, 1993; Vogt & Au, 1995). However, what is less clear is how one becomes reflective - and how one best selects the topics/events upon which to reflect to maximize professional growth.

In their work with preservice teachers, Stahlhut and Hawkes (1997) required students to select from three mediums for assigned weekly reflections: written journals, electronic mail (e-mail), and personal conferences with mentor teachers, peers, and university professors. Stahlhut and Hawkes found that students' choice of medium related to the problem they identified through their reflections. Students tended to use journals for sharing everyday teaching events with their cooperating teachers. They often relied on observation sessions...
with their professors to address issues beyond the classroom (e.g., administrative questions or schoolwide concerns). Interestingly, students chose e-mail when they felt a sense of urgency about a specific issue and wanted to solve an immediate problem. While the authors were able to identify recurrent themes in student reflections, they noted that "student teachers need precise training related to the use of the reflection process" and that although "student teachers enjoyed having technology available to them because they got rapid feedback . . . there was no direct evidence the reflection process was improved because of e-mail communications" (1997, p. 5).

Because communication impacts all facets of education, educators search continually for economical, efficient, and expeditious communication methods to enhance students' learning. Telecommunications (i.e., e-mail) can be defined as the use of a computer, phone line, and modem (or alternative connection, i.e., cable) to send and receive messages as well as communicate with others asynchronously. E-mail represents a telecommunications system which is a mainstay in the business world and has been available on most large academic campuses for over a decade (Bull, Harris, Lloyd, & Short, 1989; D'Souza, 1992).

There are several advantages to using e-mail communication. Sending messages is fast with most transmissions taking only seconds. It is asynchronous communication where unlike conversations, both senders and receivers do not attend to the communication simultaneously (Broholm & Aust, 1994; D'Souza, 1992; Eiser, 1990). While advantages are quickly identified when implementing technology into courses or projects, there are also some barriers which need to be considered. Access to a computer has been identified as a major barrier in several projects (LaMaster & Tannehill, in press; Tannehill, Berkowitz, & LaMaster, 1995; Thompson & Hamilton, 1991; Zack, 1995). Participants tend to interact more often when they have a convenient access to a computer and electronic communication. Lack of comfort or familiarity with computer technologies has also been cited as a major barrier to using telecommunications (Nantz & Wilkins, 1995; Thompson & Hamilton, 1991; Zack, 1995).

As e-mail has become more commonly used among university colleagues the realization of increased speed and effectiveness provided opportunities for researchers to examine further possibilities. Use of telecommunications to supplement classroom communication and to seek information became more common (Durham & Sunal, 1991; D'Souza, 1991; Poling, 1994; Schrum, 1988, 1991). The major benefit of most of these projects has been increased professor access through e-mail messages. E-mail enables extended student-teacher communication beyond the confines of office hours and class time. Given 16 graduate students in a clinical setting, we could see clear benefits of providing access to the professor beyond the Reading Center hours.

Telecommunication systems also include electronic listservs which allow group interaction through public message posting. A listserv is a list consisting of individuals with e-mail accounts who have a common interest. Individual e-mail addresses are added to the list and once on the list they will receive any messages sent to the listserv. Listservs are a way to "reach out" to other educators that are on line, or connected to the system (Kearsley & Lynch, 1992). A major benefit of listservs is that messages can be posted for anyone to read and respond, with no need to coordinate time schedules (Bishop-Clark & Huston, 1992). For this project, four listservs were set up with graduate students assigned according to client needs. Our intent was this would provide our graduate students with a natural communication need as they sought to understand the characteristics of a client, they could turn easily to their on-line peers for help and advice.

After reviewing the possible benefits and challenges of electronic communication, we believed it would offer a useful communication channel for our inquiry. We posted, based on past experiences, that our graduate students would be geographically scattered, busy, and task-oriented. The opportunity to reflect with others through an electronic listserv would ideally provide a way for graduate students to explore and respond to compelling questions about tutoring their students in the Reading Center.

**Study Purpose**

Vogt and Au (1995) note that encouraging reflection among teachers takes time, and Dynak, Whitten, & Dynak (1997) suggest that wise use of collaboration enhances the process. Thus, in order to facilitate
cooperative reflection among university instructors as well as university students, this project was conceived as a team effort between two assistant professors from two different academic disciplines, both of which involve teacher education: Reading/Language Arts and Exercise and Nutritional Sciences.

This project ran for 16 weeks, building on a previous 1-semester course taught by the same Reading/Language Arts instructor. Three focus questions formed the foundation of this study:

1. What reflection themes do graduate students enrolled in a Reading/Language Arts Master’s program exhibit at the beginning of their clinical reading experience?
2. How are the responses of graduate students influenced by explicit attempts to guide their reflections along two specific paths (reading/language arts and exercise/movement)?
3. How are graduate students’ reflections demonstrated in electronic mail interactions as compared with formal lesson plans and other written materials?

Data Sources & Methods

The participants for this study were 16 volunteer graduate students enrolled in the Reading/Language Arts Master’s program. These graduate students participated in a clinical reading experience throughout the study. During the course, graduate students worked in small groups and individually with learners experiencing difficulty with reading. Prior to the beginning of the study participants were asked to complete a permission form to release data to the study, a project contract, pretest scenarios, and send an e-mail message to the primary investigators. This initial e-mail message confirmed that all subjects had obtained an e-mail account and had basic understanding of e-mail.

Participants were assigned to four listservs according to their clients’ ages and characteristics. The primary researchers were included on all four of the lists to monitor and provide guided reflection. Four separate lists were created so subjects would not be overwhelmed by the amount of messages generated throughout the 16-week study. At least once a week, participants posted to their class lists reflections on their teaching and interaction with their learners. Peers read and responded to postings throughout the week leading up to the next teaching opportunities. All participants were urged to maintain communication with their peers through the e-mail class lists.

A two-week baseline of graduate students’ reflection patterns on e-mail occurred at the beginning of the project. Following this baseline a series of three interventions were implemented. The first intervention was conducted by the reading/language arts specialist who suggested ways to better instruct learners (reading and language arts strategies) and reflect on personal practice. The second intervention was conducted by the physical education pedagogy specialist. The final intervention was a combination intervention in which both specialists provide pedagogical feedback to the subjects. Each intervention was separated by a one-week baseline during which no explicit guided reflection suggestions were offered by the specialists.

Instruments

In addition to the e-mail methods described above, two other instruments were created for this study. In order to assess graduate students’ typical views about the integration of movement with reading/language arts instruction, graduate students read and responded in writing to three brief scenarios that could arise in the Reading Center. They were asked to describe and rank three teaching interventions they would use in the given situation. They responded to the scenarios again at the conclusion of the study.

A checklist was created and used while supervising participants’ actual instruction to clients at the Reading Center. This checklist included key aspects of guided reflection feedback given by each instructor to enable supervisors to ascertain possible enactment of particular suggestions.

Data Analysis and Findings
A grounded theory approach was used for data analysis of e-mail entries, formal lesson plans, scenarios, end-of-semester reflections and other related artifacts (Strauss & Corbin, 1990). Three goals directed the data analysis: 1) to identify the reflection themes graduate students engaged in throughout the study; 2) to determine whether graduate student reflections changed during the intervention periods of the study; 3) to determine how graduate students' reflections were demonstrated in e-mail interactions as compared with formal lesson plans and other written materials. Because this study spanned 16 weeks, opportunities for triangulation (Lincoln & Guba, 1985) occurred naturally and varied over time. Three independent researchers read and categorized e-mail messages into emerging categories. After consultation and discussion 100% agreement was achieved.

Additionally, information gained from the pre- and post-test scenarios and the observation checklists aided researchers in confirming emerging hypotheses. Scenarios were read and coded as to determine the suggested strategies for intervention with the client. Movement and technology references were of concern to the researchers and were compared between the pre and post test scenarios.

Discussion

Several barriers impeded the initial e-mail communications including lack of access, remote connection problems, and novice computer skills. However, a majority of graduate students did send e-mail messages throughout the study. Fourteen categories were thematically identified by the researchers and included; greetings, requests, guided reflection, reflection, movement, direct response, problem, rapport, groupness, strategy, technology, information, future, and out of clinic/teaching related. A majority of messages sent to the listserv focused on requesting suggestions or ideas for upcoming teaches and discussing their client problems. It was noted that listserv communications seldom focused on teaching strategies or teaching reflection unless guidance was provided by the course professor. Even after e-mail interventions minimal reflection occurred on-line. One possible explanation could be there were several first year teachers in the class and they frequently expressed a concern for keeping up with the demands on their time. Additionally, this group of graduate students had several courses together and could converse often which may have impacted their lack of sharing using e-mail.

Group e-mail communication patterns emerged during the study. One of the more experienced and verbally reflective students summarized something we saw repeatedly across all four groups - the tendency to use e-mail for communication rather than reflection: "I guess I found myself using e-mail when I had to communicate something, and not necessarily to process or reflect." Unique patterns among groups included a tendency to focus on a particular issue or type of interaction pattern. One group focused on technology while another focused on activities they were doing with their clients.

Written lesson plans revealed a higher level of reflection than found on e-mail. Researchers believe there may be several factors impacting this disparity between written and e-mail reflection including comfort level with technology and the peers on their listserv. Comparison of the pretest and posttest scenarios indicates that these graduate students were able to identify more teaching strategies upon completion of the Reading Center course. However, it was also noted that there was a decrease in the use of movement strategies in the written teaching interventions between pre and posttest scenarios.

Proving Our Case While Avoiding Type I Errors

R. Bruce Lewis, Ed.D., School of Education, Freed-Hardeman University, USA, rblewis@fhu.edu

Abstract: Educational Psychologist Richard Lookatch wrote in the Summer 1995 edition of TECHNOS that research literature that he had monitored since the early 1980's had never established that using technology improved learning. His analysis was that all of the studies were flawed with Type I errors. Mr. Lookatch's sweeping generalizations tend to overlook the value of many initial studies into the new field of computer and technology enhanced learning. The author's dissertation research avoided both Type I and Type II errors.

A few years ago, Educational Psychologist Richard Lookatch wrote in the Summer 1995 edition of TECHNOS that research literature that he had monitored since the early 1980's had never established that using technology improved learning. His analysis was that all of the studies were flawed with Type I errors, finding benefits that really were not there, as summarized in the November 1995 edition of Education Digest (Lookatch, 1995).

As the author was planning his dissertation research in Instructional Technology under Dr. Charles Dickens of Tennessee State University, Nashville, he was made aware of the necessity of avoiding both Type I and Type II errors by several of his professors. Dr. Carol Stice impressed upon her class in Research Methods that researchers can only conclude within a stated probability of error that the decision to reject the null hypothesis is the correct decision. As there is always a possibility that the decision reached by the researcher is wrong, two kinds of incorrect decisions can be made (Crowl, 1996).

In Type I errors, the researcher incorrectly concludes that the null hypothesis should be rejected, when in actuality there really is a significant difference between the means -- too different to be the result of chance error. In Type II errors, the researcher incorrectly concludes that the null hypothesis should not be rejected, when in actuality there really is not a significant difference between the means (Crowl, 1996; Gay, 1981).

Type I and Type II errors usually occur when the study is constructed in such a way as to ignore established rules of proper research. Whereas Type I errors involve setting the level of significance in data analysis so low as to find benefits that are not really present, Type II errors involve setting the level of significance in data analysis so high that benefits that are really present are overlooked. Failing to control for a host of conditions that may account for the observed impact on learning also leads to Type I errors (Crowl, 1996).

The author's 1998 research study took place in about a dozen 4th grade classrooms over a period of almost three months. During this time, weekly lesson plans were developed by the author and implemented by the classroom teachers of the six treatment classes. The treatment used social studies simulation software and the Internet, integrated into the regular curriculum in one-computer classrooms. Teacher training was provided and weekly contact was made with each of the treatment classrooms and their teachers.

Through the guidance of Dr. Charles Dickens, the author's dissertation research avoided both types of errors. Type II errors were avoided by setting the level of significance at the .05 level, but the actual outcomes of the study showed the data analysis definitely avoided the Type I error as well. The ANCOVA results of the pre-test and post-test data were extremely significant in proving that the author's treatment could impact critical thinking.
Mr. Lookatch's sweeping generalizations that all of the studies that he had reviewed contained a fundamental flaw, i.e. Type I errors, tends to overlook the value of many of these initial studies into this new field of computer and technology enhanced learning. Certainly, the pressure is there for researchers to overstate their case, but scholarly journal review boards and dissertation committees have an obligation to ensure that the research is properly conducted and adequately reported. Such was the fulfillment of the duties of the author's dissertation committee and of his dissertation chair, Dr. Charles Dickens. The author's research findings are statistically significant and stand upon their own merits.

GENDER DIFFERENCES ON ATTITUDES TOWARD COMPUTERS: A META-ANALYSIS

Yuen-kuang Cliff Liao
Department of Elementary Education
National Hsinchu Teachers College, Taiwan
Yliao@cc.nhctc.edu.tw

Abstract: A meta-analysis was performed to synthesize existing research of gender differences on attitudes toward computers. One hundred and six studies were located from three sources, and their quantitative data were transformed into Effect Size (ES). The overall grand mean of the study-weighted ES for all 106 studies was 0.19. The results suggest that male subjects had slightly higher attitudes toward computer female subjects. While many authors have indicated that women and girls are more likely to hold lower attitudes toward computers (e.g., Jagodzinski & Clarke, 1986), the results of this study provide an accumulated research-based evidence to support this hypothesis. Left unanswered is the question of what factors truly contribute to the differences. Studies of this question will require further clarification of the exact relationship between gender and computer learning. This meta-analysis points out only that gender differences on attitudes toward computers exist.

Computer attitudes usually refer to people's reactions to computers. These reactions include liking about, confidence to use, belief about the usefulness of, sex stereotype of, and ability stereotype of computers. As computers have been increasingly used in our society, many studies have reported people's attitudes toward computers (e.g., Campbell, 1992; Chu & Spires, 1991; Gordon, 1993; Kay, 1993; Whitley, 1996). In particular, much research effort has gone into looking at gender differences and their causes on computer attitudes (e.g., Blumer, 1987; Campbell, 1988, 1989; Chen, 1986; Koohang, 1989; Loyd & Gressard, 1986; Meier, 1988; Wallace & Sinclair, 1995; Woodrow, 1994). This issue is critical since the U.S Department of Labor had predicted that by 1995 at least 2 million people would be in occupations related to computers and millions of others would be using computers as part of their jobs (Armitage, 1993). Nowadays, it is reasonable to believe that the number of people who need to use computers to fulfill their job requirements is much more than in 1995.

Computer use has been portrayed in our society as more appropriate to men and boys than women and girls (Whitley, 1997). Computer games and educational software have been designed to appeal more to boys than girls (Kiesler, Sproull, & Eccles, 1985). Computer use in schools has also been linked to traditionally 'masculine' subjects such as science and mathematics but not to traditionally 'feminine' subjects such as art and literature (Hawkins, 1985). These gender differences in socialization have led to the hypothesis that women and girls are more likely to hold more negative attitudes toward computers.

Although many studies have been conducted on this hypothesis (Blumer, 1987; Campbell, 1988; 1989; Chen, 1986; Koohang, 1989; Loyd & Gressard, 1986; Meier, 1988; Wallace & Sinclair, 1995; Woodrow, 1994), the results of existing studies have reported a confusing picture. For example, Campbell (1990), Chen (1986), Colley, Gale, & Harris (1994), Jacobson (1991), Loyd & Gressard (1986), Wallace & Sinclair (1995), Whitley (1996a;1996b), and Woodrow (1994) all reported significantly higher computer attitudes for males than females, while Blumer (1987), Campbell (1986;1989), Cantrell (1995), Chu & Spires (1991), Francis (1994), Koohang (1987;1989), Loyd & Gressard (1985), Loyd, Loyd, & Gressard (1987), Mertens & Wong (1988), Pope-Davis & Twing, and Robertson, Calder, & Jones (1995) have indicated that there is little, if any, differences of computer attitudes between males and females. Owing to the mixed evidence provided by existing research in the area, this study attempts to use the meta-analytic approach to investigate the gender differences on attitudes toward computers. The results from this meta-analysis will help provide clearer conclusion.

PROCEDURES
The research method used in this study is the meta-analytic approach which was similar to that described by Glass, McGaw, & Smith (1981). The studies considered for use in this meta-analysis came from three major sources and were published from 1984 to 1997. One large group of studies came from computer searches of Education Resources Information Center (ERIC). A second group of studies came from Comprehensive Dissertation Abstracts. A third group of studies was retrieved by branching from bibliographies in the documents located through review and computer searches. One hundred and six studies were located through these search procedures; 19 studies came from ERIC and conference proceedings, 80 studies were retrieved from published journals, 7 studies were from Comprehensive Dissertation Abstracts. Several criteria were established for inclusion of studies in the present analysis.

1. Studies had to assess the differences between males and females on computer attitudes.
2. Studies had to provide quantitative results from both male and female subjects.
3. Studies had to be retrievable from university or college libraries by interlibrary loan or from ERIC, Dissertation Abstracts International, or University Microfiche International.

There were also several criteria for eliminating studies or reports cited by other reviews: (a) studies did not report sufficient quantitative data in order to estimate Effect Sizes; (b) studies reported only correlation coefficients -- r value or Chi-square value; (c) studies could not be obtained through interlibrary loans or from standard clearinghouses.

Outcome Measures

The outcome measure most often in the selected studies was survey data from participants, as indicated in various instruments for examining participants' computer attitudes. For statistical analysis, outcomes from a variety of different studies with a variety of different instruments had to be expressed on a common scale. The transformation used for this purpose is the one recommended by Glass et al. (1981). To reduce measurements to a common scale, Glass and his colleagues coded each outcome as an Effect Size (ES), defined as the difference between the mean scores of two groups divided by the standard deviation of the control group. For those studies that did not report means and standard deviations, F, ort, values were used for estimating the ES.

In most cases, the application of the formula given by Glass and his colleagues was quite straightforward. But in some cases, when more than one value was available for use in the formula of ES, the value, which measured outcomes most correctly, was selected. For example, some studies reported both differences on pretest measures and differences in posttest measures. In such cases, pretest measures were selected for estimating ES so that any treatment which may change participants' general feelings about computers could be avoided.

In other cases, several subscales and subgroups were used in measuring a single outcome (e.g., those that reported separate data by ethnicity or grade). In such cases, each comparison was weighted in inverse proportion to the number of comparisons within the study (i.e., 1/n, where n = number of comparisons in the study) so that the overweighing of ES of a study could be avoided (see, for example, Waxman, Wang, Anderson, & Walberg, 1985, p. 230).

Variables Studied

Nine variables were selected for coding each study in the present synthesis. These variables are listed in Table 1. The first 2 variables were coded so that potential different effects for subjects with different background could be detected. The following 2 variables (i.e., type of publication and year of publication) were coded because it is important to know how effects are related to sources of information over time. The next 4 variables were coded so that effects related to characteristics of research design could be detected. The last variable was coded because it is critical to know how effects are associated with different types of attitudes. Each variable was employed as a factor in an analysis of variance (ANOVA) to investigate whether there were significant differences within each variable on the effect size.

<th>Year of Publication</th>
</tr>
</thead>
</table>
RESULTS

Of the 106 studies included in the present synthesis, 85 or 80% of the study-weighted ESs were positive and favored the male subjects, while 21 or 20% of them were negative and favored the female subjects, indicating that males had lower computer anxiety than females. The range of the study-weighted ESs was from -0.85 to 0.881. The overall grand mean for all 106 study-weighted ESs was 0.192. When this mean ES was converted to percentiles, the percentiles on computer attitudes were 58 for the male subjects and 50 for the female subjects. The standard deviation of 0.286 reflects the small variability of ESs across studies.

Among the 489 ESs included in the present synthesis, 363 or 74% were positive and favored the male subjects, while 121 or 25% were negative and favored the female subjects. Only 1 or 1% of the ESs indicated no difference between male and female subjects. The range of the ESs was from -0.85 to 0.881.

Table 2 lists the F values for the 9 variables for all study-weighted ESs in the study. Descriptive statistics for the 9 variables are presented in Table 3. The positive means for liking, belief/usefulness, confidence, and mixed indicate more positive attitudes favor male subjects; however, for sex stereotype and ability stereotype, the positive means indicate a higher sex and ability stereotype for male subjects.

For ANOVA, 1 variable, type of attitude, showed statistically significant impact. The post hoc test for type of attitude, $(F(6,232) = 2.554, p<.05)$, showed that the mean comparison of studies that measured sex stereotype was significantly higher than studies that measured liking, anxiety, belief/usefulness, confidence, ability stereotype and mixed attitudes. In addition, the mean comparison of studies that measured belief was significantly higher than studies that measured mixed attitudes.

Note. a Some studies reported more than one comparison groups.

**DISCUSSION**

The results of this meta-analysis indicate that, overall, male subjects had slightly higher computer attitudes than female subjects. An effect is said to be small when ES = 0.2, medium when ES = 0.5 and large when ES = 0.8 (Cohen, 1977). Eighty percent of positive study-weighted ES values and 74% of positive ESs...
overall also confirm the gender differences on computer attitudes. The slightness of the differences must be keep in mind, however; the overall study-weighted mean ES of 0.192 only indicates 8 percentile scores higher than the female subjects. The percentile scores for the overall grand mean and median were identical, reflecting the small variability of ESs across studies.

The significant differences found among the mean comparison of studies that measured sex stereotype and studies that measured liking, anxiety, belief/usefulness, confidence, ability stereotype and mixed attitudes were quite interesting. It is possible because male subjects hold higher sex-related stereotype toward computer use, and this tendency influences female subjects’ feelings about computers that results in females’ overall more negative attitudes toward computers. In short, the gender differences on sex-related stereotype toward computer use may be the key factor that yields the gender differences on overall attitudes toward computers. More studies need to be addressed on this hypothesis.

CONCLUSION

Although many studies have been conducted to examine the hypothesis that women and girls are more likely to hold more negative attitudes toward computers (Blumer, 1987; Campbell, 1988; 1989; Chen, 1986; Koohang, 1989; Loyd & Gressard, 1986; Meier, 1988; Wallace & Sinclair, 1995; Woodrow, 1994), and still fail to get a clearer picture, the results of this study provide an accumulated research-based evidence to support this hypothesis. Left unanswered is the question of what factors truly contribute to the differences. Studies of this question will require further clarification of the exact characteristics of each type of computer attitude (e.g., anxiety, confidence, and sex-related stereotype) and their relationships with gender. This meta-analysis points out only that gender differences on attitudes toward computers exist. That information by itself is useful.

GENDER DIFFERENCES ON COMPUTER ANXIETY: A META-ANALYSIS

Yuen-kuang Cliff Liao
Department of Elementary Education
National Hsinchu Teachers College, Taiwan
Yliao@cc.nhctc.edu.tw

Abstract: A meta-analysis was performed to synthesize existing research of gender differences on computer anxiety. Forty-one studies were located from three sources, and their quantitative data were transformed into Effect Size (ES). The overall grand mean of the study-weighted ES for all 41 studies was 0.28. The results suggest that male subjects had slightly lower computer anxiety than female subjects. While many authors have indicated that women and girls are more likely to hold higher anxiety toward computers (e.g., Jagodzinski & Clarke, 1986), the results of this study provide an accumulated research-based evidence to support this hypothesis. Left unanswered is the question of what factors truly contribute to the differences. Studies of this question will require further clarification of the exact relationship between gender and computer learning. This meta-analysis points out only that gender differences on computer anxiety exist.

As computers have been increasing used in modern American society, many studies have reported people's attitudes toward computers (e.g., Campbell, 1992; Chu & Spires, 1991; Gordon, 1993; Kay, 1993; Whitley, 1996a). In particular, much research effort has gone into looking at gender differences and their causes on computer anxiety (e.g., Blumer, 1987; Campbell, 1988; 1989; Chen, 1986; Koohang, 1989; Loyd & Gressard, 1986; Meier, 1988; Wallace & Sinclair, 1995; Woodrow, 1994). The computer anxiety is referred to a “phobic” response that inhibits people from interacting with computers (Pope-Davis & Twing, 1991). Many authors have suggested that negative reactions to computers (such as computer anxiety) are associated with the failure of particular computer applications (e.g., Jagodzinski & Clarke, 1986). Elkins (1985) notes that teachers' attitudes toward computers are critical to the successful implementation of such system in special education classes.

Computer use has been portrayed in our society as more appropriate to men and boys than women and girls (Whitley, 1997). Computer games and educational software have been designed to appeal more to boys than girls (Kiesler, Sproull, & Eccles, 1985). Computer use in schools has also been linked to traditionally 'masculine' subjects such as science and mathematics but not to traditionally 'feminine' subjects such as art and literature (Hawkins, 1985). These gender differences in socialization have led to the hypothesis that women and girls are more likely to hold higher anxiety toward computers.

Although many studies have been conducted on this hypothesis (Blumer, 1987; Campbell, 1988; 1989; Chen, 1986; Koohang, 1989; Loyd & Gressard, 1986; Meier, 1988; Wallace & Sinclair, 1995; Woodrow, 1994), the results of these studies are mixed. For example, Campbell (1990), Chen (1986), Colley, Gale, & Harris (1994), Jacobson (1991), Loyd & Gressard (1986), Wallace & Sinclair (1995), Whitley (1996a;1996b), and Woodrow (1994) all reported significantly higher computer anxiety for females than males, while Blumer (1987), Campbell (1986;1989), Cantrell (1995), Chu & Spires (1991), Francis (1994), Koohang (1987;1989), Loyd & Gressard (1986), Loyd, Loyd, & Gressard (1987), Mertens & Wong (1988), Pope-Davis & Twing (1991), and Robertson, Calder, & Jones (1995) have indicated that there is little, if any, differences of computer anxiety between males and females. Owing to the mixed evidence provided by existing research in the area, this study attempts to use the meta-analytic approach to investigate the gender differences on computer anxiety. The results from this meta-analysis will help provide clearer conclusion.

PROCEDURES

The research method used in this study is the meta-analytic approach which was similar to that described by Glass, McGaw, & Smith (1981). The studies considered for use in this meta-analysis came from three major
sources and were published from 1984 to 1997. One large group of studies came from computer searches of Education Resources Information Center (ERIC). A second group of studies came from Comprehensive Dissertation Abstracts. A third group of studies was retrieved by branching from bibliographies in the documents located through review and computer searches. Forty-one studies were located through these search procedures; 9 studies came from ERIC and conference proceedings, 30 studies were retrieved from published journals, 2 studies were from Comprehensive Dissertation Abstracts.

Several criteria were established for inclusion of studies in the present analysis.
1. Studies had to assess the differences between males and females on computer anxiety.
2. Studies had to provide quantitative results from both male and female subjects.
3. Studies had to be retrievable from university or college libraries by interlibrary loan or from ERIC, Dissertation Abstracts International, or University Microfiche International.

There were also several criteria for eliminating studies or reports cited by other reviews: (a) studies did not report sufficient quantitative data in order to estimate Effect Sizes; (b) studies reported only correlation coefficients -- r value or Chi-square value; (c) studies could not be obtained through interlibrary loans or from standard clearinghouses.

Outcome Measures
The outcome measured most often in the selected studies was survey data from participants, as indicated in various instruments for examining participants’ computer anxiety. For statistical analysis, outcomes from a variety of different studies with a variety of different instruments had to be expressed on a common scale. The transformation used for this purpose is the one recommended by Glass et al. (1981). To reduce measurements to a common scale, Glass and his colleagues coded each outcome as an Effect Size (ES), defined as the difference between the mean scores of two groups divided by the standard deviation of the control group. For those studies that did not report means and standard deviations, F, or t, values were used for estimating the ES.

In most cases, the application of the formula given by Glass and his colleagues was quite straightforward. But in some cases, when more than one value was available for use in the formula of ES, the value that measured outcomes most correctly was selected. For example, some studies reported both differences on pretest measures and differences in posttest measures. In such cases, pretest measures were selected for estimating ES so that any treatment which may change participants’ general feelings about computers could be avoided.

In other cases, several subscales and subgroups were used in measuring a single outcome (e.g., those that reported separate data by ethnicity or grade). In such cases, each comparison was weighted in inverse proportion to the number of comparisons within the study (i.e., 1/n, where n = number of comparisons in the study) so that the overweighing of ES of a study could be avoided (see, for example, Waxman, Wang, Anderson, & Walberg, 1985, p. 230).

Variables Studied
Eight variables were selected for coding each study in the present synthesis. These variables are listed in Table 1. The first 2 variables were coded so that potential different effects for subjects with different background could be detected. The following 2 variables (i.e., type of publication and year of publication) were coded because it is important to know how effects are related to sources of information over time. Last 4 variables were coded so that effects related to characteristics of research design could be detected. Each variable was employed as a factor in an analysis of variance (ANOVA) to investigate whether there were significant differences within each variable on the effect size.

RESULTS

The number of comparisons and the study-weighted ESs are reported in Table 2. Of the 41 studies included in the present synthesis, 33 or 80% of the study-weighted ESs were positive and favored the male subjects, while 8 or 20% of them were negative and favored the female subjects, indicating that males had lower computer anxiety than females. The range of the study-weighted ESs was from -0.52 to 1.923. The overall grand mean for all 41 study-weighted ESs was 0.284. When this mean ES was converted to percentiles, the percentiles on computer anxiety were 61 for the male subjects and 50 for the female subjects. The standard deviation of 0.413 reflects the mild variability of ESs across studies.

Among the 55 ESs included in the present synthesis, 41 or 74% were positive and favored the male subjects, while 13 or 24% were negative and favored the female subjects. Only 1 or 2% of the ESs indicated no difference between male and female subjects. The range of the ESs was from -0.52 to 1.923.

Table 2. Number of Comparisons and Study-weighted Effect Sizes

Table 3 lists the F values for the 8 variables for all study-weighted ESs in the study. Descriptive statistics for the 8 variables are presented in Table 4. For ANOVAs, 1 variable, type of publication, showed statistically significant impact. In addition, 1 variable, sample size, showed an approaching significant impact. For each of these variables, a post hoc (Fisher's Protected LSD) test was performed.

The post hoc test for type of publication, \( F(2,38) = 3.887, P<.05 \), showed that the mean comparison of studies coded as dissertation (mean = 0.996) was significantly higher than studies coded as journal (mean = 0.22) or ERIC/conference (mean = 0.337). However, since there are only 2 studies that coded as dissertation, this result may be considered tentative.

For sample size (\( F(2,38) = 2.915, p = 0.067 \)), the post hoc test showed that the mean comparison of studies in which the sample size was less than 200 (mean = 0.433) was significantly higher than studies in which the sample size was over 400 (mean =0.07). There were no significant differences found between the mean comparison of studies in which the sample sizes were less than 200 and 200 - 400 (mean = 0.255). The results seem to suggest that gender difference on computer anxiety may decline when the same size increases.

* p<.05
CONCLUSION

The results of this meta-analysis indicate that male subjects had slightly lower computer anxiety than female subjects. An effect is said to be small when ES = 0.2, medium when ES = 0.5 and large when ES = 0.8 (Cohen, 1977). Eighty percent of positive study-weighted ES values and 74% of positive ESs overall also confirm the gender differences on computer anxiety. The slightness of the differences must be kept in mind, however; the overall study-weighted mean ES of 0.284 only indicates 11 percentile scores higher than the female subjects. The percentile scores for the overall grand mean and median were 61 and 59, respectively. The difference of 2 percentile points between them was possibly attributed to the overall grand standard deviation (0.413).

While many authors have indicated that women and girls are more likely to hold higher anxiety toward computers, and this negative reaction to computers may be associated with their failure of particular computer applications (e.g., Jagodzinski & Clarke, 1986), the results of this study provide an accumulated research-based evidence to support this hypothesis. Left unanswered is the question of what factors truly contribute to the differences. Studies of this question will require further clarification of the exact relationship between gender and computer learning environment. This meta-analysis points out only that gender differences on computer anxiety exist. That information by itself is useful.

References

Abstract: Students' attitudes toward computer technologies have been found one of the important variables that influence their computer achievements. Research has shown that students' experience of using or learning computer technology influences their attitudes toward computer technology. The current study investigated the influences of different teaching methods on students' computer attitudes. Two teaching methods were used in this study: (1) teacher-centered instructive method, and (2) student-centered constructive method. Two groups of teacher education students served as the sample, each of which learned basic computer skills with one of the two teaching methods. Their computer attitudes were measured and compared in four attitude variables—enjoyment, motivation, importance, and freedom from anxiety. Differences were found between the two groups.

Introduction

Positive attitude toward computer technologies has been widely recognized as a necessary condition for effectively using and learning information technology (Woodrow, 1992; Knezek, Christensen & Rice, 1997), and student computer attitude has been found an important variables that influence computer achievement (Liu & Fernandez, 1998; Liu & Johnson, 1998). Therefore, to help students build up positive computer attitude becomes one of the critical issues in technology education. Research findings suggest that the instructional strategies a teacher used in teaching computer technologies influence student computer attitude (Dickens, 1998; Kovalchick, Milman & Hrabe, 1998). The current study examined the influences of two teaching methods on student computer attitude. The two teaching methods were (1) teacher-centered instructive method, and (2) student-centered constructive method. Four computer attitude variables—enjoyment, motivation, importance, and freedom from anxiety—were measured and compared between two groups of students who learned computer technologies with different teaching methods.

Literature Review

Constructivism versus Instructivism

Conventional teacher-centered instruction has been in our classrooms for many years, it is now confronted with the challenge of the rapid development of technologies (Brooks, 1990). Constructivism has emerged in opposition to conventional teaching. Much educational research has been undertaken to find "What Works" in our classrooms, especially in our information technology classroom (Kerzer & Wright, 1997). To find the answer to this question, discussion of constructivism has been a theme widely spreading in the literature. What is constructivism? This is the question from those who attempt to gain a meaningful understanding of the implication of constructivism for teaching. The literature reflects wide-range of views. Jonassen (1996) describes a well-accepted definition of constructivism that learners construct their own reality through interpreting their experiences. Existing views also hold that constructivism is a collection of theories (Newby, Stepich, Lehman & Russell, 1996), and an instructional model (Roblyer, Edwards & Havriluk, 1997). These diverse perspectives provide educators with ideas regarding how constructivism may improve student learning.

Keizer and Wright (1997) introduced a constructivist model that was designed to maintain a quality with limited resources when the instructional technology faculty was faced with staff reductions and limited equipment for basic computer skills' instruction. Based on constructivist principles, a course was specifically designed that essentially tripled the enrollment without increasing staff or the number of computers available. Using constructivism can, on one hand, effectively use the existing resource of technology. On the other hand, with the constructive method, students, instead of
In this learning process, learners create meaning and are not passive recipients of information (Roth, 1989).

Between the two approaches of teaching/learning, is constructive method better than instructive method in technology learning? Does constructive method work more effectively than instructive method? When should we use constructive method? When instructive method? Numerous studies have been undertaken to find the answers. However, few studies have occurred regarding these questions: what impacts might the constructivist perspective have on teacher education students' attitudes toward computer technology? From which teaching approach could more positive computer attitude be derived? The current study was to investigate the impacts of different approaches on students' computer attitudes.

**Computer Attitude Variables**

Students' attitudes toward computer technologies have been found to be one of the major factors relating to their success in learning about and using them (Francis & Evans, 1995; Freedman & Liu, 1996; & Liu & Johnson, 1998). Computer attitude can be viewed as a many-faceted variable, for it is difficult to define a single variable called attitude. Studies have focused on investigating computer users' attitudes in relation to one or more variables, such as (1) enjoyment—the degree in which students are interested in, and like learning and working with a computer (Cooper & Stone, 1996; King & Bond, 1996); (2) motivation—the degree to which students are willing to learning and working on the computer (Kellenberger, 1996); (3) importance—the extent to which students feel learning and using the computer is important; and (4) computer anxiety—the degree to which students feel anxious while learning about and using a computer (King & Bond, 1996).

These variables are essential to computer achievement. How could an educator help students build up more positive computer attitudes? What factors would influence students' computer attitudes? Liu and Johnson (1998) found that some environmental conditions—such as, computer access, convenient helper, and requirement to use computer on the assignments by other courses—had functional relationships with positive computer attitudes. This study was a continuation of Liu (the author of this paper) and Johnson's 1998 study to investigate the influence of different teaching approaches on students' computer attitudes.

**Research Questions and Hypothesis**

The purpose of this study was to investigate whether using different teaching methods—instructive method or constructive method—would influence students' computer attitudes on the four attitude variables: enjoyment, motivation, importance, and freedom from anxiety. The research questions examined in this study were:

1. Are students' computer attitudes on the variable "enjoyment" different between those who are taught computer technologies with constructive method and those with instructive method?
2. Are students' computer attitudes on the variable "motivation" different between those who are taught computer technologies with constructive method and those with instructive method?
3. Are students' computer attitudes on the variable "importance" different between those who are taught computer technologies with constructive method and those with instructive method?
4. Are students' computer attitudes on the variable "freedom from anxiety" different between those who are taught computer technologies with constructive method and those with instructive method?

It was hypothesized that the difference would be found in at least one of the four attitude variables.

**Methods**

**Subjects**

The subjects of this study were 36 teacher education students enrolled in two sessions of a basic computer technology course in an eastern state university. The subjects' ages ranged from 18 to 37 (the average age was 23.48),
including 10 males and 26 females. Around 90% of them had no previous computer skills, beyond using a word processor.

**Instruments**

The instrument used in this study was derived from Aiken’s (1979) Likert-type questionnaire consisting of 24 statements that measured the four computer attitude variables. The 24 statements were sorted into four categories with six statements in each category. Statements in each category measured on attitude variable with three positive attitude statements and three negative attitude statements. The answer options for each statement were Strongly Disagree (SD), Disagree (D), Undecided (U), Agree (A), or Strongly Agree (SA), from which one answer must be chosen. For the positive statements, the score for answer SA was the highest (5 points); for negative statements, the score for answer SD was the highest (5 points). The score for each variable was the sum of the six statements. So, higher scores represented a more positive attitude.

This instrument has been tested and found to be a valid instrument to measure each of the four variables independently (Aiken, 1979).

**Research Method**

This study was to find the different influence of two teaching methods on students’ computer attitudes. Although it was not an experimental design, the sample was two existing groups of students. It was assumed that the two groups of students were from a homogeneous population. This assumption was based on the facts that: (1) they all were undergraduate teacher education students; (2) around 90% of them had no previous computer skills, beyond using a word processor; (3) pretest and posttest were employed, and the results of pretest suggested that there is no differences of students’ computer attitudes between the two groups (see the Results session). Therefore, it was assumed that all other conditions were under control and different computer attitudes measured at the end of the course were, at least partially, due to the different teaching methods used in the learning process.

**Procedures**

The subjects were teacher education students in two sessions of a basic computer skill course. They learned the same technology skills, such as word processor, graphic design, spreadsheet, database, Internet applications, PowerPoint presentation, and multimedia authoring program.

In one session, teacher-centered instructive method was employed. In each learning task, first, the instructor introduced related concept and functions of the software package. Second, the instructor demonstrated the software with some application samples, and explained the lab work in details. Third, students worked on computers with step-by-step instruction materials and with the instructor’s help.

In the other session, student-centered constructive method was applied. In each learning task, first, the instructor briefly introduced the software package about what it can do, and explained some concept. Second, the students received the learning task—to solve one problem. Third, to solve this problem, students needed to explore most functions of the software. They started from explore the functions, command menu, online samples, and then decide how to solve the problem. Last, they created their applications. The following is an example of the student-centered method with which students constructed the knowledge from their own experience:

**Task:** Learning Mail Merge function in MS Word

**Problem:** You are a school principal. You have 500 students in your school. You need to send a letter to the 500 parents informing them some policy changes of the school administration. Find out a simple way to print out the 500 letters and mail them to the parents.

**Introduction:** You can use MS Word to solve this problem. You only need type one letter and the parent address list. You will use a tool under the Tools menu.

**Lab Work:** Students explored Mail Merge and Label Merge, and wrote down the steps they worked.

**Products:** Students printed out five sample letters, and address labels.

Pretest and posttest were employed. The computer attitude questionnaire was given to and answered by the two groups of students at the beginning and the end of that semester.
Data Analysis

According to the design of this study, mixed model repeated measure was the appropriate method for data analysis. A SAS macro MIXRPT (Fernandez, 1997) was used to perform the data analysis and assumption checking. The plots obtained from this macro showed that the assumptions of normality, equal variance, and extreme influential outliers were not violated. The significant level for these analyses was set at $\alpha = 0.05$.

In the data analysis, the two groups to be compared were Group A (teacher-centered instructive method group) and Group B (student-centered constructive method group). The four computer attitude variables—enjoyment, motivation, importance, and freedom from anxiety—were repeatedly measured in each group.

Results

First, the pretest results show no difference of the computer attitudes between the two groups ($F_{1,34} = \text{0.0246}, P < 0.45$); no difference among the four computer attitude variables measurements ($F_{3,102} = \text{2.1375}, P < 0.39$); and no interactions between the two groups on any of the four variables ($F_{3,102} = \text{3.0051}, P < 0.34$). The assumption that the two groups of students were from a homogeneous population was based on these results.

Second, the posttest that was taken at the end of this course appeared to have the evidence that the differences did exist. The results are shown in Table 1.

Table 1. Results of the Repeated measures

From Table 1, first the interaction between the two groups on the four attitude variables should be checked. The term that presents the interaction is GRUP*ATTI. The results show that the interaction is significant ($F_{3,102} = 13.92, P < 0.0001$). Since the interaction is significant, we need to check where the differences are. The interaction mean plot produced from the data analysis (will be presented on SITE) and results of the differences of least squares means indicate that:

1. The difference between Group A (teacher-centered instructive method group) and Group B (student-centered constructive method group) on the computer attitude variable “freedom from anxiety” was found to be significant ($t = \text{3.34}, p < 0.0012$). The comparison was performed as “compare Group A to Group B,” therefore, the positive $t$ value indicates that Group A’s mean score is higher than Group B’s. If the $t$ value is negative, that means Group A’s mean score is lower than group B’s.

2. The difference between the two groups of students on their computer attitude variable “motivation” was found to be significant ($t = \text{-3.79}, p < 0.0003$). This results indicate that Group A’s mean score is lower than group B’s.

3. There are no significant differences between the two groups of students on their computer attitude variable “Enjoyment” ($t = -0.40, p < 0.6868$), nor on their attitude variable “Importance” ($t = 0.91, p < 0.3651$). The results of interaction may explain some other values in Table 1. In Table 1, the main effect of Group is not significant ($F_{1,34} = 0.00, P < 0.9862$). Since there are differences between the two groups on some of the variables, why are the main effects between the two groups not significant? The explanation is that Group A’s mean score is higher than Group B’s in the variable “freedom from anxiety,” but lower in the variable “motivation;” then the difference between their main effects must be zeroed down.
Conclusions

In conclusion, the results of the data analysis answered the four research questions. The research hypothesis was tested to be true for this set of data. The findings of this study suggest that:

1. Using teacher-centered instructive method is helpful in reducing students' computer anxiety, especially for those who just start to learning computer technologies.

2. Using student-centered constructive method is helpful in increasing students' motivation to learn and use computer technologies.

The two variables—computer anxiety and motivation—have been found, from previous studies, the important variables to students' computer achievements. According to the findings of the current study, one question may be raised: Could we increase student' motivation and reduce their anxiety simultaneously by integrating the two teaching methods into technology courses for our teacher education students?

Further studies could be conducted to investigate multiple strategies for multiple learning styles. An instructive-constructive approach could be examined to determine its influence on computer attitude, or even on computer achievements.

Abstract

This paper investigates computer attitudes of technological and teacher college students in Taiwan and compares student computer attitudes by type of college. The results indicate that these college students have positive attitudes toward computers. They value educational computing highly. Most of them do not report high anxiety using computers nor perceive any difference in computer use between males and females. There was, however, significant difference in students' view of computer use by high- and low-achieving students. Teacher college students perceived greater ability-related difference than technological college students. Chi-square results also reveal that teacher education students had less experience working with computers than technological students. Implications of the findings are discussed in the paper.

In the past two decades, computer and technology products in Taiwan have gained great attention. The advancement of computer parts and programs there have also been internationally recognized. Relatively less known is the application of computer technology in education in Taiwan. In fact, one of the greatest challenges in higher education there has been trying to effectively integrate technology into college teaching and learning. Many educational institutions offer courses in computer technology for college students with the purpose of preparing these students to be productive members in the high-tech society. Experts on education reform in Taiwan also stress the need to enhance prospective teachers' computer literacy and skills. As a result, education students, like students in other colleges, have great access to computers. Many teacher colleges require students to complete at least one course in instructional technology to graduate.

With the increasing availability of computer education and training, it is important to investigate cutting edge college students' attitudes toward computers in Taiwan. The close relationship between attitudes toward computer technology and computer use has been well documented. Prior studies on college students' perceptions of computer technology have found that college students' attitudes changed more positively with respect to using computer in instruction (Brownell, Brownell, & Zirkler, 1993; Huang, Waxman, & Padron, 1995, Liao, 1993).

Although there are a number of research paradigms on the study of college students and computers, these inquiries, however, tend to focus on (a) the use of computers as teaching aids at the post-secondary level (Sammons, 1995; Fox, 1993), (b) the implementation and evaluation of instructional computing programs (Handler, 1993, Park, 1994), and (c) the factors affecting the access and utilization of computers (Awbrey, 1996; Cummings, 1995, 1996; Gradgenett & Harrai, 1994; Oliver, 1994). Research has found that most college students want to use computer technology, but their use has been limited to
fairly narrow applications (Fulton, 1993). Previous research further found significant relationships between computer attitudes and computer achievement (Marcoulides, 1988, Wiggins, 1984). Very little research, however, has compared college students' attitudes toward computers. Therefore, this study focuses on investigating computer attitudes of college students in Taiwan and compares student computer attitudes by type of college. The dimensions of student attitudes being investigated include liking, value, anxiety, beliefs in gender- and ability-related differences in using computers.

The present study attempts to provide a knowledge base of what college students feel and think about computers and whether if there are differences in computer attitudes between students from technological institutes and teacher colleges in Taiwan. The findings of this study may help the integration of computers into the teaching and learning processes for college students. More specifically, the present study addresses the following research questions:

(a) What are college students' attitudes toward computers in the dimensions of anxiety, value, liking, gender- and ability-related differences?
(b) Are there any significant differences between technological students and teacher education students' attitudes toward computers in the five dimensions?
(c) Are there any significant differences between technological students and teacher education students in their demographic and computer background?

Methods

Subjects

The participants in the study were 310 technological college students and 372 teacher college students from the outskirts of a large metropolitan city in northern Taiwan. Both types of colleges offer several computer courses at the undergraduate level. In addition, a computer course has been mandated as a part of degree requirements. Among these college students, 30% were male and 70% were female. Ninety-nine percents of them were between the age of 18 and 25. Nearly 11% of them had used computers for less than three months, 17% of them had used computers for three months to one year, and over 58% of them had used computer(s) for more than two years.

Instruments

In the present study, two instruments: The Computer Attitude Scale (Violata, Marini, & Hunter, 1989) and The Ability Differences in Computer Use (Waxman, Huang, & Padron, 1992) were adapted into one survey that was administered to all the subjects. The Computer Attitude Scale consists of four scales: (a) Liking -- the extent to which students like to use computers; (b) Value -- the extent to which students perceive the value of computers; (c) Anxiety -- the extent to which students have anxiety in using computers; and (d) Sex Differences -- the extent to which students perceive gender-related differences in working with computers. The Ability Differences in Computer Use consists of five items measuring the extent to which students believe in ability-related differences in computer utilization. All the scales are on a 5-point Likert rating with 5 indicating strongly agree and 1 indicating strongly disagree. A section on these students' background characteristics was also included on the final survey. These instruments have been found to be reliable and valid. For this study, the internal consistency reliability coefficients range from .60 to .88 for the five scales for students from technological colleges and from .62 to .89 for students from teacher colleges.

Procedures and Analysis

The survey was administered at the end of the academic year to the college students by experienced researchers. The survey took approximately 30 minutes to complete. These students were told that this questionnaire was not a test and they responded anonymously. Descriptive statistics were used to describe these college students' attitudes toward computers. Multivariate analysis of variance (MANOVA) was used to determine if there was an overall significant difference in student computer attitudes on the five
scales by type of college. When the overall significant difference was found, follow-up analyses of variance (ANOVA) were used to determine where the difference(s) were.

Results

The results indicate that, in general, these college students had positive attitudes toward computers. All responded with a mean value greater than 3.00 in Value and Liking and a mean value lower than 3.00 in Anxiety, Gender-and Ability-Related Difference. These students valued educational computing very highly ($M$=4.14, $SD=0.48$). Their rating of liking was also positive ($M=3.63$, $SD=0.54$). Most of them had low Anxiety ($M=1.59$, $SD=0.68$). A majority of them did not perceive any difference in computer use between males and females ($M=2.26$, $SD=0.75$), nor did they perceive remarkable difference between low- and high-achieving students' use of computers ($M=2.84$, $SD=0.80$).

The MANOVA result indicates that there was an overall significant difference in computer attitudes between students from technological colleges and students from teacher colleges ($F(5,667)=5.00$, $p<.001$). Follow-up ANOVA results indicate that the significant difference was found in students' view of computer use by high- and low-achieving students ($F=17.37$, $p<.001$). Teacher college students perceived greater ability-related difference than technological college students. There were no significant differences between teacher college and technological college students in their liking and value of computers. Nor were there any significant differences between these two student groups in their computer anxiety or perceptions of sex-related difference. Table 1 displays the ANOVA results.

***$p<.001$.

Chi-square results indicated that there were significant differences between the two student groups in their gender distribution, age, and years of computer experience. There were more male than female students in teacher college student group as compared to technological student group ($p<.01$). There were older students in teacher college than in technological college student group ($p<.05$). In addition, teacher education students had less experience working with computers than technological students ($p<.01$).

Discussion

The findings of the present study support previous research reports that college students in Taiwan generally have positive attitudes toward computers (Huang & Padron, 1997, Liao, 1993). Both technological and teacher college students value computers highly. They think that it was necessary and worthwhile for college students to learn how to use computers. They do not report high anxiety or being uncomfortable working with computers. Nor do they view any significant difference between males and females in computer use. In other word, they do not think that it is more important for male students to use computers than for female students, or that it is more difficulty for female to use computers than for male students.
There is a significant difference between technological and teacher college students' attitudes toward computers in terms of ability-related difference. More teacher education students have greater confidence in high-achieving students than in low-achieving students in computer use. Although these college students do not view ability as an issue in terms of students being able to learn and enjoy computer applications, more teacher education than technological college students perceive that (a) working with computers is more difficulty for lower-achieving students than for higher achieving students, (b) using computer is more enjoyable and more important for higher-achieving students than lower-achieving students, and (c) lower-achieving students can not do as well as higher-achieving students in learning about computers. This discrepancy may be partially due to the stereotype of teacher college students. They tend to over emphasize the relationship between ability level and academic achievement of students. It may be partially due to the fact that they had less computer experience than technological students, and therefore had less confidence in believing that all students can learn computer well. Further research needs to identify factors that may explain this difference and design strategies to overcome the ability-related bias of teacher education students.

The findings of the present study have several educational implications. First, the findings provide insight into understanding college students' computer attitudes and how students from various colleges may differ in their perceptions of computer use. Higher education institutions may thus design more effective curriculum to bring about desirable changes for their students. For example, Stephen & Ryan (1992) suggested how institutions may increase the knowledge and use of technology for college of education students. Second, the study identifies differences in college students' demographic and computer background variables, and allows future research on exploring the relationship between these variables and students' computer attitudes to verify findings of previous research studies (Huang & Padron, 1997). Third, this study can serve as a basis for comparing computer technology attitudes among college students across different institutions and cultures.

Mining for Knowledge about Technology Training

A. Dale Magoun, Ph.D. and Charlotte H. Owens

Department of Computer Science
Northeast Louisiana University

Introduction

This paper concentrates on an evaluation of the NSF/NLU Teacher Enhancement program (TEP). The TEP, a three-year project sponsored by the National Science Foundation (NSF), allowed the Department of Computer Science to bring to Northeast Louisiana University sixty (60) teachers from the surrounding fifteen (15) parish area and train them in computer related technologies that could be integrated into their classrooms. The participants of the program were introduced to technologies such as multimedia, the World Wide Web (WWW), and electronic mail (e-mail). They were also instilled with the confidence to become technology trainers for their districts. The focus of the evaluation is centered around the success of the participants in their role as technology trainers for their districts.

Survey Instrument

In order to assess the success of the TEP, the Teachers' Attitude Toward Information Technology (TAT) version 1.1 survey instrument was distributed to the faculty of two local school systems. The TAT, which is composed of ten separate indices, was developed and verified by the Texas Center for Educational Technology (TCET) which operates under the auspices of the University of North Texas (Christensen and Knezek, 1998). Eight of these indices were constructed using Zaichkowsky’s (1985) Modified Personal Involvement Inventory, which is a context free sixteen item semantic differential scale that focuses on “a person’s perceived relevance of the object based on inherent needs, values, and interests.” The other two areas of the TAT utilize Kay’s semantic perception of computers (Kay, 1993) and D’Souza’s (1992) classroom learning via electronic mail.

The Survey

The research project surveyed teachers from the Ouachita Parish School System (OPSS) and the Monroe City School System (MCSS). These systems were chosen because of their system-wide commitment to technology. Approximately four hundred (400) questionnaires were distributed to the faculty of these systems. Of these one-hundred and sixty-nine (169) were returned for a return rate of 42 percent. The gender dichotomy represented 36 males and 133 females.

The survey sample consisted of various levels of experience and types of training received. The more seasoned teacher represented 44 percent of the respondents; whereas, the lesser experienced teachers represented 21 percent. Teachers from the MCSS represented 59 percent of the respondents and OPSS represented 41 percent, respectively. Four of the teachers did not respond to the question pertaining to teaching experience. The TEP trained respondents represented 62 percent of the sample and were fairly balanced between the two systems. Fifty-two percent of the TEP trained teachers were employed by MCSS and 48 percent of the TEP trained teachers were employed by OPSS. Of the 65 respondents in the Non-TEP group, 72 percent were from MCSS and 28 percent from OPSS.

Of the one hundred sixty-nine questionnaires, thirty-eight of the respondents omitted one or more of the subscales leaving one hundred thirty-one completed questionnaires. The two systems were adequately represented in both gender, level, and training received. The data collected exhibited an internal consistency reliability, Cronbach’s Alpha, comparable to the literature (Cronbach, Gleser, Nanda, Rajaratnam, 1972). The TAT reliability estimates for K-12 teachers from the Ouachita Parish School and Monroe City School systems ranged between 0.88 and 0.90.
Research Hypotheses

The research hypotheses of interest are multifaceted and consist of comparing the attitudes toward technology by school system and method of training. Of interest in this study is the evaluation of the success of the NSF/NLU TEP program. As mentioned previously, a major component of the TEP was to develop technology trainers for the school districts. The TEP trained technology instructors were used by their districts to provide training for their colleagues. To measure or assess the success of the TEP in this endeavor, the attitudinal responses toward technology of the faculty from the two systems were collected via the TAT. The effects of the TEP are examined by arranging the data into one of four groups. These groups are summarized in Table 1.

<table>
<thead>
<tr>
<th>Experimental Groups</th>
<th>Explanation</th>

</tr>
<tr>
<td>Group 3</td>
<td>TEP Trained Teachers from OPSS</td>
</tr>
<tr>
<td>Group 4</td>
<td>Non-TEP Trained Teachers from OPSS</td>
</tr>
</tbody>
</table>

The arrangement of the data into one of the four groups represent a one-way classification or a completely randomized design. This design was selected over a factorial model due to the inconsistencies in the Non-TEP groups between the two systems. Some of the faculty in the Non-TEP group from MCSS were trained by the university faculty who later served as the staff of the TEP. This pre-TEP training was sponsored by MCSS through state supported technology grants. The success of this program provided the foundation upon which the TEP project was developed. This additional training of teachers by the TEP staff was not the case for the teachers in the OPSS Non-TEP trained group. Under these assumptions, then, the research hypotheses of interest are:

Hypothesis 1: Teachers who have received training from the participants of the NSF/NLU TEP program have a more positive appreciation of what technology can do for their students and for themselves when compared to the teachers who have received training from other sources.

Hypothesis 2: Regardless of where they received technology training, teachers from the Monroe City School system have a more positive attitude about technology than the teachers from the Ouachita Parish School system due to the long-term MCSS commitment to training.

Latent Variables

According to DeVellis (1991), what is of interest in a survey, composed of scale items such as the TAT, is the underlying phenomenon or construct reflected by the scale items. These underlying phenomena are usually referred to as latent variables and are related to the scale items that are inadvertently measuring the phenomena. One theoretical model that has been successfully used to describe this relationship is the general factor model. The general factor model allows multiple latent variables to serve as causes of variation in a set of scale items. Factor analysis, thus, is a beneficial procedure that can indicate the important properties of a scale. The primary functions of this analytical procedure are threefold. First, factor analysis will assist in determining how many latent variables are underlying the set of scale items. Secondly, factor analysis provides a means of explaining variation among original variables using relatively few newly created variables. Lastly, factor analysis aids in defining the meaning of the factors or latent variables by estimating the loadings which each scale item has with the newly created latent variables.

With this research data, factor analysis indicated that two significant factors or latent variables are present. DeVellis (1991) states that factors are defined by the items that load most heavily on it, that is, those loadings which are greater than 0.50. Thus, Factor-1 is heavily loaded with the TAT subscales of F3, F4, F5, F6, F7, F8, and F10. F10 relates to the teacher perception about computers; whereas, the other items address attitudinal responses of the teachers on the different components of the technology issue. Factor-2, on the other hand, relates to F1, F2 and F9.
which measures attitudinal responses of the teachers' perception of the benefits of e-mail for their students, to themselves, and for their classrooms. Thus, Factor-1 is a general technology appreciation factor; whereas, Factor-2 is an e-mail appreciation factor. The two latent variables derived from this survey data are mathematically defined as follows:

Factor-1 = 0.81469*F3 + 0.80566*F4 + 0.81413*F5 + 0.76876*F6 + 0.77667*F7 + 0.66822*F8 + 0.69933*F10

Factor-2 = 0.66678*F1 + 0.81555*F2 + 0.88759*F9

Prior to analysis, the survey data was re-coded using the two latent variables. The newly generated data and the ten NIT subscale scores were analyzed by the ANOVA procedure.

**Latent Variable Analysis**

When considering the technology appreciation factor (Factor-1), the analysis of these data indicates that attitudinal differences are present among the four groups (F = 4.6202, p-value = 0.0041). The average technology appreciation values are 33.57, 33.05, 32.50 and 28.28, respectively for the samples representing the MCSS: TEP trained, MCSS: Non-TEP trained, OPSS: TEP trained, and OPSS: Non-TEP trained groups. Ancillary analysis further indicates that the teachers in this study who represent the Monroe City School system have a more positive appreciation (t = 3.2518, p-value = 0.0015) for technology than the teachers representing the Ouachita Parish Schools. The post-ANOVA analysis indicates mixed conclusions about the effect of training. In the Monroe City School system, the analysis of attitudinal differences between TEP trained versus Non-TEP trained teachers is inconclusive (t = 0.5014, p-value = 0.6169). However, within the Ouachita Parish School system the teachers representing the TEP trained group have a more positive appreciation for technology (t = 2.8636, p-value = 0.0049) than the teachers representing the Non-TEP trained group.

The analysis of the E-Mail factor (Factor-2) also indicates that attitudinal differences among the four groups prevail (F = 2.7585, p-value = 0.0447). The average E-Mail appreciation values are 10.96, 11.24, 10.01 and 9.78, respectively for the samples representing the MCSS: TEP trained, MCSS: Non-TEP trained, OPSS: TEP trained, and OPSS: Non-TEP trained groups. The post-ANOVA linear contrasts further indicate that an attitudinal difference was noted between the two systems. The teachers representing the Monroe City Schools have a more positive appreciation for what E-Mail can do for themselves and their students than the teachers representing the Ouachita Parish Schools (t = 2.69998, p-value = 0.0079). The statistical tests comparing training techniques within each of the systems proved to be inconclusive. Thus, one can conclude that differences in the E-Mail appreciation factor only existed at the school system level and is not dependent on the training that the teachers received.

In summary, the analysis indicated that teachers from the Monroe City School system have similar attitudes toward technology and e-mail as a tool for themselves and their students regardless of type of training. However, this was not the case for the teachers representing the Ouachita Parish Schools. The teachers from OPSS who received training from the TEP participants have a more positive appreciation for what technology (Factor-1) can do for them and their students when compared to the teachers from OPSS who were trained by other sources. Additionally, the teachers from the Monroe City School system have a more positive appreciation for what technology and the e-mail can do for their students and for themselves than the teachers from the Ouachita Parish School system. This latter conclusion may be reflective of the long-term training commitment made by MCSS.

**NIT Subclass Analysis**

As with the latent variable analysis, the ten NIT subclasses F1-F10 were analyzed. The analysis consisted of pooling the secondary school, middle school and elementary school data into one of the four experimental groups representing the two systems and the two training methods. The analysis of this multivariate data indicated that differences in preference patterns among the four groups are present (Wilks’ Lambda = 0.686418, p-value = 0.0294). To delineate the differences, subsequent subsections will focus on each of the NIT subclasses grouped according to the subclass categories relating to the “To me...” and “For my student,...” questions.
Subclass Analysis: “To me,...”

The NIT subclasses referencing the teacher’s attitudes toward technology focuses on the e-mail (F1), multimedia (F3), productivity (F5), the WWW (F7), e-mail in the classroom (F9), and computers in general (F10). Table 2 describes the F-tests and their associated p-values for testing the null hypotheses of no differences among the group means for each of the NIT subclasses. As can be seen from this table, all six F-tests rejected the null hypothesis at the 0.05 level of significance.

<table>
<thead>

</tr>
</tbody>
</table>

Thus, for the four groups under study, the teachers’ attitudes comprising these groups are different. Table 3 summarizes the results of the linear contrasts used to delineate differences between systems and training. In this table Contrast-1 compares MCSS vs. OPSS regardless of training, Contrast-2 compares TEP Trained vs. Non-TEP Trained in MCSS, and Contrast-3 compares TEP Trained vs. Non-TEP Trained in OPSS. Contrast-1 indicates that the teachers’ attitudes between the two systems are different for each of the six NIT subclasses. The significant t-tests indicate that the teachers representing the Monroe City School system have a more positive attitude toward technology than the teachers representing the Ouachita Parish School system. Furthermore, from this table it is also seen that training source had no effect on the teachers’ attitudes toward technology when considering the teachers from the Monroe City School system. Contrast-2 was not significant for each of the six NIT subclasses. However, this was not the case with the Ouachita Parish School system. Contrast-3 indicates that differences were observed in the subclasses of multimedia, productivity, and computers in general and that the TEP Trained teachers in OPSS did have a more positive attitude about these NIT subclasses than their counterparts in the survey who represented the Non-TEP Trained group.

among the groups. As can be seen from this table, all four F-tests were inconclusive at the 0.05 level of significance, but with a relaxed significance level of 0.10, two of the subclasses were significant. Table 5 summarizes the three linear contrasts which compares the two systems and the two training sources within systems. As can be seen from this table, the TEP-Trained teachers in OPSS do exhibit a more positive perception about the impacts of multimedia on their students and felt that their students would be more productive when compared to their counterparts. This table also indicates that the teachers from MCSS have a more positive perception about their students’ attitudes for the NIT subclasses of multimedia and productivity than the teachers from OPSS.

NIT Subclasses: Summary

The analysis of the NIT subclass data was fairly consistent, regardless of the subclass. When considering the impacts on computer technology as it relates to the teacher, it was seen from the above analysis that teachers representing the Monroe City School system have a more positive appreciation for the different facets of technology than the teachers representing the Ouachita Parish School system. Furthermore, when viewing the impacts of training, attitudes were affected only in the Ouachita Parish School system. TEP trained teachers in OPSS have a more positive attitude about technology than the Non-TEP trained group. These latter differences were present in the NIT subclasses of multimedia, productivity, the WWW, and general feelings about the computer. When considering the impacts of computer technology as it relates to their students, the teachers had positive feelings about the impacts, but at the 0.05 significance level none were significant differently from the others. These non-significant findings were consistently observed between the two systems and the two training sources.

Conclusions

The survey indicates that MCSS teachers do have a more positive attitude about technology than their colleagues in OPSS. The attitudinal differences are consistently observed regardless of the analysis approach. Differences between the systems were noted for the two latent variables as well as the NIT subclasses. The latent variable approach gave a collaborative overview of the differences between the two systems; whereas, the NIT subclass analysis focused on area specific differences. The two approaches jointly reinforce each other in their conclusions about system differences.

The success of TEP, as measured by observed differences in teacher attitudes between the two training groups, is accentuated in the OPSS system. TEP trained teachers in this system do have a more positive attitude about technology than their Non-TEP trained counterparts. This attitudinal shift is observed for the NIT subclasses of multimedia, productivity, the WWW, computers in general, and the latent variable Factor-1. The lack of discernible effects for the e-mail categories indicates that the training received did not affect attitudes about e-mail.
The lack of significance within the Monroe City School system is more related to the type of training that the teachers received in the Non-TEP group and to the long-term commitment that MCSS has made to training. Thus, the non-significant training effects observed in MCSS may be interpreted as an effect which measures the effectiveness of the TEP. That is, the training of teachers by the TEP participants is as good as the training of teachers by the university faculty who latter became the staff of the TEP. The effectiveness of the TEP to produce good trainers along with the successes observed in OPSS jointly reinforce the conclusion that the NSF/NLU Teacher Enhancement Program was an effective program that can serve as a model for others to follow.

This expert system is designed to help in the selection of the applicable statistical procedure for use with any given research problem. It is based on the following research problem attributes: a) the number of variables involved; b) the number of measures per variable; c) the type of theoretical/statistical model (randomization, data reduction/classification, distribution, difference, or correlation) at hand; d) the specific scales of measurement (nominal, ordinal, interval, ratio) involved; the sample's size; and f) the normality of the distribution of the data. The system has been used successfully to enable teachers in introductory research courses, as well as more experienced researchers, to quickly and accurately select the applicable statistical procedure for any given research problem by thinking of the problem in terms of these key attributes. A computer program can be obtained free of charge by submitting a 3 1/2" IBM disk to the senior author.
Incidental Learning in a Higher Education Asynchronous Online Distance Education Course

Karen M. McFerrin, Ed.D.
College of Education, Educational Technology
Northwestern State University (LA)
United States
mcferrin@alpha.nsula.edu

Abstract: The purpose of this study was to examine and describe the incidental learning activity of students in an asynchronous online course in a higher education setting. This research was conducted with data collected from interviews, journals, observations, email messages, and online conferencing software postings of 22 members of three sections of a graduate-level asynchronous online distance education course at Northwestern State University of Louisiana in the spring of 1998. Two types of incidental learning outcomes were observed. The first developed from the students' use of the technology itself. The second centered on an improvement in certain areas of the students' personal development. An increase in time management ability, self-directive behavior, self-confidence, and self-discipline occurred. The results of the study illustrate the value of incidental learning in an asynchronous online course and the need for coursework development that fosters the growth of incidental learning.

Introduction

The information and resources offered on the Internet, or the World Wide Web, are becoming a normal part of the academic lives of students in institutions of higher education throughout the United States and the world. Statistics about the Web and its users are changing daily, and the numbers are increasing rapidly. The Web provides a vital link to information and research. Colleges and universities have discovered that learning does not have to be confined to the four walls of a traditional classroom, and institutions of higher learning are harnessing these resources to reach their students and provide crucial, timely, and in-depth material, often through the method of distance education. Higher education faculty and administrators need to look at what students are learning in their online distance education courses in order to design effective online courses. A statistical analysis completed by the National Center for Education Statistics (NCES) in 1997 shows that a third of higher education institutions offered distance education courses in the fall of 1995 and another third planned to offer such courses in the next three years. Computer technology is becoming an important element for distance learning. It provides a powerful way to communicate, search for and retrieve educational resources both locally and globally, network using media such as the Internet, and access collaborative learning environments (Franklin, Yoakam, & Warren, 1996). Institutions of higher education are discovering that courses conducted online through this electronic medium benefit both the institutions and their students.

Incidental Learning Research

Research beginning as early as 1928 showed no significant difference in the comparative impact of technologies on the students’ primary learning (Russell, 1997). This primary learning is the learning that is obtained by students from the formal curriculum of a particular course. However, unintended or unanticipated learning does occur in these technologically diverse settings (Mealman, 1993). The general literature concerning incidental learning describes student learning outcomes that have not been part of the planned curriculum (Apps, 1978; Brookfield, 1986). It is suggested that the unintended consequences of a learning situation are often more important to the learner than the original objectives (Jones, 1982).

Not all incidental learning is positive or desirable. Ragsdale (1997) discusses what he terms "unanticipated outcomes" when technology is integrated into the classroom setting. When students are left
alone while they use technology, teachers tend to overestimate the computer skills of the students. He found that students tended to skip from one task to another and had difficulty completing their tasks.

Several researchers have focused on informal learning as it relates to the adult learner. Withnall (1990) identifies definitions and types of informal learning and examines issues such as the utility of informally learning the processes involved, and the lack of methods to assess the quality of learning acquired informally. Lankard (1995) addresses some of the new ways adults learn at work, including action learning, situated learning, and incidental learning. She writes that incidental learning is unintentional and unexamined. It is not based on reflection; thus the learning is embedded in the learner’s actions. The difficulty in validating incidental learning as an effective learning strategy is that learning is not anticipated; therefore, it is not easily assessed. The primary intent of the activity is to accomplish the task, not to learn. When incidental learning occurs, it is a byproduct of other activity. The learner discovers something while in the process of doing something else. The learner must pull away from the primary or planned task and examine the discovery clearly before he can learn from it.

One case study of incidental learning by adults in a nontraditional degree program appears to be the most definitive (Mealman, 1993). The study looked at the nature of students’ incidental learning and specified the role that incidental learning played in the student experience in the nontraditional adult degree program. Mealman found that students did not make distinctions between incidental and intentional or formal learning. He also found that incidental and intentional learning played equally important roles in the students’ overall experience.

Purpose and Research Questions

Because of the need for understanding the experiences of students concerning incidental learning in asynchronous online distance education courses, the researcher of this study looked for answers to two questions: “What incidental learning occurs in a particular graduate level asynchronous online distance education course?” and “What is the nature of the students’ incidental learning?” The purpose of the study was to examine and describe the incidental learning activity of students in an asynchronous online class in a higher education setting. This study was based on a deliberate research method with the following characteristics: dialogue with graduate students, direct observation of online activity, email summaries, posted class materials, and semester-length student journals.

The researcher considered questions involving the nature of the students’ incidental learning, the characteristics of the individual participants in the electronic online course, the students’ degree programs, and the amount of time the students invested in the course. She also observed the frequency of conference postings by the students, the motivation of the students to participate in this particular type of educational course, the nature of the students’ enthusiasm for the use of current technology for educational purposes, and the changes that participants perceived in themselves as a result of participation in this electronic online course.

Methodology and Data Collection

A qualitative methodology was used to collect data from students in the three sections of a graduate level distance education online course during the spring, 1998, semester. The study consisted of an individual initial interview with each participant, an individual exit interview with each participant, and a late-semester email checkup with the participants. The researcher monitored all conference postings and email messages to the instructors and to individual students and conducted several observations of students as they posted material to the conferencing software. The researcher analyzed a small collection of journals kept throughout the semester by a few of the participants and investigated the official grade books and grade sheets used by the instructors of the two groups.

The physical locations of the participants varied widely. Some were on the local university campus; many were near the main campus of the University in Natchitoches, Louisiana, or the surrounding small communities; a large group was in the middle schools of Bossier Parish, Louisiana; some were in other parts of Louisiana; and several were in other states. None were outside of the United States.

The researcher conducted two standardized open-ended interviews with each of the participants. The interview at the beginning of the semester was designed to determine the current technology learning level of
the participant, to delineate participant experiences with online courses, and to elicit participant beliefs concerning necessary skills, time involvement and anticipated learning in this particular online course. Twenty-two initial interviews were conducted. The interview with each of the participants at the end of the semester was designed to determine the participant’s unanticipated or unexpected learning outcomes. The researcher conducted twenty-one exit interviews. The researcher analyzed student journal entries for student insights. The participants could choose not to allow the researcher to use the journal to acquire data. Instead, the participants could use the journal solely for their own personal reflection. In this case, the researcher was able to access some of this information in the end-of-semester interviews with each participant. Nine participants kept journals throughout the course, and four participants gave their journals to the researcher at the end of the semester. The researcher asked the participants to include electronic mail communications received throughout the semester in their journal entries so the researcher could access and analyze this data. The researcher traveled to the physical location of eight participants to observe behavior in composing and posting messages to the conferencing software, TopClass and WebBoard. The researcher observed the participant’s interaction with the technology, methods of posting, and collected field notes in a descriptive form. She read, organized, and analyzed all written online conference postings to document the learning that was taking place during the course. The researcher acquired all email messages received by the instructors of all sections of the course and all email messages posted through the conferencing software. She recorded her own personal experiences throughout the study to use as a reflection of the field experience. The researcher acquired responses from an informal open-ended questionnaire conducted via email at the mid-semester point of the study. Triangulated information was gathered from participants by use of official documented data, interviews, email surveys, observations, and journals.

The researcher observed and analyzed the written material posted online by each of the students in the course, formally interviewed the participants in both sections of the class at the beginning and end of the respective semesters, observed participants as they prepared and posted online material for the course, compiled answers to a mid-semester email questionnaire sent to participants, and collected and analyzed data from journals that participants kept throughout the semester. The data from all interviews, observations, journals, and conference postings were compiled and analyzed by the researcher to determine the amount, type, and effect of incidental learning that occurred throughout the course.

The Conferencing Software

To be able to participate in an online class, students need more than just computers and phone lines. Some type of software that facilitates sharing and communicating of information is required. This study deals with World Wide Web software for text-based, asynchronous group discussions. It is not concerned with real-time (synchronous) chat, video, or audio conferencing, although all of those are excellent means for students and instructors to communicate over a physical distance.

Two sections of the course used TopClass (TopClass, 1997), a system for developing and delivering Web-based training, including discussion forums. Its developer is WBT Systems and it runs on UNIX, Windows, and Macintosh systems. This software was put on a server under the direction of the Northwestern State University’s Academic Computing Office (TopClass at NSU, 1998). Eight other online courses were using this software for the spring of 1998 semester. It reveals its inner workings in the form of database contents which can be accessed through a Web browser which is exactly what the 11N an 01N students did. Each student, regardless of physical location, could log onto the conference through an Internet browser. TopClass is password protected and only members of the class had access to the information it holds.

The third section of the course used an older package called WebBoard (WebBoard, 1996). Its developer is Duke Engineering and is marketed by O'Reilly Software. It runs on Windows NT and 95 platforms. WebBoard was loaded on the College of Education Educational Technology server and ran through its Learn Net website (Learn Net, 1998). WebBoard is software for intranet- or Internet-connected Windows 95 or NT computers that allow Web site visitors (in this study, students in the ETEC 5710 course) to interact via threaded discussion forums and/or real-time chat, using regular Web browsers such as Internet Explorer or Netscape.

Findings and Conclusions
To reach the desired goal of discovering what incidental learning occurred in this course, the researcher asked questions and watched for behavior that addressed multiple issues both at the beginning of the course and the end of the semester. At the beginning, issues included reasons for taking the course, first thoughts and initial expectations of the course, the skills the student felt were necessary to complete the course, and the possible differences between skills needed for an online course and a traditional course. Other early-in-the-semester issues were time expectations, specific learning outcomes the student wanted to acquire in the course, and the students’ main concern about the course. At the end of the course, issues of importance to the students had been modified. Topics of discussion and concern included self-ranking for success, skills that helped the student achieve success, the main skill learned or gained during the semester, and skills that differed from the traditional courses. The researcher also asked questions concerning the type of “poster” each student was when working with the conferencing software. Students listed not what they wanted to learn but what they felt they had learned in the class. They also compared their initial thoughts and expectations of the course with what they actually encountered throughout the semester. Students were asked whether the course took more or less time than they expected and to describe their workplace. The thoughts of the students towards future online course work for themselves and towards the future of online learning in general were gathered.

The researcher found that two types of incidental learning occurred. The first developed from the students’ learning to use the technology itself. Accessing the Internet, learning to develop Internet search skills, working within an online course, and using the conferencing software fit in both the primary and incidental learning categories. While part of these activities can be classified as primary learning, the maneuvering and mechanical operation of the technology was not the prime objective of the course. Students learned how to conquer the conferencing software, how to post, how to use search engines and how to phrase words for a search frequently. Some learned the effective and proper use of bookmarking when working within the Internet environment. Others mastered word processing skills. Students learned how to cut and paste from one document to another, to save work frequently, and to use the spellchecker. This learning occurred as the student worked to acquire the primary learning to meet the goals and objectives of the course.

The researcher defines incidental learning as unplanned and unanticipated learning outcomes not identified as part of the formal curriculum that students obtain while participating in the class. If the strict definition is followed the outcomes in this first group of learning outcomes can be classified as incidental learning. The course is basically concerned with learning how to integrate technology into the classroom, not with learning how to master the technology.

Other learning outcomes more easily and obviously fit into the incidental learning classification. Students learned to learn in an isolated situation and learned more patience. Other personal skills were acquired by students. Students learned to procrastinate less; they grew in self-confidence and self-worth. An increase in self-discipline is mentioned frequently. The ability to adapt to non-traditional learning environments is an important learning outcome. Other task-oriented skills were learned that were not required by the syllabus for successful completion of the course. One student taught himself to use an authoring program because he felt it should be included in the syllabus, but it was not.

The researcher found that the strengthening of self-discipline and self-confidence was a direct result of these teachers taking and being successful in an online course. The value of being successful in a graduate level online course was stressed by several experienced teachers. They are often looking for something new and interesting. Online course work interested them and provided a challenge that could be achieved. Students in the online course exhibited an increase in self-knowledge, the development of self-confidence, and the belief that more new goals can be set and successfully accomplished. Their technological skills and understanding of their present and future world increased.

The issue of time management was important. Students frequently discussed personal growth in this area as the semester concluded. While they found the process stressful at times, the improvements made in the more appropriate management of time were a positive force.

The researcher supports Mealman’s (1993) assertion that students do not differentiate between incidental and intentional learning. Students do not make distinctions that would support the categorizing of learning outcomes into primary and incidental by the instructor or the institution. The two types of learning outcomes play equally important roles in the students’ overall experience.

Eight research questions guided the examination of learning in this asynchronous course. The responses to these questions were addressed as related to the findings of the study. The nature of the incidental learning has been previously reported. Novices rated themselves lower in terms of success than did experienced computer and Internet users. More novices failed to complete the course in the specified time allotted and had
to finish the coursework after an “incomplete” was given, but all did complete the course. Incidental learning outcomes were apparent for participants who were taking the ETEC 5710 course to foster their knowledge about technology, participants who were completing master’s and specialist’s degrees, and those who were obtaining additional certification or hours towards their master’s plus thirty classification. The degree program of the student appeared to make no impact on the amount or type of incidental learning acquired by the participant.

Students were evenly divided over the issue of actual time needed versus time they expected to need for successful completion of the course. Each group was proportionately divided between novices and experienced computer and Internet users. The researcher found no relationship between the amount of time expected or the amount of time taken by the participants and the amount and type of incidental learning that occurred within the course during the semester. The researcher found no evidence of a relationship between the frequency of conferencing postings and the amount and type of incidental learning acquired.

Finding a connection between motivation to participate in this online course and incidental learning proved difficult. Basically, all the students did well and acquired significant primary and incidental learning outcomes. All students were motivated by something; some were following a degree plan, some were impressed by the idea that they did not have to drive to the main campus, some were pleased the course tuition was being paid for through a grant, some just like to learn new material. The researcher found that motivating education graduate students was usually not a problem. Students who enrolled in this course were motivated, and they all learned. Some had problems with time allocation and some had mechanical/technical problems, but all persevered and completed the course satisfactorily. The researcher found that those who were motivated by an enthusiasm to learn more about technology ranked themselves as more successful in the course. They were able to circumvent the inevitable crises that technology often creates during the semester. Many of these participants expressed a strong increase in self-confidence upon completion of the course.

Participants reported an increased ability to manage time, a belief that more online coursework was possible and probable, a higher level of self-confidence and patience, and more effective self-discipline. Research, writing, and word processing skills improved. The students’ ability to use the Internet for online course work and researching improved. The few who did not rate themselves as successful learned more about their own learning styles and personality traits. Several said that a different type of online course might be more effective in acquiring primary and incidental learning outcomes.

**Discussion and Significance of the Study**

When this study began, I expected to find multiple examples of incidental learning occurring among all students in the graduate online class including development of Internet search skills, improvement of typing skills, and strengthening of research skills. I expected that these unintended consequences of a learning situation would be at least as important to the learner as the original objectives specified in the course syllabus. These expectations proved to be true, but I also learned that incidental learning is a complex issue, and its effects were important to the overall learning outcomes which were occurring within the course. An additional, unforeseen set of unexpected learning outcomes surfaced. Incidental learning affected the development and strengthening of several major personal attributes of many of the students. Students repeatedly reported an improvement in self-confidence and self-determination. Students who were at first intimidated by the prospect of a technology-based, online graduate-level class were amazed and thrilled that they had not only survived but usually had flourished. Many were fueled by a basic desire to learn something new. When they accomplished this goal, they felt good about themselves and continued to learn more about integration of technology into the classroom. Students who began with basic technology skills and an expectation to succeed did well and accomplished their goals. Students reported improvements in time management and organizational skills. I saw and heard excitement and enthusiasm in the voices, writings, and actions of adults. Such motivation is rare in a traditional classroom setting. This acquisition of enthusiasm through the attainment of learning outcomes fostered by incidental learning may be a key to successful lifelong learning for our educators. Perhaps the availability of online courses for educators may be a way to keep excitement in learning for all students.

The results of the study will be used to gain a more comprehensive understanding of the learning that occurs in a university-level graduate online course, to identify such experiences, and to related them to activities occurring within the framework of a particular course. The significance of this study goes beyond a particular online course. The data gathered, analyzed, and summarized in this study can be used to better understand the nature of online learning in general. Understanding the nature of the learning that is occurring in online courses
will allow higher education faculty and administrators to design courses and programs that produce higher student learning outcomes.

Historical and Current Attitudes Toward and Uses of Educational Technology

Chapter Two

Dr. Neva Ann Medcalf-Davenport, Associate Professor
Department of Education, St. Mary's University, One Camino Santa Maria, San Antonio, TX 78228-8533
Edneva@stmarytx.edu

Abstract: This is a final report on research conducted to determine the attitudes, beliefs, and preparation of in-service teachers, pre-service teachers, and student teachers regarding the uses and integration of technology into the classroom and curriculum. Data was collected in Elementary, Middle and High Schools in several school districts and at St. Mary's University in San Antonio, Texas. The results were compared with data gathered over seven years from pre-service teachers in the teacher certification program at the university and with research regarding national trends. The question was, "Are teachers feeling comfortable and confident in implementing and integrating the uses of technology in everyday classrooms?"

Background

The Council on Basic Education (1998) has said "(t)o be effective, technology certification for educators needs to be part of formal education policy and a required element of school and teacher evaluations. ...Educators need a system of technology training and certification." Research has found that teacher skill in using technology is a major factor in improving student learning with technology. Teachers must know not only how to use technology but also when and why to use it (Burke, 1998). Because of a national mandate by President Clinton in 1996 that every young person must be technologically literate by the 21st century, Texas adopted standards to assure the development of technologically literate individuals possessing the knowledge and the skills to solve problems, make decisions, and be lifelong learners in a society increasingly dependent on rapidly changing technologies. The Texas Essential Knowledge and Skills (TEKS) curriculum components adopted by the State Board of Education in 1997 consist of basic understandings, knowledge and skills, and performance objectives required of K-12 students. For the first time, standards had large sections devoted to technology of all types for all grade levels. Teachers are expected to integrate the TEKS into the curriculum during the current school year and will be held accountable for student performance on the Texas Assessment of Academic Skills (TAAS) to evaluate student achievement and qualify students for graduation from high school. According to the latest publication by Southern Regional Education Board (1998), Texas has adopted proficiencies to "plan, implement and assess instruction using technology and other resources" through adoption of The Learner-Centered Proficiencies for Teachers. The application of the standards means that the Texas State Board for Educator Certification with the Texas Education Agency is developing technology proficiency requirements for use in teacher licensing. Universities with teacher certification programs are watching this development carefully and working to stay abreast of the changes in licensure with changes in the program requirements for inservice teachers.

To meet the demands of both the Presidential mandate and the Texas Education Agency, teachers must be trained and be comfortable with the uses and integration of technology into the curriculum. If technology integration and use is to become a part of the classroom on a consistent basis, the training should happen while pre-service teachers are being educated. Pre-service teachers often are not exposed to the uses of any technology in the school classrooms as they observe and do field experience, so they do not understand the importance of training before they
enter the teaching work force. "We teach as we were taught, therefore, teachers rarely see examples of technological integration into the curriculum after which they can model their own teaching" (Davenport, 1995). University professors do not model the uses and integration of technology, so it is difficult for students to imagine the uses of such things as hypercard, multimedia presentations, and interactive video. Beaver (1990) stated that there is a void in the training of teacher education faculty and this void is passed on to their undergraduate students.

The Study

Three surveys were developed to ascertain the attitudes, beliefs, and preparation of in-service teachers, pre-service teachers, and student teachers. The sample population surveyed included: 1) all teacher certification students, elementary and secondary, enrolled in education courses. These were University juniors, seniors and post-baccalaureate students; 2) all student teachers enrolled in either Elementary or Secondary Classroom Management; 3) in-service elementary and secondary teachers in various school districts in San Antonio. The final results and analysis of the data from these surveys were compared with data gathered over the past seven years regarding the uses, integration, training and attitudes concerning the use of technology by pre-service teachers in the teacher certification program at St. Mary's University. A four-point scale was chosen to force respondents to either agree or disagree with each survey statement.

Findings

The findings were as follows:

<table>
<thead>
<tr>
<th>Comfort Level with the use of Common Technologies</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
</tr>
<tr>
<td>Transparency</td>
</tr>
<tr>
<td>Education Student</td>
</tr>
<tr>
<td>Student Teacher</td>
</tr>
<tr>
<td>In-Service Teacher</td>
</tr>
</tbody>
</table>

These Comfort Levels indicate that all parties felt confident in using the common technologies that many have in their own homes; namely, the VCR, tape recorder, and video camera. They also felt confident in the use of the
overhead projector with transparencies, the most common technology in classrooms. The levels of comfort were generally highest for those most experienced with the technology.

<table>
<thead>
<tr>
<th></th>
<th>Laser Disc</th>
<th>Computer Projection</th>
<th>Auxiliary Camera</th>
</tr>
</thead>
<tbody>
<tr>
<td>Education Student</td>
<td>22.6</td>
<td>3.2</td>
<td>13</td>
</tr>
<tr>
<td>Student Teacher</td>
<td>10</td>
<td>20.7</td>
<td>3.3</td>
</tr>
<tr>
<td>In-Service Teacher</td>
<td>25</td>
<td>25</td>
<td>5</td>
</tr>
</tbody>
</table>

The Comfort Levels with the use of the newer technologies, however, was sharply lower, with education students lowest, followed by student teachers and then in-service teachers. These technologies, laser disc, computer projection and an auxiliary camera are the technologies which enable teachers to integrate information from the web and laser discs into the curriculum. However, teachers have not been trained in the use of them and feel very uncomfortable trying to do so.

<table>
<thead>
<tr>
<th></th>
<th>Equipment Maintenance</th>
<th>Trouble Shooting</th>
</tr>
</thead>
<tbody>
<tr>
<td>Education Students</td>
<td>9.7</td>
<td>10</td>
</tr>
<tr>
<td>Student Teachers</td>
<td>7</td>
<td>6.9</td>
</tr>
<tr>
<td>In-Service Teachers</td>
<td>15</td>
<td>15</td>
</tr>
</tbody>
</table>
The lowest Comfort Levels were with equipment maintenance and trouble shooting. Teachers are often not willing to try to use technology in their lessons because of fear that the technology will not work and they will not know what to do about it or know how to make it work. Therefore, it is "safer" to teach with the tools they are familiar with and know they can rely on; namely, textbooks, chalk and chalkboard, overheads, and perhaps a video from time to time.

### Beliefs about Use of Technology for Education

<table>
<thead>
<tr>
<th></th>
<th>Help Students Learn</th>
<th>Efficient</th>
<th>Important in Schools</th>
</tr>
</thead>
<tbody>
<tr>
<td>Education Student</td>
<td>54.8</td>
<td>77.4</td>
<td>83.9</td>
</tr>
<tr>
<td>Student Teacher</td>
<td>76.7</td>
<td>89.7</td>
<td>70</td>
</tr>
<tr>
<td>In-Service Teacher</td>
<td>95</td>
<td>85</td>
<td>90</td>
</tr>
</tbody>
</table>

Overall, all subjects believe that technology for educational purposes helps students learn, makes students and teachers more efficient, and is important in schools. It seems that they want to be able to use the technology, integrate it into the curriculum, view it as an assistive learning tool, they just do not know how, feel uncomfortable with making sure it will work correctly, and have not been trained in the most current uses.

### Conclusions

If we are to truly effect change in the way teachers are teaching and have technology integrated into the curriculum, we must change the way teachers are trained in their preservice education. To affect this change, St. Mary's University has developed a new technology course for teacher certification students. It will be taught by computer department faculty with input from education department faculty and will stress advanced skills integrated in unit and lesson plans in the content areas. The progress of the university in providing technological support for students, professors, and support staff and the future plans for meeting this ever-changing frontier will be analyzed and compared with national trends to determine further necessary course development, content and training at the preservice level. Implications for further study and for training design will be examined.

INTEGRATING COMPUTER TECHNOLOGY IN CLASSROOMS: TEACHER CONCERNS WHEN IMPLEMENTING AN INTEGRATED LEARNING SYSTEM

Steven C. Mills, Ph.D.
Schiefelbusch Institute of Life Span Studies
University of Kansas
USA
stevem@ukans.edu

Abstract: Schools cannot expect to obtain gains in learner achievement from computer technology if it is not properly implemented. The concerns of teachers in integrating computer technology in the classroom may impact how computer technology is ultimately implemented. This study examined the concerns of elementary school teachers implementing computer-delivered instruction. The findings of the study support the position that teachers' concerns and perceptions of an ILS influence the way in which they implement an ILS.

Introduction

The usual expectation associated with the integration of computer technology into instruction is that it will enhance student learning while significantly reducing instructional costs (Green & Gilbert, 1995). Unfortunately, during the last decade the rapid deployment of computer technology in classrooms created several problems. For instance, it was not unusual for a school to install computers and educational software and learners begin to use the computer systems before anyone questioned the implementation of the technology. The problems associated with the implementation of computer technology were intensified when schools lacked adequate funding to train teachers in the appropriate implementation of this technology. The entire process by which computers and learners came together in schools was often "inefficient, poorly planned, and incredibly chaotic" (Maddux, Johnson, & Harlow, 1993, p. 220).

Implementation in schools is the placement of an innovation in the instructional process and is distinguishable from adoption because many innovations are adopted but never implemented (Bond, 1988). Fullan and Pomfret (1977) described implementation as a "phenomenon in its own right" (p. 336) and suggested implementation studies should measure the correspondence of actual use of an innovation with its intended use. Hord and Huling-Austin (1986) cautioned that implementation does not equal delivery of an innovation and that users of an innovation do not necessarily implement an innovation in the way it is intended to be used. Smith and Ragan (1993) advised that "in drawing the line of causation from the instruction to the results, it is critical to be able to identify the degree to which the description of the program represents what actually occurred during instruction with the new program" (p. 416).

The process of educational change and innovation that results from technology integration in classrooms is extremely complex. To deal with this complexity, educational change models often attempt to assess and explain the change process in terms of dimensions or degrees of change. For instance, researchers at the Apple Classroom of Tomorrow (ACOT) project observed distinguishable changes in classrooms in technology-rich schools and regarded instructional changes in ACOT classrooms as an evolutionary process in which teachers moved from concerns about technology to the development of powerful learning experiences for their students (Dwyer, Ringstaff, & Sandholtz, 1991).

Implementation is often difficult and complex due to the variety of curricular programs, computer platforms, and educational populations served by various courseware products. Consequently, schools cannot expect to experience gains in learner achievement and motivation from computer technology if it is not properly implemented. One type of computer-delivered instruction that accounts for a significant share of the educational software market is integrated learning systems (ILSs). ILSs are computer-delivered instruction packaged as comprehensive software systems operating on networked hardware platforms. ILSs provide a
multi-year curriculum sequence of instruction that is controlled by a management system enabling teachers to assign lesson sequences, monitor learner performance, and generate learner progress reports. (Mills, 1994). ILS appeal seems to be based on the fact that ILSs offer a comprehensive one-stop solution to instructional computing (Robertson, Stephens & Company, 1993). By some estimates, ILSs account for nearly 50% of total educational software purchases (Bailey, 1993).

Several researchers postulated that the way in which users of an innovation perceived the innovation was fundamental to their level of use of the innovation (Fullan & Pomeret, 1977; Hughes & Keith, 1980; Kimpston, 1985). Hughes and Keith reported that an innovation as perceived by the potential user of the innovation and not the innovation itself was the critical variable in explaining the degree of implementation of an innovation. Kimpston reported that "teachers' beliefs and practices about the importance of and participation and involvement in curriculum implementation tasks were more pronounced for teachers who were most closely attending to the curriculum prescribed by the district" (p. 195). Hall, Wallace, and Dossett (1973) postulated that the concerns or attitudes individuals had about a change was an important dimension in the change process.

The role of the teacher in ILS implementation is particularly important because much of the decision-making about how the technology is used is often the responsibility of the individual teacher. In fact, teachers have considerable discretion in determining whether an ILS is even used or not in accomplishing educational goals. The concerns or attitudes that teachers have about the use of an ILS and computer technology in the classroom are fundamental elements in the educational change process and may impact how the technology is ultimately implemented. This study examined the concerns of elementary school teachers implementing ILS technology.

Stages of Concern

Hall, George, and Rutherford (1986) described the concept of concerns about innovations as an aroused state of personal feelings and thought about a particular issue or task and determined that certain demands of an innovation were perceived as being more important than others. Therefore, the type of concern and the degree of intensity about an innovation will vary on the depth of one’s knowledge and experience using an innovation.

Stages of concern described how users perceived an innovation from the time they first became aware of it until they gained mastery of the innovation (Hall & Loucks, 1978). Users were initially concerned about how an innovation affected them personally and later became concerned with how the innovation impacted their work environment. A Stages of Concern Questionnaire (SoCQ) was developed from the original conceptualizations provided by Hall et al. (1973). Seven stages of concerns that users or potential users of an innovation had were identified (see Table 1). These stages of concern were distinctive but were not necessarily mutually exclusive (Hord, Rutherford, Huling-Austin, & Hall, 1987). The seven stages varied in intensity and, consequently, characterized the developmental nature of individual concerns.

Table 1: Stages of Concern about an Innovation (Hord et al., 1987)
The developmental nature of concerns was reflected by grouping the stages into three dimensions: Self, Task, and Impact (Hord et al., 1987). In the early stages of a change effort individuals were more likely to have personal concerns with the change while in the latter stages of usage of an innovation concerns about the task and the impact of the innovation on users became more intense. An individual was likely to have some concerns at all stages. According to Hall et al. (1986) subjects moved from unawareness and nonuse of an innovation into a more highly sophisticated use. Therefore, the intensity of concern was initially high in Stages 0, 1, and 2 and ultimately high in Stages 4, 5, and 6. To interpret the SoCQ, an overall view of the relative intensity of different stages of concern is developed to profile the intensity of the types of concerns among the respondents.

The SoCQ was developed and validated to provide a quick-scoring measure of stages of concern and is applicable to almost any educational innovation. The SoCQ focuses on the concerns of individuals involved in change. In an educational setting teachers are often the focus of change and innovation and so this instrument is generally used by teachers. For this study the SoCQ was adapted to measure the level of concerns of teachers implementing an ILS.

The instrument consists of 35 items that teachers rate using an eight point Likert scale. Percentile tables allow for converting raw scale scores. Percentile scores reflect the relative intensity of concerns by the user of an innovation in a particular stage. Interpretation of the SoCQ is performed by the examination of percentile scores for peak stages, second highest stage, and high stage for groups or individuals (Hall et al., 1986). To substantiate the internal consistency and reliability of the SoCQ for this study, a pilot study of 33 elementary school teachers from five elementary schools implementing an ILS completed the SoCQ. Total test reliability and item-total reliabilities were computed for each of the seven stages of concern scales. The pilot test yielded a coefficient alpha of .90 for the total scale and item-total reliability coefficients for Stages 1-6 were high (p < .01) while Stage 0 yielded a reasonably high item-total reliability coefficient (p < .05).

**Method**

To collect data for this study, the SoCQ was administered to all ILS-using teachers in four elementary schools in an urban school district implementing an ILS. Of the 93 teachers in the four elementary schools who were handed a questionnaire, 65 completed and returned the SoCQ for an overall return rate of 71%. Reliability coefficients were computed for each of the seven stages of the SoCQ employing a two-tailed test. The 35-item questionnaire yielded high reliability coefficients for all stages (p < .01).

To analyze the SoCQ, data item responses were grouped and summed according to each of the seven stages of concern. Raw scores were converted to percentile scores for each of the stages and response patterns were examined as high and second high stages of concern. Both the second high stage score and the peak stage score were evaluated. Overall, highest levels were at Stage 0 and second highest at Stage 1. Although there was an overall high response tendency among all the stage scores, high Stage 0 scores may indicate either an unconcern about the innovation or users who are more concerned about things not related to the innovation (Hall et al., 1986). Tables 2 and 3 provide matrices of the frequency and proportion of the high and second high stages of concern scores.

### Table 3: Proportion of Highest and Second Highest Stages of Concern, n=65

**Stages of Concern Profiles**

When scores were considered and viewed by individual school, trends were more obvious and easily interpreted. Therefore, a profile for each school was formulated. These profiles include charting the SoCQ cumulative scores compared to the mean overall trend (see Figure 1).

**Figure 1: Stages of Concern Cumulative Scores by School and All Schools**

**West Elementary.** A high Stage 0 — *Awareness* indicated established users who were no longer particularly concerned about the innovation (the ILS) or users who were more concerned about things not related to the innovation. The second peak at Stage 3 — *Management* suggested that teachers had logistics, time, and management concerns. The tailing-up on Stage 6 — *Refocusing* suggested that teachers had ideas about how to improve the use of the ILS. There appeared to be a progression from self concerns (Stages 0, 1, 2) to task concerns (Stage 3). Task concerns are typically more intense during the early period of use of an innovation (Hall et al., 1986).

**North Elementary.** The SoCQ profile for North Elementary suggested a general awareness and concern about the innovation and an interest in learning more about the innovation (Stage 1 slightly higher than Stage 2). Although a high Stage 0 — *Awareness* indicated established users who were no longer particularly concerned about the ILS or were more concerned about things not related to the innovation, a second high Stage 1 — *Informational* suggested that teachers wanted more information about the ILS. With the absence of peaking at Stage 3 — *Management*, there was no clear indication of progression from self to task concerns. Low Stage 4 — *Consequence* and Stage 5 — *Collaboration* suggested some lack of concern about consequences for learners. The tailing-off at Stage 6 — *Refocusing* revealed no other ideas were competitive with the use of the ILS.
South Elementary. The profile for South Elementary resembled the profile of West Elementary except at higher levels of stage scores. A high Stage 0 indicated established users who were no longer particularly concerned about the ILS or users who were more concerned about things not related to the ILS. The second peak at Stage 3—Management suggested that teachers were transitioning to logistics, time, and management concerns and clearly indicated a progression from self concerns (Stages 0, 1, 2) to task concerns (Stage 3). The distinct tailing-up on Stage 6—Refocusing indicated that teachers had ideas about how to improve ILS use.

East Elementary. The SoCQ profile for East Elementary suggested a slightly different spin on the interpretation than that of the other schools due to modest differences in the response pattern. Although a high Stage 0—Awareness indicated established users who were no longer particularly concerned about the ILS or were more concerned about things not related to the innovation, Stage 2—Personal concerns were equal to or more intense than Stage 1—Informational, which suggested users were concerned more about how they were affected personally by the innovation than in learning about the substantive nature of the innovation (Hall et al., 1986). The peaking at Stage 2—Personal also suggested that teachers had personal concerns and consequences for themselves. The distinct tailing-up on Stage 6—Refocusing clearly indicated that teachers had ideas about how to improve the use of the ILS.

There appeared to be some progression from self concerns (Stages 0, 1, 2) to concerns about the impact of the ILS on learners (Stage 4) based on the peaking that occurred at Stage 4. The difference in the concerns pattern for East Elementary compared to the overall pattern of concerns for all four schools, particularly in regard to Stage 4—Consequence concerns, were due, in part, to the fact that this school (both principal and teachers) had been implementing the ILS for a longer period of time than the other schools.

Although the frequencies of highest stage of concern levels were at Stage 0 and second highest at Stage 1, the overall trend for the SoCQ seemed to indicate a slight peaking of concerns at Stage 3—Management and then a distinct peaking at Stage 6—Refocusing. This pattern would seem to suggest an implementation where, on average, concerns for the innovation were evolving from a dimension of self concerns to a dimension of task concerns. Additionally, the tailing up at Stage 6 supported the notion that the average implementer had ideas about how to change or improve the innovation.

Discussion of the Data Analysis

The developmental nature of individual concerns about the ILS was apparent in both the overall profile, the school profiles, and the individual profiles of the stages of concern. Three of the schools in the study (West, North, and South) had been implementing an ILS for a little less than two years and the fourth school (East) had been implementing an ILS for a little less than three years. This distinction in the length of the implementation period between East and the other three schools was reflected by a progression to a higher level of concerns of East teachers on how the ILS impacts learners.

The teachers in this study most often expressed awareness, informational, or personal concerns. These teachers wanted to know more about an ILS—what an ILS is and how using it affects them. These expressions of concern were typical of a nonuser or inexperienced user. The peaking on Management concerns indicated some movement along the concerns continuum from self concerns to task concerns. According to Hord et al. (1987), Management concerns become more intense during the early period of use of an innovation. The peaking at Stage 4—Consequence concerns by teachers at East Elementary who had been implementing the ILS for a year longer than the other teachers in the study indicated that these teachers were just beginning to be concerned about the impact of the ILS on learners using the ILS.

Regardless of the level of concern about the ILS, most users had refocusing concerns—ideas about improving the ILS that would make it work better. This phenomenon is more indicative of experienced users of an innovation who have used the innovation with efficiency for some time and are concerned with finding better ways to impact learners. One explanation for this phenomenon in this study may be a lack of a basic understanding or knowledge about the ILS that may have been the result of a lack of sufficient training. Rogers (1983) suggested several reasons for re-invention of an innovation that may apply to these findings: (1) the complexity of the innovation, (2) a lack of detailed knowledge about the innovation, (3) an innovation with many possible applications, and (4) an innovation that is implemented to solve a wide range of problems.

The findings of the study support the position that teachers’ concerns and perceptions of an ILS influence the way in which they implement an ILS. Implementation of an ILS doesn’t happen by itself. ILS implementation is a complex and prolonged process that must be nurtured and sustained. The concerns of users of an ILS change and reformulate over time to reflect a relative intensity that corresponds with the users' level
of experience using an ILS. The reality of organizational change and innovation in schools is its contingency on social conditions and human interactions more than on technological feasibility or cost-benefit (Jaffee, 1998). For schools to experience significant change or reform due to the integration of computer technology in classrooms, the existing instructional concerns and practices of teachers must be carefully considered. Furthermore, the integration of computer technology must be approved, accepted, and implemented by teachers for computer technology to ultimately impact student learning while reducing instructional costs.

Abstract: Drawing upon a Constructivist design, in particular, Cennamo's Layers of Negotiation Model, which emphasizes reflection, articulation, and exploration, The Roundtable hopes to help graduate students help themselves in developing the skills necessary to become accomplished, successful journal writers and conference presenters. In learning good research methods, members navigate their way through the multitude of journals available for publication, learn to write to their intended audience, and finally, face the expectation of regular submissions of journal manuscripts and conference proposals.

Graduate students hear it all the time, "That would make a good article. Why don't you research that and write it up?" For experienced faculty members and researchers, this comment is no big deal. They can often turn out article after article without giving the process a second thought. But, for many graduate students, this may be their first exposure to a lifelong expectation – publish or perish. How do you publish if you’ve never done it, and don’t know how?

Asking themselves this question, doctoral students in the Instructional Technology program at Iowa State University decided to try to rectify the situation. Meeting for a brainstorming session in Feb. 1998, they agreed that the best way to tackle the problem would be through a peer support group.

The Design Process

The initial task was to accept and explore the overall complexity of designing such an entity. Interested members began by outlining what they thought the group should and shouldn’t do. Since no one in the program had experience with such a group, there was no prior knowledge to draw from, the members had a blank slate upon which to do their design.
Meeting both formally and informally, the group began to take shape. Adhering to Constructivist principles, and following Cennamo's Layers of Negotiation model of design, provided structure and guidance as members outlined what each envisioned the group becoming. Members met both formally and informally as they agreed to certain principles.

Hierarchy

First, it was agreed that the group would have no formal hierarchy of "command". Since all the members were graduate students of more or less equal standing, a formal hierarchy made no sense. Instead, group members agreed that members of the group should, at varying times, each be responsible for leading the discussion, providing information to other group members, or otherwise directing the group's activities. For example, one week Student A may be responsible for providing a mini-lesson on developing Internet search skills. The following week, Student B may be responsible for providing a cheat sheet on editing marks.

It was essential that the membership acknowledge that peer constituents possessed information worthy of their time and effort. Each member offers a different piece of the puzzle, and has an equal say in the progression of the group as a whole. This is exhibited week after week, as members offer suggestions for changing the agenda for the either the current week, or for coming weeks.

Similar Groups

As members continued to define what their group should be, they began searching the literature for other groups of similar nature. A group at the Washington University, the PhD Student Writers Group, was of particular interest (Page-Adams, Cheng, Gogineni, & Shen, 1995).

The Washington University group began with six doctoral students in the fall of 1992. Of those students, four submitted or published at least one paper. Group members wrote, submitted or published a total of 19 papers during their first year. As a comparison, non-group doctoral students in the same program, produced a total of five papers during the same time period (Page-Adams et al., 1995).

Reflection

Building upon this foundation, Roundtable members began to set goals for themselves. At this point, step 3, Examine information relevant to the design of the instruction at multiple times from multiple perspectives, and step 4, Nurture reflexivity in the design process, proved of extreme value (Cennamo, Abell, & Chung, 1996). Members found that in order for the group to succeed, it would be necessary to look at the questions, concerns and desires of each member from several different points of view. Was a request to learn Internet searching skills really a request to learn searching skills, or was it really a request to look at the expansion and exploration of a research idea in its early stages. By taking on and examining different points of view, members began to understand that the question raised on the surface rarely reflected what was happening deep within the other person's mind.

Reflection was a natural element of the group's progression. By constantly examining and adjusting the group's ability to match each individual's needs, it was easier to continue to hone in on those individual needs. Since graduate students are notoriously short on time, members found it very effective and helpful to begin each session by evaluating what worked in the last meeting and what didn't work. This became a natural part of the meetings, and of the continual design process.

Meeting Goals
As members continued to define and shape the group, the calendar indicated that the first set of deadlines was quickly approaching. Members had set for their first goal that each member would submit a minimum of one conference proposal for the spring conference "season". It was time to put the group to its first test.

Each member was told to select at least one research idea and one conference appropriate for presentation of that idea. Members then began meeting two and three times a week, encouraging, supporting and coaching each other through the submission process. This presentation and the accompanying conference proposal and paper are all a result of this group process. While each member is responsible for developing individual publications and proposals, this particular presentation represents the ability of the Constructivist design and learning process to succeed.

The group effort proved successful. Each member had at least one proposal accepted for at least one conference. Some members had multiple proposals accepted for multiple conferences. All group members reported that they felt their success was due, in part, to the advice, guidance and support they received from other Roundtable members.

Expanding the Group

Once the initial goals of the group had been met, Roundtable members decided it was in the best interest both of the individual members and of the group as a whole, if membership were expanded to include any interested graduate student or faculty member in the Instructional Technology department. Opening the membership garnered three additional members, one doctoral student, one masters student and one faculty member.

This expansion of membership proved invaluable for the group and its membership. Upon the initial announcements that the group was soliciting new members, several individuals expressed an interest in membership. However, upon further reflection, many of these people felt that they were not ready, or did not require the support, of a group with such intense expectations and goals.

Members used this "rejection" as a means of further defining the goals and expectations for the Roundtable. Were the expectations too high? Were the goals too lofty? Members reflected on this, and other issues which had been raised. It was determined that those members who had chosen to participate had chosen to do so specifically because of the high expectations of members. While the group does continue to include a masters student, it was decided that this type of group might not appeal, or be of benefit to, the "average" masters student. The goals and expectations of the Roundtable relate to helping doctoral students develop into competent, polished professionals capable of submitting publishable articles and conference proposals.

Conclusion

Members of the Roundtable continue to meet and refine the group on a weekly basis. Refinement may consist of something as simple as a suggestion, "I think we should...." Or, it may involve a request for a larger change in the structure or organization of the group. Members continue to adhere to basic Constructivist principles and to Cennamo's design model. While it would be comforting to declare the design of the group as "complete" or "right" within the Constructivist frame-work that isn't possible. This group will always be a work in progress. The recursion in the design process is infinite. Clients are able to "refine their needs as the project evolved, to clarify needs as additional data became available, and to constantly be involved in the decisions at each stage in the design negotiation process." (Cennamo et al., 1996) While we will never be able to truly measure the worth of such a group, the results will speak for themselves as members develop basic professional competencies, which will enable them to compete and survive in the publish or perish world of academia.

Abstract: Computers are everywhere. However, when we compare the typical school environment to the business environment, it is noticed that schools have lagged far behind in implementing the use of computers. The results of implementation of computers in teaching and learning are apparently not as glorious as educators and researchers expected. Then, what classroom teachers believe today? What should we be aware of the implementation of computer technology in pre-service teachers training? Presenters randomly selected more than 57 pre-service and in-service teachers to talk about the computer technology in the classrooms. Based on teachers' perspectives, presenters found that some classrooms are still lacking of computers, which is definitely blocking the way of implementation of computer technology in the classroom instruction and learning. Presenters also realize that there is a difference between pre-service and in-service teachers' perspectives on how to use computers in the classroom settings. In this paper, presenters summarize teachers' perspectives, discuss the implementation of computer technology in instruction, and provide insight views of pre-service teachers training.

Computer technology is believed as a uniquely effective tool to revolutionize teaching and learning. It is so flexible that it can be applied to an almost unlimited variety of across subject disciplines and across an array of human endeavors (Maddux, Johnson, and Wills, 1997). Computers are everywhere. According to the national survey report, 100% schools own computers and the ratio of computer to students has become 9:1 in the United States (Electronic Learning, 1993; Office of Technology Assessment, 1995). Abrams (1996) believes that there will have about 30 million CD-ROM drives sold by the year of 1999, and at least 2,000 CD-ROM, videodisc packages will be titled for education. To face the challenge of computer technology, the Education Department has projected that all children in the United States will have access to Internet in their classrooms by the year 2000.

However, when comparing the typical school environment to the business environment, researchers notice that schools have lagged far behind in implementing the use of computers. Although computers become very common in the schools today, the incredible growth of the computer presence in the United States takes place dramatically in the business world (Maddux, Johnson, and Wills, 1997). The results of implementation of computers in teaching and learning are apparently not as glorious as educators and researchers expected. Then, at the time close to the end of the 20th century, what is the reality in schools? What pre-service as well as in-service teachers believe in the computer technology? What should we be aware of the use of computer technology in the classrooms, more specifically, in teacher education for the 21st century?
Eighteen pre-service teachers and eighteen in-service teachers at Kennesaw State University, GA, and twenty-one pre-service teachers at Bemidji State University, MN were randomly selected to participate in presenters' survey. Pre-service teachers were in their senior year's teaching methods classes. In-service teachers were graduate students in their education technology class. The survey include four short essay questions: 1) What kind of computer technology in available in your classroom or in the classroom you have observed? 2) If you have a computer in your classroom, what can you do with this computer to improve your teaching and students' learning? 3) If you have 3-5 computers in your classroom, what can you do with these computers to improve your teaching and students' learning? 4) If you can have a computer lab to use, what can you do with the lab setting to improve your teaching and students' learning? In-service teachers were also asked to talk about their computer technology implementation plans in their own instruction.

**Computer facility in the classroom**

The first survey question is: What kind of computer technology in available in your classroom or in the classroom you have observed? Teachers' responses to this question showed us an interesting picture. The responses are simple but the numbers of computers in the classrooms are varying from zero to six. Presenters found that the majority of schools at least have one computer in their classrooms. Some of classrooms, particularly, the classrooms in GA, have five or six computers. However, several teachers responded that they only have Apple II e or MAC II c computers in their classrooms. 11 out of 57 teachers answered that there is no computer in the classroom at all, although computers are available in the schools media centers or computer labs.

Computers are indeed everywhere. One hundred percent of schools have computers. Based on the results of survey, presenters found that the numbers and qualities of computers in the classroom are unbalanced. Although the ratio of students to the computers has dropped to 9:1 in the past years, nearly 19% classrooms have no computers. Although Pentium II, Power Mac, and more advanced multimedia computers have become very common, some of the classrooms still depend on their old Apple He, Mac IIc machines. It is no doubt that lacking of appropriate computer facilities in the classroom will block the way of implementation of computer technology in teaching and learning.

The implementation of one computer in the classroom

The second survey question assumes that there is a computer in the classroom. This question is: If you have a computer in your classroom, what can you do with this computer to improve your teaching and students' learning? Pre-service teachers responded that the computer can be used for learning word processing and keyboarding, for rewarding students who finish the assignments earlier, and for providing tests on computer. They also stated that it could be used to run software at different disciplines, to access Internet, and to make presentations with HyperStudio or PowerPoint. Besides, the answers were scattered from using computer for the enhancement of learning to using computers for instruction, unit and lesson planning, and grading. The interesting issue is that there were four out of 39 answers indicated having no idea of how this computer to be used in the classroom.

When asked the question of implementing one computer in the classroom, in-service teachers responded that one computer could be as a center for students based on a schedule table. Software such as Tom Snyder Rainforest Researchers, Accelerated Reading, Word Munches, Grolier's Encyclopedia, Magic School Bus Visits the Solar System were listed for the center use. Add-on story writing and editing activities were recommended. On the other hand, many of in-service teachers suggested that one computer in the classroom be used by the teacher only. Teacher can use the computer to write letters to parents, prepare lessons, design the instruction, create instructional materials, handouts, worksheets with word processing package, to keeping students' grading with spreadsheets, assess to e-mail for communication etc.

There obviously exists a difference between the responses from pre-service and in-service teachers. Pre-service teachers talked about the use of one computer in the classroom more generally, while in-service teachers had more specific and detail implementation ideas.

The implementation of 3-5 computers in the classroom

The third survey question is hypothetically dealing with an environment of 3-5 computers in the classroom. How are these computers can be implemented in teaching and learning? Pre-service teachers agreed that the computers can be implemented in center activities, be used for tutorial learning, and be connected to Internet for research. Other than that, computers can be used for students' daily free time.
There did have three responses related to subject matters. Those responses suggested to have computers be used as a language arts/math station, and be connected to daily teaching subjects, so that students can work at the station by turns, and reinforce their learning on an individual basis. However, there is no clear vision of the implementations of 3-5 computers in the classroom.

Comparing with pre-service teachers' answers, in-service teachers answered questions more realistically. In-service teachers believed that 3-5 computers in the classroom can be used for students' group activities in a rotating manner. Group of students can work on writers' workshop, compose newsletters, and conduct research on the Web. They can practice budget planning with spreadsheets, compile data with database, and work on group presentation together. With 3-5 computers in the classroom, teachers can design various activities for reinforcement of subject teaching and learning, such as letting students work in group to create presentations with Power Point, or Hyper Studio based on the unit/chapter learning.

The implementation of computer lab settings

Nearly every school has at least a computer lab, although some of the labs are not up-dated with newly developed computers and other facilities. With a computer lab setting, a teacher's implementation approach will certainly be different with one-computer or 3-5 computers setting in the classroom. Pre-service teachers' responses included: hands-on learning, whole class activities, writing stories or papers, working on software, learning programming, conducting research, having individual learning, learning about computer and word processing skills. There were also two opposites in the responses. The two answers were very general. One indicated that the computer lab could do "a lot." On the other hand, one expressed "not sure" of how to use computer lab environment for teaching and learning.

With a computer lab setting, in-service teachers' responses implied that whole class could work on a same program, such as reading or math series program at individual's learning pace. Students could have e-mail pals to facilitate multi-cultural learning, practice writing and publishing on computers, and learn how to operate computers, handle diskettes, and work with some available packages, such as KidsPix, ClarisWorks, HyperStudio, etc.

Both pre-service teachers and in-service teachers suggested that the computer lab setting is good for every student to have hands-on learning, particularly to have basic computer skills training. Should we have the curriculum taught in the classroom aligned with the facilities, both hardware and software packages, in the computer labs? Should we have students' learning activities more connected to the classroom teaching? And how can we strategically and pedagogically use computer lab setting to improve teaching and learning? The presenters did not find any related information in the teachers' responses.

In-service teachers' implementation plans

In-service teachers have their own classrooms, and were taking educational technology class at the time the survey was conducted. Therefore, the presenters asked them to talk about their implementation plans in the coming semester. The majority of in-service teachers showed their excitements of implementing computer technology into their teaching and students' learning. Most of them planned to apply their training in the technology class to their instructions in the classroom. The implementation of computer technology becomes more teaching subject related, more curriculum oriented. Here are selected examples of partial responses for sharing.

[Talking about one computer in the classroom] I have two old Apple II E computers in my classroom. I was told that I would be receiving a new multi media computer center. I hope to be able to do some of the same things that we did in here [in the education technology class]. I would use the new computer as an incentive for the students in my class. When their work was complete, they would earn points which would be transferred to computer minutes. Three students would be assigned to the computer at a time. Hopefully when the school year begins I will have a brand new multimedia station which combines a computer, monitor, printer and laser disc together. I will use this system to develop lesson plans, PowerPoint presentations, and outlines of class lectures and discussions, generate tests and keep class grades. My students will be able to use the station to make PowerPoint presentation for class projects.
[With a few computers in the classroom] I plan having the students create a HyperStudio project on volcanoes. For this first project since many of my students may have not done HyperStudio before, I plan to create a template that they just have to fill out. I also will have the template and a picture file loaded on the server.

I plan to use the web page I created in class weekly in my classroom. I have an "author of the week" and I plan to visit the page to share about the authors with my children.

I also plan to keep my lesson plans on the computer so that in coming years I can go back and easily revise them for coming years. I am planning to use the computers to allow the students to type papers, create spreadsheets relating to our class, and present presentations using multimedia software such as power point. I have learned a lot this quarter [semester], and I can not wait to share this new knowledge with my students. I am very excited about using the spreadsheet and database programs for all kinds of things in my classroom. My teacher plan book will be beautiful, yet functional. I also plan to have my students do a biweekly newsletter to send home to parents. And certainly I will communicate more with parents using the database to send them personal letters about their child. I hope to be able to do slide presentations with Clarisworks for various thematic units as well. In addition I will have them do research and sorting tasks with various databases. I am excited!

[With computer lab settings] I am planning to use the computers in the computer lab to do various writing assignments throughout the year. We will use it to create a database of books and authors we have read, including a rating of the book, a comment, a brief [1-2 sentences] summary, and whether it is an Accelerated Reader selection. We have this program at our school. This database would help students when they are choosing a book to read for their reading parallel credits. I would also like to incorporate Power Point presentations at various times as well as use the links that we put together last week so that students can go to the sites during our research paper on a writer.

Pre-service and in-service teachers' concerns have made us to rethink the integration of computer technology. First of all, computer facilities are the material basis of implementation computer technology in the classroom. Lacking of good quality computers, the implementation would be fruitless. Both classroom setting and lab setting are necessary to quicken the pace of implementation of computer technology in instruction and learning. One computer in the classroom is not enough but it is better than nothing. Teacher can use the computer for presentation, lesson planning, and instructional material designing. Three to five computers in the classroom are appropriate, so that teacher can have his or her own computer and students have theirs. Students can work at computers by groups or pairs. Meanwhile, the lab setting should and must be scheduled for individuals' hands-on learning and practice.

Second, it is also more important, teacher education program should include strategic and pedagogical computer technology training components. If the computer facilities are considered as a material basis of implementation, pre-service and in-service teachers' technology training are viewed as an intellectual foundation of implementation. Unless teachers know how to use the computers and what computers can be used for instruction and learning, they can take the advantages of computer technology and avoid its limitations, and integrate the computer technology into classroom teaching and learning.

The third area is the ways of training. Comparing pre-service and in-service teachers' responses to the survey questions, we can easily see the differences. One is oriented to respond in general terms of use computer technology, the other is tended to answer question with more specific and practical on the implementation plans. Presenters believe that teacher education program must be able to provide pre-service and in-service teachers with required and meaningful technology training. It is suggested that pre-service teachers' technology training can be integrated into service learning, let curriculum teaching and work experience make the training become more meaningful.

Finally, computer technology itself has nothing wrong. It is believed that education can profit from the computing in the classrooms. Still, there is no such thing as a free lunch. Computer technology has its advantages, it does have limitations in the classroom, it is a tool, like any other tools, it can be poorly or misused. How effective this tool can be used, depends on the tool user; how competent the tool
users can be, depends on the user's trainer. As far as prevention and invention strategies for problem domain computers bring into the classroom are concerned, prevention strategy is more important and essential in pre-service teachers training.

Introduction. The purpose of this study was to investigate the attitudinal changes toward technology as a result of the National Science Foundation/Northeast Louisiana University Teacher Enhancement Program (NSF/NLU TEP), which was funded in 1995 (Eaton, 1995). The attitudinal differences addressed within this study are in the areas of what is known as the New Information Technologies (NIT) - multimedia, electronic mail (e-mail) and the World Wide Web (WWW). In addition, other NIT areas such as the use of information technology to improve teacher productivity and an overall general feeling about technology were included in the study.

The Survey. Christensen and Knezek (1998), Teacher’s Attitudes Toward Information Technology Questionnaire (TAT 1.1) was used to collect quantitative data from selected K-12 schools in the Monroe City School (MCSS) and Ouachita Parish School (OPSS) systems. These schools were selected because they have successfully implemented a technology plan that provided Internet access for the chosen NSF/NLU TEP participants to utilize in their classroom training. Data was gathered for ten separate indices from the respondents. Zaichkowsky (1985) Modified Personal Involvement Inventory, a context free, sixteen- item semantic differential scale that focuses on Aa person’s perceived relevance of the object based on inherent needs, values and interest= was modified to construct eight of the ten subscales used by the TAT (1.1) questionnaire. The other two subscales included instruments for comparative purposes: 1) Kay’s semantic perception of computers (Kay, 1993) and 2) D’Souza’s (1992) classroom via e-mail.

Approximately 400 questionnaires were delivered to the faculty of the MCSS and OPSS systems. Of these, 169 were returned for a return rate of 42 percent. The distribution of the returned questionnaires is given in Table 1.

The gender dichotomy represented 36 males and 133 females.

Table 2 summarizes the type of training received and the number of respondents by system. As can be seen from this table, the TEP trained respondents represented 62 percent of the sample and were fairly balanced between the two systems. Fifty-two percent of the TEP trained teachers were employed by MCSS and 48 percent of the TEP trained teachers were employed by OPSS. This was not the case for the respondents who have training from other sources. Of the 65 respondents, 72 percent were from MCSS and 28 percent from OPSS. This discrepancy could be reflective of the level of commitment of the two systems.

In summary, 169 respondents returned the questionnaire for this research. Of the 169 questionnaires, 38 of the respondents omitted one or more of the subscales leaving 131 completed questionnaires. The two systems were adequately represented in both gender, level, and training received. The data collected exhibited an internal consistency reliability.

Overall Comparison of School Systems. As can be seen from Table 4 several significant effects are noted. The analysis indicated that differences between the two school systems and the training techniques exist for several of the attitudinal characteristics being investigated. The findings of this study indicated that MCSS teachers have a more positive attitude than their colleagues in the Ouachita Parish School system in 9 of the 12 categories studied. In addition to the differences between the two systems, the study also indicated that TEP trained teachers from OPSS have a more positive attitude than their counterparts within the same system in 5 of the 12 categories studied.

Significance Level: 0.05

Unless otherwise stated TEP > Other and MCSS > OPSS for all significant cells.

Note: S Significant
     N Non-significant

As can be seen from this Table 4 (Contrast-1), MCSS teachers exhibited a significantly more positive attitude than their colleagues in OPSS when considering the two latent variables (Factor 1 and Factor 2) and the NIT subclasses of F1, F3, F4, F5, F7, F9 and F10. These findings indicated that MCSS teachers have a more positive attitude about the impacts of e-mail, multimedia, the WWW and computers in general than their OPSS counterparts. Furthermore, MCSS teacher exhibited a more positive attitude about the relationship between computers and their productivity and about using e-mail in the classroom. In addition to these findings, the MCSS teachers have a better perception about the attitudes of their students as it relates to the use of multimedia. The significance of the two latent variables Factor 1 (the general technology appreciation factor) and Factor 2 (the general e-mail appreciation factor) reinforces the
When considering the effect of Training (Contrast-3), TEP trained teachers in OPSS have a more positive attitude about technology than their Non-TEP trained counterparts. In particular, the TEP trained teachers exhibited a significantly better attitude than the Non-TEP trained teachers for the latent variable Factor 1 and the NIT subclasses of F3, F5, F6 and F10. The latent variable Factor 2 and the NIT subclasses relating to e-mail (F1, F2 and F9) did not exhibit any discernible differences between the two training groups. The lack of discernible effects for the e-mail categories indicates that the training received did not affect attitudes about e-mail.

Training in MCSS (Contrast-2) did not produce any significant effects for the 12 categories under investigation. The lack of significance within the Monroe City Schools could be in part related to the type of training that the teachers received in the Non-TEP group. MCSS has been involved in technology training since 1991. In 1992 and 1993 several groups of MCSS teachers received training under the guidance of the staff of the TEP. The success of this program provided the foundation for the proposal that was submitted to and funded by the NSF. Thus, the non-significant effects observed with training in MCSS could be interpreted as an effect, which measures the effectiveness of the TEP. That is, the training of teachers by the TEP participants is as good as the training of teachers by the staff of the TEP.

In summary, TEP-trained teachers in OPSS have a more positive attitude than the Non-TEP trained teachers in OPSS when considering technology in general, multimedia as it relates to them, productivity as it relates to them and their students, and computers in general. These effects were only observed in the Ouachita Parish School system and not in the Monroe City School system.

Comparison by Grade Level. The analysis of the secondary school data indicated that differences between the two systems and the two training methods were present. Table 5 summarizes the findings of the analysis of the secondary school data set and shows that 9 of the 12 categories studied were significant between the two systems (Contrast-1) and 6 of the 12 categories studied were significant between the two training methods (Contrast-3) in the Ouachita Parish School system. Analysis of the training data in MCSS (Contrast-2), as with the overall comparison of school systems, was inconclusive.

Unless otherwise stated TEP > Other and MCSS > OPSS for all significant cells.
Note: S Significant
N Non-significant
The findings indicated that MCSS teachers have a more positive attitude than their OPSS counterparts for the latent variable Factor 1. Furthermore, the analysis indicated that MCSS teachers had a better appreciation for the NIT subclasses of F1, F3, F4, F5, F7, F8 and F10. These findings indicated that the MCSS teachers have a better appreciation for technology in general, e-mail as it relates to them, the impacts of multimedia and the WWW as it relates to them and their students, and computers in general. With regard to training, the findings indicated that TEP trained teachers in OPSS have a more positive attitude than their Non-TEP trained colleagues for the latent variable Factor 1 and the NIT subclasses of F3, F4, F5, F7 and F10. These findings indicated that the TEP trained faculty in OPSS have a better appreciation for technology in general, the impacts of multimedia as it relates to them and their students, the impacts of the WWW as it relates to them and computers in general. Training in MCSS did not have a significant effect on the attitudes of the teachers. The underlying reason for this is probably due to the training that the MCSS teachers received by the staff of the TEP prior to the inception of the TEP. The analysis of the middle school data was inconclusive and provided no discernible effects between the two systems and between the two training methods for both the latent variables and the NIT subclasses. Table 6 summarizes the findings of this investigation. The lack of significance probably was due to the missing Non-TEP trained group in OPSS. An interesting point did arise during the analysis of this data concerning the latent variable Factor 1 at the 0.10 significance level. At this significance level, the findings indicated that TEP trained teachers in OPSS have a more positive appreciation about technology in general than the TEP trained teachers in MCSS. This reversal in the attitudinal response is contrary to the above findings.

**Effect of Technology Training on the Attitudes of Teachers and their Students.** Proper technology training appears to be strongly related to teachers' attitudes toward computers and technology. It can be conjectured that training of colleagues by school district personnel who have received proper training is as good as training that was received from other professional services. This conjecture is supported by the attitudes of the teachers in MCSS who were trained by the TEP participants and the staff of the TEP, but this conjecture probably warrants further study on its own. Long-term commitment by districts also appears to be strongly related to teachers' attitude toward computers. This conjecture is supported by the differences in teacher attitudes between the two systems in this study. In MCSS, which has been involved with technology training since 1991, teacher attitudes toward technology were consistently more positive than the attitudes observed in OPSS. This long-term commitment conjecture should be studied in longitudinal studies of the two systems. The direct effect relating to impacts on students was weaker than the impacts on teachers in this study; however, an impact was present. The amount of impact best be addressed by surveying the students as well as the teachers. This conjecture could also be addressed in future longitudinal studies.

For quite some time now, professionals in the area of computer technology have been advocating that technology alone is not enough. Teacher training will reduce teachers’ anxiety about technology and should be the focal point of any district’s technology plan. Reducing teacher anxiety will give teachers the needed confidence to integrate technology into their classrooms.

It was apparent from this study that inadequacies in training exist. The secondary teachers in this study felt more comfortable and had a better appreciation for technology than did the teachers in the lower levels. Although the study did not take this into consideration, it could very well have been that the secondary teacher sample clustered on teachers whose academic training was in the areas of mathematics and science; whereas, the middle school and elementary school samples were not. Planning training sessions for the classroom teachers should emphasize their respective academic areas. That is, training should focus not only on those teachers in the mathematics and science fields, but also on teachers in other areas such as the social sciences, history, and languages. Realizing that not all students will become scientists and engineers, the school districts must put forth an unprecedented effort to train teachers who
will serve as role models for the students who will comprise the non-scientific work force of tomorrow. Thus, training must be grade-level and area specific.

In addition to training, this study indicated that long-term commitments to technology training were beneficial. Monroe City and Ouachita Parish School systems are very progressive in their efforts to not only infuse dollars into technology but also to infuse dollars into a broad based technology training program. These two systems are the leaders in the fifteen-parish area that comprises northeast Louisiana school districts. Yet, it was very apparent from this study that the teachers from the Monroe City School system had a more positive appreciation for technology than the teachers from the Ouachita Parish School system. This significant effect could very well have resulted from the fact that MCSS made the commitment to technology several years prior to the commitment from OPSS. Training was incorporated into the MCSS technology plan in 1991; whereas, OPSS began its involvement with training in 1995. The staff of the TEP program worked closely with the MCSS training program and this involvement provided the impetus for the teacher enhancement proposal that was funded by the National Science Foundation. Thus, commitment is essential. School districts must take that extra step and provide proper training for their faculty.

**Recommendations for Future Studies.** The entire area of teacher anxiety and perceived computer importance by students deserves additional longitudinal study. The longitudinal studies should be time and district driven. This study did indicate that within urban school districts such as MCSS and OPSS long-term commitment to training influences attitudes. This conjecture can only be assessed over time. The conclusions drawn from this research focused on urban schools and do support the research done by Christensen and Knezik and others. The conjecture here is “Commitment to training is long-term.” What was not addressed in this research was the impact of training on both rural and urban schools. Are the same anxieties present in the rural systems as they are in the urban systems? Is training in the rural systems as good as training in the urban systems? Do the rural systems have the same commitment to technology as the urban systems? Are the level specific differences present in the rural systems as they are in the urban districts? These questions and others need to be addressed in the future. Our educational community needs direction. If we are to provide this direction, then studies need to be designed to address the issues and provide the guidance needed for successful implementation of technology into the lives of our faculty and their students.

Effective Approaches To Teach Computer Applications To Teachers

Alex C. Pan
The College of New Jersey

Abstract: Having a good command over basic computer applications is essential for teachers to integrate technology in the school. Teachers should learn how to maximize the power of computer for their teaching and administrative work. This paper focuses on some effective approaches that can help teachers learn to use computer applications successfully. First, common computer tasks were categorized based on their features. A series of enhancement instruments were designed and developed and implemented in computer application courses throughout a two-year period. Data were gathered and interpreted about effective approaches.

Overview

Computer has become an indispensable tool for teachers. Vockell and Sweeney (1993) point out that competent computer-using teachers used computers more often and in more effective ways than less competent teachers. Teachers today should learn how to maximize the power of computer for their work. Presently, there are more teachers using computers than ever. However, most computer-using teachers that we know spend time mainly on basic-level tasks, i.e., using word processing for typing papers or reports, browsing on the Internet, and sending e-mail. To take advantage of the capability that computers can offer, teachers need a higher level of computer expertise and an effective instructional approach is essential to help teachers master necessary computer applications and attain this level.

Teaching computer applications to teachers has presented challenges to college professors. Currently, computer application courses have become widely available in various teacher preparation programs. Many known factors, such as unequal access to hardware and software, diverse interest, background, and skill levels, insufficient learning resources, and inadequate platform differences, have discounted the computer instructors’ effort and distracted the focus of proper instructional design and implementation.

There have been several studies examining how computers interact with users in the learning of application tasks. Larner and Timberlake (1995) suggest that the major obstacle to instructional technology is negative attitudes toward technology, and the lack of expertise or experience is the major reason for such negative attitudes. Studies also support that appropriate preservice and inservice training can reduce reluctance to use computers in classroom instruction (Brennan, 1991; Kolehmainen, 1992; Pina & Harris, 1993). Forcier (1996) points out that many researchers believe that one of the most effective strategies to engage teachers in acquiring the needed computer knowledge and skills is the task-oriented approach. To pursue effective approaches to optimize computer application instruction for teachers, the current study aims at exploring an integrative task-oriented approach and investigating effectiveness of various instructional devices.

Computer tasks and instructional enhancements

With many years of experiences in teaching computer applications to teachers, the author uses a modified framework, modeling the four domains of teaching (Danielson, 1996), which comprises planning and preparation, the classroom environment, instructional design, and professional responsibilities. To help learners appreciate the power and possibilities that computers may offer, task-oriented approach and hands-on activities are crucial to successful computer learning. However, simply putting teachers to work on computer tasks does not necessarily help them master needed skills and cope with the learning curve. An effective, meaningful approach is to connect the learning tasks with the learners’ real-life experience. The author also finds that during teaching and learning, some tasks are more problematic than the others for certain users. With careful analysis, computer tasks may be categorized into the following three groups based on the nature of the tasks.
1. Conceptual tasks. The conceptual tasks include basic computer operational concepts such as how computer process information and how software operates. Some common examples for the conceptual tasks are as below.
- What is the difference between closing a document and quitting a program?
- How do computers process copying and pasting?
- What happened when a disk is initialized?
- How do computers handle graphics and text differently?
- Why do users have to specify a proper printer if more than one printer is connected to the computer?

2. Declarative tasks. The declarative tasks refer to the understanding of functions, features, and technical terms. The following are some common examples for the declarative tasks.
- Icon bar, tool panel, task bars, application menu, and ruler
- Justification, spacing, columnization
- Header and footer
- Macro or shortcuts
- Fonts, colors, and style sheet
- Cell references in a spreadsheet

3. Procedural tasks. The procedural tasks refer to intellectual steps to accomplish a given integrative task, or to trouble-shoot problems in a complex setting. The following tasks require the procedural knowledge.
- Organize a newsletter, make a calendar, create a slideshow, or customize a business card.
- Develop a database and a gradebook for an entire class.
- Correct some formatting errors by using search and replace function.
- Simplify the repetitive tasks with macro functions.
- Convert data files with different formats.

Although these task categories are fundamentally different, it is sometimes difficult to distinguish from one category from another. Frequently a procedural task may require the integration of various knowledge and skills from both conceptual and declarative task category. Smith and Ragan (1993) pointed out that in many cases conceptual and declarative tasks are essential to learning intellectual tasks. Anderson (1985) suggested that procedural knowledge must pass through the declarative knowledge stage. To enhance the computer application courses, examining the relationship between types of tasks and users' performances are indispensable.

Purpose of the study

This study focuses on various tasks, instructional device, and factors that may have contributed to teachers' successful learning of computer applications. Goals of this study are to explore the following issues:
- How do novice computer-using teachers differ from experienced computer-using teachers?
- How do inservice teachers differ from preservice teachers in computer learning?
- What kinds of devices can help novice users master the computer tasks and accelerate the learning curve?
- What factors can contribute to effective learning about computer applications for teachers.

The information regarding both preservice and inservice teachers' learning performance was collected. Other data from the past two years, including interviews with teachers, survey, and error frequency analysis from microcomputer application courses were also collected and interpreted.

Methodology:

Subjects:
The subjects of this study include 186 undergraduate preservice teachers and 112 graduate inservice teachers in the microcomputer application courses throughout four semesters in two years.

Instruments:
To assess students' performance, the following instruments were developed and used.
Initial survey: Students were surveyed for prior experience, interest, and attitudes toward computer applications.
Error log: Students were required to keep a weekly log and to report the errors they made.
Written quiz: Quizzes were used to assess if students had acquired needed conceptual and declarative knowledge.
Final portfolio: Students were required to develop an integrative portfolio to demonstrate what they had accomplished in the course in terms of tasks reflecting teachers' needs in a real classroom setting. They were allowed to focus on tasks related to either teacher's productivity or instructional enrichments or both. The grade for the portfolio was based on student efforts, thoughtfulness of the tasks, original ideas, creativity, and levels of difficulty. The final portfolio was used to assess intellectual procedural knowledge.

Assignments: Five types of exercises were given at various stages to help students consolidate their learning.

Post survey: Students were surveyed for perceptions about the usefulness of instructional enhancement device.

Final interview: Two students from each group were randomly picked for an interview at the end of each semester to provide feedback on the course.

Instructional enhancement devices
To help teachers smoothly and effectively master the learning of the application tasks, a series of instructional enhancements were designed and developed for this study. These devices are highlighted below.

- Detailed step-by-step information for the task in print and on the web.
- On-line help and tutorial.
- General information and terminology.
- Review of related tasks and features to the real life experience.
- Quizzes in the format of standardized test and on-line computer tasks as the formative evaluations.
- Team projects which provide students opportunities to learn from each other.
- A collection of model work samples and students' model work from the past.
- Five types of exercises, including, a) follow-along exercises as provided during in-class demonstrations, b) mock-up exercises as used after class to reinforce the skills learned, c) creative exercises (or open-ended mini projects), d) think-through exercises, and e) challenge exercises as to invoke deep thinking and application.

Procedure
Students (including all inservice and preservice teachers) started the course with an initial survey where they rated their own computer experience and skill levels. All students were then taught in depth about ClarisWorks, Netscape, and other application programs. As they made progress, they were asked to work on exercises, mini-projects, and portfolios. Students then reported on the errors they have made and the amount of time they had spent on which tasks. Students' quiz scores and final portfolio grades were also used to show their performance. At the end of the course, students were surveyed for their perceptions about the effectiveness of the instructional enhancement device. All data collected were analyzed to address the above-mentioned research issues.

Choice of the programs
ClarisWorks and Netscape programs were adopted as the primary tools for this study because they were readily available for various platforms in the computer lab. Both programs were also considered feasible to meet teachers' computer needs. Using the Netscape to browse the web as well as to construct a web page has been a popular practice that might increase teachers' willingness to put in good efforts for the exercises. ClarisWorks has been a popular integrated program which offers a wide range of tasks to address the needs in almost every aspect of teachers' work. In addition to ClarisWorks and Netscape, other popular programs, such as PowerPoint, HyperStudio, and some courseware titles were also adopted throughout the semester.

Results of the study

Student's self-reported computer experience and skill levels

Table 1. Self-rated as novice and experienced users

<table>

<td>15%</td>
</tr>
</tbody>
</table>
Students were asked to rate their own computer experiences and skill levels. Based on such information, they were categorized into four groups: preservice novice (PN=21%), preservice experienced (PE=41%), inservice novice (IN=23%) and inservice experienced (IE=15%) as shown in Table 1. Only a few students had prior experience in using the Claris Works and the Netscape, but their experiences were not extensive enough to affect the tasks to be learned and accomplished.

<td>87.95</td>
<td>77.95</td>
</tr>
</tbody>
</table>

Students were given freedom to choose either basic mockup tasks or creative tasks for mini-projects as exercises. Although they were encouraged to attempt the creative tasks, many students chose to work on simple mockup tasks, as examples provided in class demonstration. As shown in Table 3, those who chose to do the creative tasks also performed better than those who did not. It is likely that those who chose to do mockup tasks did not feel comfortable or ready to do the creative tasks. The fact that fewer novice users chose to do integrative tasks may have explained this concern. However, the fact that those novice users who dared to try out the integrative tasks performed exceedingly well in their final portfolio probably suggests that integrative or creative tasks might help computer learners accomplish more.
Table 4. Mean quiz scores and portfolio grades between preservice and inservice teachers

</table>

As shown in Table 4, undergraduate preservice teachers seemed to have better basic skills and did well on the quizzes. However, for the portfolio, the preservice teachers did not outperform the inservice teachers who had more experience in the public school classroom setting and had better ideas of how to apply computer skills.

</tbody>
</table>

Based on a five-point scale survey (with 5 meaning most useful and 1 meaning least useful), students were asked to rate the usefulness of the enhancement devices for computer learning. The mean scores in Table 5 show that experienced users and novice users significantly disagreed on item 1, 2, 3, 7a, 7b, and 7e, where novice users appreciated receiving more general information and simple, easy-to-follow tasks.

Discussion of effective approaches

From the results of the study, the effective approaches may be characterized as the following.

- **Computer time and access is essential.** Time spent on exercise is a widely known factor to the successful accomplishment of almost any learning tasks. Students who spent more time on the computer tasks performed better on both quizzes and the final portfolio than those who did not. Because both Netscape Navigator and ClarisWorks were available across the platform, a few teachers expressed their appreciation that they would be able to practice tasks at home. Six teachers bought new computers after they took the course because they sensed that easy access would make a greater difference for their learning.

- **Move from basic to advanced tasks.** To accomplish the more complicated integrative tasks, users need to combine conceptual, declarative, and procedural knowledge and skills. Successful learners differ from the others not just in the knowledge and skills they have, but also in the way they explore computer programs. Those students who were flexible in trying out creative and integrative tasks performed better.

- **The thinking-through process can help.** Thinking-through exercises may help students develop an ability to synthesize the information they have learned in order to develop more complex integrative tasks. A few novice students were not able to accomplish the given tasks and asked for help. When the tasks were analyzed and broken into smaller pieces, these students could handle individual tasks separately without problem. After the
thinking-through exercises, they understood the concepts and were able to accomplish the given tasks. The thinking-through exercise help students master tasks and gain confidence.

- **Prior teaching experience is helpful.** Several preservice teachers voiced concerns that they had no ideas about what kinds of teacher tasks they could do with computers. However, such concerns were not an issue for inservice teachers. This explains why preservice teachers had better conceptual and declarative knowledge (as shown in their quiz scores) but did not outperform inservice teachers on final portfolio. To help the preservice teachers, more model example tasks should be provided to help them connect their computer learning with real-life activities and to bridge the gap between preservice and inservice teachers.

**Conclusion**

Technology offers teachers the opportunity to become efficient at work and to conduct effective instruction. Task-oriented approaches to engage teachers in active learning about computer application is necessary but not sufficient. Teachers should acquire conceptual and declarative knowledge as well as the procedural knowledge described in this paper. The current study examined information about computer users' behavior and the type of tasks. Novice users needed to work on all types of tasks to improve their knowledge and skill levels.

To master computer applications, users should spend sufficient time on meaningful integrative tasks. The results suggested that practicing on integrative procedural tasks might help computer learners to perform better. The results also suggested that it is important to relate the computer tasks to the practical classroom setting and to lead undergraduate preservice students to become more aware of practicing teachers' tasks.

Nonfictional Educational Narratives of Computer-Mediated Communication Technology Among Technologically-Novice K-12 Teachers: An Exploratory Methodological Study

Michael D. Rapp
Department of Curriculum & Instruction, The University of Houston, USA, mdrapp@bayou.uh.edu

Abstract: This study explores the usefulness of the nonfictional educational story (NES) methodology in gaining a fuller understanding of computer-mediated communication (CMC) technology use among technologically-novice K-12 teachers. Three elementary school teachers were interviewed and exemplars of their experiences, perceptions, and feelings of CMC technology are presented. The results point to a potential of the NES method to alleviate the scarcity of qualitative research on what it means to be a teacher who potentially or actually uses CMC technology in the classroom.

With institutions of higher education and companies turning increasingly to the use of computer-mediated communication (CMC) technologies, students and new employees are expected to be familiar with their use (Scott & Rockwell, 1997). Yet, school systems are expressing fear that their graduates will be unprepared for the workplace because they lack experience and competence with technology (California Department of Education, 1996). Indeed, this fear is not unfounded as research suggests that new employees do not feel prepared to use CMC technologies (Siebold et al., 1992).

When seeking to understand why some teachers do not seem to implement CMC technologies in the classroom, the nature of teachers' perceptions of both CMC technologies and their uses in the classroom must be explored. Of particular relevance to the issue of low use of CMC technologies in the classroom is the technologically-novice teacher. Scott & Rockwell (1997) found that experience with CMC technologies is a substantial predictor of reported likelihood of future use. That is, teachers who do not have high experience with CMC technologies would tend to be the least likely to adopt and implement the technologies in the classroom. Thus, when examining the nature of teachers' perceptions of CMC technologies, concentrating on technologically-novice teachers may provide unique insight.

This research seeks to explore a method for understanding technologically-novice teachers' experiences, perceptions, and feelings of CMC technology use in the classroom. First, relevant research literature dealing with CMC technology adoption and use in K-12 schools is reviewed. Next, the research methodology used for gathering teachers' experiences is presented. Then, experiences, perceptions, and feelings of three technologically-novice teachers are detailed. Finally, implications of this research are discussed.

Background and Literature Review

Empirical research on actual CMC technology use in instruction is not as pervasive as the literature concerning the use of computer technology in general in schools. Yet, a review of recent research highlights several innovative uses. CMC technology has been effective in creating "global classrooms" among students in different geographic locations (Moss, Amodeo, Bullowa, & Detjen, 1997); facilitating foreign language learning through interaction with native speakers (Tella, 1992); encouraging understanding of global scientific phenomena (Leyden, 1997); providing students contact with subject matter experts (Sanchez & Harris, 1996); improving reading and writing skills, and interest in meaningful educational activities (Reil, 1990). Furthermore, Mackall (1996) suggests that CMC technology can bring an equality to traditionally disempowered students in the learning process. However, although research has investigated how CMC technologies are being used in the classroom, research generally has not looked at how the perceptions and experiences of the teachers influence decisions to use CMC technologies.
In order to give explanation as to why some teachers adopt technology and others do not, recent research has developed several models of technology adoption (for example, see Polin, 1992). However, a weakness of these models is that they tend to focus more on the process of adoption rather than on the internal concerns and experiences of the adopter (see Hall & Rutherford, 1977 for an exception). Moreover, research has generally not investigated adoption models in the context of CMC technologies. Indeed, Harris (1994) contends that additional aspects not usually investigated in regards to innovation adoption (e.g. critical mass) must be researched to gain a clearer explanation of CMC technology use in the classroom. Furthermore, a review of the literature also presents several common factors that encourage technology integration in the classroom: environments that are conducive to teacher exploration and mastery of the technology (Greenberg, Raphael, Keller, & Tobias, 1998; Hasselbring, 1991); ongoing training and support (Hasselbring, 1991; Sheingold & Hadley, 1990); perception of the teaching value of the technology and perception of administrators' expectations for use (Greenberg et al., 1998); ease of generating uses for the technology, and ease of access to the technology (Levine, 1995). However, research has generally not investigated these issues in regards to CMC technologies.

Methodology

Three elementary school teachers from three separate school districts in the southern United States were contacted and agreed to participate in this study. All were female and experience in teaching ranged from three years to twenty-seven years. All possessed only limited experience with technology and all indicated themselves as novice users of CMC technology both in an interview and on a survey instrument measuring degree of comfort with several common CMC technologies. In order to ensure privacy of the participants and all referenced individuals, all names of people and schools throughout this paper are pseudonyms.

As Norum (1997) observes, "The available research related to how technology is actually used in the classroom is thin; of what does exist, much of it is quantitative in nature. . . . Qualitative research, particularly narrative inquiry, provides insights into teachers' actual experiences with using technology in the classroom" (p. 17). The nonfictional educational story is a particularly useful method of giving voice to an individual teacher's experiences, perceptions, and subjective realities (Barone, 1992; Norum, 1997). Barone (1992) cites three qualities of the nonfictional educational story that serve to highlight its communicative usefulness: it is accessible in that academic jargon is kept to a minimum or absent entirely; it is compelling in that it makes use of the story format and engages the reader in the human drama; and it is characterized as being morally persuasive, which refers to a content that engages the reader to rethink subjective contentions by vicariously experiencing the intentions and desires of the protagonist. This exploratory research makes use of two narrative inquiry methods proposed by Connelly and Clandinin (1990): the unstructured interview and story telling. An initial interview was conducted with each of the three teachers and was followed by a second interview a few weeks later. The researchers focused on an interviewee-led open-ended format and encouraged episodic or anecdotal elements to provide the best information on the teachers' experiences, perceptions, and feelings and to draw the interviewees' attention away from simple or superficial answers to the questions.

Results

The stories are varied, both in the amount of data gathered and in the range of topics addressed. Time and access constraints prohibited equal coverage of the teachers. Nevertheless, unique and telling accounts of experiences, perceptions, and feelings were gathered.

Lisa, Southwest Elementary

The interview with first teacher, Lisa at Southwest Elementary, unfortunately gleaned the least amount of text; however, it detailed a specific instance of CMC technology use in the classroom. Lisa has been teaching language arts in a bilingual elementary school setting for three years. Of all of the three teachers considered in this study, she is the most technologically experienced. Her affect for computers is high as she has "always had a positive attitude about them." Yet, Lisa's use of computers in her classroom is not high. She
feels that involving computers in the curriculum takes a great deal of time relative to traditional instructional methods and she does not want the students to "get too involved in something that I know I won't have time to finish." When Lisa does use computers in her classroom she tends to focus on word processing software. However, that is slowly changing.

Lisa recently began to integrate PowerPoint, a multimedia presentation software application, into her curriculum. "I really like [PowerPoint] because it's more -- it's something that I used in college, so that's something that's real life and it's something that [her students] will use in the future if they hopefully go to college." When asked how the PowerPoint implementation was proceeding in her classroom, Lisa surprisingly began not to talk about how she was using the software to teach her content area, but rather about administrative assistance in teaching the students how to use the software. Her account hints at a deferment of responsibility in that another individual takes over and explains the software, leaving Lisa to potentially teach her curriculum content with the software. Interestingly, in this account Lisa's role as teacher is reduced to that of a monitor: "Then I had Mr. Jones come in. He's been a great big, a great big help. I mean, I just walk around and monitor. He explained [PowerPoint] very well to my kids in a way that I probably -- I mean he did a better job than I thought I could have. I didn't know how to explain it in a simple way." Thus, Lisa's narrative relates a story of a CMC technology potentially providing for the enhancement of the education in her classroom with the task of the teaching of the software being a responsibility of someone other than the teacher.

Tracy, Bayou Elementary

The second interview with Tracy at Bayou Elementary gives an account of a reluctance to use any form of computer technology in the classroom, including CMC technologies. Tracy has taught elementary school for twenty-four years. She first introduced herself to computers in the mid 1980s when she purchased a computer for her children. Later, she started using the computer herself for word processing rather than using a typewriter. Tracy reflects that this computer was not user-friendly and that whenever she wished to learn something new she found the manuals difficult to read. She purchased her most recent machine primarily for word processing, but also had it in mind to try e-mail and the World Wide Web. Tracy would like to learn more about using e-mail, but insists that she needs someone to help her learn it. She asserts that she does not have much time or money to spend on learning new skills and if she did decide to take a formal class about the Internet, she would not have any idea as to which class would be the most beneficial for her. "Just reading the books on how to do these things is too laborious," Tracy concludes.

Tracy expressed a substantial amount of apprehension toward computers in the interview. "They are smarter than I am!" she insists. "I'm always afraid that I'll accidentally trash something that I don't want to trash." Tracy reports that she likes using new software, but that she does not like learning how to use it. She is afraid she will ruin it or damage the computer itself. However, once she has had exposure to the software and tackled a good portion of the learning curve, she reports that her comfort level rises.

In regards to specific CMC technologies, Tracy has only limited exposure. Of all of the common CMC technologies, she has the most experience with e-mail, but uses it only for chatting with friends. Tracy does not see any educational value in the use of e-mail. She does not believe she would ever use it in her classroom because there are "too many things to worry about with the students using it." Additionally, Tracy has tried using the World Wide Web to try to find information, but reports little success. She would like to know how to "surf the Web," adding "whatever surfing the Web means." Interestingly, regarding CMC technologies of which she has no knowledge, Tracy believes that she has no need of them, otherwise she would have heard of those technologies. Thus, Tracy's story is that of the reluctant and passive teacher in regards to CMC technology use.

Jane, Pine Oak Elementary

The final interview with Jane at Pine Oak Elementary touches on teacher training and administrative support. Jane has been teaching for twenty-seven years, starting in second grade and has worked progressively down to kindergarten. For the first half of her teaching career, she used no computer technology in her classroom, but she has used technologies such as audio tape recorders and video recorders to frequently augment her lessons.
Five years ago, the administration began a concentrated effort to make computer technology prevalent in Pine Oak Elementary. During the first two years of the technology implementation plan, teachers were given minimal to no training and Jane found herself knowing little more than how to reboot the computers. In the third year Pine Oak instituted many inservices entitled Tea and Technology. They were well attended, but Jane did not find them always helpful. The classes were on specific subjects, such as how to make a newsletter or how to scan a photo. However, the classes included teachers of varying ability. Jane felt nervous next to more competent and younger teachers. "They say we're afraid to use technology, but that's not true," Jane asserts. "We don't know how and hate to admit we don't know anything." She characterizes the sessions as being too full, along with people becoming impatient and working ahead, and others becoming lost and frustrated. Jane was in the latter category. The two technologists would often lean over Jane's computer and just complete the action, saying "it's like this" instead of teaching her how to do it. Jane reports that many teachers left feeling as helpless as when they had arrived.

The school began to have many frustrated teachers as the administration's desire for technology implementation increased. Many quit or changed schools to avoid the technology push. Jane stayed, but moved down to kindergarten to avoid the more demanding technology, such as five page computer-generated report cards, multimedia book reports, and computer-based slide shows for Parent Night. Jane routinely commented bitterly on the whole issue. "[The] plans looked great on paper, but what they said and what really happened was a different story."

Nevertheless, Jane is also beginning to explore CMC technologies. She has recently started using email, now that the school uses it for lunch and attendance counts. Jane also finds herself using it to communicate with other teachers about class projects and even for sending humorous e-mails to them. She would like to know more about the World Wide Web. Currently, Jane is just beginning to explore it using search engines and often exclaims aloud how she found a valuable site and how she wishes to share it with other teachers. Jane attributes this newfound comfort to the presence of two new technologically-proficient teachers who use their computers right next to hers. She feels freer to try things on her own, because if she erases something or "messes it up," help is immediately nearby. This is the kind of personal attention she has always wanted in the inservices. In regards to the use of other CMC technologies, Jane has no interest in integrating video-conferencing into her curriculum nor in using it personally. However, she is interested in seeing how a chat room operates. Thus, Jane's narrative is that of a journey from unfamiliarity to exploration of CMC technologies.

Discussion

This exploratory study sought an initial understanding of the meaning of CMC technology for technologically-novice K-12 teachers. Three teachers were interviewed and exemplars of their stories were presented. In this section, implications of the research are discussed.

Lancy (1993) in his chapter on personal accounts laments, "Far too often, when I expected to read a report of research, I was treated to a lecture, in which the life history material was not analyzed, but selectively drawn on to illustrate the lecture" (p. 203). This paper seeks to avoid this trap by choosing not to advance a unifying argument among the three stories, but rather to analyze a specific instance in each narrative. In this manner, over-generalization and superficial consideration of the stories will be avoided.

A point of interest in Lisa's narrative is her assertion "I really like [PowerPoint] because it's more -- it's something that I used in college, so that's something that's real life and it's something [her students] will use in the future if they hopefully go to college." Looking at how someone constructs an utterance gives understanding to that utterance (Pomerantz & Fehr, 1997). Lisa begins by making the connection between college and "real life" and that the use of PowerPoint in her college validates it as being representative of such. This implies a perception that time spent in her elementary school classroom is not reflective of experiences in the social environment outside the classroom walls (i.e. "the real world") and that the introduction and use of PowerPoint in her classroom makes her teaching more representative of real life. That is, the integration of the CMC technology of PowerPoint potentially raises the level of the education so that it is more representative of the outside or real world.

Quite possibly the most fascinating aspect of Tracy's interview is her assertion that she sees no educational value in the use of e-mail. This is a puzzling statement especially in the context that Tracy has experience with e-mail and uses it routinely to communicate with friends. The key to understanding Tracy's ambivalence is in her statement "[there are] too many things to worry about with the students using it." What is
most striking about this utterance is its vagueness. These dangers of e-mail use in the classroom were never delineated nor gleaned from Tracy in the interview, pointing to the idea that Tracy herself cannot give specific examples of what these "too many things to worry about" are. Her additional statement in which she asserts that if she has not heard of the CMC technology she probably has no need of it may provide some insight here. This statement, too, is fairly vague. Moreover, it points to a lack of knowledge-seeking in regards to CMC technologies by Tracy. She does not appear to be all that interested in adopting CMC technologies in her classroom and that if such technologies are beneficial or necessary, she would then already know about them (e.g. perhaps mandated by an administrative body).

Jane's narrative almost reads like a critical theorist's success story. She has broken through administrative obstacles and is gaining increasing familiarity and comfort with CMC technologies. The most telling aspect of Jane's increasing familiarity story is that of social support. She lists two specific instances of CMC technology use in which she is gaining confidence: e-mail and the use of the World Wide Web. Both of these CMC technologies require social interaction for Jane. Her use of e-mail, both in sending and receiving, undoubtedly provides social reinforcement for her use of the technology. The same is true for her use of the Web in that she shares sites of interest with other teachers and this social interaction further supports her continued use of the technology. Additionally, Jane directly attributes her comfort and confidence to the specific situational circumstance of having technologically-proficient teachers within immediate reach of her own computer. It is interesting to examine why she might feel more comfortable, confident, and freer to try things on her own. Jane provides an explanation in that if she makes a mistake, help is immediately nearby; yet the explanation may go beyond this. Bandura (1986) provides the concept of vicarious consequences. Jane is quite possibly experiencing routine positive vicarious consequences from being in repeated close proximity to the technologically-proficient teachers. She sees them being successful with the CMC technologies and observes their positive affect, which she then transfers to perceptions of her own behavior that further encourages her use of the technologies.

Following from the proceeding discussion, the nonfictional educational story seems to be a valid and useful tool for increasing knowledge of teachers' experiences, perceptions, and feelings in regards to CMC technology use in the classroom. Indeed, bringing to light and sharing the variety and myriad of views, considerations, rationales, and decision-making processes about CMC technologies that reside in the minds of teachers provide a way to gain understanding of teachers as a full individuals. Additionally, as the knowledge sought and the method employed are epistemologically and inexorably intertwined, it is necessary for the researcher to concurrently reflect on the nonfictional educational story as both a means and an end. As an end, it provides an understanding of the teacher; as a means it provides a mechanism to better understand one's own teaching practices (Clandinin & Connelly, 1989). Thus, the nonfictional educational story holds great promise in increasing the understanding of what it means to be a teacher who either potentially or actually uses CMC technology in the classroom.

An Investigation of the Influence of Computer Technologies on Teaching and Learning as Perceived by Students and School Personnel in Selected Public Secondary Schools in Wyoming

Carl L. Reynolds, Professor

Abstract: This paper is a report on a naturalistic study involving students and their teachers in secondary schools in Wyoming. Students and teachers in six randomly selected high schools were interviewed on-site. Students reported that word-processing was the most common application used at school. Their favorite activity was accessing the INTERNET. Students emphasized heavily that teachers should allow students to use computers more often, allow more freedom in using computer technology, and that schools should provide more computers and computer courses and provide more opportunities for computer access at evenings as well as during the school day. They emphasized that computers allowed more exploring, more independence, and more fun in learning than when it was teacher directed. Teachers were mixed in their opinions. Most welcomed the changes in student-directed learning and expressed desire to continue to learn how to integrate these technologies effectively while a few expressed concern with computers promoting weaknesses such as in spelling, writing, and mental discipline for learning.

Background and Rationale

Since 1986, public school personnel throughout the state have been encouraged to integrate computer technology in the classroom. The State Department of Education mandated a computer aided instruction in-service course as part of teacher recertification requirements. For example, The Wyoming State Technology Plan (September, 1997) has within its long-range objectives the need to establish and evaluate integrated technology practices within the public schools. School districts have requested numerous university sponsored extension courses involving new instructional technologies. Almost every district-sponsored staff development plan included some form of teacher in-service for integrating computer technology in the classroom. During this same timeframe, the College of Education implemented computer technology course requirements as part of the undergraduate teacher education program. It is unclear as to what degree schools in Wyoming have integrated computer technologies into their classrooms. Also, it is not known as to whether the College of Education is providing the appropriate support to facilitate the integration of computer technologies in public schools. Other states have begun similar investigations to determine the status of this technology integration such as the effort just begun in Missouri (University of Missouri, 1998).

Computer technologies have been hailed as the most likely innovation to effect change in the public schools (Connick & Russo, 1995). The ability to access information from world-wide sources (Leu, et al, 1997), create simulations with three dimensional effects, manipulate graphic animations and sound, without the need for programming skills on low-cost desktop and laptop computers has unleashed a power to learners that require teachers to relinquish the role of provider of all information. Someone was once quoted as saying “Overhead projectors were used in bowling alleys for 35 years before they were commonly used in the classroom”. It is hoped that computer technology integration is occurring at a better rate than what happened for the overhead projector.

It has been suggested that the role of the teacher in the classroom must change as computer technologies are integrated in the classroom (Bielefeldt, 1997, Plater, 1995, Rowe, 1993). Emphasis has been placed on the teacher as accepting a facilitative role in guiding students through information access and processing, problem-solving, and creative learning projects on the computer in a student-centered classroom rather than the traditional image as the presenter in front of the class. It has also been suggested that teacher-student interaction can be more electronic, such as email, during times other than the official school day similar to the techniques employed in distance education (Lehman, 1995).
Teachers who have effectively integrated these technologies in their classrooms have reported higher levels of motivation, interest in learning, increased problem-solving skills, and improved achievement by the students (Mingus & Grassl, 1997, Rowe, 1993, Sawyer, 1994). Based upon efforts in in-service activities with teachers in Wyoming, primarily at the elementary school level, it was a natural question to ask if the same motivation level and interest was occurring at the secondary level as well, or whether the integration of computer technologies had occurred successfully in the 9-12 classrooms.

Objectives of the Study

The intent was to determine the answers to the following questions:

1. What types and levels of computer technologies are being used by students and teachers?
2. What effect, if any, have computer technologies had on teaching and learning practices in schools?
3. What practices have been successful in promoting successful adoption of computer technologies in schools?
4. Have computer technologies changed the way teachers teach and students learn?

Procedure

A naturalistic inquiry approach was used to conduct the study. This approach was selected in order to facilitate on-site observations while schools were in session and to enable unpredicted answers to be followed by additional inquiry during the interviews (Lincoln & Guba, 1985). Selected high schools in Wyoming were contacted requesting permission by the researcher to visit during the Fall, 1998. During the visit, permission was obtained to visit students in classes, study halls, and computer labs to determine their perceptions to the four questions listed above. They were also asked to complete a brief questionnaire to determine the frequency and level of computer technology used in school. In conducting the interviews, I excused the teacher for 20-30 minutes to take a break while I talked to the students. The students enjoyed the fact that a professor from the university was willing to listen to their opinions. In all cases, the students began talking freely. Several teachers in small groups, technology directors, and school principals were interviewed and asked the same questions as those asked of the students. The data collected from subjects included field notes taken by the researcher during the interviews. Pilot test results were used to refine the list of interview questions prior to the interviews.

After refinement, the following open-ended questions were developed for structuring the interviews with both students and teachers:

3. What computer applications do you use at school?
4. Do computer technologies help you learn? If so, how?
5. In what ways do your teachers use computers either for homework assignments or in teaching?
6. What has your school done to help make use of computers possible? Do they need to do more?
7. Do you learn differently because of computers? Do teachers need to change the way they teach because of computers?

Results

The intent of the first interview question was to determine the level of technology used in schools. It was overwhelming to note the consistency in responses by both students and teachers in using word processing the most, followed by INTERNET information searching. The use of multimedia was extremely limited unless the student was in a class designed for learning those techniques. Drawing/drafting was mentioned by a few students enrolled in those technology-specific classes. One art teacher, however, described at great length how her students use web pages to analyze the different types of art, shapes, use of color, and texture in daily classes on the subject. One teacher, responsible for yearbook production, listed almost every application available on the server in the school as technology she taught her students to use in the production of the annual.

In response to the second question, students immediately focused on the power of information access from INTERNET. They also liked the way computer technologies allowed them to work at their own pace. Several students expressed higher interest levels because computers allowed them to be more creative and “make learning
more like exploring. They preferred that teachers allow them to find information using computers rather than
lecture. However, in response to a follow-up question, most all students quickly expressed the need for the teacher
to be present to assist them in dealing with frustrations, and providing guidance to help insure success in
accomplishing the task at hand.

Most students think that teachers use only word processing and gradebook software. Almost none reported
such uses as presentation technology, field data collection, simulations, or illustration purposes. Most teachers
interviewed supported the students’ perceptions. A few teachers, however, described heavy uses of the INTERNET
to update their instructional material. Three math and science teachers described how they used programmable
hand-held calculators to collect and graph field data from research conducted during out-of-classroom laboratory
sessions. It was interesting but not explained why students didn’t mention these applications.

In response to question four, most students were fairly positive toward the school’s efforts. They did have
some good solutions to suggest in solving what seemed to be the common problem, computer access. They
complained that computer labs were always tied up by scheduled classes and there was no place else to go. Several
students suggested that labs be open more often at night for student use. Several students expressed frustration with
the school’s reluctance to trust them with INTERNET and email. In one school, for example, the policy is to issue
email addresses and privileges to all students who achieve a 3.0 grade point average or better. Those students who
had not earned the privilege understood the reason but still expressed dissatisfaction in being in the ‘have-nots’
group. In regard to being able to do homework on computers, one student offered an innovative solution; have
laptop computers to check out from the library just like books. One student suggested that the school rent computers
just like the video stores rent out VCRs and movies. These ideas surfaced in two different schools visited.

Most teachers were happy with the efforts made for hardware acquisition but expressed the need for more
applicable software for their respective subject areas. They spent most of the time responding to this question by
expressing serious frustration with the lack of quality in-service and technical support. In-service appears to follow
the typical model, “too much tell about it with not enough ‘hands-on’ training”. In one school however, where the
approach has been to train the teacher to teach peers in the building, most teachers stated positive thoughts about the
technical support and in-service provided.

Question five elicited most interesting ideas from the students. Most students first began with the fun that
computers provided, that learning at their own pace was most ideal, and that computers allowed for more exploring.
They also liked the fact that work was easily redone when mistakes were found. One student talked at great length
about how computers allowed her to explore instead of just perform only routine tasks. Students thought teachers
should relax more about computer technology and admit when they didn’t know how to use some applications. One student said, “I would like to teach them (teachers) how to capture ‘cool stuff’ from the INTERNET”. Students
thought that teachers overused computers in some classes (i.e. English) but not enough in others. Several students
spoke out strongly about some traditional roles that teachers should still do such as present information that is hard
to find and help students more with difficult assignments and problems. Only one student expressed this thought,
“Teachers should disappear and let me learn all I need to know on the computer.”

Most teachers responded positively to changes that computer technologies may bring about. Most
expressed gratitude for the ability to assign their students to search for information on the INTERNET and know
that something would be found. Some teachers expressed desire to integrate computer technologies more if
someone would show them what is available, appropriate, and how to use it. One math teacher expressed how the
technology allowed him to focus on the exciting real-life problems rather than the laborious arithmetic functions that
took all his time before. An art teacher said the only thing holding her back was more computers in her room. Two
young teachers said they would hesitate a long time to consider leaving to another school because of the strong
technology support where they were. A few teachers did express concerns about traditional learning skills such as
spelling and handwriting that they thought may be weakened by the use of computers, however the debate that
ensued indicated there was not general agreement on this issue. One teacher asked, “When do we say we have
changed enough?”

Implications

It was most interesting to hear how many students in the various schools expressed the keen interest that
computers and connectivity through INTERNET and email provides. One student explained, “Using the
INTERNET is like exploring; that’s why it’s so much fun”. It was amazing to hear how many students saw
computer technologies as a way to learn on their own. They expressed a concern that many teachers maintain the
image that they cannot use any technology they don’t understand how to use themselves. One student said, “they
should let us teach them how to use the computers”. It was obvious from students’ comments that teachers must be
more student-centered in their approach and use computer technology to put fun, creativity, and independent responsibility as well as academic challenge back into learning. The message to teachers was rather clear as well, the primary item being, to lose their fears about not knowing everything and to give students the opportunity to show what they know. Teachers should feel a great deal of pride in knowing that students value their primary function as facilitator and mentor rather than the source of all knowledge.

By determining the degree to which the integration of computer technology has occurred in schools, we now better understand how to prepare teachers to teach in a way that takes advantage of this technology. Students and school personnel are benefiting from this project in several ways. By reflecting on the computer technology in their lives at school and in the future, they are discussing how they can be more effective in its integration. Teachers were also relieved to hear that students overwhelmingly still expressed the need for teachers' presence and interaction to effectively learn from computers. Teachers were curious to hear how most students described the desirable teacher-student interaction as facilitative rather than directed instruction. A better understanding of how computer technology should be integrated into pre-service and in-service teacher education will also benefit faculty at the university as well.

Abstract: This study was designed to identify cognitive dissonance in teachers prior to any major technology integration initiative. A pre-inservice questionnaire was developed for teachers based on the principles used in art-therapy and traditional forms of survey development. The questionnaire consisted of 20 questions and was administered to 30 elementary teachers. Teachers responded positively to the direct questions about technology integration. Asking the teachers to draw how they felt towards computers in their classrooms provided important information about teacher’s attitudes that were often not articulated because of perceived expectations for computer competency.

Introduction

This study was designed to measure teacher attitudes towards computers and identify cognitive dissonance in teachers prior to any major technology integration initiative. Cognitive dissonance is one factor which often undermines technology integration and is seldom accounted for in the planning stages of such an initiative. Amico (1995) discusses the importance of offering technology inservice at appropriate levels of skill and interest to enhance technology integration but does not mention any attempts to measure cognitive dissonance directly. Researchers take a variety of approaches to enhance technology integration, from categorizing teachers, setting standards, to lists of do's and don'ts (Beasley & Sutton, 1993; Friske et al, 1996; Hawkins, 1994; Bits, 1991). When teachers cognitively believe that computers should be an important part of education but have deep seated personal reservations about their ability to control their classrooms and the technology, cognitive dissonance occurs. Until the disparity between what teachers think and how they feel about computers in their classroom is dealt with, technology integration can never hope to be more than mildly successful.

Teachers often vocalize the perceived importance of the technology. Many want their students to be exposed to the myriad of computer-based instruction now available but do not have either the technical skills or the classroom integration skills necessary to be successful. Identifying cognitive dissonance in teachers prior to technology integration allows for change agents at the school and district level to probe for clarification as to the cause of the dissonance. Technical skills is usually the first deficit to be considered and is the most time consuming to remedy (Amico, 1995; Ingram, 1994; Mead et al, 1991).

Models for classroom integration are generally new and not well tested and evaluated but should also be considered in teacher training as examples of best practice to date. These can be formalized models like Bell's "High Technology Model" or it can be short presentations by master teachers who have been successful in integrating technology. Practical methods and activity-suggestions go a long way to alleviating teacher anxiety and reducing cognitive dissonance (Bailey & Bailey, 1994).
Asking the teachers to draw how they feel towards computers in their classrooms provided important information about teachers attitudes that we believe are often not divulged. Art therapists use drawing as a method to help people connect to their emotions. Knowing how teachers feel personally about the technology they have available to them should determine the kinds of training and support they receive. Identifying cognitive dissonance in teachers prior to beginning any technology integration initiative allows for the inclusion of appropriate instruction and increased awareness of potential weak points in the integration strategy.

Methods

A pre-inservice questionnaire was developed for teachers loosely based on the principals used in art-therapy and traditional survey development theory. A fundamental premise of art therapy is that the expression of creating art connects with feelings that you may not be aware of. Moon (1994) contends that art-therapy is effective with a wide range of individuals for differing backgrounds. He also maintains that "artistic expression is a healthy act" which helps individuals to connect to their feelings (76).

The questionnaire consisted of 20 questions and was given to 30 elementary teachers who were expecting to have to integrate technology into their classrooms in the near future. It was anticipated that each classroom would get 8-10 computers, a printer, and a modem for use throughout the school day. The change in classroom environment was anticipated to have a profound affect on both the teachers and their students.

Teachers were required to first draw how they viewed themselves in relation to the anticipated integration of computers into their classrooms and then write how they felt. The drawing question followed guidelines given by Oster & Montgomery (1996) and Brooke (1996). After drawing a representation of how they felt in the box provided, teachers were asked to respond to a traditional series of direct questions about technology in schools.

The degree of cognitive dissonance was determined by comparing the number of positive and negative responses to the direct questions to the degree of positive and negative emotion displayed in their drawing. Degree of positive and negative emotion in the drawing was determined by a cognitive dissonance rubric.

Results

A detailed discussion of the results of this research can be found with their supporting tables at the following URL, as they were not available at the time of the paper submission. The authors apologize for any inconvenience to the reader. Updates presented at the conference will also be available from this URL.
http://mse.byu.edu/ipt/students/ruttan/cognitivediss.html

Conclusion

Teachers responded positively to the direct questions about technology integration. However, many teachers have personal concerns about their ability to manage technology in their classrooms that they are reluctant to articulate, as evidenced by their drawings. Therefore we can conclude that what teachers say in relation to the merit of technology in schools is not always indicative of how they really feel about technology in their own classroom.

Asking the teachers to draw how they felt towards computers in their classrooms provided important information about teacher’s attitudes that are often not divulged because of perceived expectations for computer competency. Knowing how teachers feel personally about the technology they have available to them should determine the kinds of training and support they receive. Identifying cognitive dissonance in
teachers prior to beginning any technology integration initiative allows for the inclusion of appropriate instruction and increased awareness of potential weak points in the integration strategy.

Abstract: This research project examines an innovative technology integration model that includes the design, development, implementation and assessment of the use and integration of technology by inservice and preservice teachers. Personnel from a school district, an area education agency, and a college of education work collaboratively to provide the support and resources that are necessary to facilitate the exemplary use and integration of technology in elementary classrooms. The proposed three-year model provides a framework that will establish mentoring relationships between preservice and inservice teachers and will create classroom opportunities for them to infuse technology with best teaching practices. This paper will describe the purpose of the project and will discuss various activities that have occurred during the first year of the project.

Introduction

“....what teachers actually need is in-depth, sustained assistance as they work to integrate computer use into the curriculum and confront the tension between traditional methods of instruction and new pedagogic methods that make extensive use of technology” (Panel on Educational Technology, 1997, p. 49).
For years, schools have purchased large amounts of technology in hopes that students and teachers alike would use these cognitive tools to help facilitate the teaching and learning processes. Despite this huge investment, few of the nation's teachers actually use technology in their teaching (Office of Technology Assessment, 1995). Although technology access has improved, teachers have been given little support in their efforts to use and integrate technology in their classrooms (Office of Technology Assessment, 1995; Panel on Educational Technology, 1997; Sheingold & Hadley, 1990). It is a difficult task for most teachers because not only do they have to learn how to use the technologies, but also they may have to change the way they teach. Still, helping teachers use technology may be the most important task for helping students use technology effectively for learning (Office of Technology Assessment, 1995). Inservice teachers are not the only educators who are not supported in technology use. Preservice teachers who graduate from teacher education programs must be prepared to use and integrate technology when they enter classrooms as well.

Several have suggested that colleges and universities must take a leadership role in preparing preservice teachers to use and integrate computer-related technology in schools (Espinoza & McKinzie, 1994; Office of Technology Assessment, 1995). Preservice teacher education programs can significantly impact future K-12 computer-related technology use by effectively preparing teachers who have the knowledge and the ability to use and integrate computer-related technology to enhance teaching and learning (Berney, 1991). Teacher education faculty, like their K-12 colleagues, face many of the same barriers such as limited access, little knowledge of technologies, and limited time. Before technology use and integration throughout teacher preparation programs can be realized, teacher education faculty and preservice teachers must receive substantial amounts of training and support in developing effective classroom strategies and applications of technology.

The potential use of instructional technology to improve teaching and learning in K-12 schools is great, yet it has been problematic because typically, inservice and preservice teachers have not been given the time nor the opportunity to learn how to use and integrate these technologies throughout the K-12 curriculum (Office of Technology Assessment, 1995). For this research project, a technology integration model is being developed that provides inservice and preservice teachers the on-site support they need to use technology to impact K-6 student learning. The strength of the model exists in the fact that it brings together the efforts of personnel from three educational institutions which are actively involved in providing support for the exemplary use of technology in Iowa schools: a school district, an area education agency, and a college of education.

Background

The following three sections provide a literature based rationale for the need to support inservice and preservice teachers in their use and integration of instructional technology. The three areas reviewed include: 1) technology integration models, 2) technology support for inservice teachers, and 3) technology in teacher education.

Technology Integration Models

Potentially, technology has the ability to change the way teachers teach and students learn. New ways of teaching and learning have emerged as educators explore the many possibilities technology affords learners in classrooms. Several researchers have developed models that describe the stages educators progress through as they learn how to use and integrate technology (Dwyer, Ringstaff, Sandholtz & Apple Computer, Inc., 1990; Office of Technology Assessment, 1995).

Researchers involved with the Apple Classroom of Tomorrow (ACOT) program identified five stages of evolution for technology use in classrooms (Dwyer, Ringstaff, Sandholtz & Apple Computer, Inc., 1990). This research contributes to the growing body of evidence that "teachers' beliefs about instruction and schools is an important factor that underlies the institution's resistance to change" (Dwyer, Ringstaff, Sandholtz & Apple Computer, Inc., 1990, p.15).

The five stages that comprise the ACOT model of technology use include: Entry, Adoption, Adaptation, Appropriation, and Invention. The entry stage refers to the teachers' experience level with the
technology when they began the project. Once teachers accommodated the technology in their classroom to support their traditional methods and materials, they are at the adoption stage of technology use. During the adaptation stage teachers used various technologies as productivity tools in their classrooms and discovered students could use these cognitive tools for higher-order learning and problem solving. At the appropriation stage, teachers thoroughly understood technology as they began to emphasize project-base learning in a supportive, collaborative and interdisciplinary classroom. At the final stage, invention, teachers begin to invent new learning environments that use technologies as flexible learning tools. These learning environments become constructivist in nature as learners construct their own knowledge rather than receive it from someone else. This notable research helps other educators realize the time it takes for teachers to use and integrate technology successfully in classrooms and identifies various stages K-12 teachers progress through when using technology with students.

In the report, Teachers & Technology: Making the Connection, three levels of technology use in teacher education are identified: 1) discussion/demonstration, 2) technology practice, and 3) professional practice (Office of Technology Assessment, 1995). The order of these levels suggests a developmental model of technology use in teacher education; the progression through which preservice teachers are guided to acquire basic skills as well as sophisticated models of technology integration for classrooms. At the discussion/demonstration level, a professor might discuss how to use a database in an elementary classroom to an entire class of preservice teachers. The second level of technology use, technology practice, provides preservice teachers with hands-on technology practice. For example, preservice teachers in a reading methods course might spend time in a computer lab reviewing and examining several elementary word processing programs. Viewed as the most complex level of technology use in teacher education, the professional practice level focuses on integration of technology into K-12 classrooms. At this level, preservice teachers are either observing technology-based learning in K-12 classrooms, designing lesson plans that integrate technology, or teaching with technology in K-12 classrooms. Ultimately, preservice teachers design curriculum materials that infuse technology and practice teaching with technology in classrooms.

Technology Support for Inservice Teachers

There are not enough teachers in the K-12 schools who have acquired the necessary computer skills to utilize technology for classroom instruction (Office of Technology Assessment, 1995). Some reasons for the shortage of teachers who are capable of using instructional technology include the lack of technology courses offered in teacher training institutions, the inability of economically pressed school districts to hire new teachers with computer experience, and inadequate technology staff development programs (Office of Technology Assessment, 1988, 1995).

National surveys have been conducted to determine if computer inservice education and staff development programs are available for teachers. Data from the report, Teachers and Technology: Making the Connection, suggested that K-12 teachers still have very little training available for them to learn about technology and its education uses (Office of Technology Assessment, 1995). Less than half of the respondents reported having computer courses available for their teachers either at the district or local college level. Findings from this study indicated that more resources had been allocated to purchase hardware (55%) and software (30%) than were allocated to provide training and support (15%) for teachers. Respondents noted that most of the computer inservice training sessions for teachers focused on learning about computers, not on learning how to teach with the technology. This study indicated that teachers perceive the most effective staff development programs were ones that include follow-up support after the initial training.

Under the direction of the President’s Committee of Advisors on Science and Technology, the Panel on Educational Technology (1997) was given the task to provide the President with advise on the application of instructional technologies in K-12 schools in the United States. The panel reported that K-12 teachers receive little technical, pedagogic or administrative support for using technology in their classrooms as of 1997. This report indicates that only 15% of a school’s typical technology budget is used for professional development, rather than the recommended 30% that is considered by most to be the minimum.

While K-12 schools and school districts continue to plan for technology use and integration, teacher education institutions typically have not done the same (Schrum, 1994). Little has been done by most teacher education institutions to help faculty use instructional technology or to prepare preservice teachers who are capable of using technology in classrooms.
Technology in Teacher Education

Several teacher education institutions identified the need to improve upon their efforts to promote the use and integration of instructional technology by teacher education faculty and students (Kortecamp & Croninger, 1994). Preservice teachers enter schools inadequately prepared to integrate technology effectively into their teaching repertoires (Davis, 1994). It is evident that many preservice teachers feel they lack the necessary skills and experiences to use technology for teaching and learning. In fact, not only must preservice teachers understand the potential of technology, they must understand how to use technology in the classroom with students (Barron & Goldman, 1994). To develop this vision, preservice teachers must have educational experiences that model how instructional technology can be used for instruction and as learning tools throughout their preparation program (Byrum & Cashman, 1993).

Many of the challenges that teacher education faculty members encounter in their attempts to use and integrate technology are similar to barriers K-12 teachers experience. Teacher education faculty stated they lack the necessary time to become more knowledgeable about instructional technology (Office of Technology Assessment, 1995). Teacher education faculty can be certain that learning how to use and integrate technology will take time, as it will probably be several years before they are comfortable using these technologies with students in their courses. As noted by Becker (1994) and Sheingold and Hadley (1990), if often takes K-12 teachers more than five years to become accomplished computer-using teachers.

Description and Implementation of the Project

As recommended by the Panel on Educational Technology there is a need to conduct “early-stage research aimed at developing innovative approaches to the application of technology in education....” (Panel on Educational Technology, 1997, p. 124). This research project examines an innovative approach to technology integration in a school district that includes representatives from a number of educational institutions involved in the systemic change process for school improvement. One goal of this project is to provide a framework that can be duplicated or modified by other school districts or teacher education institutions where educators work collaboratively to assist preservice and inservice teachers in their efforts to design compelling uses of technology that will facilitate meaningful learning in classrooms. This innovative model provides a means to which there is a shared responsibility of providing the necessary support and resources to increase the exemplary use of technology in schools.

The educational institutions involved with this collaborative project include a school district, an area education agency and a college of education. North Polk Community School District includes four small towns and the surrounding rural area and serves approximately 900 students. Heartland Area Education Agency (AEA) is a regional service center that serves 56 public school districts, 35 approved non-public districts, 120,531 students and 9,031 certified staff members in an eleven county area. An instructional technology team that consists of five members provides leadership and expertise in educational technology at the local, state and national level. The Department of Curriculum and Instruction in the College of Education at Iowa State University (ISU) prepares 1025 undergraduate elementary education majors and 500 undergraduate secondary education majors. The undergraduate and graduate instructional technology programs in the Department of Curriculum and Instruction have traditionally been known for preparing preservice and inservice teachers to use computer-related technology for learning and teaching.

Plans and preparations for this project began with meetings and discussions between key personnel from North Polk, AEA, and ISU in 1997, but the actual research project and related activities began in September of 1998. Project activities that have been implemented during the first year of the project include the selection of project participants, the collection and analysis of first year data, and the design and delivery of professional development activities.

Project Participants

Both inservice and preservice teachers volunteered to participate in this three-year research project. Inservice teachers from the North Polk school district expressed that they viewed this as an opportunity to
mentor preservice teachers on best teaching practices while receiving support in their use and integration of technology. Nineteen teachers representing various grade levels and specialty areas from two K-6 elementary buildings are participating in the project. In addition, ISU preservice teachers are excited to have the opportunity to share their working knowledge of information technology with an experienced teacher and to participate in a number of classroom-based learning experiences while completing their degree. Sixteen preservice teachers who are majoring in elementary education, secondary education or early childhood education are participating in the project. The majority of these preservice teachers will have completed the required introductory instructional technology course, will complete their freshman or sophomore year this spring and will pursue a minor in educational computing offered by the Department of Curriculum and Instruction at Iowa State University.

Collection and Analysis of Data

Since this research project is in the initial stages of implementation the data analysis and findings will not be reported in this paper. Data will be collected throughout this project to monitor the progress of participants in learning to use and integrate technology in classrooms. Several of the methods used to collect data include participant interviews and focus groups, direct observations and questionnaires.

Professional Development Activities

Participants involved in this three-year research project will be introduced to a framework that provides them with support and hands-on experiences using technology to enhance the instructional goals of their classrooms. Within this framework, various professional development activities will be introduced and implemented at various times each year. These activities will include technology and curriculum inservices, a preservice/inservice teacher mentoring program, courses, focus groups, and classroom support experiences. The project members who are responsible for the design and delivery of the professional development activities include two instructional technology consultants from the AEA and a professor and a graduate student from ISU. In addition, preservice and inservice teachers will be more involved in the delivery of the professional development activities as the project evolves over time.

The professional development activities that have taken place during this past fall semester were primarily designed for the teachers at North Polk. The majority of the teachers in this school district have had little experience using technology in the classroom, so the professional development team designed and scheduled activities that would provide support for the teachers in a variety of ways. During the first semester of the project the professional development opportunities have focused on introducing teachers to email and one-computer classroom approaches to using technology with students.

Although the North Polk teachers have had access to email in their schools, the electronic mail system they were using was not considered to be user-friendly by many. One of the AEA instructional technology consultants worked with both the district and elementary technology coordinators to set-up and install QuickMail for all elementary teachers. Then, the AEA technology consultant met with each teacher individually during the school day to provide him/her with the instructions on how to use the new email system. The AEA consultant continues to follow up this introductory session with weekly email messages to the teachers that provide them with additional instructions that help them use other features of the email system.

Since the focus of the project is to improve the use and integration of technology in classrooms, significant time has been spent designing professional development activities that will assist teachers in their use of technology in classrooms. To accommodate teachers' schedules, several approaches have been used to deliver these staff development activities. District administrators gave teachers the opportunity to participate in whole group inservices during district inservice days. This semester, the purpose of the whole group inservices was to introduce teachers to one-computer classroom software. Following these inservices, teachers could sign up to have one of the professional development team members come into their classroom to teach a lesson using one of the software programs introduced during the whole group inservices. To participate in this classroom activity, teachers had to verify that the software used and lesson created supported grade level curriculum initiatives. Then, a professional development team member went into the classroom and taught the lesson with assistance from the classroom teacher. In most cases, the teacher was then responsible to continue...
or follow up the initial lesson with activities of their own. These classroom team-teaching activities were highly successful and will be continued throughout the project as more software programs are introduced.

As this project moves into its second semester of implementation the preservice teachers will play a major role in supporting the teachers as both discover ways to integrate technology into teaching and learning environments. To meet a university field experience requirement, each ISU preservice teacher will spend approximately 2-4 hours per week in a classroom with a North Polk teacher. Specific course activities are being planned for the preservice teachers as they participate in this field experience with teachers. Preservice teachers will also be encouraged to participate in the technology inservices that will be offered next semester.

Other professional development activities are being planned for spring semester and beyond. There will be a two-day workshop for participants (i.e., inservice & preservice teachers) this summer. Next fall, inservice and preservice teachers will be taking a three-credit university course in which they will learn and support each other as they continue to explore the possibilities of using technology in elementary classrooms.

Summary

This project is the result of collaborative planning efforts by administrators and teachers from a school district, instructional technology consultants from an area education agency, and faculty and preservice teachers from a university. The major goal of this technology integration model is to create a community of learners where all participants share their knowledge and expertise with each other to ultimately improve the learning process for elementary students.

The Relationship between Cognitive Strategy Use and Students' Hypermedia Navigation

Noelle Wall Sweany
The University of Texas at Austin
United States
sweany@mail.utexas.edu

Abstract: Hypermedia applications provide a new approach to education and present another advancement for student knowledge building; however, little research has been done to investigate how students interact psychologically with this new medium. As hypermedia becomes a more common instructional format, researchers need to anticipate the difficulty students will encounter while working in this new environment. Applying the conceptual frameworks and findings from strategic learning research in traditional learning environments to the research in hypermedia learning environments should be helpful in preparing students to work effectively and efficiently in hypermedia learning environments. This study compares one aspect of strategic learning, students' reported use of cognitive strategies in traditional environments, with the students' hypermedia navigation. It is anticipated that the use of cognitive strategies may mediate the relationship between hypermedia navigation and achievement.

Statement of the Problem

As technology has transformed home and office environments, it also has the opportunity to enhance the educational system. A shift is occurring in both teaching and learning because students are spending so much more time working with computers. Unfortunately, the advancements in technology are outpacing the advancements in our understanding of the psychological aspects of working with computers. This is a particular problem for instructional psychologists. Researchers do not fully understand how students interact with computer-learning environments and as a result we cannot determine which types of instructional design methods could improve the learning process and make it more effective and efficient for the students. This type of research is not only important for K-12 or college-level students, but also for continuing education and training in business and industry. Thus, there is a tremendous need for applying educational psychology theories to instructional technology research.

Current Instructional Technology Research

The use of hypermedia learning environments in education has not fulfilled the expectations of many instructional technology researchers. Three major assumptions have guided recent hypermedia investigations: (a) the node and link structure of hypermedia corresponds to the associative nature of the human mind; (b) the non-linear format of hypermedia forces learners to take an active role, thus promoting self-regulated, constructivist learning; and (c) the use of multimedia corresponds with the cognitive principle of utilizing multiple modes of representation to enhance learning and memory. However, the empirical results of these investigations have not supported these assumptions (Tergan, 1997). Rather than the design of the hypermedia programs promoting more active learning, it is becoming apparent that the learner's characteristics are interacting with the design characteristics to result in various levels of performance. In addition to the structure of the hypermedia program, the cognitive activities of the learners themselves also seem to be a significant factor in determining achievement (e.g., Dee-Lucas & Larkin, 1995; Lee & Leeman, 1993).

One of the often cited benefits of the use of hypermedia in instruction is the ability to incorporate additional resources, such as databases, glossaries, video clips, search engines, etc. However, students will not automatically use the computer facilities in an optimal manner simply because the tools are available (McKnight, Dillon, & Richardson, 1990; Tergan, 1997). Rouet and Levonen note that students have not had the chance to develop effective strategies for working with hypermedia (1996). Reading traditional printed text requires a significant amount of practice and refinement of specific strategies. These strategies are usually dependent on familiar text.
structures. Hypermedia represents an unfamiliar text structure to which students must adapt their traditional reading methods. In this new non-linear environment, students must keep track of where they are and where they want to go while building a mental organization of the material they are encountering (Rouet & Levonen, 1996). Certainly the research on cognitive strategies may be applied to the hypermedia learning environment in order to improve the quality of learning while working with a computer system. The students must possess the requisite knowledge of how to use the system effectively in relation to their own learning goals. This requires that the students must be “strategic learners,” or students who know about themselves as learners, who are aware of the task characteristics, and who can implement the necessary skills to reach their learning goal.

It is also becoming apparent that the research on learning with hypermedia needs to be based on a theoretical framework (Astleitner, 1997). Performance cannot be attributed solely to characteristics of the hypermedia learning environment. Rather it is the result of a complex interaction of the learner variables, instructional methods, task characteristics, and attributes of the media (Tergan, 1997). Future research must take these variables into account to more fully understand the nature of learning and instruction with hypermedia programs.

Applying Strategic Learning to Hypermedia

One well-developed area of educational psychology is strategic learning research. Educational psychologists describe strategic learners, or self-regulated learners, as learners who are behaviorally, motivationally, and metacognitively active participants in their own learning (Zimmerman, 1986). Learners can influence how they process incoming information, and in turn to what degree they actually “learn” the information and transform it into organized knowledge (Weinstein, 1994; Weinstein & Mayer, 1986). In contrast to how learners are depicted in behavioral theories, the cognitively-active learner is not a passive respondent to environmental conditions or demands. Individuals can take specific steps to effectively evaluate, integrate, analyze, and retain new knowledge.

Hypermedia applications provide a new approach to education and present another advancement for student knowledge building; however, little research has been done to investigate how students interact psychologically with this new medium. As hypermedia becomes a more common instructional format, researchers need to anticipate the difficulty students will encounter while working in this medium. Applying the conceptual frameworks and findings from strategic learning research in traditional learning environments to the research in hypermedia learning environments should be helpful in preparing students to work effectively and efficiently in hypermedia learning environments.

Weinstein has developed a Model of Strategic Learning which is composed of three distinct components: Skill, Will, and Self-regulation (Weinstein, 1994). The Skill component consists of five basic categories of knowledge that strategic learners possess: (a) knowledge of themselves as learners; (b) knowledge about different types of academic tasks; (c) knowledge about strategies and tactics for acquiring, integrating, applying, and thinking about new learning; (d) prior content knowledge; and (e) knowledge of both present and future contexts in which the knowledge could be useful. The Will component consists of the affective aspects of the learners, such as their motivation, academic goals, beliefs, and volition. The Self-regulation component consists of things such as the metacognitve awareness and control of the learners, their execution of time management skills, and their execution of systematic planning skills. The Skill, Will, and Self-regulation components surround the core of the model, which represents the individual learner’s long-term goals and his/her general self-system variables, such as self-concept, self-expectations, and self-efficacy. For learners to reach an academic goal, they must have the necessary skills, motivation, and self-regulatory processes.

Self-regulated, or student-directed, learning has been termed the highest form of cognitive engagement (Corno & Mandinach, 1983), yet many students have difficulty adjusting to a self-regulated environment because they lack the effective strategies necessary to succeed (McCombs, 1988). Hypermedia educational programs can provide powerful environments for student-directed strategic learning. “Users with the abilities to select information, make connections with existing knowledge, organize their approach to accomplishing tasks, and monitor the process will be those who can perform effectively in the type of self-regulated environment of a hypermedia system” (Gay, Trumbull, & Mazur, 1991). However, this claim has not been investigated adequately by researchers.

My dissertation research will examine the relationship among all of the components of the Model of Strategic Learning and students’ hypermedia navigation. However, the most important variable for this paper is the knowledge and use of learning strategies. Learning or cognitive strategies are defined as “behaviors and thoughts that a learner engages in during learning that are intended to influence the learner’s encoding process” (Weinstein &
Mayer, 1986, p. 315). The use of these strategies allows the learner to become an active participant in the learning process rather than passively receiving the information. Weinstein and Mayer (1986) outline the three major categories of learning strategies: Rehearsal, Elaboration, and Organizational. Rehearsal strategies are most useful for basic memorization of facts or ideas. Examples of rehearsal strategies include mnemonics and highlighting. Organizational strategies help the learner structure the material in a more personally relevant fashion. Examples of organizational strategies include diagramming and outlining. The goal of elaboration strategies is to transform the incoming information and make it more relevant by integrating it with the student's prior knowledge. Examples of elaboration strategies include summarizing and paraphrasing. Organizational and elaboration strategies require deeper processing and generally result in more long-term learning.

Research has consistently shown that the knowledge and use of cognitive strategies is associated with increased levels of performance (Pintrich & Garcia, 1993; Weinstein & Mayer, 1986; Zimmerman & Martinez-Pons, 1990). The use of cognitive strategies facilitates the encoding of information and aids in the subsequent retrieval of information. Current studies have suggested that students who use cognitive strategies in traditional environments will generally be able to regulate themselves in a learner-controlled computer environment (much like hypermedia) more effectively than students who do not use cognitive strategies in traditional environments (Young, 1996).

Research Study

Approximately 360 students enrolled in a first-year, first-semester French course are currently participating in the study. The students meet once a week in the computer lab to work with a hypermedia CD-ROM, Parallèles Interactive. The students' navigational trails while working with the program are automatically logged by the computer.

The final data will be collected at the end of the Fall, 1998 semester. Cluster analysis will be performed on the students' log files to examine patterns of individual differences based upon the computer features accessed by the students. The log files will be coded according to: time on task; frequency of accessing nodes containing either grammar, lexical, or cultural information; listening to full-length audio; listening to line-by-line audio; accessing the dictionary; answering the comprehension questions; and accessing the Internet. Patterns relating to achievement across clusters and patterns relating to achievement within clusters will be examined. For example, one possibility across clusters could be high achieving students will use more of the computer features whereas low achieving students will not use as many features. The higher achieving students may recognize the benefit of using more of the supports whereas the low achieving students may not. Within a cluster, it may be that some students do not use a lot of the supports and still score higher in achievement, whereas other students who did not use a lot of supports scored lower in achievement. It is expected that the students' reported use of learning strategies will mediate this relationship. The high achieving students may use the computer features strategically in order to accomplish their task and in turn earn higher grades, while the low achieving students who also access the same features do not use the features strategically.

Students' reported use of cognitive strategies will be measured by the Rehearsal, Elaboration, and Organization subscales of the Motivated Strategies for Learning Questionnaire (MSLQ). Achievement will be measured by chapter exam grades. At the time of this writing, the data collection was in process. The paper presentation will describe the actual data analyses. The various navigational profiles as well as the profiles' relationships with achievement and reported use of cognitive strategies will also be discussed. If the hypothesis of this research is supported, it will yield support for the importance of considering instructional design in relation to the students' individual differences with respect to strategic learning. Although instructional designers may include tools to aid students in their learning, the students may not use the tools effectively because they do not know how to use them.

Summary

I believe applying the findings of strategic learning research in traditional environments to instructional technology research will give us a more complete picture of what characteristics students bring to the learning situation and how these variables may impact the use of a hypermedia program. Specifically, the use of cognitive strategies may mediate the relationship between hypermedia navigation and achievement. As more options are added to hypermedia programs, people need to understand how to work with the medium more. We need studies in
applied research to examine the relationship between the various strategic learning variables and students' interactions with hypermedia learning environments. The results from these studies should help instructional designers improve the content of the hypermedia programs as well as help students to interact with the programs more effectively.

Formative Evaluation of a Multimedia Case: A Test of Practice

Ellen van den Berg
Faculty of Educational Science and Technology
Department of Curriculum
University of Twente
The Netherlands
Berg@edte.utwente.nl

Abstract: This paper reports about a formative evaluation of a multimedia case for elementary science teacher education. This case has been developed in the framework of the MUST project. The formative evaluation had the form of two micro-evaluations with prospective teachers. These teachers are the primary target group of MUST products. Besides a conformation of our general ideas and design, the evaluation results provide many suggestions for improvement both at the interface and technical level as well as at the more basic educational level.

Introduction

The central theme of this paper is the formative evaluation of the multimedia case "Liquids in test tubes". This case has been developed in the framework of the MUST project. The acronym MUST stands for MUltimedia in Science and Technology. The main aim of the project is to develop and to evaluate multimedia cases for elementary teacher education in the Netherlands. The multimedia case that is central in this paper contains the following components: video of a lesson, comments on the lesson, background information of the school, curriculum information, lesson plans, specific information about the science content of the lesson, learning tasks, and an orientation on the program.

In the first section of this paper the design of the formative evaluation is presented. Subsequently, an overview of the results is given. Finally, the conclusions and decisions for improvement of the prototype are presented.

Design of Formative Evaluation

The overall design of the formative evaluation consists of three stages: micro-evaluations, try-outs and effect studies. In this paper the focus is on micro-evaluations. In a micro-evaluation a limited number of members of the target population (i.e. prospective teachers) uses the program. The evaluations were guided by three main questions:

- How do respondents perceive the usefulness of the different components of the multimedia case?
- How easy to use is the interface?
- What is the opinion about the educational value of multimedia cases in teacher education?

In the two micro-evaluations the 10 respondents combined two roles: the role of a learner and the role of a reviewer (cf. Nieveen 1997). Data were collected by means of questionnaires, observations, interviews and analysis of assignments.

Summary of Results

Perception of Different Components of the Multimedia Case

The core of the multimedia case is a non-scripted 17-minute video of a lesson about liquids in which the learning cycle of elementary science teaching is applied. All 10 respondents agreed that such a video is an important
and enjoyable component of the multimedia case. As expected they were, compared to the other components, most positive about this part of the multimedia case.

The multimedia case also includes comments on the video-lesson from the video-teacher, experts in the field (two teacher educators and a curriculum specialist) and two prospective teachers. The aim of the comments is to warrant different perspectives on the lesson. In general, the respondents valued this part of the CD-ROM. However, the evaluation results revealed some interesting differences between respondents. Firstly, some respondents tend to value the comments of the experts as more worthwhile than the other comments. According to them: “You learn most of those comments.” However, one respondent expressed an opposite opinion: “The comments of experts are dull, it is like listening to a textbook”.

Another, non-anticipated, result appeared from the evaluation. Some respondents who saw “their teacher educator” on the CD-ROM ignored the comments of other experts. They seem to think that it is most important to know what your teacher educator says about the video-clip of the lesson. Students who did not have the opportunity to consult the comments of their teacher educator gave equal attention to all comments, and elaborated on the differences between them.

There were also differences in the appreciation of the comments of fellow prospective teachers on the CD-ROM. Some respondents enjoyed these comments very much, while others mentioned that comments of fellows are not very useful. One respondent stated: “You cannot learn very much of those comments”.

The background information of the school where the video was recorded (including information about the teacher and the students) was valued, but the respondents ask for more focused information. General information, such as hobbies of the video-teacher, was regarded as superfluous. However, according to the respondents, more information should be added about the teachers’ vision on elementary science and about the way he teaches science in his classroom. The respondents would also appreciate more information about the students of the class.

The components curriculum information, lesson plans and specific information about the science content of the lesson were regarded as useful, although the way the information was presented (text) could be more attractive. Moreover, respondents would like to obtain more in-depth information about the science content of the lesson.

Two comprehensive learning tasks were added to the multimedia case. Respondents perceived these tasks as useful, because it helps them to give focused attention to the information in the case. However, they also perceived these tasks as rather difficult and made suggestions to improve them. An analysis of the way they conduct the learning tasks revealed that the respondents could make a rather elaborate analysis of the lesson and could relate the information in the case to their own experience. However, it seems quite complicated for them to formulate precisely what they would do differently, when they were asked to implement lessons of this kind themselves.

The orientation on the program was meant as an introduction and as a means to motivate students. However, it did not serve its purpose. Some respondents doubted whether such orientation is necessary, because the program is clear and motivating enough. Others, however, recognized the potential value of an orientation, but suggested redesigning it.

Practicality of User-interface of the Multimedia Case

Most respondents perceived the user-interface as comfortable to handle. Especially inexperienced computer users were pleased that they could easily find most information. More experienced computer users expressed some critical comments on the interface, they thought the two different ways to navigate are unnecessary redundant.

The most critical problem with the interface was the filing of information users could actively add such as their completion of the learning tasks. It was very difficult, especially for the inexperienced users to find the files back in their computer system.

The CD-ROM ran smoothly on the rather sophisticated computer networks of teacher education colleges, but when some respondents played the CD-ROM on their home computers, it turned out that the program did not run very well on older computers.

Overall, the evaluation of the user-interface also provided detailed information for debugging and other minor suggestions for improvement.

Educational Value of the Multimedia Case
After working with the CD-ROM, eight out of ten respondents were convinced of the educational value of the multimedia case. The reasons why can be summarized as follows:

- it illustrates and provides a clear impression of the difficulties of elementary science teaching;
- it allows for exploring questions about elementary science teaching;
- it is motivating to work in such a different way.

One of the two respondents who had doubts about the usefulness of the multimedia case had severe technical difficulties with the user-interface, and the other did not like the topic of the video-lesson at all. Moreover, the latter student experienced difficulties with the language level of some parts of the multimedia case, since Dutch was not her mother tongue.

Conclusions and Recommendations

The first question of the formative evaluation of the multimedia case “Liquids in test tubes” was about the appreciation of the different components of the multimedia case. Overall, all components were rated positively by the prospective teachers, but the evaluation revealed also many interesting suggestions for improvement.

As far as the component comments is concerned, an idea for improvement is to communicate to the users clearly that especially the differences in comments are meant to be a source for reflection and learning. Discussing the evaluation results with regard to the comments-page in the MUST team, also led to modifications of the comments. We decided to highlight the differences between the comments more clearly, and to reduce the number of persons who give comments from six to four. The latter was done, because, on some aspects, the comments had quite a lot in common. This redundancy is not stimulating for users to analyze the information.

Although the background information about the school (including teacher and students) was regarded as useful, the evaluation results give reasons for major improvements. Prospective teachers want more focused information and additional information about especially the teacher and the students. Although, it is not possible to collect this information for the prototype under evaluation (because for budget reasons we used an already existing video of 1993), in the next MUST productions this information will be far more elaborated. Amongst others, much more student work will be included in further multimedia cases. Within the MUST team, there has been a discussion about the ethical aspect of including personal information about students in a multimedia case. The conclusion of this discussion was that for privacy reasons we do not include, for example, test scores or opinions of the teacher of individual students. Instead, we asked students to give some personal information and to give their opinion of elementary science, themselves. The students were also invited to present themselves by their Christian name only. Moreover, all student work that is directly related to the videotape will be included in further cases.

Based on the evaluation results, the decision was made to make the curriculum information, lesson plans and science content information more attractive. This will be done by a more appealing presentation of textual information. Moreover, the science content will also be presented by means of instructive computer animations.

The learning tasks on the CD-ROM caused, from a technical perspective, major problems. This was one of the reasons to exclude learning tasks from the next version of the CD-ROM. In addition, a more important reason for this decision has been our growing insight that predefining learning tasks is not in line with the “flexibility in use” rationale of the MUST project. Therefore we decided to opt for a web-based interactive database that contains a variety of learning tasks (for more details see paper of Nieveen & van den Berg, 1999 in this SITE conference).

The orientation on the multimedia case was not appealing to the users, therefore we completely redesigned it.

The second question concerned the user-interface of the multimedia case. Although it was easy to handle, the user-interface has been redesigned as well. This was mainly a consequence of the necessary modifications following from other evaluation results and was also based on suggestions gathered during an expert appraisal. Because users were not completely comfortable with the navigation options in the first prototype a navigation option has been included in the revised version that makes short cuts possible. Moreover, explicit system specifications will accompany the second prototype.

The third question was how prospective teachers would perceive its educational value. The results show that a fast majority of the respondents was positive about this educational value. However, a minority did not share this opinion. From their comments we gained two ideas for improving the prototype. Firstly, the filing system of the learning tasks should become user-friendlier and the language level of the learning tasks should become less complicated, especially for prospective teachers who are of non-Dutch origin.
In sum, we may say that the micro-evaluations with a limited number of potential users provide many ideas to improve our product. We learned once again that these kinds of small-scale evaluation are very informative and cost-effective.

Evaluating NCATE Technology Standards Implementation in a School of Education

Rachel A. Vannatta
Educational Foundations & Inquiry
Bowling Green State University
rvanna@bgnet.bgsu.edu

Abstract: This article describes the process of a school of education in its early stages of technology planning that entails: the development of a technology integration task force; the evaluation of current faculty levels of technology proficiency, integration, and implementation of the NCATE technology standards within the SUNY Oswego School of Education; and the development of recommendations for a long range technology plan. Sixty-five full time education faculty members were administered two surveys through campus mail. Results (N=45) revealed that moderate to high levels of faculty proficiency and integration were limited to the areas of word processing, email and Internet related activities. The leading predictor of implementation of NCATE standards was not overall proficiency of computer hardware/applications but proficiency in instructional methods of technology integration. Recommendations for long range planning address equipment, faculty training, as well as programmatic changes.

Introduction

In the last eight years, the National Council for Accreditation of Teacher Education (NCATE) in conjunction with the International Society for Technology in Education (ISTE) has developed several sets of guidelines and standards to strengthen the support for technology use and integration in professional teacher preparation programs. While each set of standards has provided further guidance to improving teacher education programs, each set has also called for a deeper commitment toward the infusion of technology by schools, colleges, and departments of education (SCDEs).

The first set of guidelines was released by ISTE in 1991 and established technology standards for all teachers. Adopted by NCATE and utilized in the accreditation process, these thirteen technology competencies not only set a benchmark for all current teachers but also a guide for teacher education programs across the nation (Thomas 1991). In response to these standards, several SCDEs have required preservice teachers to attend a course(s) on educational technology and to then demonstrate technology competencies prior to graduation (Hess, 1992). Although a technology-specific course develops basic computer skills, several studies have concluded that a stand-alone course does not prepare educators to utilize technology in a variety of instructional settings (Handler & Pigott 1994; Office of Technology Assessment 1995; Wetzel 1993).

In 1994, NCATE and ISTE set forth accreditation guidelines that focused more on the integration of technology in professional teacher preparation programs. These guidelines require teacher candidates to complete a sequence of courses/experiences to develop an understanding of the impact of technology on schools and to use of technology in instruction and assessment and for professional productivity. In addition, these guidelines require that education faculty be knowledgeable about current practice related to computer use as well as integrate technology in their teaching and scholarship. As SCDEs have developed training programs for faculty to facilitate the infusion of technology within the education curriculum, many SCDEs have encountered several obstacles, such as a lack of faculty interest, information, expertise, time, equipment, and software (Parker 1996; Wetzel 1993). However, in an attempt to overcome these obstacles while creating technology-using educators, many SCDEs are developing comprehensive technology plans that encompass equipment needs, student and faculty technology proficiencies, as well as course and programmatic changes. Such long range plans have spawned the creation of many innovative strategies and programs as well as the evaluation of such plans.

While several SCDEs have developed and implemented technology plans, other SCDEs are just beginning to address the problem of technology integration. However, since the 1997 recommendation from the NCATE Task Force on Technology and Teacher Education that requires accredited SCDEs to develop and implement a plan for technology, more SCDEs are initiating the technology planning process. This article describes the process of a school of education in its early stages of technology planning.
Methodology
The Process

When I arrived as a new faculty member in the department of curriculum and instruction at SUNY Oswego in 1996, the school of education (SOE) had just developed an educational technology course and was in the process of developing a new education computer lab. Unfortunately, most preservice teacher education students were not receiving any instruction on computer applications or integration methods since this newly developed technology course was not a program requirement and conflicted with most required courses. In addition, education students were experiencing few computer-related activities in their education courses due to a lack of equipment and faculty expertise. Frustrated with the lack of technology resources available as well as the lack of technology skills among education faculty and students, I proposed to the Dean of Education that a technology task force be developed to assess the school’s current technology use and to create a long term plan for technology integration. Since the school was seeking NCATE accreditation, the Dean believed that data generated from the task force would not only assist the NCATE process but also address a concern that had been repeatedly expressed by area superintendents—that education graduates are not prepared to integrate technology in the classroom. The Dean forwarded the proposal to the SOE’s faculty council, which approved the creation of a technology task force in November of 1997 and outlined its charge as the following:

- define technology;
- develop a snapshot of where the SOE is presently in terms of faculty skill/comfort levels in using technology, availability of technology to faculty and students, and level of faculty integration in education courses;
- conduct a review of the literature that includes an examination of what other schools of education are doing to increase technology integration; and
- develop recommendations for a long-range technology plan.

The task force was asked to complete its work by April 15 and met several times to create a plan, collect and review data, and develop recommendations. All six department chairs were asked to appoint at least one department representative; however, individuals from only five departments either volunteered or were appointed for a total of seven members. During its first meeting on January 30, the task force developed a plan of action by accomplishing the following: elected a chair, reviewed task force objectives, defined technology, identified methods of data collection, decided to elicit student assistance in conducting a literature review on technology integration in schools of education, reviewed and developed survey instruments, determined a time line to satisfy the SOE deadline of April 15; and scheduled additional meetings for data review and discussion. The task force’s definition of technology would be that of educational technology, which would encompass computer technology and applications. The task force determined that two surveys would be administered to measure faculty technology proficiency, integration of applications, perceived barriers to technology integration, training preferences, and NCATE implementation.

Participants

Of the 65 full time faculty members in the school of education, 45 completed both evaluation surveys. A full time faculty member was defined as being a full-time instructor or tenure-track faculty. Approximately 90% of the SOE faculty were Caucasian. Response rates and percents for each of the SOE departments were: counseling and psychological services (n=9, 81.8%), curriculum & instruction (n=15, 68.1%), educational administration (n=3, 100%), health, physical education, & athletics (n=5, 45.5%), technology (n=8, 66.7%), and vocational technology education (n=3, 60%). All respondents reported having a computer at home, while only 95.3% reported having an office computer. Unfortunately, only half of the respondents reported having an office computer with adequate memory, hardware, and software.

Instrumentation

Two surveys were developed for this evaluation: SOE Technology Integration Survey (SOETIS) and the NCATE Implementation Survey (NIS). The SOETIS consisted of 32 items that had been adapted from a survey developed by the author the previous year for a Goals 2000 grant (Vannatta & Reinhart, 1998). The revised survey measured five areas: background information, proficiency in computer equipment and applications, integration of technology in education courses, factors that impede technology integration, and training preferences. Background information, such as department membership, type of computer at home and office, platform preference, and access to computer lab for student instruction, was addressed in the first six items. Items 7 - 27 asked faculty to identify current proficiency using computer equipment, applications, and instructional methods for integrating technology. These 21 items utilized a Likert scale of 1-4 in which 1 represented no proficiency. Item 28 asked faculty to
identify, from a list of fifteen computer applications/activities, which specific activities were currently being integrated in their education courses. In this item, participants distinguished between faculty demonstration/use and student use by writing "p" for professor use, "s" for student use, and "ps" for use by both. Faculty also identified factors that were perceived as impeding their technology integration, as measured by item 29. From a list of thirteen possible factors, faculty ranked the top three barriers most encountered when using or trying to use computer technology in instruction. The next two items addressed faculty preferences for future training topics and format. Faculty ranked the top five topics for future faculty training on technology (Item 30). Rankings were made from a list of seventeen topics. Item 31 asked faculty to indicate a format preference for future training. Format options were: two hour training sessions; half day training workshops; peer mentor program, in which a skilled colleague would work with a faculty member; and student-faculty mentor program, in which a trained student would work with a faculty member. Although technology training, usually in two hour blocks, had been offered to faculty for years by the university and most recently in the department of curriculum and instruction, these sessions were not regularly attended. Therefore, the task force was particularly interested in determining if alternative training formats would be well-received. The final SOETIS item asked faculty to provide any comments regarding technology integration. Comments were to be written on a separate piece of paper and attached to the survey. SOETIS item responses were analyzed for reliability using Cronbach alpha and were determined to be reliable (r = .8203).

The other survey developed for this evaluation was the NCATE Implementation Survey (NIS). This survey asked faculty to identify which of the 13 NCATE technology standards were being implemented in specific education courses. Each faculty member listed courses that he/she instructed and checked the standards that were being implemented in each course. NIS responses were also analyzed for reliability using Cronbach alpha and were determined to be reliable (r = .9356). Both surveys were administered to all SOE faculty via campus mail. The two surveys were sent out in the month of February. A reminder along with the necessary instrument(s) were sent to faculty in March. By April 1, 45 faculty members had returned both surveys.

Results

Technology proficiency varied among faculty. The greatest percent of faculty reporting moderate to high proficiency were in the areas of: general computer use (90.7%), word processing (93%), and email (92.8%). Only 40.4% of faculty members indicated moderate to high proficiency in instructional methods for integrating technology. In terms of computer applications being integrated into education courses, 75.6% of faculty reported having both students and self utilize word processing in courses. Other applications used by both faculty and students in courses were email (62.2%) and Internet (48.9%). Implementation of NCATE technology standards was primarily limited to standards that address computer use to access information, enhance productivity, and utilize software (See Table 1). Specifically, Standard 12—Use computer-based technologies to access information to enhance personal and professional productivity—was implemented by 71.1% of faculty in one or more classes.

Table 1: Percent of faculty addressing NCATE technology integration standards in their education courses.
while 48.9% implemented it in all courses taught. Standard 1—Operate a computer system in order to utilize software—was implemented by 62.1% of faculty in one or more courses and by 44.4% in all classes.

Surveys also elicited faculty responses regarding perceived barriers to integrating technology as well as training preferences. Faculty identified lack of equipment and lack of time to learn new technologies as leading barriers to integrating technology. Forty percent of the faculty identified instructional methods of integrating technology as their number one preference for future technology training. Faculty also indicated a desire to receive training on computer presentations. Preferences regarding training format were peer mentor program (42.2%) followed by two hour group sessions (31.1%), student-faculty mentor program (28.9%), and half day group sessions (11.1%).

Data were also analyzed to identify any predictors of technology integration in education courses. The following variables were utilized in this analysis:

- Overall technology proficiency—sum of proficiency in 21 areas from SOETIS Survey;
- Proficiency in instructional methods of integrating technology—Item 27 on SOETIS Survey;
- Integration of computer applications—sum of course integration of 15 computer applications from SOETIS Survey. Since faculty indicated the level of use as student, faculty, or both for each of the 15 applications, responses were assigned a numerical score as follows: student use=1, faculty use=1, both student and faculty use=3; and
- Implementation of NCATE technology standards—average number of standards implemented per course from NIS Survey.

The Pearson correlation matrix of these variables is presented in Table 2. Overall technology proficiency was not highly related to integration of computer applications (r=.3366) or to implementation of NCATE standards in education courses (r=.4694). However, proficiency in instructional methods of integration technology was fairly related to integration of computer applications (r=.5645) and implementation of NCATE Standards in education courses (r=.6057). These results lead the task force to conclude that faculty members do not need to be proficient in a variety of technology applications in order to integrate technology, rather they must be as proficient in a few computer applications and most importantly be knowledgeable in instructional methods of integrating technology in the classroom.

Recommendations
Equipment

Although nearly 100% of all full-time SOE faculty reported having an office computer, only half had a computer that was even capable of connection to the new campus network and has a CD-ROM and adequate memory for running up-to-date software. Consequently, many faculty were limited to the computer applications of old equipment—word processing and email. In addition, faculty identified lack of equipment as the number one barrier to technology integration. Upon reviewing this situation and recognizing that many other institutions have found it necessary to develop equipment standards (Northrup & Little, 1996), the task force provided its first recommendations.

Recommendation #1—Develop a standard for all future SOE computer purchases, such as requiring a CD-ROM and high memory. This standard should be revised annually to accommodate the increasing demands of software.
Recommendation #2—Develop a plan to replace low performing office computers on an ongoing basis. Faculty cannot increase their skills until they have the equipment to do so.

It was also determined that very few departments have computer equipment that can be used in the classroom. Although computer labs are available for classroom use on a reservation basis, an entire lab is not always necessary. Much of the time, faculty and students are in need of a computer and an LCD projector for presentation and/or demonstration purposes.

Recommendation #3—Provide each department with a portable presentation unit (laptop computer and portable LCD projector). Ideally several classrooms should be permanently furnished with such equipment.

Faculty Technology Proficiency and Integration

SOE faculty were most proficient and most frequently integrating word processing, email, and the Internet in their courses. An interesting finding regarding proficiency and integration was that overall technology proficiency was not a strong predictor of technology integration, rather feeling proficient in instructional methods of integration was more of a predictor. In addition, faculty (60%) overwhelmingly indicated that future training should focus on instructional methods of integrating technology. Consequently, the task force concluded that faculty training programs should not strive to develop a broad range of technology skills, but rather emphasize the facilitation of instructional methods for technology integration and the development of proficiency in a few personally selected areas of technology.

Recommendations regarding faculty training were guided by several other factors. The task force determined that a variety of training formats were essential to fulfill the many different preferences faculty reported. Consequently, the task force believed it necessary to continue large group training sessions in two-hour blocks but also to develop two new training programs that would fulfill the desire for one-on-one instruction as well as peer observation. Although faculty preferred the development of a Peer Mentor Program, the task force believed that this format was not feasible since the number of faculty able to provide one-on-one mentoring is minimal at this time. However, the task force did believe that a Peer Mentor Program could provide faculty with opportunities for peer observation, through which faculty would observe skilled faculty integrate technology in the appropriate field of instruction. Such a program would require fewer skilled faculty members. The task force asserted that the implementation of a Student-Faculty Mentor Program would fulfill the faculty desire for one-on-one technology training. Such a program has been implemented at Iowa State University and has been very successful in providing faculty members with one-on-one support and training as well as increasing their integration in education courses (Thompson, Hanson & Reinhart, 1996). This innovative training method utilizes undergraduate or graduate education students to mentor education faculty on computer use and integration techniques and is also a requirement of students enrolled in an advanced educational technology course. Although SUNY Oswego does not currently have an advanced educational technology course, it is hoped that once the introductory course becomes a requirement in most education programs more students will have the skills to provide basic instruction to faculty as well as the interest to pursue additional courses in educational technology. Having reviewed several training options, the task force set forth the following.

Recommendation #4—Implement a variety of technology training programs that require faculty to establish technology goals for the each academic year.

- The Peer Mentor Program would arrange to have faculty observe other faculty who are effectively integrating technology in instruction.
- Student-Faculty Mentor Program would be attached to an advanced educational technology course in which students would be required to mentor a faculty member. Faculty members would volunteer to participate and would have to commit to meeting with their mentors an hour each week of the semester. This program would be similar to the one implemented at Iowa State University.
- 2 Hour Training Sessions would provide faculty with instructional methods of integrating technology.

Finally, although the primary objective of this task force was to develop a plan for increasing technology integration among education faculty, the underlying goal is to increase the technology proficiency among our education graduates. Many schools of education have established technology benchmarks/competencies for education graduates to provide accountability for programs, faculty, and students. Although NCATE has established technology standards for teachers, these standards do not take into account the unique role technology plays in each education department and program of study. Consequently, the task force recommends the following:

Recommendation #5—Encourage departments to identify appropriate benchmarks/competencies for
program graduates and to create a plan that will facilitate student achievement of competencies. Such a plan would include identification of required education courses that address technology proficiencies and how technology will be infused in these courses as well as an assessment plan for measuring competencies.

Summary

Since the 1997 recommendation from the NCATE Task Force on Technology and Teacher Education that would require accredited SCDEs to develop and implement a plan for technology, more SCDEs are initiating the technology planning process. This article described the process of a school of education in its early stages of technology planning. Although the previous recommendations require a great deal of effort on administrators and faculty, K-12 schools are demanding that our graduates be proficient in not only using technology but also teaching with technology. While technology courses can instruct students on technology skills, preservice teachers who do not have the opportunity to observe effective use of technology in the classroom and to use it under the guidance and facilitation of faculty instruction will likely graduate with limited professional skills and lack an understanding of using technology as a tool in education (Handler & Pigott, 1994).

R2D2: A Constructivist/Interpretivist Instructional Design Model

Jerry Willis, jerryw@iastate.edu
Muktha B. Jost, mbjost@iastate.edu
Polly Mumma, pollym@iastate.edu

Abstract: Until recently the great majority of instructional design (ID) models have relied on behavioral and information processing theories (Dick, 1996). There is, however, a growing body of literature on the practice of instructional design from a constructivist perspective (Winn, 1992). Much of this literature has emphasized the types of learning environments that can be developed such as anchored instruction or problem-based learning (Cognition and Technology Group at Vanderbilt, 1993; Wilson, 1994; Bransford, Hmelo, Kantor, Hickey, Secules, Petrovino, Goldman, and the Cognition and Technology Group at Vanderbilt, 1996). In 1995 I described the first version of an instructional design model based on constructivist instructional and learning theories and an interpretivist philosophy of science (Willis, 1995). It was developed during work at NASA's Johnson Space Center in Houston and at the Center for Information Technology in Education at the University of Houston. The model, named Recursive and Reflective Design and Development (R2D2), was one of the first to lay out in some detail an approach to creating instructional material that was based on constructivist theory. This paper, which is based on work at Iowa State University, describes a revision of the R2D2 model and discuss some of the practical issues involved in using an ID model.

An Overview of the Revised R2D2 Model

The original R2D2 model has gained some attention in the literature. It is now covered in a number of instructional technology courses around the country (e.g., Bell, 1997; Turner, 1997; Santa Fe College, 1997) and the developers of other C-ID models such as the Layers of Negotiation model (Cennamo, Abell, and Chung, 1996), A-Maze (Bing, et al., 1997), and the Jigsaw ID model (Robinson, 1997) have cited R2D2 as one of the influences on their model.

R2D2 has also generated some criticism. Apparently because the 1995 paper on R2D2 challenged some of the long-held assumptions of traditional instructional design theory, Braden (1996) commented that the author was "much like an arrogant adolescent with a chip on his shoulder" (p. 19). For a more thoughtful comparison of the Dick and Carey ISD model and the R2D2 model by one of the creators of the ISD model see Dick (1996).

I have now had an opportunity to work on a number of projects, including several dissertation studies at the University of Houston, that used the R2D2 model. That experience, plus discussions with graduate students and colleagues, my own reflections, and the useful criticisms of designers such as Braden (1996) and Dick (1996), have all influenced the evolution of the R2D2 model.

General Principles Versus Detailed Steps

The R2D2 model is based on the assumption that general principles can guide us as we come to understand the specific context of design and deployment. Trying to follow detailed, specific rules of design is discouraged because each context is unique. There is no Platonic "ideal form" of ID that can be used as a guide in all situations. The best we can do is work from general principles and our base of experience. R2D2 is based on three "guiding principles" or, to use Winn's terminology, three "first order principles." They are Recursion, Reflection, and Participation, and flow naturally from constructivist theory.

Recursive (Iterative), Non-linear Design

Fundamentally, iteration is the process of developing all or part of the instructional material in a form that allows both users and experts to fully participate in the process of revision and reformulation. This may happen over and over again in a complex project. It may also happen at many levels. Members of the design team may initially look at little more than scribbles on a flip chart. More accurately they create the scribbles on the flip chart through collaborative development of the concept. Later they may go through a scenario that tells the story of how the material would be used in a class and revise their conceptions of what it is that they will create. Still later they might look at rough and then progressively more complete prototypes of the material. Finally, relatively finished alpha and beta versions of the material would be used.

The concept of recursion (iteration) that we have in mind here is more than simply giving end users a chance to "have their say" about a product. That level of recursion is in most ID models. Somewhere in the process formative evaluations generate data from end users. Revisions can then be based on that data. In my view, more formative evaluations throughout the design process is better than the one or two that are typical of ID. But recursion as I see it involves more than that. It involves...
Reflective Design

Reflection is perhaps the most difficult of the three basic principles of the R2D2 model to explain. The opposite approach, technical-rationality, is relatively easy to explain. "Technical rationality is an epistemology of practice derived from positivist philosophy, built into the very foundations of the modern research university" (Schon, 1987, p. 1). Good practice from this perspective thus involves carefully and precisely defining the problem and then applying clear, well-formed solutions derived from good research to solve the problem.

A reflective model of practice assumes that many, if not most, important problems in professional practice cannot be well-formed and solved with preformed solutions. In such a situation, "the terrain of professional practice, applied science and research-based technique occupy a critically important though limited territory, bounded on several sides by artistry. There are an art of problem framing, an art of implementation, and an art of improvisation, all necessary to mediate the use in practice of applied science and technique" (Schon, 1987, p. 13). Those arts, of problem framing, implementation, and improvisation, make up reflective practice. They are more artistic than scientific, and they call for thoughtful and careful attention to as well as understanding of the context in which the professional work occurs. Schon uses the terms reflection-in-action and reflection-on-action to refer to the type of thoughtful work in context that I believe should be an important principle in design work. Schon's books (1983, 1987) are excellent guides to reflective practice.

Participatory Design

Participatory design is one of the more controversial aspects of "alternative" ID models. Participatory design reflects a shift from the perspective that "the designer knows best" to one in which the designer is part of a team that, collectively, can accomplish much more when each person is a full participant instead of an object of study. In their classic and influential book, Participatory Design: Principles and Practices, Douglas Schuler and Aki Namoika (1993) describe participatory design as "a new approach towards computer systems design in which the people destined to use the system play a critical role in designing it" (p. xi). They contrast it with other ways of designing. "Participation stands in contrast to the cult of the specialist. In the specialist model, an expert is sought out. The question is presented to the Expert who will eventually produce the Answer. With this approach, those most affected by the conclusion must sit idly by, waiting patiently for enlightenment. PD, of course, demands active participation. PD, however, is not against expertise. There is no reason or motivation to belittle the role of expertise. Specialized training and experience, both technical and interpersonal, are important. In the participative model, however, this special expertise becomes yet another resource to be drawn on — not a source of unchallenged power and authority. A partnership between implementers and users must be formed and both must take responsibility for the success of the project" (p. xi-xii). That, in a nutshell, is the essence of participatory design.

R2D2: Procedures and Focal Points

We believe the three principles discussed in the previous section are the most important part of R2D2. In this section we will present an overview of the activities and procedures typical of design work based on R2D2 but we must emphasize that these are suggestions, guidelines, and ideas rather than "set in stone" procedures that "must" be followed. ID at this point is much more an art than a science. And, it is much more an art than it is the correct application of technical recipes that require you to match well-defined conditions to well-defined solutions. If someone followed the four principles discussed in the previous section but did not use the procedures described below, I would consider it to be more in the tradition of the R2D2 model than if someone followed the procedures but did not use the principles.

The three focal points of the R2D2 model are Define, Design and Development, and Dissemination. There are no obvious starting and ending points because the model assumes designers will work on all three aspects of the design process in an intermittent and recursive pattern that is neither predictable nor prescribable. The focal points are, in essence, a convenient way of organizing our thoughts about the work. The type of work a design team might participate in for each of the focal points is described in the following sections.

Define Focus

This approach eliminates all of the common "up front" activities of ISD: learner analysis, task and concept analysis, and creation of instructional objectives. The beginning of a project is probably the worst time to create specific, detailed objectives. Understanding will emerge across the design process and will be of much higher quality than information and perceptions gained by studying people and ideas at the very beginning.

This idea of letting understanding emerge is strongly supported by chaos theory as well as constructivist theory. You (1994) suggests that a complete analysis of task and learner performed prior to implementing instruction does not guarantee that either the task or the knowledge and skill of the learner are unchanging. "Thus, iteration of all ISD operations such as analysis, design, and evaluation at every step become imperative. . . . Further, no single ISD operation has preeminence over any other, for
each operation plays its own unique role and together they form the distinctive character of the whole" (You, 1994, p. 24-25). I
could not say it any better.

In the revised R2D2 model the Define Focus has three activities, Creating and Supporting a Participatory Team,
Progressive Problem Solution, and Developing Phronesis or Contextual Understanding. All three activities are important in
the beginning of a design project, but they must be attended to across the entire process. They are part of the entire design process,
not distinct activities that occur at the beginning of the work.

Creating and Supporting a Participatory Team

My (JW) experience, and the experience of my graduate students, suggests that this is one of the most difficult tasks
facing a constructivist designer. Creating a team is not difficult. But supporting one, encouraging one, and facilitating
participation is not easy. There are two basic ways of creating a team. One is to enlist the cooperation of a small group of
individuals who represent different stakeholder groups such as teachers, students, graphic artists, designers, and so on. This team
then constitutes the participatory group that takes the project from start to finish. We have found that this approach works well
when the team members are all heavily invested in the project and have the time to participate. When some members are less
invested, or when time and availability are a problem, this approach can be frustrating to all concerned because it is difficult to
get full participation. The result can be a project that has a participatory team in name only. In fact, only one or two people may
end up making all the decisions while the other team members do not provide significant input.

An alternative is to organize a small core team, perhaps only one or two people, and then involve different people at
different points in the process. Regardless of the form the participatory team takes, it will require thoughtful support and careful
arrangement of the opportunities to participate if the members are to do their best as collaborators. There are a number of
examples of participatory design projects in the literature. Several are reported in the Schuler and Namioka (1993) book.

Progressive Problem Solution

It is an overgeneralization to say that traditional ID models break the general design problem down into pieces and then
attack the pieces one at a time. But it is not too much of an overgeneralization. Objectives are defined and finished first, then the
criterion referenced tests are written based on the objectives, and so on. This approach, which involves finishing each task
completely before moving on to the next was termed the stagewise model by Barry Boehm (1995). Problems with the stagewise
model led to the waterfall model. Water (completed tasks) flows out of one pool and into the next where it is used to complete
the next task in the sequence. The waterfall model added a feedback loop at the end of each stage that involved getting feedback
on the product of that stage and then revising it before passing the results to the next stage. Braden's (1996) ID model is
probably the clearest example of a modern waterfall ID model. For a detailed analysis of the problems with waterfall models see

There is another way to think about the work of design. R2D2 views it as a process of progressively solving multiple
problems in context. That is, "solutions" such as the set of objectives for a project progressively emerge across the entire design
process instead of being completed early and then used to guide design and development work. The fuzzy objectives you begin
with will influence your design and development work, but conversely, design and development will also influence the
objectives. R2D2 views design work as a richly interactive process in which solutions emerge across a process in which work on
many different parts of the whole influence each other (and the whole). It is, as You (1994) described it, an "open system" that
assumes initial conceptions and frameworks will change and evolve across the process. The idea of progressively solving the
problems of design is one of the most difficult for many designers to accept because it means they must keep the process open
and accept the idea of making major changes even late in the process. Another C-ID model, Layers of Negotiation (Cennamo,
Abell, and Chung (1996), another non-traditional ID model, the Layers of Necessity Model (Tessmer and Wedman, 1990), and
Boehm's (1995) Spiral Model of Software Development and Enhancement also emphasize the emergent aspects of design. As
Cennamo, Abell, and Chung put it “Whereas traditional instructional design models often include discrete stages of analysis,
design, development and evaluation activities, . . . we addressed the question of design in a spiral fashion, progressing through a
series of stages at one level, then spiraling back and adding more detail within . . . Consistent with the holistic manner in which
experienced designers often apply traditional models . . . we initially made decisions across stages based on the data that was
relevant, then, as more information became apparent or relevant, we spiraled back and added more detail across stages” (p. 43).

Developing Phronesis: Contextual Understanding

Are most design contexts like other design contexts? That is, can we develop generalizations, or rules, that can be
easily applied across different design projects? Many ISD models are based on the assumption that there is much that can be
generalized and thus they emphasize commonalities across contexts. They are thus based on the idea that Plato’s epistemic
knowledge is the foundation for ID work. R2D2 and other C-ID are based on the assumption that there is much that is unique in
each design context and thus a designer (as well as the other members of the design team) must have or develop a sophisticated
understanding of the particular context in which design work will take place. Aristotle’s type of practical, in context, knowledge,
phronesis, is dominant here.

Developing phronesis can be done in many ways - via team members who are long-term participants in the setting
where the ID product will be used, by working for some time in that environment, by regular observations and interviews in that
environment, and so on. Different design jobs will call for different approaches, but the core issue is that there is no such thing as a “general ID expert” who can take his or her skills from one setting to another and design well without understanding the context. A good example of the importance of understanding context is a case study reported by Thoresen (1991). The case concerns a project to make changes in the support software for a large hospital. Several attempts to make constructive changes actually created major problems for nursing supervisors because the prototype software did not fit their work patterns. However, because this group had input into the design and development process the problems were identified and changes made. The knowledge the nursing supervisors had, phronesis, is difficult, if not impossible, for external experts to know. It is only by being immersed in the context, or by involving people from that context in the design process, that it can be known and used.

**Design and Development Focus**

The R2D2 model does not separate design from development. They are integrated activities in this model for a number of reasons that were detailed in the original article on R2D2 (Willis, 1995). Perhaps the most important reason for integrating these two activities is that the reasons for separating them in the first place were technical. In the past most development environments were not change friendly, but powerful authoring environments now make changes, even major ones, and revisions possible in a fraction of the time that was required in the older learning environments. The three activities in the revised model are Selection of a Development Environment, Collaborative Inquiry, and Product Design and Development.

**Selection of a Development Environment**

The development environment actually consists of two components: the tools of design and the process of design. Tools include everything from a flip chart to an $8000 computer-based authoring environment. The tools will vary radically from project to project, but three criteria for evaluating tools should always be kept in mind: power, flexibility, and accessibility. When graphics are being created Photoshop is one of the most powerful and flexible programs available today, but there are other programs with less power and more flexibility that are more accessible. The relative importance of each of these factors will vary from project to project, but all three will influence the way the team works and the quality of the final product.

The process of design can be thought of as having four levels: Component Design, Single Path Prototype, Alpha Version, and Beta Version. Of course, there is usually more than one single path prototype, alpha version, and beta version. Each is gradually revised and improved (or abandoned when it is necessary to start over from scratch). When revisions on the beta version of the material are complete you have Version 1.0.

There is some linearity to this part of the model because it is difficult to do a beta version before completing an alpha version. However, there is still quite a bit of flexibility. The team can, for example, decide what to develop more fully and what to leave in rough or even uncompleted form at each point in the process.

This way of thinking about the ID process - components, single path prototype, alpha version, and then beta version - has worked well for us. However, there are a number of other frameworks for thinking about process that would also be quite appropriate. Bodker, Gronbaek, and Kyng (1993), for example, describe an approach that includes four major phases. Digital Equipment Corporation’s Michael Good (1991) uses another form of participatory design that has five phases. Nathaniel Borenstein (1991) details a sequence of software development that is quite similar to Good’s approach. In his very readable book Borenstein divides development into three phases: definition, prototyping, production, and maintenance. Gitta Salomon (1991) describes yet another way of thinking about participatory design in her case study of the iterative design of an information kiosk. Salomon’s iterations were across progressively improved prototypes of the final product, and she divides the work into three phases.

**Collaborative Inquiry**

This aspect of the R2D2 model has been one of the most difficult to name and explain. Heron (1996), in his book on collaborative inquiry defined it this way:

> Co-operative inquiry involves two or more people researching a topic through their own experience of it, using a series of cycles in which they move between this experience and reflecting together on it. Each person is co-subject in the experience phases and co-researcher in the reflection phases. (p. 1)

Heron’s idea of cooperative inquiry captures precisely what I have in mind in the R2D2 ID model. Members of the team cooperatively research and reflect with an eye toward improving the material being developed. This process is continuous and begins when the idea of creating instructional material is first discussed. It continues through the entire design and development process. It is not something that is done at particular points in the process, it is a continuous, integrated process that often cannot be distinguished from other aspects of the work.

Those are the underlying assumptions of cooperative inquiry. The actual methodologies of doing it are many and varied. In fact, many of the methods of traditional ISD models are quite suited to cooperative inquiry. The way the data is collected is often the same, but the way it is interpreted and understood is different. An excellent source of guidance on how to approach the process of collaborative inquiry is a chapter by Jeanette Blomberg, Jean Giacomi, Andrea Mosher, and Pat Swenton-Wall (1993) at Xerox Corporation. Their chapter, Ethnographic Field Methods and Their Relation to Design, presents a theoretical framework for conducting what I have called qualitative research as part of the design process.
Product Design and Development

In the original paper on the R2D2 model (Willis, 1995) the example was a piece of learner-centered software and I (JW) proposed a simple categorical scheme for thinking about designing the various components of the software:

- **Surface Design** - screen layout, typography, language, graphics, illustrations, sound.
- **Interface Design** - look and feel, user interaction, help, support, navigation, metaphors.
- **Scenario** - sequence of simulation options/choices, results.

This way of slicing up the product is not suited to the design of all types of instructional materials. Since 1994 we have used the R2D2 model to develop a wide range of educational materials, from video-cases to electronic books and web sites that are resources for instructional technology courses.

I believe the R2D2 process of design can be used to create a variety of educational software. There is, however, a more serious issue involved in the way we think about the product. It relates to how broadly we define the term "instructional material." Many of the ID models in current use restrict the use of that term to a relatively narrow set of instructional materials that either deliver or support the delivery of what is generally termed direct instruction. Tutorials, drills, and some types of simulations are well known forms of direct instruction. In my opinion, if we limit the use of ID to forms of direct instruction, we make a serious mistake. I believe direct instruction will play a much smaller role in teaching and learning in the twenty-first century than it has in the twentieth century. In his proposal for a new paradigm for instructional theories Reigeluth (1997) suggests that we need broad theories, "not just in the cognitive domain, where we need theories for fostering understanding, building higher-order thinking skills, developing metacognitive skills, designing problem-based and interdisciplinary or thematic learning environments, and tailoring instructional guidance to specific content-area idiosyncrasies, but also in the affective domain, where we need guidance for developing what Daniel Coleman calls "emotional intelligence" and for what Thomas Lickona calls "character education," as well as how to develop attitudes and values and so forth. Instructional theory has been construed much too narrowly in the past" (p. 1).

Dissemination Focus

ISD models generally include four activities in their dissemination stage: summative evaluation, final packaging, diffusion, and adoption. With the exception of summative evaluation, the R2D2 model adopts a similar approach. However, the constructivist emphasis on the importance of context suggests that diffusion and adoption should not emphasize using material in the "right" way. Instead the focus should be on helping teachers and learners adapt the material to the local context and use it in ways that are appropriate to that context.

The other aspect of the dissemination focus, summative evaluation, requires some additional comment. In the R2D2 model, there are too many local, context-based variables in the use of any instructional package to make valid or "scientific" generalizations to other settings. A summative evaluation in the R2D2 model is much less ambitious. It is the story of what happens when the material is used in a particular context in a particular way with a particular group of learners. Such summative evaluations can be very helpful to others who are considering using the material, but other potential adopters must consider many variables before they decide that findings from a summative evaluation may also apply to their setting.

Summary and Conclusions

R2D2 is one of several ID models based on constructivist theory. It has been used primarily in academic and research contexts, but other, similar, models have been used widely in industrial design and software engineering for many years. The model we decide to use and the models we accept as appropriate for others to use are based on our beliefs, our experiences, and our perspectives about what design is. They are not, however, selected by any one on the basis of superior research or "solid theoretical foundations."

There is no research that conclusively (or even inconclusively) demonstrates that one family of ID models is the better choice (Dills & Rominowski, 1997). Design work is probably so complex and so context-dependent that it would be impossible to empirically test the usability of one design model versus others. We must, for the most part, fall back on Winn's first principles to guide us. Selecting an ID model is a rational, not an empirical process. That point is not always apparent to proponents of different models. There have been instances where students were discouraged from using the R2D2 model because it was not yet "proven". The plain fact is that no ID model is proven. We must fall back on "first principles" that derive from our theories to make choices. ID is thus a field with very little, if any, empirical research to guide our decision making, but it has an abundance of theoretical frameworks within which to make decisions. I believe the situation calls for considerable dialog and sharing both within and among proponents of different ID models and theoretical frameworks. When it is all said and done, none of us are very good at this, and we need all the help we can get.

Top 20 Collaborative Internet-based Science Projects of 1998: Characteristics and Comparisons to Exemplary Science Instruction

Dr. Craig A. Berg, School of Ed. The U. of Wisconsin-Milwaukee, USA, caberg@uwm.edu
Cristy Jefson, Steuben Middle School, Milwaukee Public Schools, cristyj@uwm.edu

Abstract: This paper utilizes the characteristics of model science instruction to identify exemplary Internet-based science collaborations. The filter for attaining "exemplary" status was based on state and national standards-generating initiatives and the corresponding implications for appropriate student activity in science classrooms. Twenty examples of on-line collaboration are identified, described and used as models that contain the basic components of effective on-line science collaboration. These models also serve to highlight ancillary features that make on-line collaborative investigations even more effective.

Introduction

Using the Internet as a tool to facilitate collaboration between schools for data-sharing investigations is a fairly recent phenomenon. During on-line collaborations, teachers and students complete science-related investigations using a process common to their on-line partners. The specifics and mechanics of this process greatly varies. Yet, the common core of the investigation and process contains similarities to exemplary science instruction.

Exemplary Science Instruction

First and foremost, science instruction, whether Internet-based or not, should provide opportunities for students to develop toward well-defined science goals and standards. These standards provide a vision and indicators for those involved in producing exemplary science instruction. National efforts such as Project 2061's Science For All Americans (1989) and Benchmarks for Scientific Literacy (1993), The National Science Standards (1996), and compatible, but, more local efforts, such as Wisconsin's Model Academic Standards for Science (1998) provide guidance and examples for science programs and teachers who in turn, provide science experiences to children. These efforts to define goals have made specific content objectives less elusive, and have aided to assist science educators to reach some consensus concerning general goals. In general, science teachers want science students to (Berg & Clough, 1991):

- Perceive science as a set of meaningful, interrelated concepts, rather than mastery of many insignificant isolated facts;
- Convey positive attitudes about science indicating that science is meaningful and useful to them;
- Convey an understanding of the nature of science;
- Identify and solve problems effectively;
- Understand the connection of science to their community and personal lives;
- Demonstrate an awareness of the importance of science in many careers;
- Work cooperatively with other students as well as independently;
- Demonstrate constructive creativity and curiosity;
- Access, retrieve, and use the existing body of scientific knowledge in the process of investigating science-related phenomena;
- Communicate effectively;
- Set goals, make decisions, and self evaluate, and;
- Demonstrate logical as well as critical thinking.
During this enterprise, students should:

- Actively construct knowledge from what they observe and experience during the science activities;
- Ask questions, test ideas, interpret data, gather information, challenge ideas, physically and mentally manipulate objects and experiences;
- Actively participate in science;
- Identify problems as well as solve problems;
- Make decisions related to their science study and their science activities;
- View the classroom as a place to begin science-related inquiries; understanding that in-class experiences can be transferred to investigations outside of the classroom;
- View science as having intricate connections to their daily lives;
- Develop oral and written communication skills to display understandings of the fundamentals of science; and
- Use their scientific knowledge.

It is through this lens that we examined Internet-based collaborations to determine which might be used as models of exemplary Internet-based science instruction.

**Exemplary Collaborative Inquiry**

For this paper, collaborative inquiry is defined as one classroom interacting with one or more classrooms based on a science-related investigation or topic. Collaborative inquiry, while facilitating and including many of the goals listed above, may be accomplished several different ways. For example, while much can be accomplished using only e-mail and attachments, the advent of the web with graphics, sound, and forms to facilitate instruction has made the process of displaying information and interacting with others much easier and less technically demanding. Many projects are now based from web home pages and contain more user-friendly methods of sharing data via forms on the web page. Participants simply need to input data directly into the form, as opposed to sending additional e-mail attachments. The frustration of encoding and unencoding formats properly has been eliminated through the development of data forms which are inserted directly into the web site text. In addition, project proposers and organizers are somewhat savvy to the necessary ingredients of a successful collaborative project. Their invitation to participate delineates the key foundational components needed to ensure a successful collaboration. The introduction tends to incorporate most of Harris' (1995) suggestions - the what, why, when and how so that potential collaborators know what is expected of them, as well as the potential benefits of joining the project. In addition, most home pages provide mechanisms for:

- project registration (via e-mail or web-based form)
- sending the collected data and receiving other participant's data (e-mail or web-site form, automatically resent to participants via e-mail reflectors, or stored on web site for participants to analyze).

In addition, web project pages might offer other necessary or sometimes ancillary components such as:

- Resource/related links
- A description of the experiment via text, movies or photos
- Talk to a scientist
- Archived data from past years investigations
- Real time images
- Project activities (classroom activities that extend the investigation)
- Student's projects such as artwork, writing, reports, publications
- Teacher's manual containing background information plus connections to science education standards
- Student-student or teacher-teacher interaction area: might be listserv, listserv archives, or a forum area
- Participant list with e-mail addresses
- Project-related news and announcements
While few, if any, of the projects selected contain all of the mechanisms and supporting features listed above, the projects highlighted in this paper represent collaborations that have great potential for appropriate science instruction due to both the similarity to exemplary science and the superior project planning and manner in which the project is supported, processed, and assisted by using the Internet.

**Categories and Model Collaboration Examples**

For the purposes of this paper, the model collaborative Internet-based science investigations located were separated into the following categories:

1. Observation and sampling of wildlife (self-collected data)
2. Observation and sampling of wildlife (scientist-collected data)
3. Observation and sampling of self-characteristics
4. Sampling and analysis of environmental data
5. Resource awareness and consumption
6. Content-related, participant-dependent calculations
7. Problem solving and engineering

While the categories are not entirely discrete, they serve to help delineate some aspects of participation or focus of the investigation. What follows is a listing of the Internet-based projects that we offer as model or exemplary projects.

**Wildlife Observation/Self Collected**

*Bird Watch at Feeders*: http://earth.simmons.edu/birdwatch_protocol.html
Enables students to study the various migration tendencies and behaviors of birds. An inquiry based learning experience correlated with the arrival of different species of birds. Integration of disciplines such as mathematics, geography and industrial technology.

*The Vernal Pool*: http://earth.simmons.edu/vernal/pool/vernal_1.htm
Students collect data while investigating plant and animal species that inhabit an actual vernal pool. Participants post interesting findings on the Vernal Pool listserv.

*Road Kill 98 Dr. Splatt*: http://earth.simmons.edu/roadkill/rk_protocol.html
Students predict animal species which are most often killed by motor vehicles. Discussions of various habitats as well as the ecological importance of wildlife are explored. Estimation, mapping and graphing skills are required of the students.

*Plants – Ethnobotany*: http://earth.simmons.edu/plants/plants_protocol.htm
A monitoring project which enables students to discover learning about plants from a nontraditional perspective. Students gather biochemical and genetic characteristics of plants in an attempt to either confirm or deny existing information about the plant. Nutrition, bio-chemistry, conservation, and multicultural studies are easily incorporated into this project.

*View Nesting Birds*: http://www.pittedu/~dziadosz/
This web site contains many sites from around the world that provide live video and/or update photographs of a pair of nesting birds. Some birds are tracked by satellite as they migrate from their nesting area.

**Wildlife Observations/Scientist Collected**

*Biological Timing Online Science Experiment*: http://www.cbt.virginia.edu/0111/
Students make hypothesis about the behaviors of hamsters. Live images and actual experiment results are shared with other scientists from around the world.
International science project in which students will predict the “official” arrival of spring based upon the emergence and blossoming of tulips. Students design flowerbeds according to standards set by the project. The arrival of the tulips are compared and contrasted with other student projects throughout the world.

Self-Characteristics

Genetics MiniUnit: http://www.netlabs.net/hp/ebend/genetics.html
Organized by Beers Street Middle School, students compare and contrast similarities/differences among both human and plant species through the exploration of genetics. In addition, students utilize online data sharing techniques to explore the diversity of the human species.

Environmental Data

Acid Rain: http://earth.simmons.edu/acidrain/acidrain.html
“The purpose of this project is to get students involved in measuring the pH of precipitation and to use this as a means of researching, discussing, and analyzing the complex issues of acidified precipitation and atmospheric pollution…”

Salt Track - Road Salt in Watershed: http://earth.simmons.edu/salttrack/intro.html
This monitoring project will show the results of chemical treatment for highways in winter. Early baselines of salt content will be established to provide students and teachers with an opportunity to observe the movement of a potential contaminant in surface and groundwater systems. Doing so will introduce students to the dynamics of watershed, water recycling, and ecosystem contamination. In addition, students will use concentrations of Sodium Chloride in experimenting with various “crop” plants, and observe the impacts of salination due to irrigation with groundwater supplies. This will also introduce students to the sensitivity of organisms in marine and freshwater systems to changes in salinity levels.

The Ozone project uses the EcoBadge® for determining local levels of ozone in ppb. "Applicable to K-12 students in all disciplines and teachers and students with all levels of technological ability. Entry level project participation involves the basic monitoring of classroom ozone levels. Exploratory level project participation involves additional monitoring of ozone levels outside of the classroom, and more sophisticated manipulation and analysis of data."

Global Water Sampling Project: http://k12science.stevens-tech.edu/curriculumlwaterproj/index.html
A project that teams up students from around the world to test and compare the water quality of rivers, streams, lakes or ponds with other fresh water sources around the world. Students analyzed data to look for relationships and trends among the data collected by all project participants.

Dare to Share the Air - School Building and Air Quality: http://www.eduplace.com/projects/air.html
Students determine the effect of building age on air quality using school sites as the target buildings. The Environmental Protection Agency sponsors the project by designing the survey the students will use to standardize the project. Students will send the data to other student participants via a web page designed by the participants.

Resource Awareness/Consumption

Drinking Water/Wastewater Treatment: http://earth.simmons.edu/watershed/water_quality.html
Students perform basic chemical tests on environmental surface waters (both fresh and salt) to determine water quality. Water Quality Testing includes the following tests: temperature, pH, dissolved oxygen and biochemical oxygen demand, nitrates, turbidity of dissolved solids, as well as total coliform bacteria count. Water conservation and water pollution issues are also addressed.
Out of the Bin: http://archives.gsn.org/feb98/0006.html
Encourages young people to think and learn about improving their community's use of resources. Students explore ways in which resources can be re-used rather than thrown away in their own community. They will learn from other communities around the world about new ways in which their community might use resources more efficiently.

Content-Related, Participant-Dependent Calculations

Shoot for the Moon: http://ihnet.esuhsd.org/staff/dimasd/moon.html
Students use a parallax to determine distances to far away objects such as the moon. Students utilize geometry and/or trigonometry and mathematical formulas to determine distances. Internet searches as well as collaboration with other students for scientific data is required.

Boil, Boil, Toil and Trouble: The International Boiling Point Project: http://k12science.stevens-tech.edu/curriculum/boilproj/index.html
Students discover what specific factors (room temperature, elevation, volume of water, heating device) have the greatest effect on boiling point. Standardized instructions and a web-based form to insert data allows students to compare their results with other students participating in the project.

A simple equation is used to calculate the circumference of the Earth by measuring the shadow of the sun. Students share their results by entering their data onto the project experiment report form. Mapping skills such as knowledge of longitude and latitude are required of the students.

Problem Solving and Engineering

S.O.S - Send out Snow: http://archives.gsn.org/jan98/0027.html
Topic is based on how humans have solved the insulation problem throughout history. Specifically, students create and mail a snowball in the most efficient package to snow-less, southern California. Students who send the snowball receive an efficiency rating based on the amount of snowball surviving the journey. In addition, the students are sent a precipitation acidity printout for their school location from the students in southern California.

Fanciful Machines: http://archives.gsn.org/mar98/0014.html
This is a collaborative problem-solving project which involves middle school science classrooms. Students who participate in the contest create simple machines that perform routine tasks. Students build and test their designs. Classrooms communicate their progress via the Internet. Final products are videotaped and assessed by all participating classrooms.

Abstract: The teacher professional development project, Integrating Mathematics, Science, and technology education Through the Physics of Space was developed through the collaboration of one university, three museums, NASA, and local school systems. This project is funded through an Eisenhower grant. Components of the project include two summer workshops (1998 and 1999), school-year workshops, and classroom support for teachers. The workshops are designed to provide teachers with models of technology, science, and mathematics integration, allow time to develop familiarity with new technologies, and to improve teachers' content knowledge.

Teachers participating in the project have shown increased content knowledge in math and science and have increased their use of technology, specifically graphing calculators, in their classrooms. Teachers have also increased their knowledge of useful Internet sites, although many teachers are hampered in the use of this technology by inadequate computer systems in their schools.

The need to help teachers develop their ability to integrate computer technology into the teaching of mathematics and science in schools is well-recognized and often reported (Balacheff & Kaput, 1996). Other forms of technology, however, have received less emphasis. Students will need to be adept in not only computer use but also in other forms of technology, such as the graphing calculator. In order for the graphing calculator to become a common tool, students must develop facility with its use during their upper elementary and middle school years. The graphing calculator is a recently developed technological tool and many teachers lack proficiency in using it in their classrooms. Because teachers themselves have not experienced graphing technology supported learning, they have a difficult time using graphing calculators and computers to enhance students' conceptual understanding of mathematics and science. (For example, Streibel (1998) discusses the difficulty of using computers as an intellectual problem-solving tool.) Hence, a professional development program designed to enhance teachers' ability to integrate technology in mathematics and science instruction should include sessions both on the graphing calculator and the computer. These tools should be used to develop students' conceptual understanding and problem solving ability (Battista, & Lambdin, 1994).

In addition to lack of knowledge about the uses of graphing calculators and computers in the classrooms, many teachers have not yet developed an understanding of the national mathematics and science teaching standards (National Council of Teachers of Mathematics' [NCTM], 1989; the National Research Council of the National Academy of Science's, 1996). These standards emphasize that the teaching of mathematics and science should incorporate models of instruction that encourage collaboration between disciplines, promote active student involvement in learning, advocate the use of authentic problems, and appropriate use of technology. Lack of teacher knowledge about the standards and lack of time to implement standards-based instruction foster noncompliance.
In order to help teachers increase their use of technology and to increase compliance with the national standards, we developed a project, *Integrating Mathematics, Science, and Technology Education Through the Physics of Space*. Integration of mathematics and science teaching in upper elementary and middle schools through the use of technology was the main theme of our project. During this course of this project, teachers are provided with the time to develop their expertise using graphing calculators and computers and to develop standard-based units for their classrooms. The project began in May of 1998 and will continue through June, 1999.

**A Model for Integration**

This project provides a model of integration not only in its curriculum, but also in its conception. The program was conceived through the collaboration of Eastern Connecticut State University, NASA, the Discovery Museum, the Science Center of Connecticut, Talcott Mountain Science Center, and, most importantly, local school systems. From ideas generated at a meeting of the principals and curriculum directors and through curriculum materials provided by local school systems, an outline for the project was developed. The schools supporting this proposal identified particular needs that included integrating computers and graphing calculators into the curriculum, improving integration between mathematics and science, and enhancing teacher understanding of physical science concepts (particularly in the areas of motion and energy). The project emphasized the new instructional models using technologies (particularly graphing-calculator and computer applications) and aimed at strengthening teachers' backgrounds in science and mathematics.

The project has four major goals:

1. To offer year-round professional development support and activities to bring upper elementary and middle school teaching practices and curriculum in alignment with the new national and state mathematics and science standards, through a collaboration among university faculty, experts from science museums, and school teachers that resulted in teachers' increased knowledge of mathematics and science content and improved teaching practices.
2. To increase teachers' content knowledge in specific areas of mathematics and science, particularly matter and energy and their interaction; space travel and microgravity; data analysis; and mathematical modeling that includes algebraic and graphical representations.
3. To model and provide teachers' experience with inquiry-based, integrated mathematics and science instruction.
4. To foster teacher expertise, confidence, and skill in the use of technology such as graphing calculators, and computer applications such as Excel, and use of the Internet.

**Participating Teachers and Their Backgrounds**

A total of 15 upper elementary and middle school teachers from area school districts participated in the summer workshop conducted in August 1998. Even though these were experienced mathematics and science teachers, only a few of them had basic graphing-calculator and computer skills. In addition, these teachers had little experience in designing integrated mathematics and science units. Use of the Internet for finding information relevant to mathematics and to, a lesser extent, science was also new to many teachers. Based on teachers' needs, we designed the activities to include introductory instruction for the graphing calculator, use of spreadsheets, and surfing the Internet for data.

**Development and Implementation of the Project**

This project includes two summer institutes (1998 and 1999), school-year workshops, and classroom support for the teachers. The first summer institute focused on increasing teachers' knowledge of matter and energy and its interactions; developing their abilities with graphing calculators and Calculator-Based Laboratory (CBL) units/probes; and computer applications, primarily the Internet and Excel. Teachers worked on technology-based, hands-on science projects that involved mathematical content. The activities were rich enough that they could be adapted to a variety of classroom situations and levels. The project developed four themes in order to achieve its goals. The four themes developed for the workshop were Rockets (National Aeronautics and Space Administration, 1996), Microgravity and Orbits (National
Aeronautics and Space Administration, 1997a), Toys in Space (National Aeronautics and Space Administration, 1997b),
and Mission to a Comet (Challenger Center for Space Science Education, 1995). Several activities were selected from
existing NASA and Challenger materials and adapted for use with graphing calculators. Activities were also adapted to
include the use of computer spreadsheets and the Internet. The Discovery Museum, which is also a Challenger Center, was
put in charge of the Mission to a Comet theme, the Science Center of Connecticut took charge of Rockets, and Eastern
Connecticut State University developed the materials for Microgravity and Orbits and Toys in Space. Talcott Mountain
Science Center is involved in assisting teachers in their classrooms.

An Example of Integration using Excel and the Graphing Calculator

Several examples of using Excel and graphing calculators were used in order to integrate science topics such as
motion, energy, and gravity to mathematical topics such as algebraic variables, expressions, equations, and graphs. An
element of these graphics is the construction of a parabola using the quadratic function \( h = \frac{1}{2}gt^2 \). This function gives the
distance traveled by a falling body dropped close to the earth's surface. Clearly this is an increasing function over time. As
we can see in the chart (Figure 1), the distance the object drops after one second is 4.9 meters (cell C3). The distance after
two seconds is 19.6 m. Using Excel, teachers were not only able to see the functional values for distance, they were also
able to explore the change in distance over 1-second intervals (average velocity). They were also able to explore the increase
in the change columns (average acceleration). The fact that the quadratic distance function was the result of constant
acceleration was new to many of the teachers. Excel facilitated teachers' understanding of the connection between the
numeric information contained on the table, the graphical representation, and algebraic formula. Without the use of Excel
the calculations and graphing would have been cumbersome and lengthy. If too much time elapses between students doing
the experiments and seeing the graphs, understanding of the concepts involved suffers. Therefore, Excel was viewed by the
teachers as an effective teaching tool to enhance students' understanding of mathematics and science concepts. Since the
speed of computation and the construction of the graph was much faster than doing it manually, students would have time
for interpretation, investigation, and understanding of graphs.

![Figure 1: Excel Graphic of the Motion of a Falling Body](image-url)
Later, the same data were entered into lists in the graphing calculator and the distance-versus-time graph was created. This gave the teachers an opportunity to compare the same activity using a computer spreadsheet and a graphing calculator. Although the computer graphing looked nicer, the graphing calculator was preferred by the teachers because of lower cost of the calculators compared to computers. Nevertheless, the teachers found the computer’s Internet capabilities particularly useful. The teachers enjoyed browsing through the NASA page available on http://spacelink.nasa.gov. They especially liked the photographs of scientific images.

The four-day summer workshop provided teachers with a model of curriculum integration, which would allow students to develop an understanding of space flight and Newton’s laws, while developing their mathematical abilities in graphing and algebra. The workshop increased teachers’ content knowledge in mathematics and science and developed their technical skills. Teachers also left the workshop with a better understanding of how they could integrate mathematics and science.

Follow-up Session

During the Fall 1998 Semester the participating teachers attended one follow-up workshop (NASA On-Line) and worked on implementing their new techniques and ideas. The NASA On-Line Workshop introduced the teachers to many of the NASA sites and also provided them with additional math and science activities. Our teachers are currently developing or improving a variety of units ranging from Toys in Space to microgravity. One of our parochial school teachers has managed to get her students and their parents so excited about the possibilities of graphing calculators that she has collected donations of $1000 for the purchase of graphing calculators and calculator-based laboratories. In fact, all of our teachers have reacted very positively to the use of this fairly new form of technology with the exception of one fourth-grade teacher.

Conclusions

The Integrating Mathematics, Science, and Technology Education Through the Physics of Space professional development project has developed a core of teachers who have responded very positively to the integration of graphing calculators into their curriculum and teaching techniques. These teachers will have additional opportunities to develop their skills at integrating not only technology, but also mathematics and science as the project continues through the spring semester and into the summer. Further professional activities will depend on the needs of the teachers. A survey conducted in December 1998 indicated that teachers found the program very helpful in addressing some of their professional development needs.

Abstract: The evolution of web browsers with multimedia capabilities that handle java scripting has enabled authors to move from a "click and look" environment to one in which the user can be involved through communication, interaction and reflective thinking. This environment provides an ideal format for inquiry-based science activities as promoted by the National Science Education Standards. This paper describes the NC State Science Junction website, which serves to promote the doing of science through student activities and resources for parents and science teachers.

Introduction

The advent of web-page authoring was characterized by text-dominated pages with few graphics and photographs. As the media has developed, more sophisticated techniques can be used to promote more interactivity. This includes the use of cgi, java programming, and various formats of video displays. The development of the Net Forum enables users to interact with other users using a web-based format. The use of these cutting edge developments along with more advanced web browsers allows creative authors to generate interactive web-based hands-on science activities.
NC State University provided funds for a project called The Science Junction. The primary purpose of The Science Junction is to promote the doing of science by students of grades 4-12 through web-based activities and resources. Other purposes of the site include assisting teachers and parents to locate good science learning resources, promoting communication among teachers for collaboration and for the development of a science teacher learning community, and assisting teachers in the learning of new technologies and the practicing of new methodologies.

The Science Junction is indexed into six interconnected areas: The Data Depot, the Teacher Terminal, NC State Frontiers, Student Station, Communications Bridge, and Upgrade Route. Half of these areas are dedicated to student use and half for teacher and parent use. The web site can be found at www.ncsu.edu/sciencejunction/.

Data Depot

The Data Depot contains three sections: Collaborative Experiments, Collected Data, and Simulated Data. The focus of this area is to provide a means for students to post and share data they have collected on various experiments, to extract and evaluate other data previously posted, or to manipulate data generated by mathematical models.

The Collaborative Experiments section includes two activities which involve data collection, posting, downloading and analysis. Water What-Ifs is a web site for encouraging inquiry investigations of water quality in North Carolina and Delaware. Even though the focus is water quality in those two states, everyone can learn how to collect the data and participate in the lab activities included in the site. The water quality parameters addressed at this site include pH, temperature, dissolved oxygen, nitrates/phosphates, and macroinvertebrate surveys. The links to other water quality sites are abundant and are of high quality.

Another collaborative experiment is the Sun and Shadows investigation. In this experiment, students measure shadow lengths and direction of the shortest shadow cast by an object of given height on a given day. By knowing the characteristics of the shadow at the student's location and the characteristics of the shadow cast at a second location, the circumference of the earth can be calculated. When many data are collected from sites all over the world, shadow patterns can be discovered that reveal the motion of the earth. Several activities are included to prepare the students to understand the concepts of time and elements of geometry.

The Collected Data section contains data which have been collected from previous collaborative experiments, and also contains exercises which require the extraction of data from video collections. One such exercise deals with viewing two sunsets on the same day using two video camera at different elevations at the same location. By knowing the height between the two cameras and the time difference between the two observed sunsets, the radius of the earth can be collected. Those who interact in this site must make measurements from the digital video in order to complete the task successfully.

Students can also collect data from virtual reality images. An activity soon to be added to the site will allow students to study the images of skulls of various creatures using virtual reality tools such as the QuicktimeVR Plugin. Students will be able to view the skulls from many angles and to zoom-in on specific areas of interest. By participating in this activity, students will be able to investigate similarities and differences among the skull images, and make inferences about the characteristics of the animals and in what environments they lived.

The Simulated Data section uses data generated from mathematical models. One good use of such generated data is shown in the Solar Eclipse Data Set '98. The data from the solar eclipse of February 26, 1998 was originally generated by NASA. This site includes the data in a modified data set which is useful for pattern finding and analysis. All data sets include a visualization of the data. The solar eclipse data allows the user to select two locations from where the eclipse was visible. The browser allows the user to view the eclipse at the two locations. By looking at various locations, times when the eclipse occurs, and the eclipsed part of the sun, students can discover relationships between location and the parameters of the viewed eclipse. Even though the students did not directly collect the data, they are able to sift through the information using scientific processes.

Teacher Terminal
The Teacher Terminal area is a resource for science teachers which includes IMSEnet and Science Lesson Plans. IMSEnet (Instructional Materials for Science Teachers network) is a large website which lists science websites that have been determined to be useful for science teachers. The websites are categorized by content areas and topics of interest to teachers. When a category is selected, annotations of various web sites are delivered to the user. This resource is a time saver for science teachers who do not have the time nor the expertise to search and evaluate the expanding number of science related web sites.

The Lesson Plans section contain original lessons developed by science educators at NC State to promote inquiry activities in the science classroom and laboratory. One such lesson plan, Carolina Coastal Science, uses photographs to prompt students to reflect upon environmental science issues. Within this site resides a classroom simulation/debate called The Shell Island Dilemma. The scenario of the dilemma is that the Shell Island Resort is in danger of being destroyed by a migrating inlet. Mason's Inlet is moving south rapidly. The Shell Island Resort is currently situated in an Inlet Hazard Zone and is in dire straits. The objective is to investigate the issues concerning the fate of the Shell Island Resort and then to debate the future of this and other oceanfront structures threatened by coastal erosion. As students engage in the investigation, they must identify the social, political and scientific issues with which different stakeholders must deal. The students are placed into the role of one of the stakeholders. Web-based materials are provided for student research.

NC State Frontiers

The NC State Frontiers area is the place to get information about research projects and research groups at NC State University. Users of this site are able to search by title or by index to locate current science research at NCSU. Graduate students have explained their research projects on many of these pages. Research group research projects are also described here. Read about experiments, see the students, hear about their work, and view their laboratories. This site is useful for the student who asks “why do we need to learn this stuff?”

Student Station

Student Station is a place for students to interact with science outside of a school environment. This area contains two sections: Game Room and Home Experiments. Again, the focus of this area is to promote the doing of science. The Game Room allows students to explore with science simulations, and Home Experiments is an area for sources of ideas for hands-on experiments that students can do at home.

The Game Room is a place where students can interact with computer games that teach concepts in the various sciences. For example, Space Trak is a game where the students must move a spaceship around a prescribed path by applying an impulse in a given direction. If the students move outside the path, the spaceship explodes. By interacting with this game, students learn aspects of Newton’s first and second laws of motion. Through trial and error, or through analysis of mistakes, students realize that net forces in the opposite direction to motion will cause the spacecraft to slow down, which is required to successfully navigate the turns.

Another Game Room simulation is called REACT! This simulation allows the user to manipulate a bullet molecule which will be shot into a target molecule. The goal of the activity is to make a reaction occur between the two molecules. After interacting with the simulation students will realize that in order for a reaction to occur the molecules must collide, the collision must occur in a proper orientation, and the molecules must be moving with a minimum amount of speed relative to each other. Students can control the speed and the orientation of the bullet molecule. Levels become increasingly difficult due to the motion of the target molecule. In doing this, students realize that the probability of a reaction occurring on the first collision is low within a random system. The students can also run simulations where they are allowed to observe the number of collisions of molecules in a given space. Students are allowed to control the amount of space, the number of molecules, and the average speed of the molecules.

Home Experiments section provides ideas for students to do simple experiments at home. This area is geared for upper elementary and middle school students. Egg-ceilent Adventures is a section which provides ideas for experiments with eggs. Other activities are presently in the production phase and will be added as time proceeds.
Communications Bridge

The Communications Bridge is an area which allows science teachers to interact with one another using a variety of tools. The site is for both novice and veteran science teachers. The SciTeach Forum is a web forum where teachers can easily send messages and read what others have to say. Messages are sorted by topic headings, making it easy to find items of interest. Teachers can communicate on the forum on any computer with an internet connection - an email account is not needed. The forum can be used to share tips and to ask questions. Experienced teachers can share knowledge with beginning teachers. The forum is quite active with novice teachers.

Collaborative Connections is a database designed to help teachers to find collaborators for classroom projects. Science Teachers who are interested in collaboration projects can register in the Join the Database section. This is a simple form teachers complete and submit to become part of the searchable database. There is a See and Submit Projects section which is a web-based forum for teachers to post ideas for collaborative student research. Search for Collaborators section allows the searcher to type in a keyword to search through the database of teachers who have signed up in the system. The View All Collaborators section allows the user to look at the total database of those who registered. The Collaborative Connections area is an excellent way to promote activities which can be used in the Data Depot area of The Science Junction.

Upgrade Route

Not all science teachers have the ability to attend professional workshops to learn new teaching methodologies and to practice using new technology tools due to the remoteness of their locations or to their hectic schedules. This area provides a mechanism for those teachers to learn about such topics. The Upgrade Route consists of two areas: Professional Development and Technology Skills.

Professional Development provides resources to upgrade the teacher’s knowledge of such topics as national science education standards, gender equity, cooperative learning, and multicultural education. This area is textual in nature and provides little interactivity.

Technology Skills provides information on how to use the latest instructional technology advances for science teaching. Need to brush up on using Calculator-based Labs (CBL), capturing video clips, or writing web pages? The Upgrade Route will provide step-by-step worksheets, video, and instruction manuals for a variety of tools for the science classroom.

Conclusion

The Science Junction provides the resources necessary for the promotion of hands-on collaborative science inquiry. It provides links to content sources and professional topics for science teachers which are on other web sites. It supplies a way for science teachers to develop a community with other science teachers for the exchange of ideas and for collaborative activities. It establishes a place for the exchange of data among all who wish to investigate similar topics, and to collect data from visuals and computational models for pattern finding and analysis. The site promotes the use of inquiry methods while students investigate science at home and at school.

The SERVIT Group (Science Education Research on Visual Instructional Technology) at North Carolina State University is involved in the development of this project. The web address for this group is www.ncsu.edu/servit/. Once a critical mass of activities are tested and placed on this website, the research group will study the impact of these activities on students at school and at home. The SERVIT Group solicits any ideas for additional activities to be included in the Science Junction.
"Expanded Integration of Technology with Science and Math Methods Instruction at Nebraska Wesleyan University"

Merryellen Towey Schulz, Ph.D., Visiting Assistant Professor of Education, Education Department, Nebraska Wesleyan University, 5000 Saint Paul Avenue, Lincoln, NE 68504. Voice: (402) 465-2309. Fax: (402) 465-2179. E-mail: mts@nebrwesleyan.edu

Abstract: The purpose of this project is to discuss the progress, changes, and findings from the continuation of integrating technology instruction into the science methods course and extension into the math methods course of pre-service elementary and middle school teachers at a liberal arts university. Science, math and technology instruction are extremely important in preparing today's students for the future (Bybee, Buchwald, Heil, Kuerbis, Matsumoto, and McInerney, 1989). Lack of application is often a problem and use of technology is frequently taught in isolation from methods classes. Too many times pre-service teachers do not actually use technology in practicum experiences and student teaching, but only design technology projects for pre-service requirements and infrequently utilize what they have learned. At Nebraska Wesleyan University, the technology skills learned in Instructional Technology are integrated with expectations and assignments in a block of courses, which include Teaching Math and Science in Elementary and Middle School.

One of the goals of our model for integrating technology with science and math methods is to increase the probability that Wesleyan pre-service teachers will more effectively teach these disciplines while also integrating technology in their pedagogy. Changes were made to a similar project completed in 1998 in response to student and instructor reflections and evaluations.

Background

Nebraska Wesleyan University is a liberal arts institution in Lincoln, Nebraska with approximately 1,700 students. The Education Department has approximately 230 students with all students being required to take Education 187, Instructional Technology, a 3 credit hour course. All students who are majoring in elementary education complete the integrated 6 hour block of methods courses, Teaching Math and Science in Elementary and Middle School. Last year the project focused on science methods only but this year will include math methods.

Another goal of Nebraska Wesleyan and the Education Department is to foster collaboration with surrounding school districts while modeling effective integration of technology with instruction. Consequently, collaboration with Meadow Lane Elementary, in the Lincoln Public School District, will be part of the project.

Changes from First Year of Project

Overall the 1998 project was successful. This year several changes will be instituted which will maintain previous strengths and address additional needs of students and instructors (refer to Figure 1). First, students will work at Meadow Lane Elementary which will allow each student to work with the classroom teachers who are directly responsible for science and math instruction. Technology equipment and classroom facilities at Meadow Lane will be more conducive to the project than those at the previous school which is housed in temporary quarters because of construction. Second, the teams of preservice students will be required to present weekly peer and group assessments of their progress. This will provide formative feedback for all parties and importantly allow us to make immediate changes. Third, instructors and student assistants will adjust class instruction in all three courses to allow for increased assistance. For example, the inclusion of Educational Technology lab times on Fridays from 2:00 until 3:30, will make it easier for students to obtain assistance and reduce stress caused by the need to make continual changes to websites. Students will be able to more easily alter their original websites and gain greater control of managing links. Fourth, class time in Teaching Science and Math will be adjusted. As was the case last year an entire four days of class time will be devoted to teaching students to use PageMill and create WebPages, however, this time will occur later in the term to allow students to prepare lessons and materials that will be included in their
websites. After the fourth week the sixty-five minute weekly lab period will be conducted in the computer lab so that students can work on the websites. Fifth, more class time early in the term will be allocated for gathering website resources. These resources will allow students to have increased science and math knowledge base prior to introducing HTML and PageMill elements in the fourth week of semester. In turn, increased emphasis will be placed upon providing models of effective websites and units. Sixth, the pairs of students will be determined by matching grade level and topic interest, Kolb Learning Style Inventory, and instructor knowledge of student abilities. Seven, each student will be expected to create a file of at least 10 lesson plans gathered from other students' websites for use in student teaching and future practice.

Figure 1: Science/Math Methods/Educational Technology Project

Procedure
Teaching Science and Math includes a two-hour per day, two-week practicum experience at a local elementary school. The practicum takes place late in the term after the pre-service teachers have received instruction in "doing science and math", the scientific method, pedagogy of science and math teaching and inquiry, planning lessons and
units, and employing assessment techniques. Instruction will also be given in integrating science and math with the overall curriculum and meeting the needs of individual and special needs children. New Nebraska State Teaching Standards, International Society of Technology in Education (ISTE) Standards, and the National Science Education and National Math Teachers Association Standards will be used to guide instructional decisions of the course instructors and the pre-service teachers (National Research Council, 1996).

Teaching Science and Math will be taught as active hands-on courses, including field trips to important local sources, thereby modeling good science teaching for the pre-service teachers. When it is taught as an active, hands-on experience, science is often the most interesting subject taught in elementary school (Howe & Jones, 1998). These experiences will foster more positive attitudes among the pre-service teachers toward science and math.

Early in the term students in Teaching Science and Math will be grouped into pairs. Partnerships will be determined by grade level for which students are preparing to teach. Each set of partners will be required to create a thematic interdisciplinary unit for use in their practicum classroom. By the end of the semester, pre-service teachers will have compiled files of science and math units, lesson plans, and materials including numerous hands-on exploratory activities. Students will then be able to access websites as well as use their personal files.

Each student will teach one lesson from the unit in a simulated peer teaching situation. After receiving feedback from peers and instructors, students will refine their lessons prior to presenting in the practicum classroom. We have found that peer teaching prior to delivering lessons is effective in preparing practicum students to teach more confidently during practica and more fully preparing students prior to student teaching.

Themes of the units will come from any topic within the areas of technology, physical science, life science, or earth and space science. No two units may use the same topic. In this way the students will gain exposure and materials for teaching as many topics as possible. Students will meet with practicum classroom teachers to determine unit topics that will meet appropriate school district objectives.

Following introductory sessions in which students will experience hands-on science and math lessons; review basic concepts such as the metric system, measuring, observing, and data gathering and reporting; and learn science and math teaching pedagogy, partners will choose their unit topics. Students will be expected to increase their knowledge base on the topic, to explore existing lesson plans for teaching the topic, and to create original lessons and activities to use in teaching the topic. Information that is gathered will be included in the web page that each pair will begin creating the fourth week of the term. Beginning the second week of the term students will begin to construct teaching units and lessons plans to be used in the practicum experience at Meadow Lane later in the term.

During the last month of the semester, pre-service teachers will be onsite at Meadow Lane Elementary two hours per day, Monday-Friday, for two weeks. Students will have visited the classrooms on four earlier occasions to build rapport with the students and their teacher, to learn the classroom routines, and to observe classrooms teachers engaged in teaching science and math. Classroom computers, the school computer lab, and Nebraska Wesleyan equipment will be used as the partners teach their math and science units and facilitate the children in using the web pages. Pre-service teachers will send to instructors email journals, which will provide reflection on events and episodes that occur during teaching and practicum.

During the last week of the term, students in Teaching Science and Math will return to campus where partners will share their web pages in a “Celebration of Learning” with fellow students, parents, cooperating teachers and Wesleyan Education Department members as well as any other individuals students might want to invite. The main intent of the “Celebration of Learning” will be to have students present and critique their units and websites while professionally discussing the strengths and weaknesses of their work. A rubric (developed in class) and based upon the Web Page Project Information will be utilized to evaluate presentations and the websites.

Grade and age level, the nature of the unit topic, and the computer skills of the children will determine the complexity and requirements of web pages. All WebPages from Teaching Science and Math will then be linked with websites created in 1998. This will then provide a repository of lessons for student teachers and graduates who are practicing teachers.

Technology Instruction
During the first week of the semester, students will meet in the Wesleyan Computer Lab to learn how to gather website resources for creating teaching units in math and science. During the fourth week, students will simply begin designing their website while also collecting URLs for placing on the website. Students will also view websites which have been created by previous Educational Technology students. The main intent is to teach how to effectively search the Internet for lesson plans while also acquiring skills to effectively utilize technology. Emphasis will be placed upon developing and utilizing hands-on science lessons through the use of websites.

Students will learn the basics of HTML and Adobe PageMill web editing software for designing a science and math-related website. Students will also learn how to use a digital camera and scanner. Both multimedia tools will be utilized by adding personal, science and math related images to the website after taking pictures and scanning artifacts of student work and activities at Meadow Lane. Each of these actions will model hands on learning while allowing for interactivity among K-16 students. Students will have the option to attend Educational Technology class labs as well as to sit in on the class if they have not taken the class and want added assistance. Extra lab sessions (2-3 throughout the semester) will also be established to provide continued assistance and support in developing the websites and gathering resources.

Several opportunities to present their work will allow students to develop enhanced professionalism and ability to reflect on pedagogy. The websites will be utilized in on-campus microteaching to provide opportunity to refine lessons prior to teaching in practicum. Refinements will then be made and students will be shown how to save their projects to a Zip disc (allows storage of 92 MB) so that students can simulate a live connection at practicum. This consideration allows students to individualize learning yet ensure that Meadow Lane students fully learn the science and math-related information. Participants will provide a 15-minute presentation that will be evaluated by fellow students and faculty.

All students’ websites will be linked to one another so students can learn from each other while also allowing Huntington students to link to more resources. The concept of website scaffolding is modeled as students will first design their own website while learning basic HTML elements. Ongoing development will allow students to increase the complexity and capabilities of individual websites while also linking to website of fellow students. In turn, the maintaining of websites on the Wesleyan server (at least one year beyond graduation) will allow students to access the websites beyond the formal practicum while extending into other practica and student teaching.

Objectives of Model:
1) Students will explore the Internet for science and math resources and lesson plans that can be used in teaching science and math to elementary students.
2) Students will learn basic HTML and how to use a web editor, Adobe PageMill, to create web pages.
3) Students will learn to use a digital camera and scanner with images. These images will then be incorporated into web pages.
4) Students will create science and math teaching units on various topics for use at practicum.
5) Students will create web pages that will be integrated with teaching science and math units and links to scientific information.
6) Students will teach the science and math unit to Meadow Lane Elementary students in a practicum experience.
7) An overall web page will link all web pages of Teaching Science and Math students so that students can access classmates’ websites which can be used in developing teaching files and actual lessons.
8) Collaboration will be enhanced between K-12 and higher education as preservice and inservice teachers will design units and integrate technology within science and math lessons at Meadow Lane Elementary School.
9) A repository of website-based activities for use in math and science classrooms will be established, linked and maintained on the Nebraska Wesleyan University server. These activities will be continually developed and refined for use in preservice and inservice classrooms as well as for future practicum students and use in student teaching.
10) All lessons will be based upon Nebraska Standards in Science, Math and Instructional Technology.

Evidence to Evaluate Project Success

The project will utilize formative and summative evaluation to assess success. Evidence to determine success will include:
1) Preservice students will maintain email journals during the course of the project. The journals will provide general attitudinal feedback on the use of science and math lessons and effectiveness of integrating technology.
2) The websites will be utilized in science and math classrooms. These websites will be maintained on a Nebraska Wesleyan University server and will be accessible beyond the funding of the project thus sustaining the impact of the project. The websites will be evaluated with a class-designed rubric (refer to Table 1).

3) A mid-term examination will be administered over introductory science and math concepts and methods of instruction (information which will be presented weeks one-eight). Two separate attitudinal surveys will be administered during the first week of classes. One will measure student attitude toward instructional technology and the second will gage students’ perceptions of science/math learning and instruction. A pretest on the metric system will be administered on the first day of class.

4) The number of preservice teachers attending the Nebraska State Technology Convention will provide informal assessment of teachers’ attitude toward use of technology while also allowing students to gain ideas and network with practicing teachers.

5) Collaboration will be enhanced between Nebraska Wesleyan University and Meadow Lane Elementary School by assistance of preservice students in Meadow Lane classrooms. Evidence will be determined by informal interviews with Meadow Lane teachers. Cooperating teachers will also be asked to complete a follow-up questionnaire about the program.

6) A “Celebration of Learning” will be held during Finals Week in May. Participants will provide 15-minute presentations that will be evaluated by fellow students and faculty.

Comments:

Dissemination of Results and Findings
The instructors will disseminate results and findings by submitting a proposal for presenting at Nebraska State Educational Technology Convention for K-16 teachers. All students and cooperating teachers will be encouraged to attend and two or three preservice students will assist in the presentation, thus fostering professionalism as well as
sharing of findings. Maintenance of the websites on the Education Department server will also contribute to dissemination of the results of the project.

References

Nebraska Wesleyan University is recognized as a quality institution. For example, outreach and training are provided to rural science teachers through a Howard Hughes Medical Institute grant. Dr. Michael McDonald from the Education Department has responsibility for technology-based instruction of twelve, science teachers on integrating technology (i.e., website development, use of Hyperstudio, digitizing and scanning still images and sounds, etc). In addition, he has established his classes in accordance with NCATE and ISTE Standards for Technology usage by preservice teachers. The proposed model has also been structured accordingly.

Dr. Merryellen Towey-Schulz is responsible for methods courses in teaching science and math in elementary and middle school and has extensive training and experience in science for elementary and preservice students. Dr. Schulz was instrumental in designing and implementing a technology plan at Nebraska’s first schoolwide Title I school within the Omaha, Nebraska Public School System. She has presented at local, state and national conferences (i.e., Nebraska Education Technology Association Conference) on the subject of integrating technology with instruction of at-risk elementary children as well as science education. Dr. Schulz has served as chairman of the Omaha Public Schools (OPS) Computer Outcomes Committee and worked on the committee to design and adopt science outcomes for OPS.
SIMULATIONS
A Faculty Support System for New Distance Learning Initiatives

Abstract: The purpose of this paper is to examine and describe the role of faculty support in the instructional design of an on-line course. The training model provided focuses on the adaptation of existing courses to implement new technologies. Instructors optimize their course revision efforts by extending the process over several semesters, gradually introducing new delivery strategies as technology, student ability, and institutional support improves. This process includes the choices an instructor must address in the introduction, facilitation, and evaluation of learning experiences at a distance.

Introduction

As new communications technologies impact higher education, faculty must be trained to determine the most appropriate tools for delivery of their course content. Though higher education has not yet reached the stage in which lecture is simply one option among many, the place of distance education technologies has grown to the point that they are no longer novel. Indeed, they are not, in themselves, innovative so much as they have become part of the standard repertoire of most instructors.

The need for continuing professional development and renewal to adapt to this changing environment becomes critical for every faculty member. Every institution has a concomitant need to provide a path for such development in a way that will let its instructors transfer their considerable instructional skills to new media. Unfortunately, the university support generally focuses on the technical and administrative aspects of the approved delivery software package. Armed with the quick reference guide to HTML, the user support manual for the university courseware system, and an unrelated sample course, it is easy for the instructor to lose sight of the original course objects. For this reason it is important to review course objectives in light of the new instructional design tools.

Instructor Training

A good starting place for the new instructor is the Web site for the publisher of the courseware package adopted by your university. Check for instructor training on-line and workshops which offer training beyond the technical operations. For those programs using instructor developed Web pages, on-line templates and tutorials will address the technical aspect of putting the course up, but not the instructional design and management. A Web search will provide a current list of workshop and course opportunities such as Learning to Teach On-line. (LeTTOL, 1998)
Planning and Design

In the process of developing a previously-taught course for the Internet, the instructor makes a series of decisions concerning the instructional value, the academic integrity, and the institutional efficiency of the methodology used.

Though complete re-tooling or comprehensive instructional design for individual teachers and courses is possible, the far more usual procedure is for an instructor to begin adapting a class over a period of a year or more. The instructor can use four or more iterations of the class to effect a change that is gradual and deliberate. An instructional development model that allows a phased-in adaptation to the Web will help instructors to adapt themselves to technology while preserving the best of their practice within a changed environment.

First, the best practice of current instruction must be preserved and renewed. Instructional and evaluative strategies that have been successful in face to face settings need to be examined and, if necessary, altered to continue their salutary effects with students participating from a distance.

Second, technology's instructional enhancements must be incorporated in the instructional design. As technology places new demands on traditional practice, it adds dimensions for learning that were unavailable in older settings. Instructors must recognize, master, and carefully incorporate these innovations. The instructional development model that will serve the needs of both faculty and students much be capable of almost infinite adaptability, however. Compressed and streaming video and real-time audio alter instructional choices. Enhanced web bandwidth alone promises that media such as video that are currently the property of synchronous instructional strategies will become available in asynchronous settings as well.

Moving Systematically to the Web

Staff development can further each step of the move. With planning and sharing among new and experienced faculty members, it can particularly increase the level of comfort students will find when entering instructional relationships that are facilitated by compressed video, Internet, and desktop video conferencing.

The training model focuses on the adaptation of existing courses to implement new technologies. Instructors optimize their course revision efforts by extending the process over several semesters, gradually introducing new delivery strategies as technology, student ability, and institutional support improves. The instructional improvement models followed for basic distance delivery continue to develop as distance classes, incorporating new technologies.

Let us consider the classroom before distance education. Instruction occurs with lecture, paper handouts, chalkboard, etc. Reading assignments are in the textbook or library, and students attend class, which is where the "real action" -- lecture, presentation, and tests -- occurs.

The Technology Aware Classroom

The first significant change could be called "the technology-aware classroom." Handouts and lectures migrate to presentation platforms like PowerPoint: i.e., the computer and projector replace transparencies and, to a certain extent, chalk boards. Reading lists include URLs, and students as well as instructors are expected to be able to locate, retrieve, and evaluate the sources URLs refer to. Professor & students look to search engines & on-line sources for information, and students communicate by e-mail between class sessions. Class information is transmitted between teacher & students by lecture or on paper. At no time in this process is the essential interaction between faculty member and students within the context of the classroom changed; the simple repertoire that both groups of people employ in learning is enhanced.

Instructors enhance their skills by enlarging their own reading and sources they give their students to include Internet-based documents. They can acquaint themselves with graphical software and should begin a series of visits to Web-based classes and "virtual university" sites. If campus software allows, on-line chat groups, or forums, can familiarize instructors with this form of colloquy.

The Web-Aware Classroom

With the availability of Internet access to every student, the instructor can begin requiring Web-based instructional interaction. Syllabus and handouts should become invariably available by Web or ftp, and should be available in a format that can be used by many media (i.e., .rtf or .pdf instead of simply the instructor's
favorite word processor format). Course bibliographies will include URL citations and instructors will begin assembling material for class through web-based searches.

As student activity begins to include computer interaction, parts of the Web-Aware Class are available through computer sources. Chat groups support classroom discussion; class presentations are planned in e-mail or MUD-based small groups. Student presentations involve both technology-facilitated platforms and materials -- even sites, if connectivity to the classroom is available -- garnered from the Web. Exceptionally well-prepared students begin to participate from a distance, and the classes begin to offer virtual or distance class meetings.

**Web-based Class**

In the Web-based class, the work of the previous three presentations becomes realized in the first completely distributed class offerings. Transparencies and handouts that have had an interim life as PowerPoint Presentations become Web Pages. E-mail communications become Chat or Discussion-Group interaction, often facilitated by some instructional platform the institution has purchased. URLs dominate reference lists, and html projects become as familiar among student work as printed text. Every class has a distance corollary, so that the skilled instructor can transmit both material and instructional strategy effortlessly between distance and face-to-face delivery.

The Web-based class is not a replacement for a face-to-face class, in most cases. Instead, it is a manifestation of a complete set of instructional and contemplative tools that the instructor has at hand. Designing a class becomes a matter of selecting the most appropriate tools, of course. And the question "is it Internet or Face-to-Face," while important, is no longer a question about innovation. In that context, perhaps the most innovative part of this process will occur when it the choice is only commonplace.

**Choices**

While much is available on-line and in literature about the technical aspects of electronic course delivery, research about the relationship of the individual instructor to the subject matter, course, and to the individual student is not extensive. Further, the individual choices of how to teach, how to evaluate, and how to be fair to each student remain largely unexplored, perhaps because these matters have always been dealt with by instructors individually or decided by institutional policy.

Designing and delivering instruction consists of choices: selections every teacher makes that begin with deciding whether to engage in detail or in span of subject matter and end with wondering whether individual progress or achieving an absolute benchmark of information is the proper criterion for grading. These aren’t true dilemmas, of course, for most of the answers lie somewhere between the limits of the choice.

Internet instruction offers something of the same sort of option sets: a series of points for decision that relate instructional choices to one's ethically-driven view of the student and of the instructional process. Six of those choices are both original with the Internet and ineluctable for the instructor preparing a class for that medium. These are matters of judgment on the part of a professional who must be an expert in a discipline, in pedagogy, and -- often, suddenly -- in the technology of this new instructional delivery method. Areas of choice the instructor must explore in designing on-line learning experiences must include:

- **Access** – Availability of equipment, type of equipment, and connectivity clearly influences the effective participation in the course.

- **Learning Style** – The selection of instructional medium including video, voice, sound, graphics, and text must be considered to allow for maximal learning by all students.

- **Technical Skill** – The skill requirements of students enrolling in the course and the nature of technical support to students are important aspects to be examined.

- **Equity** – While many differences are diminished by computer-facilitated communication, other differences may be magnified or hidden.

- **Instructional Support** -- Delivery of courses to students at a distance poses problems in the areas of administrative support, student support, library resources, and bookstore
• **Evaluation** -- Because of problems of test securities when evaluation takes place at a distance, it becomes necessary for instructors to develop a method of evaluation that accurately assesses student achievement without needing to be secret, singular, or independent of text material.

These course decisions can best be accomplished with the help of a mentor presently teaching on-line, either locally or at a distance. By monitoring an in-progress course and surfing for other similar on-line courses, the instructor can explore the new course tools and seeing them in action, can better organize the electronic learning environment for students.

**Conclusion**

Every instructional choice affects the learners in different ways, and is intrinsic to the subject matter of the class and the expectations of the instructor. The instructional choices of asynchronous, distance education are no different from any other setting in this regard. Likewise, the primary considerations of effectiveness, equity, and rigor do not change from one class setting to another.

Teaching people at great remove from campus, and expecting them to interact with each other and with the intellectual substance of the class without seeing one's self or each other, requires a reexamination of dozens of instructional decisions that were made for the classroom. It also requires evaluating feedback carefully. Changing so much in teaching methodology is a little frightening. Changing instruction without the ability to see or hear students' reactions to the changes can, and probably should, terrify any instructor.

Knowing what choices have been made, and examining those choices in light of student feedback and other people's experience, seems the minimum price of this degree of innovation. Internet-based communication has become a staple of academic communication: the whole system was invented to allow academics to work and talk at a distance. Not offering instruction in this medium deprives students of the opportunity to become comfortable in this central frame of discourse. And not allowing -- requiring -- this kind of access should be more disturbing than innovation at any level.

Abstract: For years, many nations have enjoyed technological innovations used in building computers, computer architecture and design, and computer mediated communications. American institutions of higher education have also enjoyed these advancements through successfully establishing Net-based curricula. Success, however, have been limited. Therefore, how might students successfully perform real lab experiments over the Net without being in a laboratory? To explore this challenge, the researchers surveyed numerous DL environments and assessed the effectiveness and disadvantages of laboratory facilities currently available over the Internet. Research revealed that coexistent labs that were promoted as virtual environments were merely software simulations and, at best, created software simulations were far from authentic lab experimentation. Hence, the researchers created an environment that renders remote performance of genuine lab experiments, or genuine remote experiments ("GRE").

1. Introduction

Research suggests that most of the tools employed to train students over the Internet are simulation software, also known as "Virtual Labs." The term "virtual" indicates that the university campus may or may not physically exist. These types of universities offer comprehensive degree programs that deliver course materials through online communications. In most cases, these universities offer the same primary tools of learning as do established universities that offer distance education programs. Hence, virtual universities have emerged as equally acceptable alternatives to conventional universities.

In such environments, the knowledge gained by the student is limited by constraints, boundaries, and other capabilities offered by the manufacturer's simulation software. The examination of literature, existing distance education web sites, and surveys indicate that students are free to perform experiments only in "limited environments" through the programmed design of the software. Hence, these constraints do not permit creativity to flourish, nor do they permit a student to experiment in natural settings where the involvement of human perception fosters learning skills.

This paper suggests an allowable, creative learning environment where authentic lab experiments may take place via the Internet and where students have the unconditional freedom to apply input and feedback of output results as though they attended the experiment in-person. The implementation of the idea is technologically conceivable from recent innovations of fast-prototyping breadboards that allow the building of complex electrical systems from discrete components without the use of wires. At that point, all system wiring (and any future rewiring) are performed via the host computer by the click of a mouse without touching the board. Unlike software simulation, this engaging technology is intended to accommodate high-end fast prototyping and true hardware emulation.

2. The Internet: Planet Information
The Internet’s boundless, polymorphous resource of media-based information connects over 25 million people from roughly ninety countries through a massive computer network (Harasim, Hiltz, Teles, & Turloff 1995; Hirumi & Bermudez 1996). Therefore, administrators of institutions of higher education are attracted to expand instructional resources via diverse distance modalities.

During the pioneering of the Internet, its potential was recognized early on as the most dynamic tool in distance learning. (Turoff 1994). The wealth of information that the Internet holds, the constant updates and the ease of transmitting information instantaneously in addition to its cost-effective methods of reproduction, produced a tremendous impetus to make use of what was until then an unattractive, scarcely noticed, mode of distance education (Hirumi & Bermudez 1996; Gaines 1996). Regardless of the costs involved in using Internet technology, few educators seem concerned with the ways that the Internet might assist educational need and learning process as a meaningful, cognitive learning tool. We must ask the following: What instructional strategies and objectives underscore the use of this newly implemented technology? Will this technology assist, enhance, or promote learning? As educators, what do we seek to foster in students?

3. Distance Education: The Tools

Without doubt, the Internet evoked an Educational Renaissance (Jones 1997). As ever-increasing numbers of knowledge-hungry students bore the costly expense of ill equipped on-campus studies, this reawakening in the sharing of information popularized distance education due primarily to outreach and convenience of self-pace (Ferrate 1997) and made learning more affordable to larger numbers of learners (Ayersman 1996). Today, distance education offers varieties of courses that cover nearly every area of study offered by on-campus programs (Walsh 1995) and its annual market of over $8.25 billion attracts some of the world’s finest universities.

Fundamentally, the method of teaching adopted in virtual education can be classified as synchronous or asynchronous in that each approach offers a unique advantage (Gibbs 1997). Synchronous teaching contributes to collaborative learning through joint problem solving scenarios and can be used in threaded discussion through active participation of the guide or teacher. Asynchronous teaching frees students from the anxieties associated with group learning and permits self-paced study through repetition (Aotani 1997).

Despite these successes, other specialized fields remain far from ready for online dissemination. Laboratory sessions are vital to engineering curricula, yet today’s distance technologies are insufficient in allowing students to complete degree requirements without physically engaging the lab facilities. Software simulations have become the leading solution to this challenge; they enable students to comprehend study materials because greater time allowance permits easy-to-use tools. Software simulation used in “performing” engineering lab experiments via the Internet fostered the establishment of web-based engineering curricula, although the quality of education remains incomparable (Harasim, Hiltz, Teles, & Turoff 1995). How to install GRE on the Internet, therefore, remains the challenge.

4. Survey of Existing Virtual Laboratories on the Internet

Full and part-time virtual laboratory programs of prominent universities in North America and the United Kingdom were examined, as were pure virtual universities that have no established campus structure. Over 80 accredited universities offer more than 2700 distance education courses; although not all of these universities offer laboratory supplements, more than 95% of all providers restrict their curricula to virtual classrooms. The others offer online laboratory courses. However, only the Open University in Great Britain (Van Gorp & Boysen 1997) answered the challenge of providing lab courses over the Internet. Nevertheless, few solutions followed (Alhalabi, Anandapuram, & Hamza 1998).

GRE & Distance Learning

In specialized courses such as Logic Design, Microprocessors, and Electronic Circuits, hands-on laboratory experiments are crucial to understand basic concepts. Describing an experiment or even watching the process being performed by another falls significantly short of the requirements necessary for proper education (Harasim, Hiltz, Teles, & Turoff 1995). Four current alternative methods that provide “lab
experiment" settings are videotapes, home experiment kits, student site facilities, and simulation software (Harasim, Hiltz, Teles, & Turloff 1995). Among these four schemes, field literature indicates that simulation software is the best alternative, because it is easily transportable and cost effective (Gorrel 1992; Thomas & Hooper 1991). The researchers confer, however, that simulation software provides least hands-on experience.

Sending videotapes to students through the mail is probably the most economical method to display GRE off-campus. The Open University in Great Britain (; Van Gorp & Boysen 1997) and Cornell University of Medical Research are academic institutions that use this method. If the demonstration of a simple experiment satisfies the requirement to reach the student in full measure, the program administrators mail a videotape of the experiment to the student. Following this process, an online examiner assesses the student’s comprehension of the subject matter by propounding a number of probing questions (Harasim, Hiltz, Teles, & Turloff 1995). Although this method may help students to understand the concept behind an isolated lab experiment, it surely does not deliver the experimental portion of the lab that hypothecates what would happen if input “x” is changed to value “y.”

If hands-on experience is deemed essential to course instruction, a specially designed home kit is mailed to the student with accompanying information that instructs the student how to use the kit. The Open University, for example, designed several kits for courses such as the electronic circuit laboratory (Harasim, Hiltz, Teles, & Turloff 1995). For example, when teaching the highly technical courses of Advanced Logic Design and Microprocessors, the process becomes cost-prohibitive and nearly impossible. Despite the sophistication of the home kit materials, the student may still not have the accessory computing facilities needed to use the kit. Further, the constraints of time and availability may deter the student from accepting these types of courses that offer this option. This method is more practical and delivers hands-on experimentation, but it is not feasible for use in remote geographical areas or in advanced classes.

The third and, perhaps, best choice is to make GRE facilities available near the student site. Although students take classes (theoretical material, exams, etc.) via the Internet, they perform experiments in physically situated laboratories. Alternately, the university can make laboratory facilities available for a week or two on its campus. Intensive laboratory activities during this period helps students so that they may complete the requirements there or in their homes (Harasim, Hiltz, Teles, & Turloff 1995). This method is by far the most satisfactory to the student, but might be unaffordable in terms of travel. In addition, it might be difficult for university staff to open the facilities for such a short duration. These difficulties potentially disrupt the schedules of students who regularly attend the campus. None of the universities surveyed in this paper use this method.

Very few universities offer comprehensive laboratory courses over the Internet, although the Open University at Great Britain has made tremendous progress toward establishing "virtual laboratories." Michigan State University (online Instrumentation Lab, http://www.vu.msu.edu/previews/tc491d) and Harvard University (Psychology Laboratory, http://icg.fas.harvard.edu/~psych17/) offers its students introductory simulation-based virtual lab facilities (Alhalabi, Anandapuram, & Hamza 1998).

Simulation software is one method that imparts practical knowledge by allowing the student, in performing the experiment, to simulate all the steps on the computer that he or she would make in a laboratory’s physical environment (Thomas & Hooper 1991). The intended design of simulation software is to deliver practicable, user-friendly laboratory facilities to the student’s doorstep (Gorrel 1992). Continual upgrades in software have made aggregate improvements in the domain of distance learning education (Thomas & Hooper 1991). In recent years, the Multiverse Project developed student-friendly software that provides step-by-step explanations of lab assignments and expected results. Software available in WEB/JAVA has, to some extent, met these requirements but is not devoid of shortcomings. This practice has yet to achieve broader acceptance, although some universities offer these options despite the obstacles.

Simulation software introduces an element of fiction; at best, it might only produce an approximation that may yield erroneous results. Therefore, the student’s comprehension of the experiment will depend more highly on the quality of the software than on the comprehension capability of the student. A simulation is not a proper substitute for a real experiment; the design depends largely on the student’s perception as anticipated by the designer. The procedures might be more advanced than what the student can capably perform; one step out of sequence renders the exercise futile. As such, the results of experiments conducted through simulation software must be programmed for use within distance learning parameters; therefore, the student must adhere to prescribed inputs that deny significant freedoms to experiment with disparate criteria. The excitement and interest that accompany GRE experimentation may
become nearly absent in simulated environments; such antiseptic conditions may fail to stimulate the student’s curiosity. Therefore, the student is more likely to rush through proscribed steps to arrive at the ultimate results. Curiosity is significant because it kindles interest; lack of curiosity by the student typically evokes listless behavior. Therefore, there are no answers to “what if,” because the student simply cannot attempt them.

Throughout most colleges, the numbers and types of experiments change from semester to semester. New experiments that accompany each semester’s revised syllabus also require content revision, which is often cost-prohibitive and time-consuming. A student who clearly understands the goal of the software at the beginning of the experiment is more likely to produce better results than the student whose understanding falls short. Undesirably, software proficiency becomes tantamount to student proficiency.

5. GRE: Distance Education Ultimate Modality

GRE experiments stimulate higher order thinking skills; GRE environments involve the student’s individual senses and learning abilities that foster the learning process. Teaching a student through simulation modalities might assist the student in meeting the course requirements but, ultimately, the student might be incompetent in repeating the experiment in a GRE. Conversely, Real Lab software is designed to bridge those needs. The element of reality is included within GRE environments to remove the student as a passive observer and involve the student as a learner.

6. The Chiller: GRE Online

Originally intended for industrial electronic fast-prototyping and true hardware emulation, the implementation of GRE is technologically possible through recent achievements in interactive breadboarding that investigates unexplored territory in software simulation and allows the wireless construction of complex electrical systems. In the real lab, students are merely rewiring the breadboard, staging the input, and observing the resulting output when they use breadboards to mount Logic Design chips, AND, and OR gates as they connect the chips with wires. Then, the students connect the board to the power supply and observe whether the circuit is functional; if it is not, the students will rewire the board and run it again. If these three actions are performed remotely, the online GRE is successful.

Because the first and third actions are simply the I/O part of the experiment, a standard computer interface with the proper instrumentation device and with an Internet connection can perform these I/O operations. The use of a host computer, however, should not be confused with software simulation because students are still manipulating physically working electronic parts and still have the freedom to make any connections they choose in these lab experiments.

The second action of wiring and rewiring is the challenge. How could students perform the physical act of changing wires on a breadboard without touching it? Standard breadboards are replaced by special interactive breadboards whose pins are connected to a programmable interconnect network controlled by a local computer with a proper software interface. A connection between any pin to any pin is accomplished by a click of a mouse on the software interface.

7. GRE: Instructional Technology and Academic Quality

As the complexity of the digital world deepens, learning institutions that adopt GRE will be able to afford such high-tech tools. Unlike time-shift instruction (experiencing instruction following the live lesson, i.e., videotape, or a software simulation), GRE or real-time instruction (experiencing instruction at some point during the live lesson or experiment) are much more effective and allow students to receive instructions without the teacher’s direct presence.

GRE via the Internet furnishes state-of-the-art research environments by utilizing breadboards with programmable interconnecting networks where students at various academic levels can perform complex system experiments without lengthy delays or the high cost of Printed Circuit Boards (PCB). In addition, time-sharing advantages allows many students to concurrently utilize the same breadboard. GRE instructions are based on the principals of Instructional Systematic Design (ISD) the systematic, reflective
process that is vital to making learning environments more creative and effective and is used in translating the principles of distance education, learning, and instruction. These processes are used in complement with the plans of GRE instructional materials, activities, information resources, presentations, process evaluation, and revision (Smith & Ragan, 1999). The ISD process is essential in remote distance education and in carrying out effective GRE instructions where students have minimal face-to-face contact with the teacher and may never step into a classroom or a lab. The Real Labs’ ID process follows:

8. Conclusion

Software simulation for academic courses that do not require lab experiments, i.e., history, can meet the needs of learners. Experiments are arranged by two categories: 1) those designed to characterize theoretical concepts to the student through the experiment, and 2) those that are designed to substitute actual experiments where the outcomes depend largely upon various experiments that the student performs. Flexibility during the experiment, the main idea behind GRE, is a perquisite to fostering cognitive and intellectual skills (Barbra 1993). Therefore, experiments that students conduct in real laboratories tend to stimulate curiosity and intensify all types of learning skills. While simulation packages contribute significantly to distance education, they can never replace the need for GRE where students are able to construct their own knowledge and set theory and practice to a real test. Hence, the authors of this paper believe that the idea of GRE could be a vinculum to online laboratories of learning excellence.

Abstract: Two efforts to provide an experiential learning experience at a distance are discussed. The first looks at the educational simulation Oregon Trail as it is conducted on-line and compares the experience with a similar in-class rendition of the same simulation. The second effort grew out of recommendations from the first project as a graduate level counseling program seeks to simulate counseling sessions via the World Wide Web. This paper will briefly describe the projects and suggest recommendations for the use of simulations at a distance.

Overview

Current models of learning call for teaching practices that require the active participation of students within the classroom. Brown, Collins and Duguid (1989) argue that all learning is activity and situation dependent. "Situations might be said to co-produce knowledge through activity" (32). Leont'ev (1972) provided a mechanism to discuss how external activity becomes internal activity. External processes are subjected to a unique transformation as they are "generalized, verbalized, abbreviated" (18). Classroom simulations have provided opportunities for such active student participation for many years (Shields, 1996). A desire to provide the simulation experience for students even when those students are distributed though space and time has been the effort of recent developments in distance education (Lewis, 1997). The following paper discusses two projects that include on-line simulations delivered at a distance within an educational experience.

The first project looks at the differences between face-to-face and on-line participation in the MECC Oregon Trail simulation. This study examines the thinking process of participants, focuses on the value of the experience as seen through their eyes, and discusses the nature of the student-teacher relationship. Ultimately the question is asked if the simulation achieved similar results when delivered at a distance rather than within typical, face-to-face, situations.

The second project chooses to explore the nature of a simulated counseling session when delivered asynchronously via the World Wide Web. Graduate students at a private Midwestern university who were enrolled in a counseling education program attempted to simulate two counseling sessions: the first employing a Rogerian Person-Centered interview technique and the second Albert Ellis's Rational Emotive Therapy. The course, taught at a distance by two-way audio/video on the Iowa Communications Network, precluded typical teacher/student interaction. A shift to asynchronous web-based sessions allowed for teacher modeling, scaffolding, and intervention (Westwood, 1994).
Oregon Trail--At a distance

Although past research has shown that students have found simulations motivational, students have not learned significantly more information than students who have learned the information by more traditional methods, such as reading and lecture (Jurica, 1997). This study examined the thinking process of elementary age children as they engaged in the Oregon Trail simulation. The participants in the study were five fourth grade students and six fifth grade students from a rural school located in the southwest United States. The students' teachers also participated in the study.

During the first six weeks of the study the fourth grade students were observed as they studied the westward expansion of the United States during the 1840s. The teacher used a variety of teaching methods during the six weeks including the in-class simulation of travel along the Oregon Trail. The fifth grade students studied westward expansion by participating in Oregon Trail On-line sponsored by the Minnesota Educational Computing Consortium. Both groups recorded their decisions on an audiocassette as they proceeded through the simulation. After completion of the simulation the students and teachers were individually interviewed.

All of the fourth grade students (in-class version) reported that they thought the simulation was a valuable use of class time because it gave them the opportunity to apply the information they had learned. Three of the fifth grade students (on-line version) reported the Oregon Trail simulation was a valuable use of class time, but only because it was fun. One fifth grade student reported he learned more information from the textbook and he did not see the value in the simulation. Only two of the fifth grade students believed the simulation was a good use of school time because of the educational benefits of the simulation.

The in-class version of Oregon Trail was Oregon Trail II, a newer incarnation of the venerable simulation classic, which provided students with more decision making opportunities. It also gave students a chance to travel the trail more than once which allowed students the chance to experiment and take chances. With Oregon Trail On-line students never had the opportunity to revisit problems and test new hypotheses as their version was identical to the original simulation. However, the structure of the on-line version capitalized on a cooperative learning environment. After receiving the question(s) for the day the class had an opportunity to discuss the problem and vote on a course of action. The daily question would also provide the teacher with an opportunity to address a particular issue.

Regardless of the method in which they are presented (on-line or in-class), computer simulations seem most successful when there is a direct connection between what the simulation teaches and the desired outcome. For example, there is a direct connection between a student pilot learning the controls of an airplane and the lessons a flight simulator teaches. However, there is not a direct connection between the Oregon Trail and the desired student outcomes as determined by many teachers. Oregon Trail simulates travel on the Oregon Trail; it does not teach facts associated with the Trail. Yet, the Oregon Trail and other educational simulations are judged based on how well students perform on an objective test. Most educational programs are judged based on how well the program helps students remember facts or how well the program helps students perform on a standardized test. Under this criteria simulations have not performed well. Yet, many students find simulations fun and motivational. The motivational aspects may increase the interest some students have in a subject. While simulations may not increase students standardized test scores, they may help students in some area that educational researchers have not yet examined. One such area may be problem solving skills. Perhaps it is time to the change the criteria of how educational programs are judged. As computers and computer software become more sophisticated, simulations may yet prove beneficial in educational settings.

Based on the observations of the two classrooms in this study, the following guidelines are offered to help teachers successfully integrate simulations similar to the Oregon Trail into the curriculum.

• Teachers need to have a strategy of how to incorporate the simulation into the lesson. The students need to understand the educational reason for engaging the simulation. Students require background information not only to help them make decisions as they proceed through the simulation, but the background information also makes the simulation more relevant. The students know what is
expected of them. The in-class group viewed the Oregon Trail simulation as part of their learning experience. They had a chance to apply what they had studied for the past six weeks. The on-line group did not understand the relationship of the simulation the Oregon Trail to their unit on the Oregon Trail.

- Although background information is important, the debriefing session at the end of the simulation is critical. A teacher who fails to debrief her students after a simulation can be compared to a basketball coach who pulls his team off the court after the third quarter. If a basketball coach expects to win the game, his team must play the whole game. If a teacher expects her class to get the full benefit of a simulation, then she must dedicate some class time to debriefing.

- Teachers likely need workshops about how to integrate computer simulations and other materials into classroom lessons.

- Teachers need time to prepare lessons that examine topics in depth.

- And finally, teachers need support from administration.

Up close and personal?

"How can I train my students in counseling from a distance? I need to be in the same room with them in order to coach them as they begin to explore the various approaches to counseling theory." One of the authors asked this question while developing his course syllabus for a counseling methods class being taught at a distance via the Iowa Communications Network. During a subsequent brainstorming session it was determined that capturing student counseling sessions through a web-based simulation and debriefing these student sessions during large group two-way video sessions might allow adequate teacher scaffolding for student development as counselors. The experiences of other simulations at a distance, such as the Oregon Trail study previously described, helped inform the decision-making process.

Counselor educators are confronted with technological innovations that are changing the nature of higher education. Distance education has proved to be a cost-effective mode of instructional delivery that increases learner access by accommodating the schedules of a nontraditional student body (i.e., older adults with job and family responsibilities). As such, distance learning is rapidly becoming an established presence in higher education. Courses and programs are being delivered through a multitude of nontraditional formats, such as computer conferences, one-and two-way interactive television, and audio and videocassette. A wide range of counseling and psychology courses and related degree programs are offered via televised instruction through the United State and other areas of the world (Burgess, 1994; National University Continuing Education Association, 1993). As a result, it is conceivable that future mental health professionals may complete much of their educational training via distance learning delivery systems (e.g., two-way interactive televised instruction and web-based instruction).

Several authors have outlined strategies for delivering courses at a distance (e.g., Naidu, 1994; Cahill, & Marland, 1995; Price & Repman, 1995). These proposals tend to focus on general teaching approaches, such as developing organized visuals, maintaining eye contact with the camera, and developing technical competence, rather than course/topic-specific instruction. Instructional software packages relevant to the counseling profession are available (Parker & Monson, 1980), and one-way television has been used in an attempt to teach counseling methods (Ancis, 1998; 1996). However, specific strategies for teaching counseling coursework using current technology (e.g., two-way interactive video/audio and World Wide Web instruction) have not yet been thoroughly researched and addressed in the literature.

Accordingly, instructional methods utilizing differing forms of distance learning technology need to be researched. For example, how an instructor may best facilitate the processing of students' varied affective and cognitive reactions to counseling experiences and what impact the instructor's physical presence (or
lack of) has on this process is necessary to the structuring of effective distance learning training. Moreover, research needs to be focused on the impact of instructional approaches designed to encourage colloquy and inner-directed thinking among students representing various levels of preparedness and cognitive development, and who are physically separated from each other. Knowledge regarding the degree to which counselor education training via two-way interactive television and web-based instruction can facilitate self-directed thinking and counseling competence is needed to structure counselor education training programs to deliver training at a distance. Synthesizing the many forms of technologically based learning into a coherent distance learning instructional program, designed to accommodate student needs while maintaining program integrity, is the task for the counseling education domain during the next millennium.

This paper will outline an approach to the challenges and potential value associated with using simulated counseling sessions when delivered asynchronously via the World Wide Web. The challenges of utilizing traditional instructional practices in a skills-based course that progresses from the learning of basic listening skills to more advanced counseling theory-based approaches using two-way television and web-based instruction are explored. The graduate counseling education course uses real and simulated videotaped demonstrations during the actual two-way televised distance learning class session that meets weekly for three hours. Then, during the interim between the weekly class session, students must log online and use an interactive web-based instructional method that illustrates two theoretical approaches to counselor interviewing.

The World Wide Web-based computer generated video depicts a counseling session in action (with actors) that model the text - and - videotape viewed counseling interview method previously discussed in the distance learning class session. Mid-way through the depicted session, the counseling role-play ceases and the student must continue the counseling session by using a response box and typing a running narrative of the remaining counseling dialogue that should ensue (based on student's knowledge of the theoretical method being depicted). The response is forwarded to the course instructor for evaluation and feedback.

The web-based simulation is but a single component of a larger Iowa Communications Network (ICN) delivered experience. The authors believe that the debriefing held during a regular ICN class provides the key for the success of the project. The debriefing allows the instructor to respond individually to each student's counseling effort much in the same manner as if the instructor were to work with a small group of students in a face-to-face situation. Other areas of importance, as demonstrated by the Oregon Trail Online simulation, are having (1) clearly articulated student outcomes, (2) training, and (3) time for proper development of materials.

**Distance Learning and Educational Simulations**

As educators confront the challenges of teaching at a distance and providing learning experiences which are both situated in activity and mediated by social interaction, new approaches to old solutions need to be attempted. The authors are encouraged by the results of the use of simulations conducted at a distance to promote motivational stimuli, social interaction, and skills-based outcomes. To provide these when students and teachers are separated by time and space is as important as if the classroom were traditionally situated.

Using a Simulation To Assess Teacher Lesson Planning for Students Differing in Emotional Intelligence

Harold R. Strang
Curry School of Education
University of Virginia
United States
hrs9j@virginia.edu

Abstract: The purpose of this study was to explore how a group of 74 inservice teachers, collaborating in pairs, planned a short language-arts lesson for a class of simulated pupils who exhibited maximum contrasts in emotional intelligence. Analysis of navigation variables revealed that the teachers expended more effort in deciding how to meet the needs of Low-EQ pupils than the needs of High-EQ pupils. Further analyses revealed that the teachers planned more structured and teacher-moderated lesson experiences for Low-EQ pupils and more flexible and student-controlled lesson experiences for High-EQ pupils.

Introduction

Much current attention focuses on how school experiences contribute to children's social-emotional development. As Daniel Goleman (1996) notes, "...the neurological window of opportunity for the emotional centers in the brain extends into adolescence. So teachers can have a more intentional role in helping children master the socialized emotional skills they need" (p. 55). The present study employs a recently developed version of the Teaching Decisions (TD) simulation to determine how experienced teachers plan a lesson for a class comprised of pupils exhibiting wide variations in emotional intelligence (EQ). This study's major goal is to uncover basic strategies that experienced teachers exhibit as they attempt to meet the needs of their individual pupils. If variables defining such strategies are found, they will be incorporated into the debriefing feedback displays that Curry preservice teachers view at the conclusion of their simulation-based lesson-planning exercises.

The Lesson-Planning Simulation

![Simulation Navigation Path](image)

Figure 1: Simulation Navigation Path
The simulation exercise entails planning a 30-minute language-arts lesson for a small class of 5th-grade pupils. The simulation's Visual Basic program, described by Strang (1996), has been reconstructed to include the two phases shown in Figure 1. The participants' sole task during an initial reflective phase is to study the specific classroom traits and general personality characteristics of six software-defined pupils. In the present study, 3 male-female pupil pairs are preprogrammed to illustrate high, moderate, and low EQ levels. Figure 1 displays the program window depicting the classroom and personality traits of a Hi-EQ male pupil named Sam. The arrow configurations in the display of a Low-EQ male named Norm would appear as vertical reversals.

![Program Window](image)

Figure 2: A Typical Profile of Pupil Classroom and Personality Traits

After familiarizing themselves with their pupils, participants complete a 3-task planning phase that includes making spatial-interpersonal decisions, determining lesson activities, and allocating teacher time commitments. The spatial-interpersonal task involves assigning pupils to locations within the room, deciding which pupils (if any) will work at the blackboard or with computers, and deciding which pupils (if any) will work together. The activity task involves assigning the sequence of and the relative amounts of time that pupils will devote to selected or participant-authored lesson activities. The teacher time task centers on allocating the percentage of the total class time that the teacher plans to spend working with individual pupils, with groups of pupils, and with the entire class. Throughout the simulation's planning phase, participants can navigate freely from one task area to another. They also have immediate access to a feedback window located adjacent to the current work window. Via a single click they can view (1) graphical depictions of decisions already registered for previously addressed tasks or (2) the individual pupil personality and classroom trait profiles that they studied in the reflection phase. After finishing the three decision tasks, the teachers complete an on-screen questionnaire before exiting the simulation.

The Current Study

The participants in this study were 74 experienced elementary and secondary teachers enrolled in parallel off-grounds Master's of Education programs at two University of Virginia satellite locations. These teachers completed the lesson-planning simulation and a debriefing session as part of a laboratory component in a course in human learning and development. The simulation introduced a unit on meeting
the needs of individual learners. The professor conducted a 10-minute demonstration at the onset of the laboratory session. Next, the teachers, randomly assigned in pairs to maximize cooperative learning, could engage in the lesson-planning activity for as long as 50 minutes. At the completion of this exercise, each teacher pair received a printed form that clearly displayed numerical information summarizing how they planned the lesson for each of the class' 6 pupils. At this time participants also completed a 30-minute group debriefing session during which they compared the information on the personalized printed forms with group averages for each variable. The group information consisted of a series of program-generated histograms and tabular reports displayed on a wall screen by an LCD projector. This rich feedback environment was designed to set the stage for meaningful discussion on how best to meet the educational needs of pupils of varying levels of emotional intelligence.

**Navigation and Outcome Variables**

Two important classes of simulation-generated variables were developed to study how the inservice teachers attempted to meet the learning needs of pupils demonstrating either very high or very low levels of emotional intelligence. The first class focused on the navigation behavior exhibited by the participants during the lesson-planning phase. Navigation variables included (1) the frequency with which teacher pairs consulted the personality and classroom trait profiles to obtain information on individual pupils, and (2) the frequency with which they changed their decisions as they dealt with individual pupils. The second class of variables addressed the outcomes of teacher planning decisions for individual pupils for the three tasks that comprised the simulation's second phase. Task 1 variables defined the nature of spatial and interpersonal assignments; task 2 variables defined the type of lesson content that was assigned; and task 3 variables defined the time commitment that teachers made to individual pupils.

**Results**

Since the purpose of this study was to explore how experienced teachers planned lessons for pupils who exhibited maximum contrasts in emotional intelligence, data obtained from the two pupils assigned "mid EQ" characteristics were excluded from the data analysis. A 2(EQ level) by 2(Sex) repeated measures factorial analysis of variance was applied to variables that were amenable to parametric testing, and descriptive statistics were applied to other variables.

**Navigation Variables**

Teacher navigation decisions during lesson planning were clearly influenced by the characteristics of individual pupils. The results of an analysis-of-variance applied to the variable that defined the frequency of teacher referrals to pupil characteristic profiles yielded two significant main effects. During their decision making, teachers studied significantly more Low-EQ pupil profiles than High-EQ profiles, $F(1,36) = 5.77, p < .05$. They also studied significantly more female profiles than male profiles, $F(1,36) = 4.93, p < .05$. Means and standard deviations for the four pupil types are shown in Table 1.

Table 1: Means and Standard Deviations for Navigation Variables
Analyses of variance were also applied to the last three variables listed in Table 1. These variables depicted decision changes concerning individual pupil lesson experiences which teachers made as they completed the phase-2 tasks. The first two analyses yielded no significant effects; the third yielded a significant EQ main effect, \( F(1,36) = 8.03, p < .01 \). The teachers changed the amount of time that they planned to interact with individual pupils significantly more often for Low-EQ pupils than for High-EQ pupils.

Planning Outcome Variables

Variables in this category included quantitative measures of how the teacher proposed to address the instructional needs of each of the class’ six pupils. Spatial-interpersonal placement results revealed that pupils, regardless of EQ traits or gender, were most likely to be assigned one or two work partners. Actual percentages for solos, pairs, and triads were 11%, 53%, and 33%, respectively. Only one 4-pupil group was constructed, and no pupils were assigned to work in larger groups. Data on the characteristics of the groups were also tabulated. Only 14% of the Low-EQ pupils were assigned to a group that contained another Low-EQ pupil, and only 27% of High-EQ pupils were matched in their grouping assignments. The probability that a Low-EQ pupil would work with a High-EQ pupil was 49%. Finally regarding gender groupings, 65% of Low-EQ students and 73% of Hi-EQ pupils were assigned to work with at least one pupil of the opposite sex.

The second planning task focused on the teacher's assigning pupils and/or pupil groups the percentage of class time that they would devote to as many as three separate content activities. Table 2 presents the means and standard deviations for the percentage of lesson time for four commonly assigned lesson activities.

Table 2: Means and Standard Deviations for Activity Assignment Variables

Each of the four analyses of variance yielded a significant EQ main effect. Low-EQ pupils were assigned significantly more time that focused on their receiving specific information about the current concept, \( F(1,36) = 5.00, p < .05 \); on their being provided with as many group examples of the current concept as possible, \( F(1,36) = 6.44, p < .02 \); and on their being provided with specific activities that the teacher created to meet their individual needs, \( F(1,36) = 3.57, p < .07 \). High-EQ pupils were assigned significantly more time that focused on creating projects that linked the main lesson concept with other concepts, \( F(1,36) = 17.26, p < .01 \).

The third planning task focused on the relative amount of lesson time that the teacher planned to devote to the class, to groups of pupils, and to individual pupils. The results of an analysis of variance performed on the variable defined by the percentage of teacher-time assigned to individual pupils yielded a significant EQ main effect, \( F(1,36) = 30.68, p < .01 \). Means and standard deviations (in parentheses) for the Low-EQ female, Low-EQ male, High-EQ female, and High-EQ male pupil types were 8.95 (8.66), 7.97 (7.65), 2.89 (3.58), 2.92 (3.60), respectively. As these means illustrate, the teachers planned to spend almost three as much time interacting individually with Low-EQ pupils than with High-EQ pupils.

Summary and Implications

The purpose of this study was to explore the strategies that experienced teachers display in planning a short language-arts lesson for a small class of elementary-level pupils who exhibit contrasting
levels of emotional intelligence. Before consolidating the results of the various analyses to discuss several
general planning patterns, it is important to note that the majority of the measures which were submitted to
parametric statistical analyses (e.g., refer to Table 1 and Table 2) exhibited a high degree of variability.
This suggests that beneath the global cohort planning patterns lies a rich store of highly individualized
strategy information—a store that is readily accessible for future quantitative and qualitative analysis.

Collectively, the group results of the parametric analyses applied to navigation variables suggest
that the teacher-pairs expended more effort in studying the characteristics of both female and Low-EQ
pupils. Furthermore, the EQ-effort factor seems to appear again by the participants' elevated frequency in
decision changes related to the amount of teacher-time that was to be devoted to Low-EQ pupils.

The group-planning outcome results complement the EQ navigation findings. Here, the Low-EQ
teacher-effort factor directly translates into a disproportionately high amount of teacher time that will be
devoted to meeting the needs of the Low-EQ pupils. The lesson-activity assignment results help to explain
the nature of the perceived needs of Low-EQ pupils. These pupils are apt to be assigned highly structured
teacher-moderated activities—activities that require the teacher to provide specific concept information,
multiple examples, and individualized teacher-authored lesson experiences. High-EQ pupils are more apt to
be assigned more flexible student-controlled activities—tasks such as projects that rely less on teacher
attention and more on the intrinsic motivation of the pupils.

The findings generated from the current study will be incorporated into the group debriefing
sessions that Curry preservice teachers engage in after they complete the lesson-planning simulation during
their coursework sequence. It is anticipated that by comparing their personal planning records with both
individual and collective planning results provided by the experienced teachers, these neophyte teachers
will have a concrete base of both personal and comparative information from which to initiate a meaningful
dialogue with instructors and classmates. This important dialogue will address specific issues relevant to
meeting the needs of pupils varying in the important adaptive dimension of emotional intelligence.

The Effects of Cooperative Participation on Preservice Teachers' Lesson Planning in a Computer-based Simulation

Harold R. Strang
Lori Howard
Curry School of Education
University of Virginia
United States
hrs9j@virginia.edu

Abstract: This study explored the effects of collaboration versus non-collaboration on preservice teacher performance on a computer-based simulation. The simulation focused on planning a short language arts lesson for a small class of fifth-grade pupils who presented high contrasts in emotional intelligence. A group of 34 elementary education students self-administered the simulation as part of a laboratory requirement in an introductory educational technology course. Findings suggested that non-collaborative participants were more likely to exhibit a higher level of indecisiveness than collaborating participants. Sustained feedback-rich dialogue with a colleague appeared to supply mutual support in dealing with a decision-making task that offered a high degree of learner choice and a minimum of distinct right-or-wrong answers.

Introduction

Over the past four years more than 200 preservice teachers at the Curry School of Education have completed a lesson-planning simulation as a laboratory requirement in an Introduction to Technology in Education class. This interactive experience has provided our teachers-in-training with valuable insights concerning their general lesson-planning strategies (Strang, 1998) and their sensitivity to the needs of individual pupils (Strang, Sullivan, and Yeh, 1996). Throughout this period efforts have been directed toward increasing the simulation's instructional benefits while improving its ease-of-use and administration efficiency. The present study explores the benefits and shortcomings of assigning the simulation as a collaborative student exercise rather than, in its traditional mode, as an individual student assignment.

The Simulation Exercise

The simulation allows participants to plan a 30-minute language arts lesson for a class of fifth-graders. The class' six "virtual" students, three male-female pairs, are preprogrammed to represent high, average, and low levels of emotional intelligence. Participants begin the exercise by engaging in a reflection phase during which they familiarize themselves with the academic and personality characteristics of each pupil. Next, during a planning phase, they complete three lesson-planning tasks that include:

1. assigning where each pupil will work, with whom the pupil will work, and whether the pupil will use blackboard or computer aids;
2. assigning the sequence of and the time that pupils will spend engaging in selected lesson activities; and
3. allocating the time that the teacher anticipates spending with individual pupils, groups of pupils, and the entire class.

During the completion of the planning phase, participants have instant access to a variety of information screens. These displays, accessed via a single click, present information ranging from the pupil characteristics presented during the reflection phase to a graphical history of participant decision-making activity during the planning phase.

After finishing the planning phase, participants are asked to complete a seven-item on-screen
questionnaire. One item cluster addresses the perceived value of the experience; another addresses the relative importance of each of the simulation's four tasks.

Several weeks after completing the lesson-planning exercise, students attend a one-hour group debriefing session during which they receive explicit personal feedback on their simulation performance. The presentation of projected graphics, depicting group averages for the total class and/or for experienced teacher cohorts, allows students to compare their own personal decision making with that of others. These feedback comparisons stimulate meaningful discussions about lesson-planning strategies. At the end of this session the students evaluate the total simulation experience via a paper-and-pencil questionnaire.

Self-administration

During the current year, participants self-administered the simulation exercise. A single floppy disk, containing the lesson-planning software, also served as a storage vehicle for participant files. The preservice teachers signed out the disk and an instruction manual from the education school library and completed the exercise at their convenience.

There were two sources of simulation-related instructions. First, an overview of the assignment and precise instructions for completing the exercise were provided in a class session at the beginning of the semester. Students were encouraged to ask both general and specific questions during this 40-minute session. Second, instructional aids were an integral component of the simulation software. At the onset of the exercise, a text screen reintroduced the exercise's two phases and four tasks and its major navigational features. As participants completed each of the four tasks, on-screen help was immediately accessible via a single mouse click.

Group Assignment

Participation in the simulation exercise was an assigned laboratory requirement in the fall 1998 offering of the Introduction to Technology in Education course taught at the Curry School. Participants in the study included 34 preservice teachers enrolled in the two elementary education sections of this course. One class section was randomly defined as collaborative; the other, as non-collaborative. Students in the collaborative group were randomly assigned a partner, and the resulting pairs (N = 11) cooperatively completed the lesson-planning exercise. Students in the non-collaborative section (N = 12) individually completed the same assignment.

Variable Categories

Three types of variables were used to assess differences between students in the collaborative and non-collaborative groups.

1. Decision-Processing Variables. These measures depict participant navigation patterns and use of available information resources. Specific variables address the frequency of revisiting planning tasks, the frequency of changing lesson-planning decisions, and the frequency of engaging in planning tasks without tapping available feedback resources.

2. Decision-Outcome Variables. These measures define the ways in which teachers, as they complete the three planning tasks, develop a lesson to meet the needs of their individual pupils. Specific pupil-focused variables include the size of work groups, the percentage of lesson time assigned to information reception and project activities, and the percentage of teacher time allocated to individual pupils.

3. Simulation Evaluation Variables. A third variable category includes the three end-of-exercise participant ratings obtained from the onscreen questionnaire. Specific variables address the simulation's user friendliness, clarity in portraying distinct pupil learning styles, and relatedness to future classroom lesson planning.
Results

Decision-Processing Variables

The first decision-processing comparison across the two groups addressed the frequency with which the teachers revisited specific tasks during the planning process. Non-collaborative teachers more frequently exhibited this behavior than did collaborative teachers, $t(21) = 1.81, p < .09$. Two variables defined by decision change were also analyzed. No statistical group difference resulted from a comparison of the task 1 variable depicting the spatial repositioning of pupils, $t(21) = 1.05, p > .1$. An inspection of group means, however, revealed that non-collaborative teachers initiated this behavior 53% more frequently than did collaborative teachers. A comparison of task 2 lesson activity changes yielded a significant group difference, $t(21) = 2.21, p < .04$. Again, non-collaborative teachers initiated this decision-change behavior more frequently than did collaborative teachers. Finally, non-collaborative teachers were significantly more likely to complete a planning task without tapping available resources which provide valuable information on pupil characteristics and previous lesson-planning decisions, $t(21) = 2.29, p < .04$.

Decision-Outcome Variables

Since this exploratory study focuses on studying how teachers address the needs of pupils exhibiting maximum contrasts in emotional intelligence, statistics were applied to decision-outcome data for pupils defined as either High-EQ or Low-EQ. The first decision-outcome variable defined teacher assignments of pupil workgroup size. An inspection of the collaborative and non-collaborative assignments for female and male pupils representing the EQ extremes revealed a high degree of uniformity in assignments. Overall, 34% of the pupils were assigned to work alone, 51% were assigned to work with one other pupil, and 15% were assigned to work with two to three other pupils. The remaining three decision-outcome variables were submitted to 2(Teacher group) by 2(Pupil EQ level) by 2(Pupil sex) analyses of variance. The first two variables addressed lesson activity assignments. For information reception, a significant main effect for sex ($F(1,21) = 4.33, p = .05$) translated into female pupils, as compared to male pupils, being assigned proportionately more activity time during which they would receive information from the teacher. For project assignment, the second activity variable, a significant main effect for EQ ($F(1,21) = 4.31 p = .05$), translated into High-EQ pupils being assigned proportionately more project-oriented activity time than Low-EQ pupils. A significant EQ main effect resulted from the final analysis of variance applied to the decision-outcome variable that defined the time teachers planned to work with individual pupils, $F(1,21) = 14.30, p < .01$. Teachers committed a significantly higher percentage of their time to working individually with Low-EQ pupils than with High-EQ pupils.

Simulation Evaluation Variables

Figure 1 illustrates the three onscreen simulation-evaluation items.

![Simulation Evaluation](image)

**Figure 1:** End-of-session Onscreen Questionnaire
Regarding the first question, 75% of the teachers assigned to the non-collaborative group and 82% of the paired teachers reported that the simulation was easy to use. A t test applied to the rating data yielded no significant across-group difference. Inspection of the ratings for the second question revealed that 67% of the teachers working alone and 73% of the teachers working with a partner identified distinct learning styles in their pupils as they completed the simulation. A t test yielded no group effects. Inspection of the ratings for the third question revealed that 33% of the non-collaborative teachers and 82% of collaborative teachers believed that basic decisions made during the simulation would translate into future real-world lesson planning. The results of a t test confirmed that the group ratings were significantly different, \( t(21) = -3.47, p < .01 \).

Summary and Conclusions

The results obtained from the three variable categories offer several practical suggestions concerning the efficacy of allowing preservice teachers to self-administer the lesson-planning simulation. First, post-participation ratings indicate that the majority of participants found the instructions easy to follow. Ratings and planning decisions also reveal that a majority of the teachers were able to identify the uniqueness of their pupils and were able to construct customized learning experiences for them.

The convergence of several findings, however, suggests that the opportunity to work with a colleague offered distinct advantages. These advantages center on the finding that, teachers working alone, compared with those that collaborated with another teacher, displayed a more conflicted navigation pattern as they completed the planning phase of the simulation. Non-collaborative teachers were less likely to navigate systematically as they completed the planning phase, were more likely to change both pupil location and lesson-activity decisions, and were less likely to tap valuable planning information resources consistently. Group similarities in estimates of the simulation's ease-of-use, in estimates of identification of pupil learning-styles, and in lesson-planning outcomes for individual pupils suggest that the conflicted navigation pattern in non-collaborative teachers did not result from their lack of understanding as to how to use the simulation. One important group difference provides insight as to the potential origins of the first group's more pronounced conflicted-navigation pattern. Participants working alone were significantly less likely to believe that decisions, which they made during the simulated planning, would transfer to their future planning in real classrooms. This finding, coupled with anecdotal pupil comments gleaned from discussions during follow-up debriefing sessions, suggests that the conflicted navigation pattern resulted from the non-collaborative teachers' ongoing uncertainty as to the correctness of their planning decisions. Teachers in the collaborative group had the distinct advantage of sustained feedback-rich dialogue with a colleague. This mutual-feedback effect appears to play out particularly well in the simulated lesson planning which offers a wide array of choices and no clear-cut correct responses. It also appears to play out well when the learning task is self-administered by participants, not by professors or teaching assistants who might provide the supportive feedback that distinguishes the collaborative from the non-collaborative conditions. While this pilot study must be replicated, the present findings suggest that educators consider the potential benefits of collaborative learning not only for simulated lesson planning, but for any complex learning experience that involves a high degree of learner choice and a minimum of right-and-wrong answers.

SOCIAL STUDIES
Infusing Technology in Elementary Social Studies Methods

Sally R. Beisser
Iowa State University
Ames, IA USA
sbeisser@iastate.edu

Abstract: This paper discusses the need for university faculty to effectively model appropriate and engaging uses of computer technology in teacher education courses. Preservice teachers need experience implementing meaningful ways to use available technologies in preparation of lessons and activities. Specific reference to infusion of technology in elementary social studies methods is explored through four methods course assignments which include software analysis, Internet site analysis, multimedia project creations, and website development. Findings indicate that overall, the students in this course evaluate themselves as competent in use of technology in the social studies content areas.

A Universal Problem:

While preservice teachers may be adequately trained to select software and hardware in introductory computer literacy courses, they seldom are provided the chance to plan or practice presenting lessons using their selections (Byrum & Cashman, 1993). Most preservice teachers receive less than 20 hours of hands-on computer training during their education (Glenn & Carrier, 1989). This training typically consists of mechanics of operating hardware and selected software applications in a required stand-alone computer technology class. The course focus becomes one of acquiring basic skills using basic tools rather than purposeful integration of technology in the curriculum content areas. Even with carefully designed computer courses in schools of education, only 29% of education majors felt prepared to teach with computers (U.S. Congress, 1988). While this study was conducted a decade ago, progress to optimally prepare America's preservice teachers to meaningfully integrate technology in curriculum content areas has not been fully realized (Brownell, 1990; Diem, 1989; Kerr, 1990; Shore, et al, 1990).

In addition to limited opportunities to implement technology in curriculum content areas, preservice students have few models provided at the university level. While many colleges of education require preliminary courses on basic computer literacy, too few teacher education programs have faculty who are modeling instructional methods that integrate computer technology (Handler & Marshall, 1992; Office of Technology Assessment, 1995). Teacher training programs must recognize the need for training in technology, taught across the curriculum. While scholars have advocated integrating technology in both methods and foundation courses (Berger & Carlson, 1988; Billings & Moursund, 1988; Bitter & Yohe, 1989), coursework needs to be redesigned to integrate technology within courses so that computers are used in relevant contexts. Computer technology should facilitate content learning from carefully designed course goals and
objectives that are developed using appropriate technology-based activities and practices (Todd, 1993).

Preservice teachers learn to teach the curriculum by using technologies they have learned or observed being modeled in their college classrooms. Without influencing role models in methods courses, preservice teachers are deprived of opportunities to witness examples of teaching with computers (Bruder, 1989; Fulton, 1989). According to Wetzel (1993), most college professors simply do not use it, despite accepted competencies indicating that education majors should learn how to use computer productivity tools for effective instruction.

The International Society for Technology in Education (ISTE) and the National Council for Accreditation for Teachers (NCATE) have established Foundation Standards that require competencies to use and evaluate computers and related technologies. Learners must operate software, multimedia and hypermedia, and telecommunications to support instruction. They must demonstrate skills in productivity tools for personal and professional use, understand equity, ethical, legal, and human issues related to technology; and stay current in educational applications of computers and related technologies. In spite of ISTE/NCATE Standards first initiated in 1991, many universities have not adhered to these guidelines nor have they taken leadership role in this movement (Wilson, 1995).

Even when promising new teachers begin their first teaching positions, their use of computers in the classroom is not what they had anticipated. Beginning teachers embark on their new teaching assignments with expectations to apply newly acquired computer knowledge and skills in their classrooms. Yet the complexities of surviving the first year teaching with new content, materials, resources, and classroom management leaves little energy for using computers in teaching and learning. Overwhelmingly, new teachers feel constrained by lack of time which inhibits technology integration in lessons and activities (Novak & Knowles, 1991). Even experienced computer-using teachers require five to six years to develop a framework for effective use of technology in teaching (Sheingold & Hadley, 1990).

This poor response to technology may be influenced by the fact that many college of education faculty lack the requisite skills or experience to model teaching techniques using computers in their areas of expertise. One suggestion includes higher education faculty infusing technology into the goals and objectives of the course content. In elementary social studies methods at Iowa State University the following technology plan was implemented.

An Infusion Solution in Social Studies Methods:

Electronic Communication: Approximately 30 preservice teachers file in the assigned university classroom for their first day of social studies methods. Like many college students they thumb through the new syllabus evaluating just how much “work” this
class will require and how accountable they will "have to" become in order to not compromise their current grade point average. On that first day, they must provide their e-mail address and phone for the class composite and try to smile as I circulate taking photographs of them using my Sony Digital Camera. They quickly learn that technology is important in this class. They will receive relevant class announcements and exam study tips via group e-mail. Exemplary Internet sites will be shared through their e-mail. Electronic communication of their ideas in response to viewing a video from the "National Women in History Project" or "Winning at Teaching" when their instructor misses class to present at a national conference is required. In fact, student opinion is enhanced when forwarding an e-mail response to the video. I hear from 100% of the students, as opposed single individuals who volunteer in class discussion after a whole class video viewing. Students learn e-mail is an efficient way to contact a very busy instructor who manages to checks e-mail messages several times daily.

**Electronic Presentations in Class:** The entire social studies course is presented on a Hyperstudio® stack outlining the required texts and materials, attendance and grading policies, course assignments, field component, and National Council of Social Studies (NCSS) Standards. After using a laptop and an LCD panel to introduce the course, this program is loaded on the hard drive of the education department computer lab "classes" file for perusal when students are preparing social studies assignments. PowerPoint® is used judiciously for class presentation of research and text material. Rather than using Power Point® as electronic overheads, discussion prompts and cooperative group tasks are included in the electronic presentation. By the second day of class, a new Power Point® contribution with each students' digitized photo along with their name is ready to present. All students learn better when they are recognized and valued. Calling students by name on the second day of class is a powerful way to include them in meaningful interactions.

**Computer Software Analysis:** Because students may have already had a steady diet of drill and practice software, one of their first assignments is to analyze interactive, engaging software for a grade level of their choice. Not only do we have class demonstrations for selecting and evaluating software for content relevant purposes, but students select four of their own software selections to analyze. Our department CTLT (Center for Technology in Learning and Teaching) laboratory has an excellent software collection, but cannot purchase every new software piece on the market. Therefore, I have found making requests to commercial software vendors, who want their software analyzed by our preservice students, to be a valuable investment. Some software must be returned to the company within a 90-day period, other demoware is ours to keep. Students evaluate software for the NCSS strand, teacher/student usability, user interaction, content development, instructional value, record-keeping ease, assessment capabilities, and modifications for a range of intellectual abilities.

**Internet Challenge:** Navigating the WWW for social studies sites begins by scanning my "100 Best Websites for Teachers" (see http://www.public.iastate.edu/~sbeisser). Students locate 5 well-selected sites for teacher or student use. They evaluate those sites for NCSS strand connection and importance to understanding geography, history,
economics, political science, sociology/psychology, or current events. Students analyze attributes of the website and the potential to invite higher level thinking. Lesson plan ideas for a specific grade level or purposeful staff development uses are described for each site. At the end of the assignment, summary statements must be outlined providing 5 good reasons for Internet use in school and 5 thoughtful cautions regarding use of the Internet in the educational setting.

**Multimedia Project:** As a final project in the course, students may complete one of four major projects: A theme unit, an interactive learning center, a multimedia project, or a social studies website. Students may work collaboratively or independently on their final projects. There are revolving due dates for project completion and presentation in class. Students are encouraged to learn from each other and to try new skills. If they have never developed a multimedia presentation using Hyperstudio® or authored a webpage, now is the time to start. The multimedia project must focus on a social studies content area and address one or more of the NCSS Standards. Their multimedia project should include use of a map or globe, user interaction, thoughtful use of sound, text, graphics, animation, and have clear navigational guidelines. It must have an assessment component, a bibliography of sources, and modification for a range of intellectual abilities. The multimedia project should stimulate the user to think critically, respond reflectively, or react creatively.

**Website Design:** This assignment is to encourage students to move beyond a typical homepage displaying their resume, personal interests, and pets. The social studies website needs to connect to the NCSS Standards, engage the user in social studies content, and invite higher level thinking. Additional considerations might include website layout, text, color, graphics, sound, video, hotlinks, user navigability and interaction. There must be a way for user feedback and site visit counts. Variation for both capable and novice WWW users must be incorporated. A bibliography of credits and citations must be available in hard copy or online.

**Responses from Preservice Teachers:**

University students prefer taking responsibility for their own learning by self-selecting relevant assignments, reasonable due dates, and choice of group membership. Infusing technology in social studies content with the NCSS National Standards was a weekly practice, not a novel or contrived assignment. Commitment to use technology continued into their student teaching practice, according to informal communication from these methods class members. Student comments from end-of-the-semester social studies methods course and instructor evaluations were encouraging.

"I now have a goldmine of great social studies Internet sites from our whole class assignment to analyze websites. You usually don’t get to benefit from everyone else’s work.”
"I learned more from this methods course than any other about how to create a meaningful webpage. I was the only female who wanted to create a webpage. At first the guys took over, then they realized I had both the interest and the skills to work on this project. We had neat hot link connections to Service Learning sites from all over the country. I really liked the service initiative in social studies education."

"Although I had never actually created a Hyperstudio® project before, I had a great partner, who was very patient and instructive. Working in a pair as we created our multimedia project on Inventions, allowed us to do our own research and to create a cool activity for 5-6th graders. We’ll be able to use this in student teaching. We spent hours and hours on this, but the time flew by quickly. We were proud to present this in our methods class."

"Teacher educators will do well to model the use of computers in instruction so as to provide realistic examples from which these future teachers can later build" (Novak & Knowles, p. 49)

In this paper we will discuss the Social Studies component of the Impact Grant, a multi-year grant to develop content-specific applications of technology in teacher education. We believe that effective integration of technology into the social studies can better promote the goals of education in a democratic society by making learning experiences more active and authentic and by promoting critical thinking. Examples of the materials we have been developing based on this premise are presented in this paper along with plans for evaluation and dissemination of these materials.

Introduction

In 1997, the President’s Committee of Advisors on Science and Technology concluded that:

the nation’s substantial investment in hardware, infrastructure, software, and content will largely be wasted if K-12 teachers are not provided with the preparation and support they will need to effectively integrate information technology into their teaching.

The Committee’s recommendations include a focus on preparing teachers to use technology to facilitate learning within their content areas rather than on preparing teachers to teach about technology.

Likewise, the White House convened an invitational conference on technology and teacher training on April 24, 1998 to highlight the importance of technology training for teachers. The National Economic Council has observed that “helping teachers use technology effectively may be the most important step to assuring that current and future investments in technology are realized.”

The goal of the Impact Project is to facilitate and accelerate change in the nation’s teacher education programs, encouraging university faculty to incorporate appropriate uses of technology in teacher preparation programs. The Impact Project promotes appropriate uses of technology in specific content areas. The first phase of this multi-year initiative addresses secondary math and social studies.

In this paper, we will discuss the Social Studies component of the Impact Project including (1) our rationale for infusing technology in this content area, (2) the modules being developed as part of this project, and (3) our evaluation and dissemination procedure.

Rationale

Effective integration of technology into the social studies can better promote the goals of education in a democratic society by making learning experiences more active and authentic and by promoting critical thinking.
Active Learning
When students have active and personal experiences it strengthens their understanding of the given topic. Active learning is advanced when teachers and students use technologies such as telecommunications (Barr, 1994; Boldt, Gustafson, and Johnson, 1995). When students communicate with other students or with experts as part of a problem solving or critical thinking activity, they are in control of their learning experience. Instead of reacting to teacher directions, communication technology gives students some control over their learning. (Berenfeld, 1996). This constructivist approach encourages student activity and motivation (Maskin, 1996; White, 1996; Wilson and Marsh, 1995).

Critical Thinking
Citizenship in a democracy implies critical thought, and critical thought requires information (Parker, 1991). Technology can make more and different types of information available to students. The Internet, in particular, has the ability to dramatically increase information and resources available to teachers and students. Technology has increased not only the availability of primary resources but how students and teacher are able to interact with them. Along with the Internet, spreadsheets and database applications allow students to manipulate information in a critical manner. When used appropriately these tools can help teachers assist students in critical analysis.

Authentic Learning
Technology offers a new way to authentically represent American society in students’ lived experiences (Tally, 1996). Using the Internet, students can interact with peers from different cultures and with experts in specialized fields. Using technology, students can produce collaborative reports, gather, share and manipulate data and create knowledge that can be used by others. Such collaborative learning experiences are not reproductions of the real world, they are the real world. Students are developing knowledge and technology skills they will use as adult citizens. The contributions they make through conversations or shared work are very real and have the potential to impact other people.

Modules
The initial phase of the Impact Project includes both the creation of technology-infused modules and the identification of existing software that can be used to enhance social studies teaching and learning. The intended audience for these modules is social studies methods instructors and their students. It is our objective that methods instructors will use these modules to model effective social studies teaching strategies in their methods courses. We are making concerted efforts to develop modules for each of the disciplines within social studies (i.e. history, geography, economics, etc.). Additionally, we are including a variety of the technology applications used in the social studies.

Module Example
The following modules represent various components of the implementation process of the IMPACT project. The first module exemplifies the integration of existing simulation/learning game software into the social studies classroom, specifically a sociology or government course. The subsequent module demonstrates the development of new technology materials to facilitate instruction across content areas.

The identification and selection of quality software materials can be a confusing and overwhelming process for classroom teachers who are bombarded with catalogues and images of new titles. Through the IMPACT Project, we have identified quality software products that exemplify how technology may be used in the social studies curriculum.

The program My City (1997) is a simulation program that may be utilized in sociology or government courses. It focuses on decision-making skills and encourages social awareness by engaging students in simulated community actions. Students serve as the elected mayor for a fictional city. They attempt to respond to a series of issues impacting their city and participate in identification of problems, brainstorming of possible solutions, research and consultation with experts, identification of resources, selection of a course of action, publication and dissemination of opinion articles, and evaluation of their decisions. The objectives of the program are for the players to remain in their elected position by retaining their financial resources, volunteers, and popularity rating throughout the game.
Just as My City incorporates the development of higher level thinking strategies by engaging students in playing an interactive, animated simulation/computer learning game, the following module fosters students' critical analysis skills through the use of spreadsheets. The lesson entitled "Using a Spreadsheet: Social Demographics and Presidential Elections Statistics" focuses on social demographics and voting patterns in Presidential elections from 1952 - 1976. The objectives of the lesson include the (1) identification of data contained in a spreadsheet, (2) the creation of a spreadsheet of presidential election returns, (3) the development of skills to use the Microsoft Excel program, and (4) the identification of voting patterns among African Americans.

Students use preestablished data to create a spreadsheet file. The table below displays a portion of this data which represents responses to surveys conducted by the National Election Studies. All numbers are percentages of the total number of votes cast by people in the demographic category. For example, in the 1952 election fifty-one percent of grade school educated voters voted for Eisenhower (R) and forty-nine percent of grade school educated voters voted for Stevenson (D).

Students are asked to create a spreadsheet and various charts of the information displayed above. (Note: graphing calculators may be used instead of spreadsheets). They then calculate averages, explore variation in voting from year-to-year and generate hypotheses about what social and political events may have influenced voting at particular points in history. For example, students may be asked to hypothesize why African-American voting patterns changed from 1952-1976 or to compare the percentage of votes cast by people living in urban areas for Democratic candidates for president from 1952 - 1976. They may also be asked to present this data in a variety of graphic formats and discuss how data presentation is influenced by what one wants to portray.

Both of these modules can be done with multiple computers or using cooperative learning groups with one computer. Assessment activities are varied and can include narrative responses and application to other time periods. Complete versions of these and other modules may be found at:

**Evaluation and Dissemination**
One of the goals of this effort is determining if Project Impact has a positive effect on social studies teaching and learning. Year One of the Impact project was spent developing modules for use by social studies methods instructors. During the current year, these modules will be field-tested by methods instructors at four universities and by K-12 teachers. Seven new methods instructors will be added in Year Three to expand evaluation and dissemination. After the modules have been tested and evaluated they will be made available to methods instructors and teachers on both CD-ROM and on the Internet.

The effect of the modules as they are used in social studies methods classes is of utmost importance. Initial studies will look at the measurable effects on students and their exposure to the modules. A focus on measuring or controlling such factors as student and instructor aptitudes toward technology and teaching styles as they are effected by using the modules will be at the heart of this evaluation design. The following will be considered in the evaluation process:

- How instructors used the modules in their social studies methods classes.
- Whether instructors were able to effectively implement the modules into existing methods courses. We will determine whether instructors are able to use these modules to model technology-infused teaching strategies in the social studies.
- The achievement and performance of preservice students who use the modules in their social studies methods classes. This will be demonstrated by students charting their experiences with the modules and will be accomplished in a bimodal format. One of these will be through traditional academic performance measures. The other will focus on the incorporation of demonstrated teaching techniques amenable to the use of technology in actual classroom situations.
- Gains in the technological sophistication, expertise and application by instructors and students using the modules. This will be accomplished through pre and post testing of technological skills in the content areas.
- Changes in attitude toward technology by both instructors and students. This will be accomplished through the use of pre and post attitude scales and interviews.
- Effects of the modules on secondary social studies K-12 classroom environments. This will be done through interviews with selected teachers who have used the modules in their classrooms.

**Conclusions**
Preservice teachers experience little modeling of effective technology integration from their methods instructors (White, 1996). It is our intent that social studies methods instructors and classroom teachers alike will have the opportunity to learn and enhance their technology skills and teaching skills by using the Project Impact modules. Methods instructors who model technology-infused teaching practices for their preservice teachers hold the potential of positively effecting not only how these students will teach social studies in their own classroom one day; but they also hold the potential of positively effecting the way our K-12 students learn.

It is hoped that educators, in other content fields, will also avail themselves of the template developed for these modules. This will be made available through the Project Impact Internet Web site:

Abstract: Reform efforts in the social studies have stressed a need to change the manner in which social studies has been taught and learned including role-playing, simulations, and other activities that go beyond textbooks while involving students in critical thinking, problem-solving, and decision-making. One especially effective way to actively involve students in these activities is to incorporate technology into the social studies classroom. This paper provides information activities developed in an attempt to integrate technology into the social studies curriculum while at the same time, encouraging skills such as critical thinking, problem-solving, teamwork, collaboration, creativity, and providing experience in using various types of technological tools.

Introduction

Over the last several years, teacher education and teaching methodologies of classroom teachers have been criticized by many groups, organizations, and individuals. One response to this criticism has been the use of constructivist learning principles in teaching. Constructivism holds that children learn in the context of culture and social interaction and that teachers should act as facilitators, helping students to construct their own understandings (Brooks & Brooks 1995). Many recent reforms in education which have supported active approaches to learning to replace traditional methods, especially those based on rote memorization have adhered to constructivist principles. It is suggested that students should construct mental models of work, so the more they interact authentically with the world, the more they will learn. Vygotsky's theory of social constructivism also requires an active teacher who acts as a facilitator and guide, not as a lecturer (Vygotsky 1986). Further, a the teacher's knowledge of the textbook content, while important, is insufficient, alone, to promote higher achievement because students must actively participate in a wide range of learning activities.
Subsequently, "constructivist trends in education have increased social studies educators' awareness of effectiveness of curriculum that engages students in learning-by-doing, problem solving, and decision making" (Fontana 1997, p.1). Reform efforts in the social studies have stressed a need to change the manner in which social studies has been taught and learned (National Council of the Social Studies 1994) including role-playing, simulations, and other activities that go beyond textbooks while involving students in critical thinking, problem-solving, and decision-making. "It is thus vital that curricula, and in particular the social studies, be designed to help students develop the intellectual skills that lead to knowledge acquisition and its application to problem solving and decision making" (Fontana 1997 p. 1).

An especially effective way to actively involve students in "authentic problem-tackling or decision-making contexts" is to incorporate technology in the social studies classroom (National Council for the Social Studies 1994, p. 165). Learning to access and utilize technology will assist students as they enter a world where their jobs and personal lives necessitate the acquisition, evaluation, and maintenance of information, and the ability to interpret, communicate, and process information by means of technology (Wilson 1997). White (1995) asserts that social studies education has lagged behind the other disciplines in integrating technology into the curriculum and suggests that the constructivist approach can address this weakness.

Recognizing the need for changes in instructional practices in the social studies classroom, teachers are integrating technology into the existing social studies curriculum to promote collaboration, problem-solving, construction of knowledge by students, having learning occur in meaningful contexts, and relating learning to students' own experiences. Such practices attempt to reduce reliance on textbooks and teacher talk and instead giving students the responsibility for negotiating the acquisition of social studies knowledge. Integrating technology with constructivism into instruction is not a simple task for these teachers. Aside from the technical aspects of using equipment, software, and trouble shooting, the instructor must be able to "launch and orchestrate multiple groups of students, intervene at critical points, diagnose individual learning problems, and provide feedback" (Means & Olson 1994, p. 18). While teachers may create authentic learning tasks without computers, and activities may move away from didactic, teacher-centered activities, computer technology can augment this process (Dwyer 1994).

This presentation will provide participants with the activities of secondary social studies teachers who have successfully integrated technology and constructivism into their classrooms. The activities were developed in an attempt to integrate technology into the social studies curriculum while at the same time, encouraging skills such as critical thinking, problem-solving, teamwork, collaboration, creativity, and providing experience in using various types of technological tools. How to implement and assess the activities will be described, as well as how they relate to constructivism. In addition, student perceptions of learning by integrating technology and constructivism into social studies classrooms will be discussed and will provide insights into the impact of integrating technology and constructivism in the classroom.

Activities

News Broadcast

In an attempt to integrate technology, one social studies teacher developed his world events class as a totally technology-based course. As a model for the students, he initially used a variety of technological resources (e.g., computers, digital and video cameras, flatbed scanner, television, VCR, Internet, cable, multimedia projector, and presentation software) in his own teaching. He then provided instruction in basic computer skills and modeled the news broadcast for the students. When the students began their projects, the teacher served as the facilitator, shifting the focus of instruction to the students for the projects. Each world events class was divided into groups of four with the suggestion that each group select a leader who was proficient with a computer and possibly had Internet access at home. The team members took turns each day watching CNN as well as other news programs. The team members then brought the news stories for that day to the group. As a group they decided on a story to use for their news presentation. On Wednesday of each week, the students went to the Internet Lab in the Media Center where students would gather additional information for the news presentations. Two of the team members conducted research, while another two developed a PowerPoint (Microsoft) presentation (any presentation software can be used). Once information was completed in the PowerPoint format, students used the VCR, video camera, and scanner to develop the multimedia presentation for the class.

The presentation format was similar to an actual news broadcast. Using a "news desk" in the classroom, the news anchors, with the aid of a multimedia presentation projected on a screen behind the
desk, delivered a newscast. The newscast included local, national, and international news as well as segments on sports and weather. The room was darkened, except for the light on the newsdesk so that the focus was on the news anchor and the multimedia presentation. A podium with an attached light was placed on one side of the room for additional reporting. During the weather broadcast, the broadcaster stood by the screen and used a pointer to deliver the weather forecast. Students viewing the presentations were required to keep a news journal where information from the news stories presented was recorded and could be referred to in future class discussions. The presentations were graded using a rubric which included technical, content, group dynamics, and presentation elements.

Internet Field Trips

The Internet has the potential to serve the classroom teacher in a variety of ways, many of which are only now being fully explored. One promising use relates to Internet field trips. Many factors, such as restraints on time, lack of adequate funding, and monumental distance, often make literal field trips prohibitive. Though there is no substitute for actually visiting sites such as the National Archives or Washington’s Mount Vernon, “traveling” via the Internet to such places of historic significance assists in providing the social studies student with rich and meaningful educational experiences. Additionally, visiting a site via the Internet prior to physically traveling to a location serves as a valuable method of introducing concepts relative to the field trip destination. Planning is essential to the development of a sound “virtual field trip” experience. A close examination of all sites that are to be utilized in the classroom environment should be conducted by the teacher prior to embarking upon the “virtual highway” with students. There are literally thousands, possibly millions of web pages that may be accessed via the Internet, unfortunately many of these are poorly constructed and/or inappropriate for children. Internet sites should be previewed just as the responsible teacher endeavors to preview videos, films, books, and other resources prior to incorporating them into classroom situations. In addition to ascertaining the appropriateness of the content of a particular web site, teachers should “visit” the site in order to prepare an Internet Travel Guide for each web site that is to be visited.

An Internet Travel Guide should provide basic directions to students beginning their journey into cyberspace. Typically, the Internet address for the site that is to be explored should be clearly written at the top of the page. Assuming students have prior knowledge relative to the use of an Internet browser, they will know that this address must be typed in exactly as it is written. It is always helpful to remind students to be exact when entering web addresses. If your school is fortunate enough to have a web site, you should consider constructing a Links Page to assist in accessing web sites.

The Internet Travel Guide should also include directions for touring a web site. Many web sites are quite intricate, and if the students are left to their own devices, they may spend a great deal of time on less valuable tasks, such as determining the proper pages within the site to explore. By providing students directions as to where to begin their exploration of a particular site, the teacher is providing the student with a “nudge” in the right direction. The Internet Travel Guide should provide students with questions that may be answered through a close examination of the site. The age and ability level of the children involved will prescribe the types of questions that are asked. Additionally, teachers may choose to incorporate drawing activities in their Travel Guide to engage the more kinesthetic learners in the group. For example, on the Destination: Jamestown travel guide that was used with eighth grade students, the students were asked to discuss the importance of building a fort at Jamestown, then they were asked to draw the fort based upon the descriptions and pictures that were provided at the Jamestown Internet site.

Many web sites actually provide an interactive, online quiz. These quizzes provide immediate feedback to students as they tour the site, and are an excellent way for students and teachers to examine what learning is actually taking place via the Internet field trip. One such site that provides this opportunity is George Washington’s Mount Vernon Estate and Gardens. Students are provided the opportunity to take the Mount Vernon Online Quiz. After completing the quiz, students learn which questions they answered correctly and which were answered incorrectly. The quiz is timed, and if all answers are correct, the student has the opportunity to enter his name in the Hall of Fame.

The students can keep a travel journal as they take their field trips, making notes about the sites they visited (e.g., the main points of the site, why they selected that particular site). Student assessment can include: Explanation of sites selected, Criteria for selection, Cohesiveness/sequence of the sites, and Partner evaluation. Though there is no substitute in the school environment for visiting historic places, the
Internet provides a unique opportunity to introduce students to places that might otherwise go unexperienced. Also, Internet field trips enhance instruction because they give students the opportunity to work in cooperative groups and discover their own meanings as they explore the field trip sites and related sites. As Internet use becomes more common, and more sophisticated, interactive learning experiences via the computer will become more commonplace in classrooms.

**Traveling Through Foreign Countries**

For this activity, students were divided into groups of five and asked to plan and research a five-day journey through several countries, using geographic, economic, and political information about the areas through which the students would be traveling. The teacher had developed various journeys in advance. Students selected different journeys, randomly. Then, the students decided that they needed information on a variety of topics, such as customs, languages, foods, water, and weather conditions that they would encounter on their journeys. The students located information on the Internet, e-mailed individuals from other countries, used available software such as Microsoft Encarta and searched other resources. Once students gathered and then synthesized information, they developed an itinerary for their trips. Then, using Microsoft PowerPoint, the groups prepared multimedia presentations. The presentations consisted of information (e.g., weather, land topography, customs, etc.) about each country as they traveled through it onscreen and included music, pictures, and videos. The presentations were projected onto a screen with an LCD panel (an attachment which projects the computer images onto a television screen is a less expensive alternative). Students viewing the presentations were asked to record the information from the presentations and develop a travel journal for future trips. This activity required the students to work cooperatively, use research skills, use map skills for tracing their journey, employ critical thinking skills to develop the journey description, and utilize technology and multimedia as a method of research and presentation. Variations on this activity could include traveling through different times in history.

Assessment for the activities included several areas: Data collection, Sources searched (a minimum of five was required), Presentation (technical aspects, oral presentation), Group member assessment.

**State Web Pages**

Students were divided into groups of three to four students and the groups were told to select a particular aspect of the state in which they live, conduct research using a variety of sources, and then create a web page presenting the information. Various topics the students selected included recreation areas, famous people from the state, state government, and state culture. The students used various methods for collecting data including searching the Internet, conducting personal interviews, researching newspapers, contacting the Chamber of Commerce, taking photographs, and using E-mail. The students took the information they collected and used it to create web pages displaying the information. The web pages were created using Microsoft Works and HTML codes and included text, video, audio, digitized photographs, and some animations. While the students were working on collecting data and creating the web pages, they were told to keep a journal, detailing their activities and reflecting on what they found. Assessment of the web page development activity consisted of presentation, content, research, group dynamics elements, and reflection. The reflection assessment involved an examination of the students’ journals. This activity had several benefits for the students including involvement in their state, web page development, relating web page development to their lives, collaboration with other students, and reflection.

**Developing a Database**

Several projects can be aided by developing a database. For example, in one social studies classroom, students from two different communities were asked to collect information on their community, put that information in a database, and then they were asked to manipulate the data to examine similarities and differences between the two communities. Using e-mail and the Internet, the students collected information about their own communities and then shared that information with each other. Other activities could include assigning a student to research and develop a database of their partner school; using
a database to collect information about leaders of a country throughout various time periods to compare the characteristics of the leaders and how they may have differed; and using E-mail to have students from different communities collect data on some aspect of the community (i.e., history, leaders, community projects), put the data into a database, then analyze and manipulate the data to examine various hypotheses about similarities and differences. The groups could include students from different states and countries, also. Similarly, teachers and students in any content area can use a database project in order to organize and utilize information in their discipline. Database development allows collaboration in problem-solving, construction of knowledge by the students, having learning occur in meaningful contexts, and relating learning to a student's own experiences.

Student Perceptions

At the end of the first semester of the world events classes discussed earlier, students were given a survey to examine their thoughts on the value of using technology in the social studies classroom. After the surveys were completed class discussions were held. Most students felt that technology had been conducive to their learning experience. Their most frequent response was that technology not only made learning social studies more interesting but also had given them the tools (word processing skills, developing PowerPoint presentations, creativity, organizing information and materials, public speaking, etc.) that they could use in college and in the business world. An example of this is one student's statement, "Yes, by having more hands-on experience I have learned many skills. One thing I have learned is how to gather information from many sources and then put it together. I have also learned how the stock market works by keeping track of a stock for several months. And finally I learned how to write HTML." In response to a question about the benefits of the learned technology skills, the overwhelming student response was that they had not only learned about what was happening in the world but had gained computer skills that would help them in college and in the business world. One student stated, "Yes, I plan to go into a career in law enforcement. Some police stations and sheriffs' offices are already using computers and the Internet. I believe this will help me a great deal."

All of the students felt that students should use technology in the lower grades. Some cited that the sixth and seventh grade would be the best place to start, but most felt that it should start at the elementary level, the reason being that students should learn technology skills in the elementary grades since they will be required to use them by the time they enter middle school. When the students were asked how technology could be better used to enhance the learning experience in the social studies classroom, the most common response was that the need for more equipment. Since this was the first technology-based social studies class offered at this school, lack of equipment was certainly a problem. Each class consisted of four groups. The equipment that was available consisted of two laptop computers, a multi-media projector, and one multi-media workstation hooked to the Internet. Even though the classes had access to an Internet lab with twenty-five workstations, it could only be scheduled one day a week. This meant that much of the work that could have been done in class had to be completed at home. The students who did not have a computer and Internet access at home were at a definite disadvantage, and many of them had to come to school early or stay late to finish their projects. It also made it difficult to keep students on task because of the shortage of equipment. This problem was helped, during the second semester, when the class received a donation of a multi-media workstation from a local business and many of the students received computers for Christmas.

Conclusions

The activities described above all integrate technology into social studies instruction. To do this successfully each of these social studies teachers developed activities which employed cooperative learning, critical thinking, and creativity. These activities can also be used with any content area to aid in integrating technology. The integration of technology in these social studies classrooms had a positive impact on many students, specifically making the content more interesting and enabling students to increase their learning by developing new skills. When one student was asked to describe how using
technology changed her view of learning social studies content, she explained: “I do not enjoy writing outlines whatsoever—boring! I like to work in groups to find out about others’ perceptions and opinions and compare them with mine.”

Rather than having the teacher act as the only source of information, student presentations offered the students an opportunity to see what other groups had developed and allowed the students to see additional points of view as evidenced by this student’s comment: “The thing that I like most about the individual groups doing the presentations is that we have someone new teaching class each week.” As we near the 21st century, the demands on graduates for technology use will be greater. Technology integration is an effective way to teach students skills they will need to function in society. Enhancing social studies instruction with technology also provides an opportunity for students to be engaged and motivated to learn more about social studies.

Technology, TEKS, and TAAS:
Critical Issues for Social Studies Teacher Education in Texas

Cameron White, Ph. D.
Associate Professor – Social Studies Education
University of Houston
United States
cswhite@uh.edu

Abstract: The issues of the Texas Assessment of Academic Skills (TAAS), the Texas Essential Knowledge and Skills (TEKS), and the integration of technology are dominating social studies education in Texas and are connected in very important ways as they relate to teacher education. Many in our society seem to blindly accept each of these influences as essentials in the social studies education of our children. Critical analysis of these issues must occur for transformative rather than transmissive approach to social studies; and this discussion must first occur in teacher education, both at the pre-service and in-service levels. The paper analyzes the impact of current praxis regarding technology, TEKS, and TAAS on social studies education in Texas. As a result of this investigation, the paper proposes a critical approach to social studies education and to the integration of technology for TEKS and TAAS achievement in Texas schools.

Introduction

Several issues permeate education and schooling in Texas. The Texas Assessment of Academic Skills (TAAS) and the Texas Essential Knowledge and Skills (TEKS) are now dominating most activities in the public schools of Texas. The role of technology in the facilitation of TAAS and TEKS achievement is also a vital issue regarding schooling in Texas. The accountability movement is alive and well in Texas. Teacher education is now being faced with dealing with these issues as professional preparation ensues.

Administrators, their schools, and their teachers are increasingly held individually accountable for TAAS results and TEKS achievement. The death knell is to receive low overall TAAS scores. It has become a competition to end all competition. Administrators and schools within the same school districts are placed at odds simply as a result of a test. Teachers are now finding themselves with various dictates to teaching TAAS skills and documenting TEKS achievement. The role of technology has been to ensure success—TAAS review or practice tests, for example.

The school culture has experienced a transformation as a result of this “accountability” issue. Entire curriculum is being rewritten to focus on TAAS skills and TEKS content. Teaching methodology, recently moving toward a more student-centered, creative focus, is now moving the opposite direction. TAAS worksheets and related activities dominate the classroom. Technology, having so much potential, has been relegated to glorified “drill and practice.” The normal school day and week are often thrown by the wayside for TAAS preparation. TAAS games and pep rallies are used to behaviorally encourage teachers and students to focus on TAAS improvement. Covering TEKS objectives (only minimal competencies) are driving curriculum and instruction. Similar issues pervade teacher education with increased accountability with ExCet (the teacher certification exam).
Despite the trend toward standardized tests, there exists a growing body of research critical of its implementation and especially its dominance. Nelson (1993) states that standardized testing does not measure effective skills taught in schools, particularly in social studies and that more authentic assessment approaches aimed at developing critical thinking, decision-making, and refinement of conceptual ideas should be the goal. According to Hardwick (1996), student motivation and learning environment issues definitely affect performance on standardized tests such as the TAAS, with a need for teachers to be more sensitive to affective needs of students. Ivory (1993) documents the cultural bias issues with the TAAS. Another example has the National Council for the Social Studies (NCSS) states in its position paper on testing and evaluation (1991) that standardized tests are biased against persons whose cultures or gender differ from those of the test developers. Many similar criticisms can be made in regard to standards such as the TEKS.

**Issues**

A test and minimum standards are now the driving force in Texas public school education. And the primary role for technology is to focus on these forces. Many well-meaning educators, professionals, and citizens trumpet the so-called benefits of this testing and these minimum standards. Some of these “benefits” many espouse include the equalization of education standards for all, improvement of public schooling, preparing students for the “world of work,” and assurance of school accountability. The realities of the situation are much different.

Equalizing education standards for all students is one suggested benefit of exams like the TAAS and standards such as TEKS. A very large assumption must be accepted for this to contain any credence. First of all, it must be agreed upon that standardization by its very nature is an equalizing agent. Many studies indicate just the opposite, that standardized tests are inherently unequalizing and often perpetuate the dominant power at the expense of the “other.” The same can be said for standards. In other words, socio-economic, ethnicity, and racial issues arise with the widespread application of standardization in the form of instruments such as TAAS and documents such as TEKS. There is a reason why “these groups” do less well with such methods.

If one listens to popular media, our public schools are a shambles, full of incompetent teachers and students who would rather be committing acts of violence against others just for fun. Berliner and Biddle (1995) counter these simplistic generalizations in their book *The Manufactured Crisis*. Proponents of exams like the TAAS state unequivocally that this is just what is needed to facilitate the improvement of public schools. Again, one must understand what these folks mean by improvement. If we are interested in schools being barometers for test-taking abilities and playing only by what are often demeaning rules and regulations, then they are probably right. But if improvement means the development of knowledge, skills, and attitudes for problem solving and critical thinking as active participants in society, then the current emphasis on standardized exams and accountability is not only wrong, it is obscene. And let us not forget the role of technology in perpetuating this practice.

The integration of technology in schools remains a hot topic. The same issues remain regarding successful technology integration including time, training, and funding. We are increasingly witnessing other issues such as web access and censorship, marketing and technology, and technology as savior. Teachers are still struggling with technology availability and application issues in their classrooms. Marketing, rather than what is really best for our kids, seems to be the driving force in technology integration in our schools. Whittle, EMG, and Jostens have all been quite successful in getting their “teacher proof” technology packaging placed in classrooms. Computer companies are also doing a great job to ensure that their computers are adopted by school districts.

We also have the use of this technology as an issue in our classrooms. If the marketing can demonstrate how the technology can affect TAAS and TEKS, then there is often little more the company need to do to convince. The role of technology is now to ensure higher TAAS scores first, and perhaps TEKS achievement second, if it exists at all. Yet another issue finds technology often used as an add-on or reward when the “real” work is completed.

1591
A major issue in teacher education is how to deal with the accountability issue dominating schooling when research and theory often contradict what is presently occurring. Perhaps the best method is to use these issues for problem solving and critical thinking. Teacher education is not only about practice, but how to be an empowered educator. Developing teachers as activists for themselves, the profession, and for their kids may be an important goal in teacher education, especially due to the disempowering practice occurring in our schools.

An Alternative

What then is the alternative? The traditional method of using worksheets and multiple choice tests have little relevance in schools today, except for preparing students for standardized tests. We unfortunately also use very traditional methods for achieving TEKS objectives. The alternative is creative and meaningful student-centered curriculum and instruction. Performance assessment in the form of student developed projects such as books, "History Fair" type projects, multimedia development, simulations, problem solving, and other creative applications are examples of more relevant assessment tools. Portfolios of student work in the form of projects developed is perhaps the most promising. Rubrics can be developed to holistically assess these projects. Performance assessment is a better gauge of whether students know and can do what is important (Nickell, 1997). There is no way to standardize knowledge, skills, and values, which happens to be the point. Humans are not "standardizable." What kind of picture are we presenting when we state the kids must fit into certain molds?

Technology can be such a powerful tool for teaching and learning if truly integrated into student-centered applications. Commercial simulations, project development software (Hyperstudio, Powerpoint), multimedia, the web, and other applications can provide much to a challenging and creative classroom atmosphere. Technology used as centers, whole class, or small group applications assist with the need for variety in our classrooms. Modeling powerful technology integration in teacher education is also a must if we are interested in transforming what is presently occurring with technology integration in our classrooms.

Despite the mythology brought about by the media, government, corporations and school bureaucracy, there is an increasing amount of criticism of TAAS type exams and minimum standards such as the TEKS from all political spectrums. Most of the criticism is being directed at issues previously discussed. A recent article in the Austin American Statesman summarized these issues focusing on its domination and narrow focus (Aug. 10, 1998). Sample quotes follow:

"Everything that goes into the classroom is based on satisfying the TAAS."
Bob Offutt (State Board of Education)

"Our educational experiences are so narrowed by what the test defines..."
Lowell Bethel (University of Texas)

"The test was never intended to be used as the end-all for evaluation of schools."
Ignacio Salinas (Texas State Teachers Association)

"Businesses have cashed in on the TAAS mania."
A. Phillips Brooks (Austin American Statesman)

It is time that we take a proactive approach to education in this state and society. Our primary goal should always be, "what is best for our children." Perhaps the best place to begin is by involving the stakeholders more in the decision-making. We do profess to be a democracy after all. Yes, that means moving away from a bottom-down approach to decision-making as is practiced in corporate and bureaucratic America. Why not involve the students and teachers more in educational problem-solving?

Technology, TAAS, TEKS, and Social Studies
Now, what about technology, TAAS, TEKS, and social studies specifically? What we are seeing is the virtual death of social studies education in elementary schools. TAAS is a reading comprehension and mathematics exam for the most part. Social studies is therefore placed on the back burner in many schools, if it is even taught at all. This is especially interesting due to the fact of the existence of the TEKS for all disciplines including social studies. Teachers are receiving directives to replace social studies with TAAS review and preparation. Even social studies specific teachers in elementary schools are receiving directives to forego some of the social studies state mandated curriculum in favor of TAAS review and preparation activities. Social studies teacher education must deal with these issues and provide student-centered and meaningful alternatives.

Many argue that all the social studies needs is to be included in this standardized testing movement for the status and amount of social studies education to improve and increase. No one really knows. What we do know that when and if this occurs, we will buy in like everyone else and just teach to the social studies portion of the test as well. We could certainly spend additional time and space in critically analyzing the traditional focus of social studies curriculum and instruction. How and why would we ever imagine that a very traditional test such as the TAAS would do anything but perpetuate traditional teaching?

The place of technology in social studies classrooms is yet another issue. The role of social studies for the most part remains to ensure transmission of knowledge, skills, and values. Traditional curriculum and instruction dominates the classroom. Technology is rarely used in social studies applications, but can offer so much. Social studies should really be about developing critical thinking and problem solving skills to promote informed and active citizens.

Social studies has always played a secondary role in schools, particularly elementary schools; and now look at what is happening. We are increasingly questioning social ills and their causes in this country, yet the discipline that perhaps offers more than any other in addressing these concerns is being ignored. Perhaps we have a simple answer to these issues, for when social studies knowledge, skills, and attitude development and learning are replaced or become secondary, what else can we expect, but societal ills and concerns.

**Issues in Teacher Education**

Rarely in teacher education programs does one find much more than the focus of applying theory to practice in the current setting, with practical applications the driving force. Ideas regarding efficacy in the teaching profession, democracy and empowerment, critical approaches to curriculum and instruction, and deconstructing the goals and objectives of education, schools, classrooms, and teachers are generally avoided in teacher preparation. The idea has been to “train” individuals to meet the grand narrative regarding what it is to be a teacher and what the teacher’s role is in society. Technology is employed to support this goal. Unfortunately, with the societal, cultural, political, and economic transitions occurring, teachers and their schools have served as scapegoats when society at large is unable to find solutions to these perceived problems and issues. But schools have often bought into this and adapted to fit society’s modernist and oppressive focus.

Teacher education institutions must address the issues of accountability in the forms of testing and standards. Critical analysis of the curriculum, instruction, assessment, and management methods employed toward achieving these goals need to be deconstructed in pre-service programs. Ideas for application that deal with the issues of empowering students and teachers, integrating meaningful and challenging curriculum, and developing necessary skills and attitudes for an informed and active citizenry should first be modeled in teacher education.

The integration of technology in social studies education has fit well within the stability, efficiency and effectiveness components of traditional praxis. It has been grounded in scientific and behaviorist paradigms, and really is grounded in this manner, given its rationale within education as assisting in preparing students for the competitive world of work. Many advocates apply technology with the notion that it is neutral and value free and that it can provide answers to educational issues. But as with social studies
education and teacher education in general, we need to also critically analyze the role of technology in social studies education and teacher education.

Examples of issues in technology in social studies and teacher education include: (1) its complex and often unforeseen impact on teaching and learning, (2) it can create and/or exacerbate social issues and changes, (3) its production and use causes ecological concerns, (4) it is often systematically developed, (5) it often is imposing regarding educational goals, (6) its development and use brings up ethical/moral concerns, and (7) it can facilitate disempowerment among students and teachers (Nichols, 1994). Another major issue is the corporate domination and market philosophy surrounding the increased use of technology in society and schools themselves. These issues indicate in the very least that discourse regarding the role of technology and its social, educational, and political implications must occur.

Until only recently, blind acceptance of the “positive” nature of technology in schools has been the party line. Corporate domination of educational technology (including the increasingly commercialized web) almost guarantees this. Perhaps the most espoused rationale for an increased technology focus is the perceived need to maintain competitiveness in the globalization phenomena. As a result of these issues, social, political, and economic concerns arise. The context of technology integration in the discourse of education for democracy and social justice must be addressed.

Prospective social studies teachers are increasingly receiving the “training” regarding educational technology with introductory courses and technology integration in methods and in student teaching. Unfortunately, most of these experiences include only the training for applying technology in the classroom. It is assumed that technology integration is a given and that teachers need only awareness, access, application ideas and technology will eventually address and solve many problems in our schools. Very little emphasis is placed on critical analysis of technology save evaluation of software, and then only superficially.

A critical debate must ensue, and perhaps the place to begin is teacher education. What is the role of teacher education but to empower prospective teachers with the knowledge, skills, and attitudes important in effecting change in the schooling process? Those responsible for teacher education preach the importance of praxis. Critical analysis and reflection are vital components of praxis in education. Again, where better for this to occur than in the social studies?

Conclusions

The accountability movement is not necessarily a bad thing; our reaction to it in allowing it to dominate school praxis and the educational methods applied to “ensure” achievement are the real culprits. Standardized tests consistently evaluate a low level of thinking and their growing use as instruments of accountability encourages schools to emphasize simple, isolated skills over more complex, holistic ones (Longstreet, 1996). Longstreet goes further by describing five arguments that summarize general arguments opposing standardized tests such as the TAAS as accountability measures. These arguments include legitimacy for accountability, the nature of curricular goals and how they are developed, the validity and appropriateness of using standardized tests for accountability, fiscal responsibility, and benefits for students. These arguments basically question the use of standardized tests as a legitimate accountability measure for the good of our children. Similar issues arise regarding minimum standards, technology integration, and the role of teacher preparation.

The contention here is that with all the issues facing our society and the world for the new millennium, more, not less emphasis should be placed on meaningful, student-centered social studies education. Meaningful technology integration and teacher education focusing on empowering teachers can only help in addressing these issues. The over-reliance and dominance of the TAAS and standards like the TEKS only serve those in power and are demeaning to students and teachers. This is not the answer. A much more rich teaching and learning experience for our children should be the goal.

Dr. D.J. Yocom, Assistant Professor of Special Education, College of Education, University of Wyoming djyocom@uwyo.edu

Abstract: US Department of Education statistics indicate that there are an increasing number of students with special needs being educated in the regular education classroom. This places increased pressure on the classroom teacher who may not feel equipped to deal with students who have special needs. Technology can play an important role in providing services to these students. At the University of Wyoming Laboratory School there are classrooms where voice to text software is used to help students with learning disabilities in the area of written language. This program is a cooperative venture between the University Laboratory School, the College of Education, the Learning Resource Center, and the College of Education Technology Coordinator to provide assistive technology for students with disabilities in the regular education classroom. It is designed to be used by classroom teachers to enhance the work of students who have disabilities in speech and language.
Integrating Technology into the Special Needs Classroom: Are Teachers Prepared?

srmehall@uh.edu

Abstract: As technology advances, the use of computers in special education classrooms has moved beyond simple classroom management tasks—it should be integrated into the child’s educational experience. Are teachers being prepared to integrate technology into special education classrooms? Are teachers taught about of how the American Disabilities Act and P.L. 94-142 may effect them? How do the new technologies help the students? This paper intends to discuss current teacher education requirements that reflect the acquisition of skills needed to use technology to teach students with special needs. An overview of assistive technologies, such as devices and Microsoft adaptations will be given. Applications of these technologies will be provided as well. Students with special needs can profoundly benefit from a classroom teacher who has been trained in the integration of technology into classroom learning. The goal is to produce children who will become computer literate and well-educated members of society.

Currently, the use of technology within the special education classroom is often limited to rote practice using games or tasks such as word processing or drawing. It is vital that as educators we integrate technology into a child’s curriculum and understanding of the workings of society. As technology advances education, it is important that all persons involved with the education of special needs students strive to merge technology into their everyday activities.

Background

In 1975, the United States Congress passed Public Law 94-142, better known as the Individuals with Disabilities Act (IDEA). The act has forced changes in the way teachers educate children with special needs. IDEA mandates that every child between the ages of 3 and 21, regardless of the type or severity of their disability, shall receive a free, appropriate public education (Heward, 1996, p. 25). One of the major aspects of P.L. 94-142 is that students are to be educated in the least restrictive environment. Often, the environment has been in a resource room or special education classroom. Many state education agencies, Texas Education Agency (TEA) included, is requiring school districts to place special education students into the regular classroom when it is beneficial to the education of the child. Regular education teachers need to be prepared to meet the individual needs of students with all types of disabilities. Recently, the use of technology is being used to meet the needs of special education students.

Learning With Special Needs

Most students with learning disabilities have difficulty learning in the conventional ways. Studies have demonstrated that students with learning disabilities require material be presented in multiple formats multiple times for retention
to occur. "A number of approaches are available to assist students with mild disabilities" (Behrmann, M., 1998, p. 1). "Technology is bursting into the classroom at all levels, as a tool for teachers to develop, monitor, and provide instructions, and for students to access and engage in learning" (Behrmann, M., 1998, p. 1).

The Necessity for Technology for Students with Special Needs

The integration of computers in the classroom has been a primary focus of teaching new teacher a way of implementing technology into the classroom. Using computers in the classroom allows teachers to offer students the opportunity to learn pedagogical material in unique ways. The utilization of technology creates multiple educational opportunities that are useful to students with special needs and is necessary for their education within the regular classroom setting. With many students the use of assistive technology is enabling them to participate in classroom activities outside the realm of special education.

What Are Assistive Technology (AT) Devices?

"The Tech Act defines AT devices as any item, piece of equipment, or product system (whether acquired off the shelf, modified, or customized) that is used to increase, maintain, or improve functional capabilities of individuals with disabilities" (Behrmann, M., 1998, p. 1). Both high technology and low technology alternatives are available to students. Low-tech devices include pencil-grips, note-taking cassette recorders, picture boards and taped instructions. High-tech devices include optical character recognition (OCR) calculators, word processors, speech synthesizers, and communication devices. These devices make it possible for children who would not otherwise be able to participate in regular education to do so.

Assistive Technology Applied to Instruction

The ultimate goal of the use of assistive technology for students is to enhance instruction and to modify the way in which a child hears, responds, replies, or implements the instructional process. Lahm and Morrissette (1994) identified seven areas in which AT can be utilized for students with mild disabilities. Those areas include organization, note-taking, writing assistance, productivity, access to reference materials, cognitive assistance, and materials modifications. Organization involves teaching students how to organize their thoughts and materials. Note-taking is simple approach to help students effectively organize written material. Writing assistance involves mainly word processing for help with spelling and grammar. Productivity includes the use of calculators, spreadsheets, and databases for work requiring calculating, categorizing, or grouping information. Access to reference materials involves using telecommunications and CD-ROMs to gather and synthesize information in a less distracting environment. Cognitive assistance uses tutorials, drill and practice, and problem solving software as well as reading assistance using multimedia CD-ROMs. Materials modification is made simpler through the use of technology such as video clips, animation, digitized pictures, etc. Materials such as these applied in an instructive fashion make learning more efficient and more hands on allowing for greater generalizations.

Classroom Applications

With computer technology, teacher education students can learn to enhance their lessons by providing various perspectives on information. Multiple formats can be integrated to provide students with a variety of methods for understanding and recalling information. One way teachers can use this technology is by instructing with multimedia, or making multi-sensory presentations. By using assistive technologies such as multimedia or hypermedia in a lesson, teachers can present information visually, audiologically, and textually.

By using widely available programs such as PowerPoint, HyperStudio, or ClarisWorks, educators can appeal to regular education students as well as students with special needs. This new focus is a way of exercising the brain and
keeping students centered on a learning task without the use of straight lecture or question-and-answer periods. These programs encourage students to view learning as fun. Teachers should be aware of the availability of the AT options. They also need to have the knowledge of how and when to use appropriate programs and assistive devices for each child.

Are Teachers Prepared?

Is it possible for teachers to make informed decisions concerning the technological needs of the student if the teacher has not been trained appropriately nor realizes what options are available? Currently TEA does not have any requirements for teacher certification concerning the need of all teachers to be trained in special education practices. Teacher education students are required to take three hours of computer literacy as it is applied to teaching in classroom situations. Topics such as the behaviorist and constructivist integration of computers in the curriculum and the uses of new multimedia software are discussed, but how these may benefit the student with special needs is not currently addressed.

Proposed Changes in Teacher Education

One of the main obstacles of using technology for classroom applications and as a part of education is the apprehension of teachers to learn the technology. Teachers need to realize that AT often makes the difference between a student being successful in the regular classroom and requiring more special education assistance.

Pre-service teachers need to be educated about inclusion and understand the implications for their classrooms. A recommendation is for college/university teacher education programs and education state boards to make observation/special education classroom teaching time mandatory for certification at all levels. A classroom laboratory setting which provides hands-on experience with AT as well as opportunities to assess individual student needs. Exposure of such materials and situations provides future teachers with the base knowledge needed to handle students with special needs in the classroom. Likewise, learning about technology is not enough. Through pre-service teacher education sessions, educators need to be trained on incorporating technology into their classrooms.

Through adequate training, new teachers will be able to integrate technology for all students. The next goal beyond incorporation is motivating these teachers to utilize the computer more often and in unique ways necessary for the learning of all students.

Conclusion

Technology helps students with special needs a greater opportunity to participate in the regular classroom setting. It is the responsibility of all teachers to have the knowledge and background necessary to determine the type of assistive technology that is needed and how it can best be used by the student. Currently, there is no requirement that teacher in Texas have the basic background knowledge of special education and are required little in terms of technology for children with special needs in the classroom. Until the time when changes are made to require teachers to have the knowledge, students with special needs are going to be at a disadvantage in the regular classroom setting.

Integrating the Internet into Counselor Education

Pamelia E. Brott
Counseling Program
University of Houston-Clear Lake
United States
brottp@cl.uh.edu

Abstract: There are numerable opportunities for counselor educators to integrate the Internet into graduate courses as a counseling resource. This article presents a variety of activities that can be integrated into the course curriculum to introduce the Internet, to use the Internet as a source of information, to access electronic sites for networking, to complete assignments, and to become familiar with professional organizations. The examples provided are activities that a junior faculty member has used to integrate the Internet into counselor education courses.

Introduction

The Internet is a source of information. On the one hand, it is a source of information that can be embraced by users as helpful and beneficial. On the other hand, it is a source of information that can be held under scrutiny as unethical and dangerous. The former can be viewed as resources; the latter can be viewed as practices. The practices of Internet counseling have professionals taking sides on a debate as either ethical or unethical. However, viewing the Internet as resources provides counselor educators the opportunity to integrate technology into the training of professional counselors.

In the early 1980s, editors of professional journals for counselor educators began publishing articles dealing with the issues and uses of technology (e.g., Phillips, 1983; Walz & Benjamin, 1983; White, 1984). The use of technology cited in these articles included word processing, instructional enhancement, career and educational information, measurement and evaluation, and research and statistics. Lambert (1988) followed four years later with a reflective look at computer use in counselor training that had been previously reported and included a review of the advances in computer technology for developing training applications in counselor education. More recently, articles have been published focusing on specific applications of technology in counseling and counselor education (e.g., Myrick, 1997; Myrick & Sabella, 1995; Stevens & Lundberg, 1998).

As a recent entrant into the ranks of counselor educators and an avid user of the Internet, I have provided introductory Internet experiences for students enrolled in the courses I teach. To date, I have integrated the Internet into four courses: Career, Vocational, and Educational Information; Guidance of Elementary School Children; Introduction to Systems Counseling; and Principles of Counseling. This article presents ideas for the introduction of Internet experiences as resources for counselor educators. Following the conclusion, the addresses are given for the Internet sites included in this article. This subheading is appropriately titled resources.

An Introductory Internet Search

The first assignment in each course is to search the Internet for counseling resources related to the course topic. For this assignment, I develop a series of questions about the course topic along with three or four suggested Internet sites for the students to visit for information that will answer the questions. The last item on the assignment instructs students to identify a minimum of three sites they have visited beyond those on the assignment. I then compile a composite listing of the Internet sites for the students that includes the Internet address and reference information (e.g., http://www.coounseling.org/ American Counseling Association [ACA] home page).
Sources of Information on the Internet

A course dealing with career development and counseling (i.e., Career, Vocational, and Educational Information) lends itself to using the Internet as a source of information and a resource for counseling. One assignment in this course is to complete research on various job titles. In completing the assignment, students become familiar with a variety of career, vocational, and educational information sources. By using the Internet, students are able to access government documents (e.g., Dictionary of Occupational Titles, Occupational Outlook Handbook), state resources (e.g., State Occupational Information Coordinating Committee), and Internet domains (e.g., Monster Board, The Riley Guide).

Another assignment, pertaining to a career counseling intake interview, encourages students to use Internet sources to prepare for the interview and to develop resources for client activities between sessions. As part of the take home final examination in the course, students complete one assessment instrument available on the Internet (e.g., The Values Game, Keirsey Temperament Sorter), develop their own card sort based on job titles, and complete two case studies. Both the card sort and the case studies have components that can be addressed using resources available via the Internet.

Electronic Counselor Education Sites

Through the introductory activity in each course, students are made aware of and are encouraged to subscribe to electronic newsletters (e.g., ACAeNews, ASCD bulletin), to participate in counselor network sites (e.g., CESNET, International Counselor Network [ICN]), and to access counseling literature.

ACAeNews is an electronic newsletter of particular interest to counselors as well as counselors-in-training. The subscriptions are free and, once an individual has subscribed, current issues of the newsletter are automatically forwarded to subscribers. Each issue contains an overview of current issues related to counseling, links to related sites, and links to expanded articles highlighted in that issue.

The counselor network sites are listservs that facilitate networking through electronic discussion forums via e-mail. An individual can e-mail a thought, question, or response to the forum, and the listserv software re-transmits the e-mail to the entire mailing list. Recently, electronic sites focusing on the concerns of graduate students in counselor education programs have emerged (e.g., COUNSGRADS) and are of particular appeal to our students.

Journals (e.g., Journal of Adult Development and Aging) and articles (e.g., ERIC Digests) available electronically give students access to information for research papers and course presentations. By using an Internet connection from home, students can access information at any time of day or night even if they do not have library access via the Internet.

Resources for Course Assignments

An objective for each counseling course relates to ethical practices. Reviewing case studies and applying the Ethical Code and Standards of Practice is an excellent way to inform students of counseling ethics and to stimulate discussion about ethical conduct. Although counseling textbooks often include the Code and Standards from one or more of the counseling associations, it may not be the most current edition. However, the Internet sites for the counseling associations do include access to the Code and Standards.

Therefore, the course assignment is for students to access the most current version of the Ethical Code and Standards of Practice (e.g., ACA, National Board for Certified Counselors [NBCC]) and to print a copy for use in reviewing the case studies. By accessing the information via the Internet, students are able to obtain the most current edition of the Code and Standards for a variety of counseling associations. This approach allows case studies dealing with ethical issues to be distributed in class one week with discussion the following week where the focus of discussion is on both the students' ethical decisions and the basis of the decision-making process. Students become aware both of the basis for decisions and of numerable Codes and Standards dealing with ethical practices in the counseling profession.
Professional Organizations

Many of the professional organizations for counselors have Internet sites (e.g., ACA, National Career Development Association [NCDA]). State counseling associations (e.g., Texas Counseling Association [TCA]) also have become accessible through the Internet. Students visit these sites for many of their assignments (e.g., how many divisions are there in ACA?), for access to membership information, and for information about professional growth opportunities (e.g., conferences, seminars). This is an opportunity to encourage the professionalization of counselors-in-training.

More Ideas

Numerable faculty members on our campus have moved into cyberspace by offering courses through distance education. Faculty members are placing syllabi on-line, students are submitting assignments via the Internet, and the university is offering entire courses via the Internet.

My next step is to develop a site for the Counseling Program that will include "hot keys" linking users to various counseling resources. The site will include links to program admission information, to the home page for individual faculty members, and to syllabi for a variety of counseling courses.

Based on my review of the literature related to the use of technology in counselor education that I completed for this article, I have identified a need to inform counselor educators of the current use and of the possible uses of the Internet in counselor education. This article is my first step in sharing the information about integrating the Internet into counselor education. In the near future, my plans are to use the Internet to collect data on the current use of the Internet by counselor educators across the nation.

Conclusion

Although the debate on Internet counseling practices continues, there are many opportunities for counselor educators to use the Internet for counseling resources. Activities to introduce the Internet, to use the Internet as a source of information, to access electronic sites for networking, to complete assignments, and to become familiar with professional organizations can be a proactive approach to integrating the Internet into counselor education. Further, counselor educators can use the Internet as a resource for counseling information, program information, course syllabi, and professional research.

An Inclusive Web: Cyber-training Regular & Special Educators

Trinka Messenheimer & Sean J. Smith, Bowling Green State University, USA

This presentation seeks to illustrate an on-line project that supports an undergraduate and graduate Exceptional Learner course (required for all pre-service regular and special education students). The web-enhanced course that we have developed offers a general introduction to the characteristics of exceptional learners and their education. The course, Exceptional Learners (i.e., introduction to special education), is dedicated to providing a general exposure to the characteristics of individuals with special needs, as well as instructional modifications and behavioral management techniques that can employed to assist individuals in the regular education environment. It is the intent of this course that participants will become more comfortable in the identification and educational requirements of students with special needs. Because legislation and subsequent litigation, related to the education of children and youths with disabilities has become increasingly specific and mandatory, this course also reviews relevant special education law and how it applies to the education of students with special needs.

We selected this course because of the direct application to a wide audience of preservice special and regular education teachers. Traditionally, this course has been a requirement for all pre-service teacher educators in our teacher education programs, (e.g., elementary, secondary, and special education) and for many individuals preparing for careers in related education professions (e.g., school psychology, communication disorders). A major goal of this project was to create a resource that would be applicable to teacher education needs beyond the confines of Bowling Green State University and University of Toledo.

The on-line project that we have developed as an introduction to special education involves three web-based components. The first, titled Course Basics, includes a section dedicated to course basics found in a typical teacher preparation course (i.e., course syllabus, readings). The second, Assignments, incorporates web applications enhancing traditional instruction, offers access to relevant special education materials, and incorporates a number of on-line library resources and related Internet applications. The final section features Web-based Case Studies which seek to combine theory with practice in an interactive manner.
The Virtual Resource Center in Behavioral Disorders: Dissemination and Evaluation of Instructional Supports via the World Wide Web

Abstract: This paper presents a World Wide Web site designed to provide training and ongoing support for students and professionals preparing to work with children with behavioral disorders, and their instructors. Design features and content of the site are presented along with a discussion of the ongoing collection of quantitative and qualitative data related to site usage and learning outcomes.

Theoretical Base

Materials designed to assist teachers in working with students with behavioral problems are currently in high demand. According to The National Educational Goals Report (NEGR, 1995), such training includes 93% of America's teachers. There continues to be a high demand for training programs in behavioral disorders from local school districts and state departments. Unfortunately, as Gersten, Morvant, and Brendelman (1995) document, there is a gap between educators receiving training and altering what happens in the classroom. The mission statement of the U.S. Department of Education's Professional Development Team, an outgrowth of the Goals 2000 legislation, emphasized the need for on-going, long-term, continuous programs designed to promote collaboration, collegiality, and inquiry by all members of the school community (1996).

The design and development of World Wide Web sites as a delivery medium for instructional supports in both pre-service and in-service teacher education have been well documented. Research and evaluation of these web-based supports, however, is in its infancy with much of the information being purely descriptive in nature (Newmarch, 1997, Windschitl, 1998). Web-based delivery of instructional supports for teachers can, it appears, overcome many of the drawbacks inherent in traditional delivery methods (Shotsberger, 1997). Although these technologies appear promising, there is a need for research focused on instructional outcomes and what teachers actually do differently or better because of their readily-available access to information and support.

Virtual Resource Center in Behavioral Disorders Web Site
The Virtual Resource Center in Behavioral Disorders (VRCBD) was constructed to provide training and ongoing support for pre-service teachers and field professionals who utilize the Teacher Problem Solving Skills (TPSS) programs and their instructors. In addition, opportunities for electronic communication provided through the VRCBD web site enable social discourse among teachers around the instructional materials and current topics in behavioral disorders.

A Tour of the Virtual Resource Center in Behavioral Disorders

A Tour of the Virtual Resource Center in Behavioral Disorders

The Main Menu (Fig. 1) of the VRCBD site was designed to give users easy access to all aspects of the Virtual Resource Center. From this screen the user can access descriptions and dissemination information about the TPSS Series. These multimedia programs use case-study scenarios and classroom videos to provide problem-solving experience in the processes of investigation, assessment, planning, and observation needed by professionals serving children with social, emotional, and behavioral disorders.

The Instructor Resource area of the VRCBD gives instructors using the TPSS Series access to teaching materials and other resources available for use in their training programs. Printable materials are available in PDF (Portable Document Format) files and include conference papers related to TPSS, transcripts of expert commentaries from the programs, and forms for use with the TPSS programs. Access to an electronic discussion forum provides an opportunity for asynchronous communications between instructors across the country and VRCBD personnel. Planning for the BDOonline Workshops and other training opportunities is facilitated through this discussion list. In addition to these TPSS related resources, links to a wide variety of Internet resources related to behavioral disorders are available through the Resource Links section of the VRCBD. Contributions of additional resources are welcomed and are easily communicated to the VRCBD staff through a hyperlink.

The authors of the TPSS series and members of the VRCBD staff provide frequent training opportunities at national conferences and at a week long Summer Institute held on the University of Missouri.
campus. Information on upcoming training events and registration for the institute are available through the VRCBD site. Other areas of the VRCBD contain information on the authors and contributors of the TPSS series.

Establishment of an online community where professionals and students in the field of emotional and behavioral disorders can interact in regular discussions and idea sharing is one of the primary goals of the VRCBD. Three online conferences (BDOngine) are scheduled for 1999. Experts in the field of behavioral disorders will establish an “online presence” through the VRCBD conference. Instructors and in-service leaders will be invited to bring their classes online during a two-week period for interaction with the expert. Readings will be furnished as PDF files for download to establish a common ground for discussion.

In addition to the virtual conferences the VRCBD can establish connections between classes using a particular TPSS program. Discussion lists have been established for each of the four programs and the VRCBD maintains a current database of instructors using the programs to facilitate these connections. Synchronous discussions between classes or in-service groups wishing to interact in real time is also possible in the VRCBD chat room. This room uses EveryChat software installed on the University of Missouri’s College of Education web server. This software facilitates online chats without the need for additional software installed on remote users’ computers. Users simply log into the EveryChat environment using their web browser.

In addition to these opportunities for online communication, the VRCBD has provided a User Exchange area to facilitate the sharing of instructional ideas and technical assistance for professionals wishing to share their ideas through the web, thus enabling transfer of training. Members of the VRCBD staff are available to create web pages or assist those wishing to create their own pages for the publication of instructional ideas on the web. Space has also been designated for instructors to share their course web pages, demonstrating how the TPSS programs are used in their course curriculum. In addition, web publishing as a means of sharing ideas is taught as part of the VRCBD Summer Institutes.

Methods for Data Collection

Reeves (1998), in proposing the best means for answering critics of media and technology, emphasized that efforts to integrate media and technology into education should be guided by strong research and evaluation. In order to evaluate the effectiveness of the instructional supports provided through the VRCBD, quantitative and qualitative data are gathered continuously from the site.
In order to determine who is using the site, a user survey was designed as a requirement for entrance into the VRCBD pages (Fig. 2). The survey consists of a simple form where the user supplies his name and e-mail address, and answers three questions describing reasons for visiting the site. This information is collected using a custom CGI (Common Gateway Interface) script. Data are available as either an HTML page displaying each user in order, or as a text delimited file that can be imported for use in statistics or database programs. Completion of this survey places a temporary “web cookie” in the user’s browser. Subsequent pages use an additional CGI script to check for the presence of this “cookie.” Attempting to enter the site without filling in the survey information gives the user an error message and returns them to the survey page.

In addition to the survey page, a custom tracker is also installed on the VRCBD site. This tracker logs site usage data including Internet addresses of visitors to the site, pages visited, and time spent at VRCBD. This information can be displayed in graphical form or is available in a text file.

In order to evaluate the growth and effectiveness of communications, data can be gathered from synchronous and asynchronous discussions at the Virtual Resource Center for qualitative analysis. All messages to the VRCBD discussion lists are automatically archived on the College of Education server. This information is searchable and can be sorted by subject, date, or author. The EveryChat software used for real time discussions creates a transcript of discussions that can be used for analysis of emerging themes and can also be sent to discussion participants via email. Additional data will be collected from participants of the online conferences. Survey instruments have been placed as PDF files on the BDOnline page. Instructors choosing to include the online conference as a class assignment are requested to collect data from their students. Survey instruments include:

- Daly-Miller Writing Apprehension Test;
• Kolb Learning Styles Inventory;
• Prior Computer and Telecommunications Use Survey;
• Education and Experience Survey; and
• Participant Follow-up Survey

Through these instruments the researchers at the VRCBD hope to gain information regarding web site usage as related to user differences in such factors as writing apprehension, learning styles, prior experience, education, and satisfaction.

In the future the VRCBD hopes that the web site will become an online forum for the sharing of instructional ideas through web pages contributed to or by professionals who are actively using the strategies and techniques presented through the TPSS programs in their work with children. The fourth TPSS program, soon to be released, presents performance support tools for developing a variety of cognitive-behavioral interventions. As teachers and professionals use these tools, their strategies will be collected in the User Exchange area of the VRCBD. These contributions will be analyzed as one more means of determining the effectiveness of these web-based instructional supports.

Expected Results

Through the quantitative and qualitative measures described above, researchers at the VRCBD will study the implementation of telecommunication supports for the purpose of understanding their impact on the development of knowledge, skills, and reflective processes by pre-service and in-service teachers and professionals. The evaluation procedures now in place for the VRCBD will enable project staff to study in depth the impact of each web-based instructional support on learner outcomes. Over time multiple data sources will be used to examine relationships and generate hypotheses for further study. Variables which impact the effectiveness and efficiency of web-based instructional supports for personnel preparation in behavioral disorders will be identified and recommendations will be made for the effective use of telecommunications in these programs.

Abstract: Who is choosing the computer software for learners with exceptionalities and special needs at your school? Is the selection and purchase of software delegated to the technology specialist or a committee of classroom teachers? Has the special education teacher been consulted during the decision making process? In any of these scenarios, how many of these educators have been trained to select developmentally appropriate software for children with special needs? This study was designed to address these concerns by surveying faculty and resource specialists from 78 elementary schools in a south Florida county in order to: (a) identify the criteria primary grade special education teachers use when evaluating computer software; and (b) identify special education teachers' needs to assist them in the selection of software for purchase.

Introduction

All teacher education programs are based on a variety of standards and criteria set forth by numerous regulatory bodies. Special Education is no exception as is guided by the Council for Exceptional Children International Standards for Teacher Preparation (1998). Today's special education teachers are expected to make instructional decisions concerning the vast opportunities technology has to offer the student with special needs. Many of those teachers are without technological foundational knowledge and competencies that are essential to improve and enhance the learning processes in the classroom. Unfortunately, many special education faculties have not been inserviced adequately to provide fundamental skills necessary to utilize technologies appropriately.

In most educational settings, technology specialists make hardware decisions and the unaware and untrained instructor makes software decisions. Thousands of dollars are spent by school districts across this nation every year to purchase software which is thought to be developmentally appropriate for young children with regular and special needs. Special education faculty without proper knowledge and training of both hardware and software may be making instructional decisions that are inappropriate or detrimental to the learning process in regards to the uses of technologies.

Although teachers have been using computers with their students in primary grade classrooms for well over a decade, the quality and availability of computer software has dramatically improved (Coley, Cradler, & Engel, 1997). Today, teachers can select from hundreds of software titles to use with their students. However, some
software is not developmentally appropriate for young children, especially young children with disabilities. With the abundance of titles available, selecting a developmentally appropriate program becomes a challenging task. Shade (1996) asserts it is critical for teachers to select developmentally appropriate computer software for use with young children. When teachers use developmentally appropriate computer software, they are providing opportunities for children to control their environment, stimulate their imagination, and use open-ended exploring to facilitate higher order thinking (Haughland, 1992). These opportunities are immensely important for students in special education in order to provide access to a range of interactive and cognitively stimulating experiences using the computer.

Despite the research supported benefits of using developmentally appropriate software to improve children's use of language, turn taking, and ability to make decisions (Borgh & Dickson, 1986; Escobedo & Evans, 1997), many teachers do not use a research based criteria for evaluating software and choosing hardware. Haughland and Shade (1992) developed a software evaluation scale that provides guidelines based on the National Association for Young Children developmentally appropriate criteria. They suggest teachers consider the developmental appropriateness of software in the following areas: (a) age appropriate, (b) child control, (c) clear instructions, (d) expanding complexity, (e) independence, (f) process orientation, (g) real-world model, and (h) technical features. By using these criteria as a guide during software selection, teachers can make informed decisions rather than using a random selection process. Bender (1995) describes the process which many teachers use when purchasing software for their classroom, "Teachers are typically given a software catalog with the titles of the software, a brief description, and price" (p.33). If teachers are using this type of illogical method for selecting software, it is probable that their software choices lack the developmentally appropriate characteristics that can provide the most benefits for students with disabilities.

Despite the plethora of software titles and knowledge of software evaluation, teachers of students with disabilities may have difficulty locating high quality developmentally appropriate software to meet the specific needs of their students. In that case, teachers can provide insight into the types of developmentally appropriate software needed in early childhood classrooms.

Research Questions

The research questions of the study were:

1. What criteria do primary grade special education teachers use when evaluating computer software?
2. What specific instructional areas do teachers identify for software development for young children with special needs?

Purpose

The purposes of our study are to investigate how special education teachers in primary grades classrooms, pre-kindergarten through second, evaluate and select computer software for use with their students as well as identifying teachers' needs in software development to meet their students' instructional goals.

Methodology

Participants

The sample included 234 faculty and resource specialists from 78 elementary schools in one Florida county. Faculty surveyed included: (a) specialists teaching in resource classrooms; (b) teachers instructing in self-contained classrooms; (c) teachers providing instruction in classrooms implementing inclusion, and (d) teachers serving students with varying exceptionalities.

Instrumentation

The questionnaire was designed by the researchers to: (a) identify the criteria primary grade special education teachers use when evaluating computer software; and (b) identify special education teachers' needs to assist them in
the selection of software for purchase. The last section includes a number of demographic questions including: (a) gender; (b) years in the teaching profession; and (c) years employed at their present school. A pilot study is being conducted at 3 elementary schools. The purposes of the pilot study are to: (a) test the questionnaire items in the instrument for item validity and reliability; (b) enable the researchers to observe respondent and instrument responsiveness; and (c) to obtain direct comments from respondents about clarity of questionnaire items, instrument length, and clarity of the directions.

Data Collection

Data are to be collected both quantitatively and qualitatively using the software questionnaire and unstructured interviews with special education faculty. Participants will have a choice of how to complete the questionnaire: (a) paper, and (b) via the Internet. A cover letter, which is part of the actual survey, and an envelope for return mailing, will accompany each paper survey. A reminder notice will be sent two weeks after the initial mailing. This reminder notice will not include a survey. A final mailing, which will include a survey, will be conducted two weeks after the reminder notice.

Data Analysis

The quantitative data from the Survey items will be analyzed using SPSS for Windows v. 8.0. A Microsoft Access for Windows 95 database was designed to improve the reliability and ease of entering and organizing the data from the completed surveys. The .05 level will be used to determine statistical significance.

The qualitative data from the unstructured interviews will be analyzed using content analysis. The researchers hope to identify themes in the data that point to something important for the participants being studied. For instance, in one study, failure to use software the "right" way became symbolic for failure to conform to organizational norms. Concepts will be developed from the data that will help to explain particular phenomenon such as a teacher's willingness to use one software program for more than one task. Triangulation will be employed to help the researchers understand the teachers' interaction with software and consequently their students.

Results

For the purposes of this presentation, the results from the pilot study and preliminary data analysis will be included. The instrumentation and research methodology will also be presented.

Implications

This study may provide a better understanding of how special education teachers in primary grade classrooms, pre-kindergarten through second, evaluate and select computer software for use with their students. If the study indicates that special education teachers make software selection decisions without being trained adequately to do so, then inservice training ought to be targeted to enhance each teacher's technological foundational knowledge and competencies. The study may also provide a means of identifying teachers' needs in software development to meet instructional goals. The results of this study can provide a means to match existing software with individual teacher needs. The study could also provide the researchers with crucial information for constructing developmentally appropriate software. Several of the researchers are involved with courseware design projects that may be tailored to meet instructional needs for enhancing and improving the learning processes in their classrooms.

Abstract: This study examined the consequences of establishing e-mail communication between two classes in different schools: a fifth grade of children with hearing difficulties and a fourth grade of children without hearing difficulties. The arrangement provided an opportunity for children to interact with peers whom they would not normally meet at school. Relying on material from their own social studies curriculum, pairs of children exchanged information in a structured fashion. This allowed children to assume the role of both teacher/resource and learner and to develop potential friendships in an ongoing correspondence. Results indicated that successful implementation requires significant teacher intervention by integrating the program with the existing curriculum. One unexpected but important effect of this bridge between schools was the exposure of participating teachers to school cultures distinct from their own, particularly in regard to differences in teaching methods. This can lead to a reassessment of values and curriculum needs.

Introduction

This paper describes a structured, collaborative-e-mail-based model for communication between remote classrooms that was used in a project in which e-mail was used to bring together two populations of children that would not ordinarily have the opportunity of interacting together. One population was a general education class within a public school and the other population was a class within a school for children with hearing impairments. The purpose of the project was to increase social and academic development for both groups. The paper focuses on the role that teachers must assume and the necessary place of the model in the curriculum if this kind of electronic collaboration effort is to succeed.

The paper also examines the potential benefit of this model for teachers who are isolated by their unique functions. For example, special education teachers using this model can gain access to perspectives and teaching methods that may have been overlooked because of their own focus on compensating for their students’ disabilities. Regular education teachers can also benefit from this interactive approach by becoming more acquainted with children whose abilities and experiences differ from what they have come to expect.

Background

Children with disabilities whose problems cannot be met in general education classes are frequently placed apart—sometimes in entirely separate schools with populations of children who share similar problems. As a result, children in general education often have little contact with these children. Attitudes that develop rely on stereotyped images that often perpetuate distorted information (Roberts & Reaves, 1983).
At the same time, an insulation results for teachers in special schools as they develop their own culture, which reinforces its own values and approaches, and primarily supports their expertise in the area of the child's disability. Lost is the interaction with colleagues in general education and access to diverse methodologies. This reinforces the focus on the disability at the expense of general needs that exist in all children.

To overcome this isolation, we developed a structured model for e-mail communication that fosters both academic and social opportunities in the context of cooperative learning. Specifically, the communication in our project is the exchange of knowledge that children acquire from their social studies curriculum. Thus children take on the roles of both teacher and learner. When the child plays the role of teacher, learning takes on greater meaning as ideas are actively reviewed and reorganized in order to explain them in writing. Thus, each child's own knowledge is deepened through rethinking and recording ideas, and by replying to further questions that the information they send elicits. Playing the role of learner—using the other child as resource/teacher—breaks down traditional stereotypes. Each child is valued for his or her complementary knowledge.

Methodology

Population

Two groups of children in different schools in Brooklyn were selected. Both groups were gender-balanced, ethnically diverse but similar socioeconomically and intellectually.

One group consisted of English-speaking fourth grade children with no disabling conditions. They attended a mixed-grade general education class in a public school where creative problem-solving through student interaction, and constructive discussions between peers was emphasized. The children in this class were also heterogeneously grouped with regard to intellectual abilities.

The second group consisted of fifth grade children in a school for the deaf. Their common defining characteristic was some degree of hearing dysfunction ranging from severe to profound loss. Their most outstanding difference with the first group was the use of American and English Sign Language as their primary means of communication. The children wrote in English, but exhibited a slower rate of progress in writing skills because of the disadvantage caused by hearing loss.

Project Procedure

Teachers in the participating schools paired children from the two groups by gender, behavior style, shared or complementary interests and as closely as possible for writing level in order to promote the social and educational goals of the experiment. The purpose of the pairing criteria was to encourage the children to become acquainted with each other over the course of the school year through a structured cooperative framework where social studies information, issues and ideas were exchanged, ultimately providing the potential for friendships to form.

The most essential procedural element for the success of this project was for the teachers to integrate the e-mail exchanges into their existing social studies curriculum. The following guidelines were given:

1) Review and chart the most interesting aspects of the social studies topic.
2) Display and provide charts, books and other materials as resources for students.
3) Have students work together to generate issues, information and opinions.
4) The message exchange should be simple and concrete.
5) Focus on the content of the message and not on a grammatically correct message.
6) Generate a list of questions about what they'd like to learn from the collaborating class.

There were two phases to the communication process.

Phase 1. The first phase helped children gain familiarity with e-mail technicalities and its informal protocols and begin the contact with their partners. During this phase, children informally shared personal information with one another. A typical message from a child with hearing limitations would include their name, age, a statement about their disability, the number of people in their family and their current interest:
Dear ____,
Write back soon!

Mail from children without the disability tended to be less formal:

Dear ____,
Hey how ya doi'n. Are you a girl or boy beacause i'm a boy. How old are you i'm 9 . Do you have a class project I do. What is your reasearch thing. Do you like Fish. Is your teacher nice WELL. I GOT TO GO NOW SEE YA

Phase 2. Next, a more structured interchange was established and continued until the end of the school year. Each message was to contain at least one piece of information that the child had found interesting in their social studies curriculum and one question that he or she had concerning the topic that the e-mail partner was studying. Teachers could introduce the social studies exchange by using some variation of the following model:

Children in class X have been studying _____ for a few weeks now. Instead of me teaching this to you, I'd like you to find out as much as you can about this topic from your e-mail partner. Let's write up a chart of questions we want to ask. Then each of you can print out what you've learned. We can put this information together into a book or we can make a chart that displays the questions and answers.

Below are some representative notes from the children during this phase:

Dear ____,
How are you? I'm fine
I have Dante's Peak at home. I reallllllyyyyyy like that Movie. I learn about Canada. They love hockey and vvvveeeerrrryyyy CCCCCOOOOLLLLDDDD weather

Dear ____,
We saw a video today and it was about the arctic. Teacher keeps on showing us arctic videos. We saw polar bears, walruses, penguins, huskkyys, and seals. In the summer in the arctic there is a tiny bit of snow and there are different kinds of wild flowers.
What are you studying now?

Dear ____,
Canada love ice hockey and ski. Canada is cold because Canada is north. see shoe and boot for cold weather outside wet socks need hang to dry. Can go skiing. Now we study Mexico.

The second phase especially required the teacher to incorporate this project into the existing social studies curriculum, to treat e-mail as an integral part of the school day and to enable all children to participate in it on a regular basis. No new curriculum material was necessary for the teachers to develop, just to review and to create questions for the other class.

Evaluation Criteria. The project was evaluated qualitatively, by examining e-mail content, and quantitatively, by considering e-mail frequency. We also looked for asymmetries in e-mail usage between the classes.

Results

As the project evolved, we began to notice that the teachers in the two participating classrooms had very different approaches to the use of e-mail, and it is this difference and its impact that constitutes the core result of this paper.
Outcome: School 1 (the general education class)

The children’s initial response to this project was one of sheer excitement. After the system was installed and we exchanged mail with each child, we visited the class. It was indicative of their enthusiasm for the new medium that children spontaneously stood up and excitedly introduced themselves. A typical comment was:

"Hi, I'm A__. I'm the one who wrote to you about X".

Early messages between children reflected the same initial excitement. For example:

hi it is me __________ i am so glad you wrote to me. my favorite tv show is the same one is yours. i will like to see you one day in person. i hope you will like to see me to.

Dear ____,

Isn't the Net cool?! I meen, I can't see you but I can read what your thinking from miles away (or just 10 minutes away). Okay we have alot of catching up to do. My favorite color is blue..."

I am glad you are my p.p. I would like you to send longer letters to me. my phone number is __________ can you give me yours. I wont to send you alot of letters so you will get alot of mail. will you give me alot of mail. How do you peronence your name.

As we will see below, limited access to the computer in School 2 led to infrequent responses to School 1. This caused the School 1 children to write messages such as, "write to me, write anything!" By June, with continued limited response from their partners, enthusiasm had changed to dissatisfaction and reluctance to participate. One youngster, speaking to his teacher said, "do I have to?". Many messages illustrated frustration with not receiving mail.

Dear _______,

Why haven't you talked to me? I would like to talk to you! Talk to me! TALK TO ME 111 mesplease!

I want to tell you my poems! I want to just say stuff! Please just at least once, Well, before I go crazy (which I am already) I'll go.

Bye!

Dear _______

Where are you? I've wrtoe and wrtoe to you but you don't write to me! Is your computer broken? Is your shool closeed? Any way wane dose your school close? I have no idea what to say so good--by from,

Outcome: School 2

Each child had one designated time each week for checking, responding to and sending new mail. However, these times were often preempted by other work. Children could only use e-mail when the teachers told them to and so the task became an assignment that lost the joy and natural curiosity it was expected to promote. These external constraints interfered with timely response to, free communication with, and a development of interest in the children with whom they were paired. The result was frustrating at best.

School 1:

HI! HOW ARE YOU? I AM FINE. WHAY ARE YOU NOT SENDING ME ANYTHING? BYE NOW

School 2:

Dear ____

HI, HOW ARE YOU? I AM FINE! WHAT HAPPEN YOU NOT E-MAIL ME? I WAIT FOR YOU E-MAIL ME!

PLEASE HURRY YOU E-MAIL ME! OK! NOW WHAT LEARN ABOUT CANADA? I LEARN ABOUT MEXICO REAL COUNTINE! I GOT GO CLASSROOM! GOOD BYE!
E-mail Tabulation

Tabulation of e-mail traffic revealed a sharp disparity in the number of e-mail messages sent between the two classes, consistent with the imbalance of class time that was set aside for e-mail use. Greater than twice the amount of messages were sent from the School 1 children than were received by them (179 vs. 81). From teacher reports and our own observations, we also noticed a disparity in the amount of time it took to write messages.

Discussion

Additional roles of the teacher

After a year’s experience in this project, we can identify three additional underlying elements of the teacher’s role:

Technical functions. The most commonly examined role is the technical one. The teacher is responsible for introducing basic machine and network access procedure, e-mail operations, editing and e-mail message conventions—particularly the one that overlooks typographical and spelling mistakes. Content is primary; form is not. When teachers belabor form, communication becomes a chore for the students and teachers alike and the effort reduces spontaneity, and makes the goals of this project less obtainable.

Integration into the curriculum. Computer access is a major source of contention both between children and for each child’s time allocation during the school day. In order for an e-mail project to benefit and not detract from other activities, it must be integrated into the ongoing activities and become part of daily ongoing assignments.

Psychological functions. Because e-mail is inherently interesting and self-motivating, initially little additional teacher intervention is needed. However, when technical problems interfere with message transfer or when e-mail partners fail to respond, children understandably become frustrated. At this point teachers must encourage children to overcome hurdles and to help them resolve problems. This role is especially important because the sense of frustration can generalize onto the e-mail partner and negatively affect attitudes toward that person. This consequence undermines the social intent of the project. Likewise, limiting computer access also affects the quantity, timeliness and quality of the messages and ultimately of peer relationships. The lack of timely responses caused the most frustration. Others have observed this same issue (Allen & Thompson, 1994).

Serving as model. Teacher’s messages can serve as a model for children to follow. More importantly, an occasional message from a teacher is always special for a child—and can smooth over rough spots such as technical problems or delayed partner response. The following are e-mail examples of teacher encouragement:

Dear ____,
Here is an old letter from ___ that didn’t get through to you
because something was wrong with the computer. Thank you for writing about Canada!

_____
___’s teacher

Hi ____,
I’m sorry that you have not received mail from ______ lately. She is not in my class so it is sometimes hard to remind myself to give her time on the computer. I will give her your message and I’m sure that she will write soon. I hope you all had a good time at the zoo. I love to go there. There are some really beautiful animals there to see. Take care, and I will talk with you again soon.

Teacher

Dear ______,
___ would really like to hear what you learned about Canada. We are about to study the Arctic, part of which is in Canada. What do you know about the weather there?

Teacher

Dear ____.
It seems that _____ was not addressing her e-mail to you correctly, so that her last 5 letters didn't get through to you. I just fixed her addresses so you should be getting lots of e-mail today! Sorry for the problem.

Teacher

Conclusion/Implications

The quantitative difference in messages sent from the two classes demonstrates a systematic teacher impact, either promoting or interfering with the development of this mode of communication.

The success of projects such as this one rests heavily upon the willingness of teachers to integrate e-mail into the children's daily classroom activities and to recognize its value as a natural vehicle for deeper understanding of curriculum through review, reorganization and written expression of ideas, for social learning and for increased self-esteem. In addition, project success depends on teachers' recognition that e-mail can function as a medium for exchanging ideas with colleagues in settings different from their own, and for gaining insights into other teaching methods through the entry e-mail opens. Teachers become exposed to differences in room arrangement and organization, scheduling, teaching methods and children's classwork.

To summarize the required teacher intervention:

a) The teachers of the paired classrooms must agree to meet regularly
b) They must agree to provide daily access to the computer.
c) Teachers must help children receive and send mail until children are self-sufficient.
d) Teachers must encourage their students to develop questions to ask of their e-mail partners.
e) Teachers must ensure that their children will be in a position to provide information about their social studies work to their e-mail partner. For example, teachers may choose to review and chart key concepts, ideas and issues that their children experienced in their social studies units and that could be included in e-mail exchanges.

This program replaces didactic approaches with an open-ended strategy that couples classroom teacher collaboration with paired student cooperation, and integrates a student-driven review of the social studies curriculum with written communication and organization of ideas. It reinforces concepts by using a new avenue for their expression. It extends naturally over the course of the school year, unlike other e-mail projects (Baugh & Baugh, 1997) which are short-lived. Furthermore, this project is completely tied into each student’s class curriculum and thus can be expanded into any curriculum area, especially those involving language arts, based on the interests of e-mail partners and collaborating teachers.

TECHNOLOGY DIFFUSION
INNOVATION.ALT -- Implications for Education of Burke's "Web" Theory of Innovations, Compared to Rogers'

labott@teachnet.edb.utexas.edu

Abstract: Educators, challenged to prepare today's students for tomorrow's world, know many things will change before today's students get there. Two well-known theorists about the causes, rates, and diffusion of changes into society are James Burke, author of Connections (both the television program and best-selling book) and Everett Rogers, author of Diffusion of Innovations. Both authors' theories have implications for educators. Burke's "web" theory of innovation is that ideas and people are linked in a "web" of knowledge and events, and that an innovation occurs when someone makes a "connection" between concepts not previously juxtaposed in that specific context, combination, or application. Since Burke assumes that almost any knowledgeable person can be a future innovator, the role of educators is seen primarily as providing students with a solid, conceptual knowledge base as well as preparing them for independent, innovative thinking.

Introduction

On the Nature of Change

All issues about change -- "What is change?"; "Who or what causes change to happen?"; and "Why does change occur?" -- are very old issues. Some say that the predisposition to ask these kinds of questions are at the very core of what makes us human.

Sometimes, in the course of human history, civilizations have arisen in which particularly intelligent or insightful individuals have used their observations of the natural world, as well as their own capacity to think, to deduce fundamental, but hitherto unknown, principles of mathematics, science, and medicine, as well as other essential areas of human knowledge. Sometimes, after a period of discovery and growth, an entire culture's progress may be buried in a mudslide of fear, disease, or violent destruction. One such period was the era, roughly 500 to 1000 AD, in Europe, in which the storehouse of accumulated human knowledge was so completely looted during and after the decay and dissolution of the Roman Empire that much of what had been achieved in human understanding until that time -- such as our acquired knowledge about our bodies, our planet, our solar system -- seemed to have been irretrievably lost. This period was so devoid of glimmerings of innovative thought that past historians dubbed it the "Dark Ages."

Subsequently, things got a little better -- but not much. In the Fifteenth Century, for example, just as the Black Death struck Europe and killed an estimated one-third of the total population of France, Spain, England, and Italy, terrified and superstitious survivors of the plague were convinced that such a catastrophe had to have been caused by malevolent agency. With piles of corpses and heaps of bones in common, trench graves stretching out from almost every city in Europe, people who were determined to affix blame for the changes to their world that they didn't understand went on witch hunts, specifically targeting women -- who had little political power and were thus, relatively speaking, safe targets. The Inquisition and the tribunals for the examination of witches operated during the same historical period, sometimes as separate entities, but urgent for many of the same reasons: Changes can be frightening. When the changes come too quickly and when people don't understand what is happening or why, they sometimes become seek to find those on whom they can vent their frustration and fear.

At least during some periods of history, a variety of societies have rejected change outright as too threatening. By some, change was seen as an outright challenge to the gods, or God, and asking questions
or presuming to understand or exert control over specific forces of nature was sometimes harshly punished -- not by the gods, but by humans who had appointed themselves guardians of the gods' presumed best interests. Asking questions deemed irreverent to the gods of ancient Greece earned Socrates his cup of hemlock, and Galileo was forced by the Fifteenth-Century Inquisition to recant -- or else be burned as a heretic -- his assertion that the earth orbited the sun instead of the reverse, which was the accepted "knowledge" of the time.

Inquisitive Minds of the Modern Era

Yet, just when ignorance and superstition seemed destined to clamp an iron mask on the face of human inquiry, during the Sixteenth Century in Europe there was a sudden burst of discovery and creativity, a rediscovery of knowledge long lost, an increase of enthusiastic interest in exploration and connection of scientific and mathematical understanding that no one -- looking at the dismal century that preceded it -- could have anticipated. It suddenly became possible -- during this rebirth or Renaissance of the progress of human knowledge -- to discuss scientific ideas, or to study anatomy and preparation of medicines -- without fear of being accused of heresy and risking execution.

The Renaissance was the gateway to our modern era. Once burst, the dam on the reservoir of human learning and knowledge has never again been reconstructed in a way that has held for long. For better or worse, we have proceeded forward in acquisition and application of information -- as well as ever-accelerating rates of change.

Burke's Connections and His "Web" Theory of Change

Burke's Connections

James Burke's popular television series, Connections, first broadcast on PBS in 1979, focused primarily on the process that led to significant changes that have created the modern world we now know. In each Connections episode, Burke focused on exploring the presumably unrelated and seemingly unlikely series of events that lead, step by step, from one historical starting point, through development of this original concept or other related ideas, to the eventual "connection" of one or more of these ideas into a specific, modern technological application -- such as the atomic bomb, telecommunications, computers, production lines, jet aircraft, plastics, rocketry, and television.

Burke's approach was, to his viewing audience, a pure delight. For one thing, he seemed always to be having great and infectious fun with what he called his "historical detective stories." For another, there was something subtly subversive about the way he described the process of development of ideas. Burke's approach was different than the typical historical trivia of assorted names, dates, and places most people memorized in school. Instead, Burke suggested that the process of change was just as big a surprise to the people who lived it as it is to us when major changes happen in our time. Change, in other words, just happens.

Burke, in the revised introduction to the recent reissue of his Connections book, says, "...there's no grand design to the way history goes. The process does not fall neatly into categories such as those we are taught in school.... Things almost never turn out as expected....Change almost always comes as a surprise because things don't happen in straight lines. Connections are made by accident. Second-guessing the result of an occurrence is difficult, because when people or things or ideas come together in new ways, the rules of arithmetic are changed so that one plus one suddenly makes three." (Burke, 1995)

Burke's general narrative structure is on the branching path of possibilities and connections that lead up to specific discoveries. In a way, Burke entertains by telling historical "shaggy-dog" stories, with the punchline being his revelation, in the final few minutes of the program or the final page of the chapter, of the particular development that all the loose threads he has been following tie into. The story itself is usually interesting to follow, because many of the landmarks he points out -- as he leads the viewer or reader, Pied-Piper-like, through the last five hundred years or so of history -- are familiar ones, but Burke makes them seem fresh, because he portrays them in a dynamic context. The Introduction to this paper was intended to provide an abbreviated, Burkean kind of context for the topic of change, in general, and points out, on the way, familiar historical touchstones -- fall of the Roman Empire, "Dark Ages," the Black Death, the Inquisition, the Renaissance -- that end up being combined in slightly new and different conjunctions than is common.
Past Changes -- Why They're Important to Understand

In the introductory and concluding chapters of his Connections series, Burke expresses his overall belief about how and why the historical development of ideas should be studied. He says, "... an understanding of how change happened yesterday may provide clues as to how it might happen in the future. (p.vii)" Burke adds, "The process of innovation is shown to be influenced by several factors recurring at different times and places; although these may not be repeated exactly each time, the observer becomes aware that they may recur in his own future, and is therefore more able to recognize them should they do so. The structural device used [in Connections] is to examine an event in the past which bears similarity to one in the present in order to see where such an event led. ... The purpose of this approach is to attempt to question the adequacy of the standard modern schoolbook treatment, in which ... historical change is shown to have been generated by the genius of individuals, conveniently labeled 'inventors.' In such a treatment, Edison invented the electric light, Bell the telephone, Gutenberg the printing press, ... and so on. But no individual is responsible for producing an invention ex nihilo. The elevation of the single inventor to the position of sole creator at best exaggerates his influence over events, and at worst denies the involvement of those humbler members of society without whose work his task might have been impossible. (p.287)"

Burke specifically rejects the standard textbook treatment of history in terms its reliance on "heroes, themes, or periods. (p. 287)" The first, or heroic approach, ascribes innovation to people that are deemed special, and who are lauded as "inventors," but such an approach, in Burke's view shows the innovator in unrealistic isolation from the environment in which he achieved something new. Newton seemed to take the same view in having once said that he was only able to achieve what he did because he "stood on the shoulders of giants." The second, or "themes" approach to history is, according to Burke, the categorization and division of the record of past knowledge or achievement into neat, but unrealistic categories, such as transportation or communications. As Burke points out, this approach ascribes to the 'inventor' an unlikely degree of precognition as to how and where his or her invention would "fit." A third, flawed approach, is the "periodic treatment," in which events are divided into historical periods, such as "the Middle Ages," or chunks of history encompassing the reign of a specific monarch or president, as though the change of the bureaucratic guard had a specific effect on innovation or acquired knowledge. (p.288) The real danger, Burke says, is that these three approaches to the study of history can cause people to develop a "linear view" of how change happens, and that such a linear view leaves people ill-equipped to understand the process of change when they see it happening. If people have a linear view, they may expect that (1) a "genius" has to come along to change things effectively; (2) that a "genius" or "inventor" would just know, in advance, the kinds of application for which the invention he or she is working on would be used; and (3) that innovation would occur in a generally orderly and continuously progressive manner, or that specific calendar or government changeovers would necessarily result in things being "different" for the innovator than they were before.

Burke's "Web" Theory of Change

Burke's "Web" theory can be summarized as a belief that scientific discoveries or technological advances come about by means of a process that involves an interconnected "web" of knowledge, and people, and events. The point at which a new idea, or a realization of a significant connection, occurs is a moment when someone makes the right "connection" between things that often have been present or publicly available for a long time, just not in that particular context, combination, or application. Further, Burke suggests that individuals' personal lives and experiences are continually coming into connection with one another's, so that -- particularly as communication methods advance to keep more and more people in closer contact with one another -- we are all interconnected in one another's lives. (p.292)

Burke agrees that there are reasons for innovation to occur, such as "greed, ambition, conviction, happenstance, acts, of nature, mistakes, and desperation." (p.viii) However, generally, change -- in the past -- has been due to a series of "serendipitous" events, and more often than not, the "lonely genius inventor" has been a myth. Instead, most innovations have been brought about by the actions of generally "normal," everyday people with "average" intelligence, working with others cooperatively. (p.291)

Burke also points out that "the ease with which information can be spread is critical to the rate at which change occurs." The more and the faster information spreads, the faster innovation happens. (p.291) Burke says, "Every time there is an improvement in the technology with which ideas and people come together, major change ensues. ... This process has been at work, with extraordinary results, during the brief lifetime
of this book. When it was first printed, in 1978, there were no laptops, personal digital assistants, electronic agents, World Wide Webs, commercial on-line services, or cellular phones. That is a measure of the speed and scale with which change is now beginning to happen, as the Information Age advances."

(p.viii)

**Burke's Ideas About Innovations, Compared to Rogers'**

Burke and Rogers have very different approaches to innovation and the diffusion of innovations. Burke is generally interested in the "innovators" more than the process of diffusion of their ideas or the products developed using their ideas, which is Rogers' primary interest. Burke particularly concentrates his focus on how the general knowledge-base, or at least the knowledge base of the scientific community of whatever historical period he's discussing, advanced just far enough so that -- when the right person was at the right time and observed the right thing -- that person made the all-important "connection" of the various loose ends into a new way of thinking about something or saw how to make a machine or other practical application of the idea.

Burke, in the original *Connections*, most closely agrees with Rogers in his agreement that "break-through" innovators are generally better educated people. Burke focuses on historically significant innovators whose ideas were well known to others in the scientific or educational community and recognized as advances. Rogers, by contrast, uses the term "innovators" to discuss those in a community who first adopt new ideas or equipment, recognizing or anticipating that these are advances that will bring some specific benefit to them or to their work.

Burke's historic "innovators" are often members of the scientific community of their day, often people who know as much as is available to be known in the time in which they live. These are people who are routinely looking for new ideas, and thus they know a good idea when they stumble over one. However, the diffusion of the idea after the innovator gets it and does something specific with it is not Burke's major interest, as it is Rogers'.

Burke's focus is on the creative idea or the adaptive leap -- how one idea "connects" to another -- by (usually) one person, a "discoverer" or an inventor -- or, since the "connection" is often how an idea or apparatus in use in another field can be adapted to a new application, this person is a "re-inventor," in Rogers' terms.

Burke, metaphorically, is saying that the "knowledge base" of any one time is like a "sea of knowledge" that everyone works and lives in. As Burke sees it, we're all connected in a "mental plasma" of diffused ideas, applications, and understandings -- as if, in our modern culture, we were all part of a huge, amorphous, amoebic creature. Innovators, generally better educated and looking for new ideas, are on the outer boundaries of this general-culture membrane. When they come in contact with a "new" idea, the innovators recognize that this is a new connection -- and, by a sort of intellectual osmosis, they pull the new idea "through the membrane," and introduce it into the diffused "plasma of ideas" that everyone shares.

In general, Rogers would probably consider this approach overly fanciful, but he would probably agree with the "through the membrane" part, with this activity ascribed to those who, in Rogers' view, are the "early adopters" or even, perhaps, "opinion leaders."

**Burke's "Web" Theory of Innovation, Compared to Others'**

The "interconnectedness" of ideas and the "serendipitous" nature of innovation have interested many thinkers, particularly with the acceleration of the changes and inventions of the Industrial Revolution -- a time of rapid social and technological changes that, in some ways, resembles our own time of accelerating change. Hegel, for example, noted that the "zeitgeist" or spirit of an age, being more oriented, for example, toward change, encouraged more change to occur. He also noted, as an interesting phenomenon, that the more strongly the "spirit of an age" favored certain types of advances, the more likely several innovators -- even if they and their research interests were unknown to one another -- were to come to the same conclusions, or even to figure out similar practical adaptations of an idea almost simultaneously.

Carl Jung, describing the same phenomenon in the cultural or social-psychology arena, described this as "synchronicity," attributing the impact and subsequent diffusion or adoption (in Rogers' terms) of "new"
cultural ideas or their symbolic representations as evidence that an innovator (often an artist or writer) was often uniquely gifted in tapping a "collective unconscious" of ideas, symbolic meanings, myths, and psychological pre-sets shared by all humans. Jung also said that -- psychologically speaking -- there is no such thing as "coincidence."

Arthur Koestler, in his book investigating the origins of innovative thinking, *The Act of Creation*, says that in order for a truly creative idea to occur, there must be an almost literal "creative leap," a cross-over of ideas from one "plane," or context, of thinking to another. For example, Koestler points out that such a "collision" of contexts is absolutely essential for humor to work, and that such a clash of contexts must be a creative "surprise" in order to catch us unawares and make us laugh.

Burke is in full agreement with these ideas. In fact, he might find it amusing that to some extent the popularity of his *Connections* series can be attributed to the fact that the ideas of these and other thinkers, ideas he is building on, have been diffused widely in the general culture.

**Implications for Educators of Burke's Theory of Innovation**

While Burke (and Rogers) would agree that no one can educate a person to be an innovator, both agree that education plays a pivotal role in preparing someone to become an innovator. The educated person, one who has a larger-than-average "knowledge base," is far more likely to be one who generates a "new" idea -- or recognizes an idea as a new "connection" and adapts or uses it for an innovative purpose -- and who understands the ways in which it is a new idea and its implications for advancement, improvement, or change in whatever context to which it is being applied.

Constructivist theory -- the currently popular theory in education that focuses on helping children to construct meaning from their own, authentic experiences -- is particularly appropriate to the training of a future generation of innovators. Constructivism focuses on helping students to recognize implications of ideas and the contexts to which that idea may apply. Burke, however, would probably caution that -- although authenticity and immediacy of experiential education models is important -- content, or the "knowledge base" -- particularly of core-curriculum subjects such as math, science, language arts, and history --is also critically important.

Innovators of tomorrow must be both aware and knowledgeable -- and both of these "preparation areas" are the primary concerns of education. In a recent presentation at Nortel, Burke summed up his expectations of education in preparing students to handle the world of tomorrow, a world in which the unwary can drown in a "tidal wave" of information, one that Burke predicts is coming and that Burke calls "information surge."

Burke says, "Only an educated electorate will be able to make informed decisions about the social changes that will be triggered by information surge in the next century. To meet this requirement, education itself will need to change. Schools and universities will need to replace their outdated reductionist forms of learning with the cross-disciplinary knowledge necessary for riding the information networks of the future. We will primarily need to take a new attitude to the matter of intelligence and qualification. Just as Gutenberg's book brought the need to be able to read, the new systems will require the ability to navigate the network rather than to know things, to be able to retrieve data rather than remember it. A life-long qualification in a single discipline will be meaningless, and along with it will go the habit by which people characterize themselves according to the job they do. New systems give minds new things to do. So, maybe for the first time, the next information surge will encourage minds to think in idiosyncratic ways that were never possible before. It may free every human being's hundred-billion neurons to express themselves in ways not limited by the availability of paper and ink or the requirements of examinations. We can only guess at the surge effect of this release. Nobody knows what a fully empowered individual can do, because there has never been one. But it is urgently necessary that we begin immediately to use information technology to prepare us for the eventuality." (Nortel, 1997)

Self-Efficacy Beliefs as an Indicator of Teachers' Preparedness for Teaching with Technology

Peter R Albion
Department of Education, University of Southern Queensland, Australia
albion@usq.edu.au

Abstract: The focus on information technology in education has shifted towards curriculum integration. Consequently teacher education programs need to prepare graduates for teaching with IT. Graduates should possess both skills in the use of IT and belief in their capacity to integrate IT into teaching. Decisions about course design might be informed by a measure that is directly influenced by course changes and also indicates likely long term outcomes for teacher behavior. Self-efficacy beliefs can provide such a measure especially in the context of preparing teachers to teach with technology.

Introduction

Beginning in 1984, Queensland State governments introduced a series of funding initiatives to promote the use of information technology in schools. Early initiatives promoted the provision of equipment to support courses that would prepare students with the skills for participation in an increasingly technological workplace. Initial funding to establish laboratories for teaching computer literacy was followed by special purpose grants for Business Education Centers and Electronic Learning Centers in specialist subjects such as Art and Music. The first general funding provision for computers in primary schools came about ten years after the first secondary program, with the goal of increasing access to computers in the final two years of primary school. In many respects this represented a continuation of the focus on workforce preparation by developing basic skills before entry into secondary school.

More recently the emphasis of Queensland government initiatives in relation to information and communication technology (ICT) in education has shifted focus. Funding is still being provided for purchase of equipment but the new focus is on integration into the curriculum. In the words of current Queensland policy, information technology should be applied "to effective learning and teaching in all key learning areas, P-12" (Education Queensland, 1998b).

The implications for schools and teachers are considerable. A requirement for students to develop work related computer skills could be accommodated through separate classes taught by specialist computing teachers. Other teachers were under no obligation to develop or apply knowledge and skills in the use of ICT. However, the new expectations effectively require that every teacher should integrate technology into his or her particular curriculum. The associated changes in teacher knowledge and skills will need to be addressed through professional development for the existing teaching workforce and through initial teacher education programs for future teachers.

Teacher education institutions, employer groups and governments are seeking to address these issues using strategies such as technology standards for teacher education programs (DfEE, 1998; NCATE, 1992). In Queensland, the most recent policy initiative included competencies that are to be achieved by all teachers in the state education system within the three year span of the program (Education Queensland, 1998a). Although there is, as yet, no stated requirement for graduating teachers to meet these standards prior to employment it seems likely that employers of teachers will soon expect that applicants are not less capable than current employees in respect of ICT. Thus the requirements mandated for serving teachers are likely to represent a de facto requirement for graduates and hence a baseline consideration for course planning in teacher education.
Preparing Teachers to Integrate Technology

Teacher education faculties have grappled for years with the challenge of preparing teachers to integrate technology using a variety of different approaches. Brownell (1997) reviewed published research about technology in teacher education which appeared between 1990 and 1995. She concluded that there seemed to be consensus that technology is important and that teacher educators need to serve as role models. However, there was little hard evidence to guide the development of effective programs and she called for more evaluative research on technology in teacher education programs.

One of the difficulties facing developers of teacher education programs is that, although the true measure of their success is in the work which will be done by teachers some years in the future, decisions about the design of courses must be made in the present. Some components of the knowledge and skills required for teaching with technology can be assessed with reasonable confidence. These include technical skills such as the operation of hardware or software and knowledge of relevant curriculum and policy documents.

Many teacher education courses have been graduating beginning teachers with these capabilities for several years. However, research suggests that this does not translate into more or better integration of ICT into teaching. Oliver (1993) found that beginning teachers who had formal training in the use of computers as a personal tool did not differ in their use of computers for teaching from their peers who had not had the training. It is at least arguable that there are factors other than technical knowledge and skill which contribute to teachers’ success at technology integration in their teaching.

If teacher education programs are to be effective at increasing teachers' capability for integrating technology, then decisions about the structure and content of those courses need to be based upon an understanding of the factors which contribute to successful technology integration. An appreciation of those factors should permit their development to be traced and the design of courses to be adjusted to achieve the desired outcomes.

It may also be possible to identify one or more measures which are directly influenced by experiences in teacher education and which, in turn, predict success at technology integration either directly or through their influence on other factors. Such measures would be especially helpful in the design and evaluation of teacher education programs where one of the challenges is to make decisions which are implemented immediately while accepting that the ultimate effects of those decisions may not become apparent until some years after graduation.

This paper argues that teachers' beliefs are a significant factor in their success at integrating technology, that self-efficacy beliefs are an important, and measurable, component of the beliefs that influence technology integration and that particular instructional strategies might be effective for increasing self-efficacy beliefs relevant to technology integration.

The Importance of Teachers' Beliefs

Teaching frequently involves solving ill-structured problems which are characterized by a large amount of information, open constraints and the absence of a single correct solution (Voss & Post, 1988). Nespor (1987) argued that the ill-structured nature of many of the problems encountered by teachers resulted in teachers' beliefs playing a major role in defining tasks and selecting strategies because, unlike other forms of knowledge, beliefs can be flexibly applied to new problems. He suggested that, rather than reflective and systematic study in the course of teacher education, it seemed "likely that some crucial experience or some particularly influential teacher produces a richly-detailed episodic memory which later serves the student as an inspiration and a template for his or her own teaching practices" (p. 320). Pajares (1992) found that there was a "strong relationship between teachers' educational beliefs and their planning, instructional decisions, and classroom practices" (p. 326) and that "educational beliefs of preservice teachers play a pivotal role in their acquisition and interpretation of knowledge and subsequent teaching behavior" (p. 328). Indeed, it seems that "beliefs are far more influential than knowledge in determining how individuals organize and define tasks and problems and are stronger predictors of behavior" (Pajares, 1992, p 311).

Decisions made by teachers about the use of computers in their classrooms are likely to be influenced by multiple factors including the accessibility of hardware and relevant software, the nature of the curriculum,
personal capabilities and constraints such as time. However, there is substantial evidence to suggest that, teachers' beliefs in their capacity to work effectively with technology are a significant factor in determining patterns of classroom computer use. Honey and Moeller (1990) interviewed 20 elementary and secondary school teachers and found that teachers with student-centered pedagogical beliefs were successful at integrating technology except in cases where anxiety about computers prevented them from appropriating the technology. In contrast, teachers with more traditional beliefs faced much greater change in their practices in order to integrate technology. A case study approach to the use of computers by four special education teachers found that for the most part they adapted computers to meet their overall goals and fit their routines with their beliefs and attitudes strongly influencing how the computers were used (MacArthur & Malouf, 1991). Marcinkiewicz (1994) found that of a number of personal variables, self-competence (belief in ability to use a computer for teaching) and innovativeness (willingness to change) were most closely related to computer use among 170 elementary teachers. Studies of computer use during teaching practicum (Albion, 1996; Downes, 1993) have found that, despite possessing positive dispositions towards computer use, pre-service teachers lacked confidence in their capacity to teach successfully with computers.

Defining and Measuring Self-Efficacy Beliefs

The construct of educational beliefs is broad and for research purposes has been refined into more specific sub-constructs (Pajares, 1992). Examples include beliefs about confidence to affect students' performance (teacher efficacy), about the nature of knowledge (epistemological beliefs), about perceptions of self (self-concept) and about confidence to perform specific tasks (self-efficacy). The latter is of particular interest because of the role it is proposed to play in determining behavior.

According to Bandura (1997), who first described the construct, "perceived self-efficacy refers to beliefs in one's capabilities to organize and execute the courses of action required to produce given attainments" (p. 3), and such beliefs are the most central mechanism of personal agency. As proposed by Bandura, self-efficacy is specific to a particular set of behaviors and comprises two components, efficacy expectations and outcome expectations which respectively relate to belief in personal capacity to effect a behavior and belief that the behavior will result in a particular outcome. As a consequence, instruments for the determination of self-efficacy typically include two scales to measure these two components.

Bandura's claims about the importance of self-efficacy beliefs in explaining behavior have been supported by research in a variety of contexts, including general health behaviors, treatment of phobias, self-regulation of pain, academic performance and career development (Bandura, 1986). Perceived self-efficacy with respect to computers has been found to be an important factor in decisions about using them (Hill, Smith, & Mann, 1987) and increased performance with computer related tasks was found to be significantly related to higher levels of computer self-efficacy (Harrison, Rainer, Hochwarter, & Thompson, 1997). An instrument including several sub-scales for self-efficacy in relation to particular aspects of computer use has been developed and validated with students studying business, nursing and education (Kinzie, Delcourt, & Powers, 1994). A recent study confirmed the reliability of the instrument and found that the most significant predictor of self-efficacy for computer use among teacher education students was frequency of computer use (Albion, in press).

Gibson and Dembo (1984) developed an instrument to measure teachers' sense of efficacy for teaching. Subsequent studies have linked this construct to patterns of classroom behavior known to yield achievement gains (Dembo & Gibson, 1985) and have shown it to be positively related to change in individual teacher practice (Smylie, 1988), ratings of lesson presentation, classroom management and questioning (Saklofske, Michayluk, & Randhawa, 1988) and teacher success in implementing innovative programs (Stein & Wang, 1988).

A more specific Science Teaching Efficacy Beliefs Instrument (STEBI) developed by Riggs and Enochs (1990) has been used to investigate the impact of variations in course design on elementary science teachers (Watters & Ginns, 1997). The STEBI was used by Enochs et al. (1993) as the basis for development of a Microcomputer Utilization in Teaching Efficacy Beliefs Instrument (MUTEBI) which was used in the evaluation of a staff development program designed to encourage microcomputer use in science teaching [Borchers, 1992 #210]. That study demonstrated that when teachers' self-efficacy beliefs in their ability to use
computers were increased through appropriate professional development they were more likely to incorporate computers into their teaching strategies.

Although there do not appear to be any other studies which specifically link self-efficacy with computer use in teaching, several studies (Albion, 1996; Downes, 1993; Handler, 1993; Summers, 1990) have identified lack of confidence for teaching with computers as a factor influencing the levels of use of computers by student and beginning teachers. Marcinkiewicz (1994) also reported that teachers' use of computers for teaching was related to their ability in their ability to do so.

Taken together, the studies referenced above point towards teachers' beliefs and, in particular, self-efficacy beliefs, being useful indicators of likely success at technology integration. Certainly they provide sufficient reason to undertake further investigations in this area and to consider what approaches to teacher education and professional development might be effective in increasing self-efficacy for teaching with technology.

Influencing Self-Efficacy Beliefs

According to Bandura (1986) self-efficacy beliefs develop in response to four sources of information. The most powerful influence on self-efficacy is "enactive experience" in which self-efficacy for a behavior is increased by successfully performing the behavior. The second most powerful influence is "vicarious experience" in which other similar people are seen to perform a behavior successfully. A third source of influence is verbal persuasion, which, if realistic, can encourage efforts that are more likely to increase efficacy through success. Finally, self-efficacy beliefs can be affected by physiological and affective states such as stress.

From the standpoint of self-efficacy theory, the ideal method for developing teachers' self-efficacy for computer use would be to provide them with training and support to work successfully with computers in their classrooms. The study conducted by Borchers et al. (1992) demonstrated that a professional development program which included several workshops over an extended period and on-site support for participants could be effective for increasing both self-efficacy and computer use.

In the context of a teacher education program, enactive experience and resultant increases in self-efficacy might be achieved through successful experiences with the use of computers during field experience. In practice, variations in the experience and expectations of cooperating teachers and in the availability of equipment make it impossible to ensure that all students will experience the success that builds self-efficacy beliefs. Vicarious experience through direct observation of experienced teachers engaging in appropriate behavior poses similar logistical difficulties and verbal persuasion has limited application unless students have opportunity to perform the appropriate behaviors.

These logistical problems might be overcome by developing multimedia materials to make examples of effective classroom use of technology available to a wider group than could participate in direct observation. Whether delivered by web (Bronack & Kilbane, 1998) or on CD-ROM (Kurth & Thompson, 1998), such materials find theoretical support in a rich literature base on case methods in teacher education (Carter & Unklesbay, 1989; Merseth & Lacey, 1993; Shulman, 1986). Viewed from a self-efficacy perspective, the mechanism of the case method corresponds most closely to vicarious experience in which self-efficacy is increased through consideration of examples of successful performance by others. The inclusion of multimedia elements in the presentation of a case adds layers of detail that are not possible with a purely text description.

Self-efficacy theory suggests that real experience is more effective than vicarious experience for increasing self-efficacy beliefs. Thus it seems reasonable to suppose that multimedia case designs which encourage increased involvement of the user in the case should be more effective at increasing self-efficacy beliefs.

Problem-based learning (PBL) is one approach to instructional design that appears to warrant investigation for this purpose (Albion & Gibson, 1998a). When students succeed in creating solutions to the authentic problems of practice which are the focus of a PBL sequence their experience should include more of the characteristics of enactive experience and thus be more powerful than vicarious experience as a source of self-efficacy beliefs. Interactive multimedia materials using a PBL design have been developed (Albion & Gibson, 1998b; Albion & Gibson, 1998c) and will be evaluated for their effects on teacher education students' self-efficacy beliefs for teaching with technology.
Conclusion

As community expectations for integration of information technology into the daily practices of teaching grow, it will become increasingly important that all teachers are adequately prepared for this dimension of their professional practice. Research suggests that teachers' self-efficacy beliefs about using technology for teaching are directly related to their practice. Measurement of self-efficacy using appropriate instruments may provide a useful indicator of the effects of teacher education initiatives intended to better prepare graduates for technology use. Moreover, self-efficacy theory may offer insights into the development of materials with more powerful instructional designs.

Abstract: The Anchorage School District and the University of Alaska engaged in a two year process to identify teacher competencies in the area of technology, develop a set of standardized courses to provide these competencies and establish a framework of student performance indicators. The credit classes were then linked to the teacher competencies and the ISTE standards. This session will describe the process used to accomplish this task.

1. Introduction

The Anchorage School District and the University of Alaska formed a partnership designed to streamline the process of providing staff development to teachers in the Anchorage School District. The two year project included:

- a list of technology competencies for all teachers;
- Professional Development Courses designed to provide training opportunities for teachers to gain those competencies;
- Student Technology Framework, including grade-level indicators tied to national and state technology standards;
- the infrastructure at the University that facilitates the implementation of professional development courses.

2. Background

The Anchorage School District has more than 48,000 students and 3100 teachers. Professional development in the district consisted primarily of state release time for in-service training, after school workshops and university credit courses. The primary source of technology teacher training in the district was a collection of unrelated professional development courses through local universities. Courses were proposed and taught by anyone who submitted a course outline, which resulted in inconsistent quality, redundancy and gaps in content. As more classroom computers became available, the need for technology training dramatically increased. With this increase, the responsibility for these staff development classes fell into the job description for the coordinator of instructional technology. It became very evident that the process needed revision to meet this growing demand.
Prior to the formation of this partnership (ACT3), a new course outline needed to be submitted and had to be approved by the university each time a course was offered. There was no system to provide consistency from course to course, to map relationships between courses, or to repeat courses without going through the entire approval process. The course outlines had no identified relationship to teacher competencies or national technology standards. All course approvals required eight weeks or more once they were submitted to the university. There was no system to pre-approve an inventory of courses. This process was time consuming and labor intensive. Each course outline was based on the idiosyncrasies of the individual instructors because there was no mechanism to collaborate or communicate with each other. This paper outlines the partnership that was formed and the system developed to provide a comprehensive standards-based curriculum which facilitates effective use of technology in the classroom, and timely, efficient course approval.

2. The Process

3.1 Year I

In the spring of 1996, the voters of Anchorage failed to pass a technology bond issue by a margin of 2:1. One of the basic criticisms of the district's technology plan was the lack of a comprehensive teacher training plan. In the fall 1995, as a result of budget cut-backs, the responsibility for managing the technology-related credit course was transferred from the district-wide Training & Professional Development Department to the Instructional Technology Department. After a year of coordinating the process as described above, it became obvious that changes were needed. Initially, the goal was to organize a list of approved credit courses. However, it was determined that the real need was to identify the instructional technology competencies that all teachers needed, from which a consistent set of course outlines could be developed.

In the fall of 1996, Sharon Bandle, Instructional Technology Coordinator, formed a task force of 24 technology leaders from across the Anchorage School District. The mission of the task force was to identify the technology competencies necessary to integrate technology into the classroom curriculum and to effectively use technology to enhance teaching and learning. Dr. Helen Barrett, educational technology faculty member in the University of Alaska Anchorage School of Education, facilitated the process. The group met for twelve three-hour Saturday morning sessions over the course of a school year, and earned up to three professional development credits. The task force reviewed previous credit course offerings and the Curriculum Guidelines for Teacher Preparation Programs in Computer/Technology Literacy developed by International Society for Technology in Education (ISTE) for NCATE.

After reviewing other examples of teachers competencies (e.g., North Carolina), the group developed a list of topics and skills Anchorage teachers needed to enhance student learning using technology in the classroom. The competencies were identified in the areas of curriculum integration, basic operations, productivity tools, multimedia and telecommunications. In the process of identifying the various competencies, it became apparent that there were also several skill levels that needed to be addressed, which were identified as: Introduction, Overview, Application and Integration. The courses that were written fell into one of these four skill levels. As a group, the decisions were made about what course topics were needed to provide the identified competencies. Each course topic was placed at the appropriate skill level. When consensus on courses was reached, training was provided to the committee members for elements to be included in the course outlines. The group was divided into teams and each team was responsible for writing a set of related courses. As course outlines were completed the group as a whole critiqued each proposal for content. At the close of the school year, the committee had created the list of teacher competencies and 22 credit course offerings that would help teachers acquire the identified competencies. By developing these course outlines, the participants in the task force also became qualified to teach these courses.

Figure 1: Courses Approved by Level

Three graduate students from the University of Alaska revised the Course Content Guides over the summer providing a consistent format and linking them to the district technology competencies and the ISTE standards. The following is a chart which includes the credit courses and their skill level placement. After the course outlines were finalized, they were reviewed and approved by the University of Alaska Anchorage School of Education and assigned permanent course numbers. Once the courses were in the University of Alaska Anchorage's course inventory, the Professional and Continuing Education (PACE) Department, worked with the Anchorage School District to streamline the process of scheduling these courses and registering students. Because of the system set in place by the University, a credit class can be scheduled by a single phone call to the PACE office and the course can begin as soon as it is scheduled in the University’s computer, which can often be done on the same day.

3.2 Year II

The Technology Leadership Task Force met again the fall of 1997. The meetings were again held on Saturday mornings throughout the school year, and participants worked toward three graduate credits. The mission for the second year was to establish a student technology framework including grade-level indicators tied to national and state student technology standards. This process included the review of numerous websites and district student performance indicators as well as the emerging National Educational Technology Standards (NETS) under development by ISTE. Once identified by teachers at different grade-levels (i.e., primary, intermediate, middle and high school), the indicators were grouped into three main domains: Basic Operations and Concepts; Tools for Communication and Research; and Social, Ethical, and Human Issues. There was a strong consensus to connect these indicators to the state technology and content standards. The group was divided into sub-groups by content areas (language arts, social studies, math and science) and grade levels. Each group identified the performance indicators when introduced, reinforced and mastered by grade level. The following is a representation of the relationship among the age/grade levels, the technology skills and the content area standards.
After identifying the student performance indicators, the grade-level teams developed Units of Practice which integrated the acquisition of technology skills with standards-based curriculum units. A few of the task force members also developed a framework for their portfolio which demonstrated their achievement of the NCATE standards for a basic endorsement in educational technology.

![Figure 2: Anchorage School District Technology Framework](image)

4. Results

- As a result of the efforts during the first year of the project, 74 credit classes were offered to the district teachers with 800+ teachers attending. Each one of the 22 credit course was offered at least once during the year. In addition, with funds provided by a federal Technology Literacy Challenge Fund Grant, 61 of the credit courses were offered to Anchorage School District teachers and administrators during the summer of 1998 with 747 participants. There are 55 credit course which have been offered or will be offered during the 98-99 school year with an anticipation of an additional 30 to be scheduled by individual schools. In two years, Anchorage School District teachers have doubled participation in professional development courses sponsored by the University of Alaska Professional and Continuing Education Department. Prior to 1996, there were very few courses offered to Anchorage teachers by the University of Alaska Anchorage.

- With the teacher competencies in instructional technology clearly identified, the Anchorage School District now had guidelines for the skills required of new teachers. The Executive Director of Personnel endorsed the process and supported requiring these technology competencies, once identified, of all teacher applicants.

- Furthermore, as a result of this collaboration, pre-service education about instructional technology changed dramatically. Prior to 1995, there were no required technology courses for pre-service teachers. Today, undergraduate education majors must take a two credit Foundations of Educational Technology course; graduate students are required to take one of several three-credit graduate courses in educational technology. Prior to 1995, there was no permanent faculty member responsible for educational technology; in the fall of 1996, Dr. Barrett was appointed to a tenure-track position, responsible for educational technology.
undergraduate and graduate programs. As a result of communication with the Anchorage School District, a plan for developing a competency-based endorsement in educational technology, based on the NCATE standards, was also designed. In addition, a M.Ed. Master Teacher with Emphasis in Educational Technology was approved by UAA in the fall of 1997.

Abstract: From 1993, the Education Network of Ontario has grown from eighteen to sixty thousand registered educators, half of the eligible teachers, administrators, teacher trainees and elected education officials in the province. This report details a variety of implementation stories - the building of financial support, qualitative and quantitative analysis of users and activities, classroom and educator projects, and successful technical changes as the project moved from text-based, terminal emulation Internet activities to web-based mail, conferencing, and model curriculum and classroom projects.

The paper illustrates what teachers do as professional development from home, from school and from Faculties of Education whether as pre-service, in-service or post-degree teachers. Included are the curriculum projects that educators develop and how the Education Network of Ontario continues to stimulate award-winning development at every level. Practical tips to entice even the most telecommunications-resistant teachers are illustrated since this project is now working with those educators who do not adapt to change or technology readily.

Introduction

The initial stage of the Education Network of Ontario (ENO) was a UNIX-based, cross-platform, TCP/IP protocol distributed network application which provided bilingual (English and French) electronic mail, moderated conferencing (facilitated newsgroups), and database and Internet access across Ontario. It started with just eighteen members in 1993 and has grown to register more than sixty thousand teachers, administrators, trustees and education faculty, nearly half of the K-12 education personnel of the province. The project migrated to Web-based conferencing, electronic mail, document publishing and classroom projects. We have learned a great deal about how educators use this suite of services. Presently, we are coaching over six thousand students engaged in teacher-devised classroom projects. Their personal and project work is published on-line for their families and communities to view.

Financial Support and Management

The primary client of the Education Network of Ontario is the Ontario Ministry of Education and Training. Originally, the Ontario Teachers' Federation, the professional union organization of the 115,000 teachers of the province, mentored the organization. It is now an independent non-profit corporation with a fully functioning Board of Directors. The core funding has grown from $200,000 to over $4,000,000 per year as more teachers, administrators and students use the services. The corporation has become so entrepreneurial that the total budget is over $5.5 million. The federal level Youth Employment Program funds the training program in which unemployed or under-employed teacher graduates are employed for several months in specific schools to assist with telecommunications skills and resource development. The Ontario Ministry of Energy, Science and Technology will fund research into IP Telephony which is not just technology exploration in a relatively narrow band infrastructure but also implementation exploration from a human resource and training perspective relative to new technologies.
There is a very small central management staff of eight with a trained field staff of approximately 60 who moderate newsgroups, initiate technical exploration and classroom curriculum projects, and train colleagues in their home environments in either English or French. In the coming months, there will be a continuing emphasis on training teachers, administrators and students throughout the province. Moderated newsgroups, the private professional environment, universal access, and educator-originated projects continue to differentiate ENO's service from other Internet Service Providers or bulletin boards.

**Technological Partnerships**

The vast majority of the budget is allocated to infrastructure development and maintenance. Many of our more successful partnerships arise from investigation and implementation of new services and equipment. This allows ENO to do more technical development, implement better solutions, assess unique pieces of equipment, or acquire in-kind licenses or services.

For instance, AT&T Canada works with ENO to create the most cost-efficient '800 service' which allows members to access ENO using long distance lines without enormous costs. In doing this, we are using software-based switching and blocking to bar local users from abusing 'free' long distance lines. We will progress to using this service to build in automatic redundancy should one of our thirty (30) points of presence or 'POPs' fail.

We are working with 3Com/US Robotics to implement digital technology using innovative 'rack-mount' modem chassis with built in routers and management tools. ENO finds this new equipment cost-effective because it reduces errors and client support costs. It also allows ENO to serve specific clients with access to ISDN-level speeds. We are involved in the Canadian program of beta testing 3Com hardware and software in the IP Telephony project.

We signed an agreement to work on Internet videoconferencing with White Pine, the company developing the videoconferencing software, CUSeeMe. A software and implementation solution by ENO was compensated with a licensing agreement. This technology may then be integrated with the IP Telephony project to move administrators and politician-trustees from face-to-face meetings to PC-based meetings with shared applications and workspace.

**Technical Issues**

The network has a base wide area network (WAN) of thirty points of presence or 'POPs'. Each POP is a remote access system capable of analogue V.90 and digital ISDN connections and is comprised of a Pentium II UNIX server running online services and authentication. Each had a minimum of 23 modems. These POPs are connected in a Wide Area Network using frame relay at speeds to T1 to a backbone infrastructure. ENO's backbone is Gigabit Ethernet on Layer 3 switches connected via ATM to the Internet. The mail, conferencing, and web access all use off-the-shelf protocols and software to maintain the open systems standards and avoid ongoing software and upgrade fees. The major proprietary piece is the authentication server since few other networks are authenticating over 60,000 members to selective services depending on whether they are students or adults, and the activities to which they are subscribed with transparent, province-wide access.

Users can dial a 'POP' from anywhere in the province free of charge and establish standard PPP connections enabling graphical display with a standard browser such as Netscape Navigator or Microsoft Internet Explorer. Members may also establish a text-based connection if they do not have a graphics-capable machine or wish higher speed access to documents without graphics.

Of course, members can access the system from the web site and be authenticated to the Intranet or private conferences through the authentication server. Thus the project can present services to a much larger
number of members than would be possible through dial access alone. ENO separates Internet access from Intranet services and allow members to use their home, commercial, or community access points.

Statistics and Effects

During a typical month, more than thirty percent of these 60,000 teachers, administrators, trustees, technical and support staff, education faculty, their students, and Ministry of Education officials participate. The network logs over 5000 dial participants a day and over 4 million minutes a month of connect time. A typical moderated conference, an Intranet newsgroup, generates several thousand threaded, searchable messages within a few weeks. To handle this volume of access and activity in such a large geographic area, we have modified the software from a simple bulletin board application to an integrated, Web-based suite of tools on a system of thirty instantly updated servers throughout the province. However, the objectives remain those of a tightly knit education community: equality of access, pedagogic integrity and classroom-based action research.

Almost since the beginning of the project, women have participated at a level of 30% or higher. In fact the number of women in the group of those who access once a week or more is higher than that average. This reflects other projects which have investigated gender and women’s participation in professional Internet activities.

Reasons for Success

Major factors in the system’s success have been the freedom enjoyed by all participants and a supportive government grant structure. The ability of educators to use the facilities at any time of day, from both sophisticated and minimal machines, from school, library or home, in both English and French makes the process relevant for both classroom activities and lesson discussion and preparation.

Educators share a personalized environment of professional conferences selected from a list created by them and moderated and maintained by colleagues who receive a small honorarium or modest time relief. Members change their newsgroup subscription list to reflect personal changes in interests or needs.

As well as the assistance and encouragement they receive from the on-line moderators, teachers receive an active program of orientation and training about telecommunications from early navigation of electronic mail and the conferencing system to document retrieval from Internet sites and educational servers.

ENO’s focus on creative classroom projects using connectivity among students and teachers continues to provide impetus to teacher participation. Personal student access codes have been a great success for the 10,000 students who have participated thus far.

ENO has a fully bilingual telephone support service and is busy creating a ‘support’ web structure with a registration page, traditional frequently asked questions, and modem and browser settings.

Activities

The major activity of the teachers continues to focus on the moderated conferences that they open to solve such endemic concerns as ‘local’ versus ‘standardized’ evaluation, reporting to parents, community work/learn programs, and general subject-based or level-based curriculum issues. A second established use occurs whenever a new provincial license for software is purchased. A conference is opened in which the technical support team from the vendor can discuss issues of use and technical implementation with teachers throughout the province.

Smaller groups of teachers voluntarily initiate a series of professional activities such as writing primary school curriculum units themed on two-dimensional measurement. A typical and very successful example
is the web-based project devoted to showing young students how to conceptualize two dimensions with a central fictional character called 'flat Stanley'. After the provincial collaboration, teachers mount the curriculum units on an ENO web site. Those who create the material then update and maintain it. The project is now international with hundreds of schools participating.

Administrators are creating a centralized resource of activities for teachers and administrators of northern schools who have no outside student recess for as long as six weeks in mid-winter. Teachers create a file of model parent letters and report cards for middle school students during a period of education reform. The network has a forum for school administrators in which teachers who wish to be administrators are mentored concerning effective career paths. Teachers, with education faculty and students, work on computer literacy curriculum units, plan professional development conferences, and hold meetings of subject-specific committee executives. One school of over two thousand students used the system for its internal electronic mail, information distribution and meeting scheduler. Another district's school custodians are working on practical identification and warnings about workplace issues and hazards.

Currently, we are developing on an on-line course about telecommunications in which templates for classroom activities are discussed, implemented in specific classrooms and improved for the system as a whole. Our largest project to date is an online environment to assist the Canadian National Marsville Program, a project based on intermediate-level students creating a living environment for the pioneer astronauts and settlers of Mars. Students are uploading their air, water and food supply system drawings to their team's web pages. They access mentors' comments from Spar Aerospace and the Canadian Space Agency. They communicate with one another to prepare for the final 'link-up' day. Using this on-line environment prior to the main event enhances classroom learning activities.

Summary

Because ENO’s funding is limited, we continuously seek support from individual grants and strive to use resources outside of our small staff complement to accomplish tasks. For instance, we share points of high-speed access with other public sector agencies and ministries. Special educational projects and district school boards purchase infrastructure or conference ‘space’ and moderation. We are instrumental in providing Ontario student access to the federal program, SchoolNet and look forward to greater integration with a more national SchoolNet implementation of ENO’s Intranet newsgroups.

As we stabilize our network and work toward province-wide direct dial and school access, we look forward to fulfilling our potential as a ubiquitous background tool for elementary and secondary education in Ontario. Our implementation focus concerns student projects and environment and our organizational focus is on financial sustainability. Our technical focus is increased access, speed, reliability, and functionality through continuous experimentation with new modem, server and transmission equipment and technologies.
Diffusion of Educational Technology: Teaching and Collaborative Education

Walter Heinecke, University of Virginia, USA
Dorothy Vasquez-Levy, University of Virginia, USA
Laura Blasi, University of Virginia, USA

A new classroom is emerging as teaching styles influence the use of instructional technology across a distance. In a panel along with Jerry Willis and Rhea Walker from Iowa State University, we will discuss interactive technology from the instructor’s point of view, in the context of a course design joining Iowa State University and the University of Virginia. The course was created through the combined vision and time invested by professors from Instructional Technology, Research and Evaluation, and Curriculum and Instruction. This session is to be complemented by a session designed by graduate students who participated in the course.

Course Overview:

The content of the course focused on technology and policy. Participants in the University of Virginia’s Diffusion of Technology: Policy and Practice explored the nature of the educational-technology policy process in two states. As a collaborative effort between Curry School of Education at the University of Virginia and the College of Education at Iowa State University, the research conducted on this course over the Fall semester of 1998 provides us with a window into what happens when different teaching styles have an impact on the use of IT. IT, as it is used for collaboration over a distance, is shaped by each instructor’s teaching preferences at the same time it requires the classroom dynamic to depart from the lecture format.

The technology was configured to accommodate each instructor’s approach to teaching in our Collaborative E-learning Laboratory (CEL). Our two-way white board and on-line conferences using NetMeetings, was augmented Collabora Newsgroup discussions. In the course of the discussions, the content determined when and how technology would be appropriate. NPR audio files and Washington Post articles available through the Web quickly become part of the course’s evolving syllabus. A document camera was
implemented when the lack of face-to-face communication was raised as an impediment to holding deliberative discussions at a distance.

Before we could look at how we were doing this, we surveyed our options to plan what we would do. This plan evolved over the semester. The following chart by Glen Bull offers a range of options for schools considering Collaborative Learning, but concerned about costs:

<table>
<thead>
<tr>
<th>Designing a Collaborative Education Laboratory (Three Examples)</th>
<th>Inexpensive</th>
<th>Low Cost</th>
<th>Moderate Cost</th>

A second class held between Iowa and Virginia, *Philosophical Foundations of Instructional Technology*, from Iowa State University consisted of a dozen students at one site and a half-dozen students at the other. Classes of this size would have formerly been too small to be economically feasible. The rationale underlying the Collaborative Education model is not efficiency or cost savings, but creation of a richer, more diverse class than otherwise would have been possible.

The Collaborative model, which evolved from our work across a distance, challenges traditional definitions of distance education, in which one instructor might lecture via video to a passive audience or administer the entire course through Web-based fill-in-the-blank assignments. Collaboration over a distance required that teachers facilitate more often than lecture, as Newsgroup exchanges during the week outside of class meeting times became an asynchronous possibility.

Drawing from qualitative research, we intend to share our lessons-learned regarding course structure, computer-mediated communication, and the change in pedagogy that occurs when a course is constructed towards effective collaboration at-a-distance.
Instructor Perspective:
Walter Heinecke, University of Virginia, USA

Context:

As an affiliate professor in the educational technology program at the University of Virginia I teach a course on educational technology policy every two years. The course is aimed at doctoral students who want some of the policy background conditioning the implementation and use of educational technology in classrooms. When I first taught the course two years ago I was new to the profession and had no experience teaching in higher education. I did not employ any technology the first year I taught the course. I was and still consider myself to be a low to moderate technology user. I consider myself to be still working on becoming a proficient classroom teacher. I worry about such issues as the balance between lecture, discussion and student participation. I worry about remaining sensitive to the needs of my students and reaching them through various learning modalities.

Setting:

The class was small and this was due to our tentative treatment. The class had not been advertised in the class schedule or through announcements. Many students did not know when the class would be meeting and this affected the enrollment. I had no connection with the ISU enrollment process. The class dynamics were influenced by student characteristics, by the novelty of the technology, and by the nature of the computer-mediated communication. The technology seemed to change weekly. Some of this was by my design as instructor. In other words, I would teach the class and recognize that certain limitations hindered my ability to naturally teach the course. From my perspective I was trying to make the technology seamless and invisible. During my portion of the course the classes were still fairly teacher-centered. As I mentioned I was still struggling with basic teaching issues and as I was learning the technology I was using it in fairly conventional modes.

Changing expectations:

We were able to make changes so that I could get documents and charts scanned in and used for presentations. We struggled with the intergroup communications issues. I found it difficult to be talking at the speakerphone rather than at images of the students at ISU. I think if the speakerphone were more naturally aligned with the video image that would have improved communication. We also struggled with the room arrangement. It seemed to change weekly and I couldn't get used to it as an instructional environment. In the last few weeks we had problems getting all participants on the video screen. I think group CMC got better as time went by. The conversations and discussions seemed to flow more naturally and people all had assigned tasks for readings and discussion. My colleague was definitely better at collaborative teaching than I and the technology appeared to work for her in terms of student directed presentations and discussion. I think we could have done better at student use of the technology. The course was more teacher centered than it could have been. The technology made me more conscious about how I taught. It forced me to think about using all the technological resources available to me as an instructor. It
also forced me to deal with issues of student collaboration. I was continually concerned about issues of involvement and how the technology might be affecting class participation. In summary, I feel that this technology has tremendous potential for opening modalities of instruction previously closed to traditional distance education. It is extremely useful for small seminars in which collaboration and interaction are central.
Instructor Perspective:
Dorothy Vasquez-Levy, University of Virginia, USA

Context:

In the late 1980s I was first using Bitnet and setting up listservs for students in my teacher education classes to use for discussion. I don't want the discussion to end when students leave the room. Every semester I set up a closed, on-line discussion group, and this discussion component is an integral part of the class. I use the internet as a way for students to interact with many types of information. For example, I ask students to assess Web-based subject content by considering such factors as its selection of ideas, forms of representation, and coherence and justification of content. I use many types of technology to conduct research and write, and this is the 10th year I have been studying a closed discussion group I established while in graduate school. I have used CuSee-Me technology to take my class on-line discussion groups a step further. I have students read the most recent work by educational researchers and then "meet" with these researchers in class via electronic networks. I do not see computer technology as just another tool or delivery mechanism. "I want to create interactive technology environments that will allow students and teachers to interact in ways that they couldn't otherwise."

Changing expectations:

I believe instructional/human considerations should be considered before - during - and at the conclusion of any class. The technology component should be a means of thinking about and advancing the teaching and learning of the participants -- thus accomplishing teaching and learning in ways that would otherwise not be possible.
Diffusion of Educational Technology: 
Student Perspectives on Collaborative Education

Laura Blasi, Univ. of Virginia, USA
Lori Howard, University of Virginia, USA
Lisa Washington, University of Virginia, USA

The Course

Participants in the Diffusion of Technology: Policy and Practice explored the nature of the educational-technology policy process in two states, enriched by voices and experiences across a span of a thousand miles. This presentation by graduate students complements the session focused on pedagogy and the instructor experience. The Web, conference calls, and other interactive technologies gave us the opportunity to design this course as a collaborative effort between Curry School of Education at the University of Virginia and the College of Education at Iowa State University. We began by addressing the policy process related to educational technology, and then moved to focus on diffusion of innovations in educational organizations. Our goal was to examine and policy factors influencing the successful implementation of educational technology in Iowa and Virginia, but along the way we learned several valuable lessons which have contributed to our developing model for Collaborative Education.

The Technology

Throughout this semester-long course we configured the technology to accommodate the instructor’s approach to teaching in our Collaborative E-learning Laboratory (CEL). Our two-way white board and on-line conferences using NetMeetings, was augmented Collabora Newsgroup discussions. A second class held between Iowa and Virginia, Philosophical Foundations of Instructional Technology, consisted of a dozen students at one site and a half-dozen students at the other. Classes of this size would have formerly been too small to be economically feasible. The rationale underlying the Collaborative Education model is not efficiency or cost savings, but creation of a richer, more diverse class than otherwise would have been possible.

The Students and Environment

At the heart of our model for Collaborative Education has been the hope of sparking synergy by helping a variety of perspectives to intersect across a range of media. We began with six students. Their sense of investment in the course varied – as some took the course for credit and others audited. This did have an impact upon participation. They way students found out about the course and became involved also had an impact. Since we were only trying out this technology for the first time, we had a small group and momentum was difficult to maintain. This was made especially challenging by frequent interruptions as observers entered the classroom or as technological glitches required attention. Our students had varying levels of content experience. Diffusion of Technology included a former member of the educational standards board in one state and the co-chair of the commission that developed the technology standards for instructional personnel in another state, both serving as resources as the course was taught.

Changing the Architecture of Academic Courses

As Gail Hawisher and her colleagues have explained, "Many students who know a teacher is observing their conversation will self-discipline themselves and their prose in ways they consider socially and educationally appropriate. Constructing such spaces so that they can provide room for positive activities -- for learning, for the resistant discourse characteristic of students thinking across the grain of convention, for marginalized student voices -- requires a sophisticated understanding of power and its reflection in architectural terms" (64). We have only begun to understand more clearly the change in architecture when two-way video and computer-mediated
communication are introduced into a course. This panel complements and earlier session focused on the changes in teaching styles and perceptions. This panel focuses on the student experience while in a collaborative course held ata-distance.

Malcom R. Parks exploring earlier negative reactions to the use of text-based technologies for on-line discussions in the *Journal of Communication* has cited research on the effect of time allocation in on-line discussion: “Walther and his colleagues found that the proportion of socio-emotional content was higher when interaction time was not restricted (Walther et al., 1994). Thus, the negative effects attributed to the computer as a medium may have instead been the result of the stringent time restrictions placed on interaction (82). In addition to the two-way video, our use of computer-mediated communication, in Newsgroups, was shaped by the restrictions created by students derived from their own concerns and expectations – as much as the interactions were shaped by the modelling provided by professors.

We have found that collaboration is difficult when new technologies are introduced, even if the students have experiences with IT. This seems to be partially because of the new skills needed, but is also a result of the challenge such a change presents to each students’ fixed idea of how a course should unfold and what kind of contributions and collaborations they are used to and expect to make towards a class. Our presentation will include discussion of the paper writing process. We found that a new model developed as we shifted to coordinate research and writing without a high level of physical interaction, and while writing in a format that was easily accessible over the Web. The hesitancy students may feel towards trying out new approaches for collaboration may make instructors more reluctant to try new things, if students are not readily flexible. On the other hand this challenge reminds course facilitators to address cultural issues early-on in the class and explicitly state their expectations. This should occur at the same time that the instructor tries to determine student expectations and norms towards academic work. While our evaluation of the medium is still unfolding, we have seen that student comfort-levels with autonomy are influenced by their learning styles, but these levels are also shaped by the level of specificity given towards developing course objectives and expectations. The impact of these levels are felt across the distant sites, depending upon the degree of contact fostered among and towards students who are not physically in the same room as the instructor.

Student Perspective: Lori Howard
University of Virginia, USA
lah9n@virginia.edu

Context

Currently, as a doctoral student (Educational Psychology) I am involved as a research assistant with a computer based teaching decision simulation. This teaching decision simulation will be available in a Web based format in the future. Due to my past experience and interest in technology, I enrolled for the Diffusions of Innovations course. At the time of my enrollment, I was unclear that this would be a distance education course. Upon learning that the course would use Internet II technology and Net meeting, I was very positive because this course was providing me with a personal experience as a student with distance learning. My main reason for taking the course was to broaden my understanding of how technology policy is made and implemented in K-12 classrooms. The content outlined in the course syllabus was very intriguing to me and provided an opportunity for me to expand my knowledge base about how technology effects the classroom environment, while expanding my personal knowledge of the impact of technology on the learning environment.

Setting

Due to the innovative nature of the class, it seemed to me that the technology itself was the focus of class during the beginning of the semester. I believe that the technology was enhanced and changed to create a better situation over the course of the semester. Initially, two way communication was established via a speakerphone. As a student, this required greater effort on my part to concentrate on my classmates in Iowa. I missed having body cues and faces to connect with voices. Later in the semester, two-way video connections were established. The first video pictures were somewhat unclear and I found it distracting to see my classmates in Iowa because the video and audio were often out of sync. I vividly recall, the first occasion when the video was clear and I had a crisp image of Rhea
Walker because it seemed that this was the first time I actually “met” her. For me, this is when the class began to gel and I understood how learning could be enhanced with technology. The class also used a web-based discussion group to exchange ideas and to comment on readings. Initially, I found myself hesitant to post my thoughts. During the course of the semester, I began to post more often, but the discussion group did not provide me with human feedback.

**Observations**

Initially, I felt that all class members would need to demonstrate goodwill and patience for this technological approach to learning to work. I retain positive feelings toward my classmates despite feeling that I haven’t gotten to know my Iowa classmates. I was surprised to note my own ambivalent feelings toward the use of technology. Ironically, the very technology that seemed to be enabling me to collaborate with classmates in Iowa felt as though it was creating a distance between us. The discussion group which was established to help us function as a group felt artificial to me. I never felt a sense of “self” with the other posters to the list and admit that I was uncomfortable sharing my own self with the others.

I also noted that as a student, my normal learning style needed to be modified. I am very dependent upon metacognitive structure and often found it difficult to follow conversations with people I could not see. Participation in class demanded that I actively participate in ways that were different from other seminar classes I have taken. Specifically, I tend to be a conceptual thinker and often lose focus with too many details. In this class, I found it helpful to come to class with a general conceptual framework rather than develop one during class.

**Lessons learned**

I have learned that more research may be needed in to the impact of individual learner differences and the use of technology. Specifically, not all learners may benefit from distance education type courses. In addition, I developed great admiration for the faculty involved as they were flexible, open to change, and supportive of the student efforts with technology in this class. They were great role models for how teachers should incorporate technology without fear and with a willingness to make mistakes.

---

**Student Perspective:** Lisa A. Washington
University of Virginia, USA
law7x@virginia.edu

**Context**

Beyond my use of computers for personal productivity, I am a graduate instructor of a project-based software applications course that teaches students how to use the Microsoft Office suite of applications including Word, Excel, Access, and PowerPoint. The course also provides instruction in developing Web pages, Internet searching, and digital image capture and manipulation. In addition to my position as a graduate instructor, I teach similar computer applications courses to in-service teachers and pre-service administrators. My interest in the *Diffusion of Educational Technology: Policy and Practice* course was twofold. First, I was interested in further exploring the ideas of Everett Rogers, to which I had been exposed in a previous course. I also have an interest in policy implementation and wanted to be exposed to thoughts and literature related to the development and implementation of technology policy. I am particularly interested in the trickle-down effects of policy and the transformation of policy interpretation into policy in practice. I was also interested in experiencing a shared learning experience across distance. I wanted to know what it would be like to learn and share in a distanced education environment.

**Setting**

In the first few weeks of the course only a speakerphone and white board connected students at the University of Virginia (UVa) and Iowa State University (ISU). Unlike a traditional seminar where formality and courtesy often take a back seat to allow for the active and free flowing exchange of thoughts and ideas, the sharing of these same
thoughts and ideas via telephone introduced a series of what I considered unnatural, albeit courteous, pauses between each speaker. A Netscape Collabra discussion group served to keep the students connected outside of class. I was not an active user of the discussion group. I was much more comfortable posting information to the group than I was posting my reaction to a particular reading or responding to questions posed by the instructors or other students. My resistance to using the discussion group had to do with not being able to take back my words once they were posted and not being able to see others' reactions to what I had posted. In a face-to-face discussion non-verbal communication plays a key role in interpreting others' thoughts and there is an opportunity, absent in Web-based discussions, to receive immediate feedback or provide explanations to expressed thoughts. Once the video was introduced I did not feel more connected to the students at ISU. In fact, I felt distracted by the slightly out of sync audio and video transmission. I preferred to sit in a location that did not give me a direct view of the monitor on which we were viewing the ISU students. By the time the video was set up I felt that I already knew the ISU students by their voices and it was a distraction to watch them on a monitor while I was trying to listen to what they were saying.

Observations

There were times throughout the semester when I felt very detached from the ISU students. I felt as though we were actually two separate classes instead of one. My previous experience in seminar classes is that relationships among class participants develop and flourish outside of class. Opportunities for informal meetings and interpersonal communication in between class sessions foster this development; opportunities that are absent in a course offered across distance.

Lessons Learned

I learned that I have an aversion to online discussion groups and as such, regardless of the course content, I am not inclined to seek out future distance education courses that require such participation. I much rather prefer to interact with people, instructors and other students, in person. For me, part of the learning comes from face-to-face interaction with the people with whom I'm sharing my thoughts and ideas.

I feel I may have benefited more from the learning experience if I had been paired with one of the ISU students, rather than working all semester in a group with the UVa students. I think that particular class dynamic contributed to my feeling that we were two separate classes. Creating mixed pairs of student groups could have promoted more collaboration and a greater appreciation for varying perspectives on our class project.

The inauthentic communication created by interacting across a distance was the most significant difference of this experience for me, as compared to a traditional classroom setting. We were all very polite—we did not speak over each other nor did we interrupt or speak out of turn—and waited a noticeably extended period of time after someone had finished speaking to begin speaking. While it tapered off after the video connection was made, we almost always identified ourselves before we began speaking. I appreciate the power that the telecommunications and video technology we used has to connect students and faculty across distance, however the power of face-to-face interpersonal communication should not be forgotten in the evolution of this technology.
Infusing the use of technology into the school curriculum is not an easy task. Educators want to know how they can do this when they already have much to do and they must use the STANDARDS. This ongoing project matches curriculum standards with web sites, tool software, curriculum-based software and other resources.

Students at this state university have developed and are continuing to update links to instructional resources that support various curriculum standards. The students have studied the standards, explored the Internet, reviewed and evaluated software, books, and other resources and have created a web page that will give educators what they are looking for - assistance with the infusion technology into the curriculum.

The use of this project is as simple as 1,2,3...
1. Go to the web page or CD-ROM.
2. Click on curriculum area of interest.
3. Click on grade level.
4. Click on standard.
5. Select resource.

Abstract: The creation of technology rich learning environments is a common goal of today's educational institutions. For this goal to be realized, it is generally assumed that teachers and/or administrators need to be competent in using technology in meaningful ways. The authors argue that there are two avenues that are generally taken when pursuing this objective: an administrative "top - down" approach that attempts to directly infuse technology into the classroom and a "bottom - up" approach where individual teachers with interest are encouraged with the hope that this interest will slowly spread throughout the school. With preliminary results from a network of middle school computer clubhouses, the authors discuss the possibility of a third "backdoor" approach utilizing student interest in technology.

The creation of technology rich learning environments is a common goal of today's educational institutions. For this goal to be realized, it is generally assumed that teachers and/or administrators need to be competent in using technology in meaningful ways. Currently there are two avenues that are generally taken when pursuing this objective. The first is an administrative "top - down" approach. This typically includes a purposeful infusion of technology into the classroom through the purchase of computers and providing teacher training. The second is a "bottom-up approach" where technology is not intentionally introduced, but individual teachers with expertise, sometimes encouraged by the administration, generate interest from their colleagues through the sharing of information and resources. It is hoped that this active involvement will generate momentum that will result in school-wide technology adoption. Either of these approaches may or may not be successful. Community Computer Clubhouses introduce an alternative "backdoor" approach. This method utilizes student interest in technology. Computer access and education is provided to students outside of the classroom through after-school Computer Clubhouses in combination with community support and involvement. Computer Clubhouses provide a safe, after school, learning environment for middle school students. It is hoped that as students gain technological proficiency they will become a resource to peers, teachers and the community. Computer Clubhouses could then accomplish the goal of providing technologically rich learning environments as a result of developing
teachers into effective users of technology by not only providing the necessary computer technology but also through the support of student technicians and a collaborative effort with the community and other schools. A Network of Michigan Middle Schools has developed a consortium of nine districts that sponsor ten (10) Computer Clubhouses with technical and managerial support from a large mid-western university. The middle school Computer Clubhouses will serve these urban and rural communities as 21st Century Community Learning Centers and form an innovative virtual statewide learning community through a Web-based network.

The districts where these clubhouses are located, represent remote, sparsely populated and core urban areas and are characteristic of a wide range of geographic and demographic diversity. They all have large percentages of students who fail on indicators of academic achievement, receive special academic assistance, and have the potential to be victims of violence and drugs. A majority of the districts report that 30% to 90% of their students are living within the poverty range based on data compiled by the Michigan Department of Education. Students from these communities have limited employment potential and expectations as they move toward adulthood.

Parents in these communities are demanding that schools improve academic achievement for their children and curb violent behavior, substance abuse, including alcohol, tobacco, and other drugs, and teen pregnancies. Reported incidences of teen violence are increasing; yet, in these communities, there is very little for middle school students to do after school, over weekends, and during the summer. In a study of the quality of life in one of the small rural school districts, findings suggest that 25% of the students are at risk at school, at home, and in the community. The principal reports that "several students do not want to leave the school at the end of the day". These communities and the other communities in this consortium are struggling to find ways to improve community support for education, offer safe, positive after-school environments for middle school students, and increase student engagement in learning.

The intended purposes of the Community Computer Clubhouses are to:

1. Increase student engagement in learning through the use of computers and computer-related technology in safe, positive environments,
2. Provide meaningful, integrated, and authentic learning opportunities through service learning,
3. Foster the capacity for collaboration among students, schools, and communities among the project partners and their communities,
4. Develop an innovative model of statewide collaboration for building student and staff capacity through the sharing of resources,
5. Provide a safe learning environment during and after school hours.

The Computer Clubhouse approach is unique in that it does not apply a "top - down" approach to developing technologically literate teachers - infusing the school/district with technology and training teachers. Neither, is it a "bottom up" approach - mandating classroom use of technology but, allowing and even encouraging its use when introduced indirectly. The Computer Clubhouse "backdoor" approach is directed at student development of the necessary technical skills required to educate their peers, educational staff, and the community.

This roundtable submission will highlight the preliminary findings related to teacher technology use associated with Clubhouse endeavors. Discussion will center around the implications these preliminary results may have on the future direction of the Computer Clubhouse method as well as teacher technology education in general.
Technology adoption at the college level: Multiple representations of technology integration

Sean Farmer, Michigan State Univ., USA
Richard E. Ferdig, Michigan State Univ., USA
Mark Chaplow, Michigan State Univ., USA
Rick Banghart, Michigan State Univ., USA
Yong Zhao, Michigan State Univ., USA

The College of Education at Michigan State University has developed and implemented a highly innovative environment for integrating technology in teacher education. Rooted in a deep understanding of teacher learning and technology adoption, this model strives to achieve and sustain systemic change in teacher education and K-12 learning through creative use of technology.

This poster presentation would provide an opportunity to showcase and describe numerous innovative initiatives aimed at preparing a new generation of K-12 teachers, teacher educators, and educational administrators. These initiatives address human and technical infrastructure, research and development, and teacher education projects. Listed below are five such programs we would like to highlight, in hopes of providing direction and support in the drive towards integrating technology into teacher education.

TechGuides

The TechGuides are a group of graduate students employed by the College of Education to provide expert technology and technology-based curriculum advice to teacher educators and teacher candidates. Under the leadership of Yong Zhao, the TechGuides help teacher educators become technologically fluent educators.

Additionally, the TechGuides maintain a Web site, publish a newsletter, and provide a Kiosk on teaching with technology. TechGuides are also encouraged to study the process by which teachers and teacher educators integrate technology into their teaching.

eWeb

eWeb, an integrated Web-based learning environment, consists of a set of Web server plug-ins that work with a Web server and database applications to offer a suite of multifunctional tools in an integrated fashion for teachers and students to use within a Web browser. Within this environment, the learners are enabled and encouraged to explore, experiment, and experience independently and collaboratively with their peers from the same or other schools. Tools are also provided to help students develop metacognitive skills and become goal-oriented, self-regulatory, independent learners.
eWeb has been used by teacher educators in the college to support class projects and model pedagogical uses of advanced technology. eWeb has also been used to support research on virtual communities, teacher reflective discourse, distance learning, and other issues.

Community Computer Clubhouses

This project seeks to establish an innovative consortium of ten (10) middle school clubhouses in nine rural and urban school districts (two in Detroit) to serve as community learning centers. Michigan State University (MSU) will provide technical and managerial support to consortium. The school districts represent the demographic and geographic diversity of Michigan, but they are all struggling to increase student engagement in learning, offer safe, positive after-school environments for middle school students, and improve community involvement in the schools. Computer clubhouses present a powerful intervention strategy for solving those pressing problems and achieving four overarching project goals:

1. Increase student engagement in learning through the use of computers and computer-related technology in safe, positive environments,

2. Provide meaningful, integrated, and authentic learning opportunities through service learning,

3. Foster the capacity for collaboration among students, schools, and communities among the project partners and their communities,

4. Develop an innovative model of statewide collaboration for building student and staff capacity through the sharing of resources.

Through the resources of edtech.connect, a technology outreach initiative of the College of Education, the middle school clubhouses will access research, best practice, and on-site assistance for engaging all students in authentic learning experiences. For the students, the clubhouses will provide safe in learning environments, teach them to help others, and expand their horizons by sharing across the consortium network.

Reading Classroom Explorer

The Reading Classroom Explorer (RCE) is a hypermedia environment which contains video clips of reading classrooms, transcripts, questions to ponder, further reading resources, and an interactive notebook. The video footage of exemplary teachers teaching reading (at this point, all video is on loan from the Center for the Study of Reading's "Teaching Reading: Strategies from Successful Classrooms" 6-part video series) drives users' inquiries. RCE aims to broaden preservice teachers' opportunities to observe...
children and teachers from different cultural backgrounds, environments, and theoretical perspectives.

RCE provides multiple examples of successful teachers who are teaching thoughtful curriculum to students of diverse backgrounds. Through RCE you can explore a variety of literacy practices (e.g. literature-based, phonics, whole language, emergent literacy, basals, writer's workshop, etc.). The video clips demonstrate teachers using a variety of instructional formats (e.g. small group, large group, discussion, etc.) while working with students in grades K-5 including ESL and special needs students.

The videos, accompanying questions, and transcripts provide teachers with opportunities to learn more about reading and writing instruction. Preservice teachers can use RCE not only to see multiple approaches to literacy instruction but also to compare and contrast those approaches. RCE provides opportunities for professional development for inservice teachers as they view and reflect upon the teaching of others. Teacher educators can use RCE to help bridge gaps in theory and practice by providing real world portraits of literacy teaching and learning.

**Expert Database**

The EXPERT database is a database-driven Web site aimed at assisting teachers with technology problems by giving them access to experts. To become a user of the system, you may register your name, password, and area of interests, as well as areas of expertise. You may then ask a question under a certain category which is automatically sent to whomever is listed as an expert for that category. When the expert responds to your question, you are immediately notified by email. However, the answer is also stored in an on-line database. Future goals include making the system "intelligent" such that you will be able to ask the system a question and it will first check the database for an appropriate answer prior to asking an expert. It will also increase the usability by allowing the user to rate the appropriateness of the particular response.

The EXPERT database is one example of the numerous research and development projects at the College aimed at providing teachers and administrators with the cognitive tools they need to implement technology in education.
A Multi-Stage and Multi-Component Program Plan to Integrate Computing and Technology into a Division of Education

David C. Fletcher, Ph.D.
Department of Specialized Services in Education
Lehman College, The City University of New York
United States
fletcher@alpha.lehman.cuny.edu

Abstract: The effective integration of technology and computing tools by faculty into the courses offered by their Division of Education must take full advantage and make use of as many resources as are available or can be made available. In the this paper, I will describe the multiple stages and the many components of a long range technology plan that several faculty members and I developed and have continued to develop, implement and assess. I will also describe several of the problems with which we have had to contend and some of the solutions we have used. Throughout this ongoing process, we have been guided by the principle that improved student learning must guide our plan and its implementation and progress.

Introduction

We are a Division of Education composed of approximately 40 full-time faculty members, divided into three departments (Early and Elementary Education, Secondary Education, and Specialized Services in Education). We primarily serve six community school districts and the Bronx High School Division. Our Division prepares and trains a sizeable number of the preservice teachers who must qualify for a provisional licensing status so they can begin teaching. We also offer several master level degrees to a large number of the same provisionally certified teachers and to others who must earn a masters in New York State in order to qualify for their permanent teaching license.

For the past two years, we have been engaged in the committed development of a five year Technology Plan that is now guided by parameters that perhaps best describe the anticipated 21st century classroom that our N12 teachers must be prepared to enter. We must prepare our preservice teachers and inservice teachers to become problem posers, problem solvers, effective users of telecommunications and information technologies (Dede, C., 1998), and literate information users (Breivik, P.S., 1998) in the evolving global communities that will characterize the 21st century.

Today's workplaces and communities -- and tomorrow's -- have tougher requirements than ever before. They need citizens who can think critically and strategically to solve problems. These individuals must learn in a rapidly changing environment, and build knowledge taken from numerous sources and different perspectives. They must understand systems in diverse contexts, and collaborate locally and around the globe (Jones, F.B., Valdez, G., Nowakowski, J. & Rasmussen, C., 1995, p. 5).

This is for us a very significant and critical challenge to meet and one that will take time, effort, and patience to attain. How have we as a Division begun to move to meet this challenge?

Within Our Division of Education: Building Toward the 21st Century Classroom

The best approach we have found in creating and implementing a technology plan that supports the ideals of the 21st century classroom, is a problem posing, problem solving approach that allows for the creation of constructive initiatives and as much participation by the many potential collaborators as possible. The specific goals and objectives have been defined by ISTE (1998) for all preservice teachers being prepared for the 21st century classroom.
Developing a Technology Plan Guided by Student Learning

Following our participation at the 1998 Dean's Forum on Technology in Teacher Education, sponsored by NetTech (the Northeast Regional Technology in Education Consortium), we began to more seriously contend with the problem to have student learning and student performance outcomes direct and guide a Division Technology Plan. NCATE's (National Council for Accreditation of Teacher Education) representative at the Dean's Forum made it very clear to all participants that, unless student learning outcomes were improved, what then were the real and actual benefits of a technology plan? Upon returning to the College, I began to reshape and reframe our developing technology plan to meet NCATE’s recommendations. Through many discussions, our Division has come to accept that the 21st century classroom as described above represents K12 performance outcomes that we must prepare our faculty and their preservice and inservice teachers to meet.

Building a Division Infrastructure that Support Faculty Initiatives

Teacher education faculty cannot be expected to prepare their students to enter into the 21st century classroom unless they are familiar with such a classroom and supporting infrastructure. Although by Spring term, 1997, all faculty had desktop, internet-connected computers, many of these were of the 386 to 486 model and simply out-of-date. Grant funds were obtained and all faculty have since been upgraded to Pentium II multimedia stations, with intranet and internet capability. In addition, we have upgraded our Division server to a Windows/NT server, added a newer version of listserv software for each faculty to create a listerv for courses and projects, added ease-of-use webpage software, and recently added Internet course software for those faculty interested in placing all or a portion of their courses online. Faculty can now include software in their department and Division supply requests.

In order that faculty integrate technology and computing tools into their courses, as many flexible resources need to be provided as possible. One of our earlier goals was to provide faculty with access to laptops and portable projectors that can be easily plugged into intranet/internet connection located in all classrooms. Even though six such connections are going to be provided by the College by June 1999, the laptops and projects are not yet ready and may not be for a while longer. However, we also realize that projectors and laptops only allow for demonstrations and the more traditional lecture format. Our students need as much hands-on experience as possible to be prepared for their role as teacher-as-facilitator rather than teacher-as-lecturer. Therefore, rather than using our available funding for the lecture-type setups, we decided to build two additional computer classroom for general use and a specialized classroom for science and mathematics instructions. These classrooms can now be made available for faculty to use for classroom instruction across the content areas and to simulate the three to four computer station setup found in many K8 classrooms. This will require that our faculty learns to plan for the effective integration of technology and computer tools into their content areas. This will take a predictable two to three years.

Faculty Development

Beginning Spring term, 1998, I have been given one course release time to provide faculty with faculty development workshops and one-to-one assistance to develop competencies to use their new multimedia stations and, most importantly, to plan how best to integrate technology and computer tools into classroom instruction. We designed our professional development workshops based on faculty needs assessments and focused on their readiness to learn. In the workshops, I stressed the importance of their identification of performance outcomes to improve their work as faculty and to improve the learning of their students. Since we do not have funding for an actual faculty developer support staff and I am the only assigned faculty developer, I decided that a team approach would allow faculty to consider themselves as collaborative team members. I based this decision on a K12 professional development model that I have been working with for a number of years. For example, when questions arose during a workshop, I would deliberately request other faculty members to provide assistance to their colleague. Or when a faculty member would stop me in the hall with an application problem, I would suggest that they also remember that one of their colleagues would know how to solve the identified problem.

1664
For the Spring term, 1999, we will provide faculty with opportunities in department meetings and in Division meeting to present and discuss how they are integrating technology and computer tools into their courses and to discuss how their use of these resources will support and extend students' learning. In these presentations, faculty will be able to share their initiatives, receive support and feedback, and, through discussion, develop ways to possibly extend their current uses. Also, the presentations will allow other faculty a non-threatening place to discover ways to develop and borrow tried and tested approaches.

Undergraduate Student and Graduate Student Preparation

In attempting to meeting ISTE's (1998) recommended technology and computing competencies, we quickly realized that far too many of our undergraduate preservice education students and master's level students were leaving our Division and entering schools without adequate technology preparation. Since many of our faculty have only within the past year begun to integrate technology and computing tools into their courses, students would, of course, not receive the quality and quantity of hands-on preparation needed. We do provide all students, graduate and undergraduate, with email accounts, but there is no guarantee that they are using these accounts at this time. A few faculty regularly use email with their students and there is much interest in attaching listservs to courses. This would not necessarily guarantee that all of our students become proficient users. Another problem compounding this is the fact that two-thirds of our undergraduate education students transfer to us at the junior level from community colleges. And for students entering our masters programs, we find that they no better prepared than our undergraduate students.

This is a major problem for us to solve and requires several approaches. At the graduate level, students admitted to the masters program in Elementary Education are required to enroll in a newly redesigned technology and computing course. This course makes extensive use of the different forms of electronic communication, the diverse range of software to support instruction, and the resources made available via the Internet. Students are also carefully guided in the evaluation and review of software and Internet applications in their design of curriculum that meets the revised standards of the New York City Board of Education and New York State Dept. of Education. However, this is only one group of our graduate students.

Recently, we designed a new undergraduate course for all preservice teachers that meet the ISTE standards. All undergraduate students declaring education as a minor in their junior year (both transfer and continuing students) must either demonstrate these competencies or must enroll in a course in which the competencies are taught. For those students who have passed their junior year, they must, before beginning their student teaching, demonstrate these competencies or enroll in workshops to acquire the competencies. We do not want the community school districts reporting to us that some of our students are not technology literate.

We are still struggling to design approaches to guarantee that all of our master level students have acquired the basic ISTE standards. This will take additional planning and a concerted effort by our faculty.

Taking Advantage of Campus Technology Initiatives and Facilities

Since we are only one Division with limited resources, our best hope to develop and implement an in-depth technology plan is to collaborate closely with the other College divisions, departments, and programs. These collaborations have few costs except for time and have brought partnerships in grant writing and program development. Also, our students must be able to make use of all available resources and our collaboration with the rest of the College makes this possible. For example, we have developed collaborative initiatives with the Library (which is now fully electronic), the Information Technology Center (which includes three distance learning facilities), and other facilities, including Continuing Education. We are also a partner with the BIN (Bronx Information Network) which provides extensive infrastructure support to local school districts (N through 12 grades), medical facilities, community organizations, and
Creating K12 Collaborations to Support the 21st Century Classroom

As a Division of Education, we, of course, do not function in isolation to Bronx school districts, community organizations, and businesses. And in reality, the Division is in actuality playing catch-up to the initiatives and efforts of our neighbors. So, our effort became to take the best advantage of these realities and to build them into the Division’s technology plan and efforts.

Advisory Committee of Technology Coordinators

In April 1997, I formed a Technology Coordinators’ Advisory Committee of the six Bronx community school districts and the high school division to provide suggestions and recommendations to the Division on its technology planning. This group has proven to be a valuable resource for they have their finger on the pulse of the technology needs of the Bronx schools. They have given me valuable feedback on the development of a technology and computing specialization and concentration and recommended the formation of the Bronx Superintendents’ Technology Leadership Forum (to be discussed below). Selected technology coordinators from this group now either teach some of our technology/computer courses or have recommended school computer coordinators and/or classroom teachers for these positions.

Best Practices Technology Schools

Another area that the Technology Coordinators’ Advisory Committee has been extremely helpful in identifying N12 "best practices technology and computing schools" for our Division faculty and their students to visit or for the teachers of these classes to visit the college classes. This arrangement allows our faculty to take the best advantage of those classroom teachers who have taken the initiative to integrate technology and computer tools into their curriculum. In addition, preservice and inservice teachers have the opportunity to talk with these classroom teachers to discuss the problems and issues that will inevitably arise with such integration efforts. The criteria for selecting the “best practices schools” was in large measure developed with the Advisory Committee and address such critical issues as assessment and the articulation of goals and objectives that support the new curriculum standards. We were also particularly interested in including those teachers who have moved forward and integrated open-ended learning environment types of tools, such as multimedia development, webpage design to support research, and the incorporation of multiple electronic sources to support research.

Bronx Superintendents’ Technology Leadership Forum

Approximately two years ago, the Technology Coordinators’ Advisory Committee requested that the Division sponsor a series of forums to support our local superintendents to develop long range technology plans. Beginning Spring term, 1999, their request will become a reality as a result of much planning and with funds provided by NetTech. The six community school district superintendents and the high school superintendent will form leadership committees, which they will actively chair, and will attend a series of workshops to become better informed about the several components that comprise a long range technology plan. After a period of preparation, the superintendent leadership teams will meet in a number of workshops with their respective principals to guide them through the same planning process. The major technology players in NY State, NY City, and the NetTech region will be invited to answer and address the questions of the superintendents and their principals. As a result of these workshops and meetings, our Division will be better able to also plan how we can collaborate and partner with the school districts to effectively integrate technology and computer tools into the curriculum to support student learning and to better prepare future teachers.
Conclusion

The tasks we have outlined for ourselves will continue to be assessed and developed as we proceed with our plan, which is, of course, always evolving. Many problems have arisen, a few have been solved, and others will continue to rise up. However, our aim is to always search for solutions and to continue to engage in thoughtful and reflective collaboration.

Avoiding Pratfalls in K-16 Collaboratives

garcia@uwosh.edu

Abstract: Technocentric collaboratives pose unique challenges to university faculty. Recommendations from prior research in the areas of technological innovation, teacher development, teacher acceptance of technology, implementation of change processes, and professional development can provide valuable insights for university faculty while informing the planning and implementation of technocentric collaboratives with K-12 schools.

Introduction

The call for collaboration between universities and K-12 schools comes from sources ranging from state legislatures to local school districts to regional colleges of education. Increasingly, universities are working towards fulfillment of the vision of the Holmes Report (1995) to form “not just a working coalition of schools and universities as they are, but a powerful synthesis of knowledge to help us find out what the schools of tomorrow might be like.” Many proposed collaboratives center on the use of computer technology in schools as local districts find themselves inundated with new hardware and scrambling to provide teachers with meaningful education on the use and integration of computers in the curriculum. No matter how innovative and creative the vision for the collaborative venture, the reality of creating working and viable technocentric collaboratives between institutions of learning whose traditional organizational patterns champion closed doors and individual initiative is often more difficult than originally envisioned. Existing research can inform the planning and implementation of any technocentric K-16 collaborative.

An Overlay of Continuums

Embedded within the culture of schools are individual teachers who could theoretically be placed on three continuums: acceptance of technological innovations, teacher development, and acceptance of computer technologies. The overlay of these continuums illustrates the complexity of the system in which the collaborative will be placed.

Continuum of Technological Innovation

Three stages can be observed as technological innovations move from potential to fulfillment (Naisbitt 1982). In the first stage, the technology is introduced in ways that are non-threatening. In schools this level was observed when Apple II-e’s, sitting in the back of the classroom, were widely used as classroom behavior reinforcement props or free-time activities.

Second stage technological innovation occurs when the new technology becomes increasingly merged with older technologies. At this stage, the new technology performs existing tasks more efficiently than older technologies. In education, teachers use electronic gradebooks, professors convert overhead transparencies to PowerPoint presentations, both students and teachers use the computer as a typewriter, and students become facile with skill and drill software aimed at mastery of discrete skills.

As people become accepting of a new technology and recognize its place in their present lives, a third stage of innovation emerges. At this stage, the innovation itself begins to drive practice in different directions while opening the door to new applications and further innovation.
Educational use of computers in today's schools illustrates acceptance at the second stage level of innovation. However, as school districts across the country are discovering, this is not exclusively the result of low levels of hardware availability in classrooms. Indeed massive infusions of hardware may impede the use of computers rather than nourish their use. The answer to this curious contradiction may lie within additional continuums that must also be considered.

**Continuum of Teacher Development**

A variety of researchers have provided descriptions of the various stages of teacher development. Whether their descriptors utilize a three stage or four stage developmental scale, all point to varying needs of in-service teachers at each stage. Each illuminates the vastly different behaviors and methodologies of teachers along their respective continuum. One teacher development scale sets forth a four-stage pattern of development with the following stage descriptors: becoming, growing, maturing, and the fully functioning professional (Gregorc 1973).

The *becoming* stage teacher was identified as just beginning to develop initial ideas about the nature of teaching, role expectations, and the role of school as a social organization. They felt that their role as a teacher was to impart knowledge to students, get through the book, and do what the principal said. In a technocentric collaborative venture, these teachers, while exhibiting great enthusiasm for technological innovations, may become frustrated at how to implement these innovations in light of the perceived need to make it through the book. Likewise, they are easily influenced by other educators at the school site and their preconceived perceptions of technology in the classroom.

As teachers moved into the *growing* stage, their concepts and stereotypes of their roles and school continued to develop but in the light of more personal knowledge and familiarity with curricula, students, materials, equipment, and their own strengths and weaknesses. Gregorc also found that some teachers made it to only this stage, stopped developing, and rejected new experiences. The group of teachers at this level, whether entrenched or merely stopping by, can provide the greatest amount of challenge in any K-16 collaborative. Having successfully completed the becoming stage, educators in the growing stage have developed a sphere of comfort and any intrusion into that sphere may be viewed with suspicion and skepticism. From this group of teachers may also come the fear of technology as one more subject to teach.

The *maturing* stage found teachers who were characterized by a strong sense of commitment to education, participation in the greater school community, and service as educational resources to fellow faculty. Earlier stereotypes were reexamined leading to new insights about education, students, and themselves. Teachers at this stage, should they personally embrace the value of integrating technology into their curriculum, will move rapidly in allowing students to serve as leaders in absence of the teacher’s personal expertise and allow technology to serve as another valuable tool in their curricula. These educators will most often be willing to share their experiences with fellow staff members. How other faculty members receive their efforts will be independently determined by each teacher’s place on the development continuum.

Finally, teachers at the fully functioning professional stage have made a full commitment to education while trying to realize their full potential both as individual teachers and as part of the larger profession. New concepts are tested and belief restructured in a continual spiraling growth pattern. Such teachers may find that technology will fundamentally change the way they teach, moving more towards project-based curriculum, collaboration with other faculty, encouragement of student cooperative groups, and educational inventiveness.

Regardless of where an educator exists on the developmental scale, the introduction of computer technology can challenge current belief systems, pedagogical patterns, and their patience. Attention must be paid to their self-concept as learners. Their acquisition of the skills needed for personal use of the computer and the ability to successfully integrate the computer into their classroom curriculum will place them on yet another continuum.

**Continuum of Teacher Acceptance of Computer Technology**

Teachers immersed in a technology rich environment move through distinct stages of use and application. A four-stage process of growth has been identified (Dwyer, et al. 1990). In the *adoption* phase, educators were involved in learning how to use the technology themselves and were concerned with how to make it work with their traditional curriculum and method of instruction. Most often they turned to
CAI software for drill and practice of basic skills. Minor technical glitches in both software and hardware were initially viewed as insurmountable obstacles. As much support was needed for these technical glitches as was needed for simple skills development. Classroom computers were turned on only occasionally and the computer lab was frequently void of students.

The adaptation phase found teachers discovering that they could cover their usual curriculum faster with technology and that left more time for experimenting with restructuring ideas such as problem-centered curriculum. Curricula were modified to take advantage of time opened up by increased productivity. Skills the teachers had worked hard in mastering for their personal use in the adoption stage such as basic desktop publishing began to be presented to students and encouraged in use by students. Labtime became a precious commodity, resulting in scheduling conflicts.

Entering the appropriation stage, the majority of teachers began experiencing a fundamental shift in their view of teaching. Technology became integrated into more innovative approaches such as team teaching, team curriculum development, student collaboration, and interdisciplinary projects. Team teaching was explored, as was flexible scheduling at the secondary level. The demand for instruction in more complex technology issues increased. Web publishing emerged as a collaborative venture for faculty. Advanced applications such as Photoshop were employed as were digital cameras and scanners. Greater interest in mastery of multimedia software emerged. Teachers found increased need for computers in the classroom as they began to facilitate student cooperative groups.

The final stage or invention phase of the study found teachers building new learning environments that employed technology as a flexible learning tool. They came to view learning as a creative and interactive process. Knowledge became something learners needed to construct for themselves rather than receive from someone else. Alternative forms of assessment were integrated and a balanced, strategic use of direct teaching and project-based teaching was developed. Computers in classrooms were turned on from the beginning of the day and used frequently by students throughout the day. Lab time evolved to a more refined usage, primarily used as an opportunity to complete projects begun in the classrooms.

The convergence of these three continuums—technological innovation, teacher development, and teacher acceptance of computer technology—occurs uniquely in each educator at each level in each school. The vision of this complexity can inform the planning of any K-16 technocentric collaborative for it points to the need for flexibility in planning and implementation to satisfy the needs of individual teachers. It can also serve to illuminate behaviors encountered as the collaborative proceeds.

The introduction of computer technology and the consideration of its infusion into a curriculum represents a significant change process. After reflection on the complexity of the individuals being served by any collaborative, factors of implementing change should be considered.

**Implementation of Change Processes**

Consideration of the myriad of possibilities afforded by an overlay of the above three continuums illustrates that the plan of any technocentric project can appear deceivingly simple if it fails to consider the complexities of initiating change in the school environment. This complexity is well described in 3 tiers of interactive factors in the implementation of any change process (Fullan 1991). The first two of these three tiers—characteristics of change and local characteristics—may inform the implementation of any collaborative.

Fullan's first tier stresses the characteristics of change and consists of four items: need, clarity, complexity and quality. It seems obvious to note that early in the implementation stage of any project, the people involved must agree that the needs being addressed are significant. However, while this may have been accomplished in the planning of the project, the larger group of participants must buy into the significance of the need as well. In complex projects, all needs may not be apparent early in the project period. Participants must be involved in hands-on projects immediately so that emerging needs may be identified and stated.

**Clarity** about the goals and means of any project presents a continuing problem. Complex innovations in a human environment highly dependent on teacher continuums increase obscurity of goals. Teachers are likely to be unable to state the vision and focus of a technocentric change at their school and may be frustrated by not knowing what change in behavior is expected of them. Revisiting the goals of the project often can be beneficial but changes in the means for achieving those goals must be approached with caution. Too much fluidity can give the impression of lack of concrete planning and may ultimately cause K-12 faculty to question the competency of both their administration and the university partners.
Complexity of change deals with the extent of change required of the participants in the project. It is compounded by each participant starting from differing positions on each of the continuums as well as the complex interactions between required skill levels and internal conflicts with existing belief systems, pedagogy, and materials. Technocentric projects are extraordinarily complex, requiring teachers to develop new skills, examine existing beliefs, and adjust current methodology.

Finally, the quality of the innovation must come under close scrutiny as it underscores the subtle interplay of need, clarity, and complexity. While the need for the innovation may be obvious, the quality of the program must not be taken for granted. Any project being brought to an educational institution must pass the “practicality ethic” (Doyle & Ponder 1977-78). Changes perceived as practical by educators will address observable needs, fit well with the teaching environment, be logical in implementation, and let educators walk away with concrete applications adaptable to their classrooms and teaching styles. The project also must be structured such that tangible successes are observable by the participants early in the implementation period (Huberman & Miles 1984).

The second tier of interactive change factors deal with local factors: school district, board and community characteristics, principal, and teachers. One significant precondition to the success of any collaborative is the track record of the school district in not only encouraging innovation but also supporting it through financial and philosophical means. While staff at a local school may be able to successfully implement a technocentric project, that project will not be replicable at other sites without top down support from the district administration. Central administration must demonstrate through actions that they will support innovation for teachers learn quickly which innovations to pay attention to and which to discount as a passing fad.

Board and community characteristics may seem at a level beyond which to consider as an implementation factor but support from both the board and the community of the local school are critical in the continuation of the innovation after the implementation phase. Involving parents and local businesses from the start provide an outer level of support for the project. The wisdom of building in exit experiences in the project that provide a showcase for board members is politically astute.

Of more obvious value to successful implementation of a technocentric project is the support of the principal and the teachers. Ultimately whether the innovation is accepted or blocked lies within the purview of the principal and the teachers. While it could be assumed that their support was part and parcel of the planning stage of the project, one must continue to plan for their support during the implementation as well. It cannot be taken for granted.

Principals must be viewed as partners in the grant implementation. Ideally, principals should act as instructional leaders and care should be taken to facilitate and encourage them in that role. When teachers see and feel the active support of their principal in any change, through psychological support, material support, and active participation in workshops, projects stand the greatest chance of success.

Obviously, teachers play a significant role in the implementation process. When teachers who are at the maturing and fully functioning professional points on Gregorc’s scale approach innovation, they do so in a self-actualizing manner with a greater sense of efficacy than do those teachers at the first two points of the scale. Likewise, relationships among teachers are of vital concern for the researcher. Schools that have a high number of change-oriented teachers who have had the opportunity to establish a learning community, albeit informally, provide a psychologically safe environment in which to experiment and learn as a professional. A technocentric project ideally involves learning to do something new and interaction is the basis for social learning. If opportunities for communal discussions do not currently exist, then the project must be structured to provide that time in a facilitated manner. Judith Little (1981) distinguished this type of social learning as, “Teachers engage in frequent, continuous and increasingly concrete and precise talk about teaching practice (as distinct from teacher characteristics and failings, the social lives of teachers, the foibles and failures of students and their families, and the unfortunate demands of society on the school). By such talk, teachers build up a shared language adequate to the complexity of teaching, capable of distinguishing one practice and its virtue from another.”

Professional Development of Educators

Technocentric collaborations must not only address sound teacher development principles but also the need for technological support of emerging learners. Needs may emerge that extend beyond the original vision of the collaborative. Whatever the needs being addressed, key elements of successful in-service teacher development programs must be addressed consistently throughout the implementation.
process. Loucks-Horsely and colleagues (1987) have identified ten characteristics of successful teacher development. These characteristics are listed below along with some applications of each in technocentric collaboratives.

<table>
<thead>
<tr>
<th>Characteristics of Successful Teacher Development</th>
<th>Application to Technocentric Collaboratives</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Collegiality and collaboration</td>
<td>Respect of teacher expertise and experience; gradually move towards collaboration (it's not native to the teacher culture)</td>
</tr>
<tr>
<td>2. Experimentation and risk taking</td>
<td>Create a safe environment by providing ample support for learners at a variety of levels</td>
</tr>
<tr>
<td>3. Incorporation of available knowledge bases</td>
<td>Teachers know where their strengths lie as an educator – allow flexibility so that they can start from that strength</td>
</tr>
<tr>
<td>4. Appropriate participant involvement in goal setting, implementation, evaluation, and decision making</td>
<td>Build in means for obtaining feedback from all participants throughout these steps</td>
</tr>
<tr>
<td>5. Time to work on staff development and assimilate new learning</td>
<td>Respect teachers' time; build in funds for release time; be prepared to provide in-class support and modeling of new processes</td>
</tr>
<tr>
<td>6. Leadership and sustained administrative support</td>
<td>Seek to have principal participate in large group activities; nourish emerging leadership among staff; use jigsaw method to create experts</td>
</tr>
<tr>
<td>7. Appropriate incentives and rewards</td>
<td>Make efforts to assure success at every stage; be creative in arranging time for teachers to collaborate</td>
</tr>
<tr>
<td>8. Designs built on principles of adult learning and the change process</td>
<td>Remember the test of practicality; recognize the unique needs of the adult learner</td>
</tr>
<tr>
<td>9. Integration of individual goals with school and district goals</td>
<td>Reflect on the continuums presented above and how those inform individual goals and the support structure for those goals</td>
</tr>
<tr>
<td>10. Formal placement of the program within the philosophy and organizational structure of the school and district</td>
<td>Find the ways technology can support the unique programs of the school; consider what will happen when the collaboration ceases as an active agent</td>
</tr>
</tbody>
</table>

Particular emphasis should be placed on the eighth characteristic, "...built on principles of adult learning and the change process." While the change process was discuss in the preceding section, research from the field of adult learning lends credence to the ability to develop on-site collaboratives that would allow teachers to integrate new information into their existing stage of development. Wood and Thompson (1980) support programs that include experiential learning and informal learning situations in the context of social interaction among participants. The following components comprise such a learning experience:

1. A brief orientation that is followed by participation in a variety of experiences embedded within a real situation. This allows learners to experience and implement the skill, concept or strategy being presented.
2. Reflection on the experience: what was learned, how this can be applied to their particular setting, analysis of the way the experience was presented and extension into the workplace.
3. Opportunity for participants to generalize and summarize this reflection, to provide closure to the situation, and to vocalize principles attained.
4. Opportunity to return to work site to try out new knowledge, principles and to develop confidence in what was learned and its real application.

When applied to a school setting, these four components can be applied within project-centered in-service segments of a collaborative. Teachers are presented with a brief orientation to the innovation at hand and then given an authentic project to complete in cooperative groups. At the end of the session,
teachers return to the large group to share their products and the facilitator leads a bridge-to-practice
closure session that promotes reflection on the experience and extensions to the classroom. Teachers can
then return to the classroom in the interim between sessions to find applications for what was presented. At
the start of the next session, teachers share successes and examples of how they applied the knowledge in
their classrooms. This iterative process of evaluation encourages experimentation with the innovation,
bridging the innovation to current practice, feedback on the implementation of the innovation, and
subsequent modification of methodology in a continual spiral of growth and evaluation throughout the
period of collaboration.

Conclusion

Collaborations between K-12 schools and universities offer tremendous potential for mutual
enrichment. Collaborations that focus on computer technology and its integration into the classroom offer
unique challenges. A number of factors must be considered prior to and during the planning and
implementation stages of the collaborative. The continuums of technological innovations, teacher
development, and teacher acceptance of computer technology can be overlaid to give a multidimensional
view of the complexities of the demands that will placed on the collaborative. The facets of initiating
change in a school environment must be considered before hand and continually revisited throughout the
implementation period. Finally, each presentation of the collaborative needs to be planned in light of
research on successful professional development for educators and the respect for their unique needs as
adult learners. Consideration of these three areas may diminish the opportunities for university faculty to
take pratfalls in their collaborative ventures with K-12 schools.

Abstract: In 1993, the faculty, students, and administrators of Wake Forest University began to develop an outline for what was to become The Plan for the Class of 2000. The University implemented this ambitious strategic initiative aimed at enriching the educational experience of all undergraduate students in the fall of 1996. This initiative embodies the widespread implementation of information technology both inside and outside the classroom. While the technology infrastructure largely is in place, work remains to infuse the use of technology in the educational process. Significant resources are required from all stakeholders in the University to further the development of innovative applications of technology in the classroom. Further examination of every discipline within the University has uncovered creative uses for technology in the instructional process.

INTRODUCTION

Wake Forest University, founded in 1834 by the Baptist State Convention of North Carolina, is characterized by its commitment to a liberal arts education, a strong sense of community and fellowship, its encouragement of freedom of expression and inquiry, and the pursuit of excellence in undergraduate and professional education. The University has made a conscious choice to remain small. In 1993, the faculty, students and administration of Wake Forest University began developing an outline for what was to become The Plan for the Class of 2000 (hereafter, the Plan). The goal of the Plan is to enrich further the University's
undergraduate education through seminars for first year students, an increase in the number of faculty and
information technology support staff, a decrease in class size, additional scholarship funds and financial aid, and
finally, the issuance of IBM ThinkPad computers to all first year students (Fyten, 1995). In the fall of 1996,
Wake Forest University implemented, upon consensus by the faculty, this ambitious initiative aimed at
enriching the educational experience of all students. The Plan has as its centerpiece the widespread
implementation of information technology both inside and outside the classroom. Implementation of the Plan
has resulted in significant amounts of time and resources being expended on technology initiatives by the faculty
as well as the University.

While the ubiquitous presence of computer technology in academe has led to the increased use of
computer-enhanced instruction in the classroom, faculty members are raising many interesting and important
issues across the country. Wake Forest University is no exception. As institutions of higher learning expand
deployment of information technology toward the betterment of the learning process, there is a need to
determine where instructional technologies fit in the higher education curriculum. Educators must have the
ability to discern those activities that might truly be enhanced by the use of technology, identify educational
opportunities that may or may not exist without the use of such technologies and align its use with learning
opportunities in the undergraduate classroom. As expected, some faculty have embraced the use of
instructional technology in the curriculum. Others have taken a “wait and see” attitude or simply languished in
the uncertainty of whether or how to use technology toward the betterment of the learning experience. While the
technology infrastructure largely is in place, much work remains to infuse the use of technology in the
educational process. Significant resources are required from all stakeholders in the University to further the
development of innovative applications of information technology in the classroom. The purpose of this study
was to examine the use of computer technology and issues surrounding its use, inside and outside of the
classroom at one university.

METHODOLOGY

This study examined instructional technology activities within the undergraduate courses of Wake
Forest University. Subjects for this study included faculty members at the University. Data was obtained
through interviews performed by the Academic Computing Specialist (ACS) for each department. As a part of
the technological infrastructure, each department of the University has an ACS charged with assisting faculty in
the implementation of computer technology in the curriculum. The data is valid because the ACS works closely
with faculty members within the particular department and is very knowledgeable about the implementation of
computer technology. Each ACS reported the number of faculty within the department who used technology
frequently (greater than 75% of the time) or occasionally (at least 25% to 75% of the time), or seldom (less than
25% of the time) or never for each category in the survey. Data were collected for all full-time faculty members
(n=369) within the University. Data was also obtained by interviewing faculty that teach in a variety of
disciplines such as religion, English, and physics. These interviews were conducted by three of the authors.

FINDINGS

Faculty members who consider taking on the task of using instructional technology in the classroom
must be willing to revisit their own pedagogy. A tremendous amount of time is required of the educator who
reexamines the curriculum and looks for ways to enhance the learning experience of his/her students. Currently, some faculty members are spending an inordinate amount of time and energy on the integration of
technology in the curriculum. As the administrators of the University encourage faculty to embrace technology,
faculty members face the issues of time constraints as well as the uncertainty of whether or not such
instructional technologies will add real value to the learning environment. The best cognitive theory that
corresponds with the use of such instructional technology in the classroom is constructivism (Chu, 1997).
Constructivist teaching involves learning activities that are more student-centered versus teacher-centered. The hands-on nature of this new learning environment calls into question the more traditional role of the educator.

The role of the educator is changing as a result of bringing technology into the classroom. Some faculty members have expressed that technology has added to their effectiveness as a facilitator of learning. Technology has allowed faculty to maintain better contact and communications with students. Faculty, in a variety of disciplines, are using the resources provided by the University to develop many innovative and timely uses for instructional technology in the higher education curriculum. As a result of the use of technology in the classroom, faculty members noted that students tend to check email more frequently and the course Web site for reading material. Faculty also indicated that students tend to show an increased interest in staying abreast of events in the course. This has led to better discussions on-line as well as in class and has allowed the opportunity to enhance the learning process. The increased use of e-mail inside and outside of the classroom is evidenced (see Figure 1). Representation of total e-mail use for the undergraduate campus at Wake Forest University is provided.

Figure 1: E-mail use by full-time faculty

The use of technology tools such as word processing, spreadsheet, and presentation software is prevalent at the University (see Figure 2). The chart below indicates the use of software/technology as a technology tool at the University.

Figure 2: Use of software by full-time faculty
Faculties resist the implementation of instructional technologies into their courses for a number of reasons. Rosener (1997) found that reasons for not using the computer included the lack of a reward system in faculty evaluation structures, lack of equipment, software and technical support, and lack of compelling reasons to change. Another study (Matthew, et al., 1998) found that faculty concerns about adoption of technology were fear of change, fear of time commitment, and fear of appearing incompetent. Faculty at Wake Forest University echoed these same concerns.

One Wake Forest faculty member felt that any model of learning could be adapted through the use of technology if consideration is given to the course content, its appropriate use, and the enhancement of the overall learning experience. It was also mentioned that while technology might provide a more attractive lecture, it doesn’t mean that it is more effective than the traditional model of delivery. Faculty expressed a positive attitude towards using the technology at times, because it allows for a more interesting class. For example, students can view a slideshow with pictures and sound that provide an opportunity to view the lesson as well as hear the lesson being taught. This proves to be more engaging than relying upon the traditional methods of delivery. Another faculty member expressed concern with the ever-changing nature of technology, citing time constraints and the discouragement of “starting over” as a major inhibitor to adopting technology.

Accommodating the various learning styles and giving consideration to how students process information differently presents additional issues. A faculty member further noted that race, gender, and technological literacy must also be addressed. Given the differences in learning styles, the faculty member provides a grading scale that allows students to weight projects and assignments in such a way as to take advantage of their own strengths. So, if a student feels comfortable putting more weight on an assignment that requires more traditional methods of delivery versus an assignment that requires greater use of technology, the student may do so without penalty. In addition to traditional teaching methods, the Wake Forest faculty employ a variety of electronic resources. Graphical representation of electronic resources used by faculty as instructional tools are provided (see Figure 3).

**CONCLUSIONS**

Of paramount importance to faculty members are the quality of instruction and maintaining that quality as a result of the integration of technology in the curriculum. “New ideas from cognitive science propose the importance of ‘anchoring instruction’ in activities that students find meaningful and ‘authentic’ in the context of their own experiences” (Roblyer, et al., 1997). While there is no evidence to prove that instructional technology has a greater impact on the learning experience in comparison to more traditional methods of delivery, there is
no evidence to disprove the enhancement of learning in a technology-intensive environment. As institutions of higher learning expand deployment of information technology toward the betterment of the learning process, there looms the significant task of creating an organizational move toward the acceptance of IT as an integral and valued part of the University's culture. Inclusion of technology initiatives in the overall culture will validate the significance of IT innovations in the teaching and learning process and evidence that this work is valued and will be rewarded.

As technology has evolved over the years, an important issue has surfaced within the halls of academe. How can constituencies remain attentive to the overarching intent of instructional technology's use in the higher education curriculum and maintain an effective balance to facilitate learning and inquiry among their students? "In education, the combination of process and product merges instructional procedures with instructional tools...Guidance in the application of tools comes from learning theories based on the science of human behavior" (Roblyer, et al., 1997, p. 8). Can one truly exist without the other?

Steps Toward Success: Technology Integration Into a Teacher Education Program

Marianne Handler, National-Louis University
Pennie M. Olson, National-Louis University
Neal Strudler, University of Nevada Las Vegas

Abstract: In order to integrate technology into the preparation of teachers, systematic change must occur. This project which includes addresses preservice faculty and student needs. Higher education faculty are provided professional development aimed at increasing technology use for instruction and for student performance expectations. Preservice students are involved in the development and demonstration of competencies to meet ISTE Foundation Standards for those seeking initial certification.

Introduction

In 1995 the OTA study, Teachers and Technology: Making the Connection, was critical of the preparation of new teachers in the uses of technology in teaching. The researchers in that study found that technology use was not central in the preparation experiences in most colleges of education. As a result, most new teachers are ill-prepared to integrate technology-based experiences into their professional practice. Thorsen and Barr (1997) report a significant challenge is the identification of technology “need-to-know” or identifying the skills and knowledge teachers need and how to test and verify that knowledge. This is not a surprising nor is it a new observation about the use of technology in teacher education programs. We believe it is safe to say that many, if not most, teacher education programs fall far short of what needs to be done to prepare new teachers for the classroom environments in which they will be working. A variety of efforts have been put forth toward helping students become better prepared technology users. Often these efforts are built on what has become known as ‘the required computer course’.

The authors believe it will take far greater efforts to make institutionalized change occur in the preparation of preservice teachers. This change must occur as a systematic process within the environment in which the future teachers are prepared. All the stakeholders need to be prepared to move the plan forward; there must be administrative support, education faculty need to be assisted as they reconsider the teaching strategies and materials they use to present the content to students, supervisors and cooperating teachers must be made aware of the expectations for the preservice students with whom they are working and these students need to understand the technology competencies to be mastered during their preparation as teachers. It is important that all of those involved in the program have a vision of what is to be accomplished and specify ways in which technology-based experiences will support that vision (NCATE, 1997).

Need To Move Integration Implementation Forward

The numbers of computers in P12 schools increase every year. Expectations that practitioners will be able to incorporate technology use into the classroom and enhance learning environments are widespread. A current concern is the lack of preparation of preservice teacher candidates to use technology in their teaching. Changes in two professional organizations have had an impact on integration efforts. The ISTE Foundation Standards were first introduced in 1992 and revised in 1995 (Wiebe & Taylor, 1997). These provide a set of competencies that all new preservice graduates should achieve. The National Council for Accreditation of Teacher Education (NCATE) also revised their precondition standards to call for a greater emphasis on technology use. In 1995 NCATE modified its general unit guidelines to require that all teacher education candidates complete a “well-planned sequence of courses and/or experiences” that help develop understanding and use of computers and related technologies for teaching and learning (Thomas, 1995, p.
For many colleges seeking NCATE accreditation, the ISTE Foundation Standards provide a framework for addressing the new technology-related unit guidelines.

Our prior work with the model suggests that a critical first step in implementing technology integration into preservice programs is obtaining the commitment of faculty involved in those programs. Faculty have always enjoyed great autonomy and, in addition, each faculty member has differing levels of comfort with the technology and interest in using it (Horgan, 1998). A key ingredient in helping faculty through this process is to blend learning the use of specific technology tools with an understanding of how it can improve teaching and learning. Professional development opportunities are needed for existing faculty to learn about the technology itself and then learn how to integrate relevant experiences into their teaching plans (U. S. Congress, 1995).

Students, too, are demanding technology experiences. They know they will be expected to use a variety of technologies in their work as teachers. In addition, few have had any experiences seeing technology modeled by their teachers during their school experiences. It is critical that faculty move toward integrating technology into their teaching so students have opportunities to acquire knowledge through observation. Lortie (1975) told us that teachers teach as they were taught. They need to move from learning in the lecture method to learning in an engaged learning environment that allows them to construct knowledge (Gunter & Lee, 1997). This college experience may be the only time that these students see technology use modeled and valued by an instructor.

How, then, can colleges of education help their faculty to revise and revision their approach in content area courses and make best practice use of technology tools available to them? What kind of assistance needs to be provided to education faculty to make this complex transition in their own teaching?

A Systematic Model

First Efforts
Handler and Strudler (1996) proposed a model based on the ISTE Foundation Standards. This model provides a framework through which faculty select the appropriate technology-based experiences for their courses and indicate the ISTE Standard to be met through these experiences. Many colleges of education have a required introductory educational computing course. This model assumes of the existence of a course in which students are introduced to the concepts and tools referred to in the standards. After students complete that course, faculty may expect that students possess certain basic skills and knowledge. Thus, in content area courses, instructors will not need to teach about the technology but will provide experiences to help students teach with the technology.

Implementation of the model should provide the full range of experiences required to meet the Foundation Standards while not putting an excessive burden on any one department or faculty member. The first step in the model has faculty working with a matrix showing the ISTE Foundation Standards on one axis and the courses in the preservice program on the other. Faculty identify the particular standards that can be reasonably met within their particular courses. This distributes the responsibility across all areas of the program. The second step is to identify the family of software that will be used to meet the goals. That is, they choose between presentation software, word processing, hypermedia, telecommunications tools and other generic areas. Lastly, specific activities are designed along with methods of assessment for the content and the technology skill. The model was piloted by Handler and Strudler at their respective institutions (National-Louis University and University of Nevada Las Vegas) and needed areas of additional support emerged from that effort (Strudler, Handler, & Falba, 1998).

Next Steps
At this time the University of Nevada Las Vegas does not have a formal effort in place to further implement the model. Serving the fastest school district in the country, UNLV has been confronted with the challenge of dramatically increasing its output of teacher education graduates. Under great political
pressure to meet this need systematic efforts in technology integration has not been a primary priority in the college of late. Current support efforts include working with individual faculty and interest groups.

National-Louis University however has made a commitment to support further implementation of the model and take a more systematic approach. National-Louis University (NLU) is able to take a more systematic approach. One of the key issues that emerged from earlier efforts is the awareness of the very broad continuum on which faculty members' technology skills lie. Some are very interested in technology use and are active personal users but have very little awareness of the materials available to meet their instructional or content area needs. Others are those faculty who rarely, if ever, touched a computer. Many faculty themselves do not yet have the skills identified in the ISTE Foundation Standards for beginning teachers. As we know from work with classroom practitioners, knowing 'how to use' the software does not mean a knowing of 'how to integrate these tools into a lesson'. This is also true of higher education faculty.

This paper delineates effort to move the model forward at National-Louis University while addressing issues raised as a result of the first efforts described by Strudler, Handler and Falba (1998). These include the need for strong administrative leadership, support for faculty as technology use is integrated into their own teaching, and access to resources. Work with faculty during this project will encourage the development of opportunities for students to recognize and demonstrate their own competency.

National-Louis University

Several factors influenced the timing for this NLU commitment. We are under the leadership of a new president and the technology infrastructure is receiving more attention than it has in the recent past. The National College of Education is in the midst of preparation for NCATE approval. The dean is highly supportive of processes that will assist the integration of needed technology experiences into our preservice programs. A considerable portion of Handler's teaching load was assigned to this effort. This use of faculty as resource is one important indication of the administrative support.

This integration effort has several strands developing concurrently. The first or faculty strand will address the need for development of faculty technology competencies, the infusion of technology experiences into their own teaching and their learning to work with the Technology Competency Database (TCD). This database will be more fully described later in the paper. The second or student strand is structured to document their mastery of the ISTE Foundation Standards. These strands are linked through course presentations, assignments, and activities that provide opportunities for students to apply the technology skills they are learning.

The Faculty Strand

The first full-day teacher education faculty retreat was held in November, 1998. The goal of the day was to involve more college faculty in moving the integration process forward. The coordinator of the elementary education programs and of the technology in education program designed the retreat agenda. Thirty faculty members were invited to participate; two from each of the courses offered in the elementary preservice program. Many participants were confident as personal technology users. Some were already providing technology experience within their courses. Others were willing and interested but unsure of themselves in the area of technology use. Invitations to participate were issued from the dean and responses were collected through her office. A Friday was selected as most faculty were available on that day. The second notices, also sent out by the dean, indicated meeting place, included an agenda and requested each participant to bring a copy of a recent syllabus. To brighten the day a continental breakfast and lunch were included.

A three-ring binder was developed for use during the day. This type of binder was chosen to encourage a 'we will be adding more as we go' way of thinking about the process. Sections of the notebook included all standards and forms, master course outlines and syllabi, articles on tools supporting student activities, faculty support materials, printouts from the Technology Competency Database (TCD) and a variety of
professional readings. The last item in the notebook was a form that could be copied and sent to Handler for additional support at any time.

After reviewing earlier efforts related to the model, the revised ISTE Foundation Standards were introduced along with a group introduction to the Handler/Strudler model. Based on courses taught, faculty were assigned to small groups. Their task was to match ISTE Foundation Standards to existing master course outlines and individual instructor syllabi while looking for student learning opportunities related to the standards. The model offers two possible choices in that task; that a standard will absolutely be met in all sections of that course or a standard might be met in that course. As expected not all of the standards were selected. They were entered into a matrix in order to identify overlaps and missing links. We are now placing the results on the computer and preparing to send out the list for its next round of selections.

A next step was for each group to consider technology-based lessons that could be woven into their syllabi as well as what teacher-led instructional experiences might look like. A second matrix listed the types of software that might be used in activities to address the selected standard. The categories (hypermedia, integrated packages, desktop publishing etc.) were listed with current example software (HyperStudio, ClarisWorks, Adobe PageMaker etc.). This list with its examples presented real difficulty and great discomfort for many participants. They were not familiar with some of the terms and many of the software titles. It was interesting to see how faculty members involved considered changing the standards identified once they had to think about creating the activities. It was a strong reminder of the necessity to move slowly through this process and of the great disparity along the continuum of faculty ability. This range of ability levels was also an issue in the earlier studies.

The third step of the day was to consider and create activities that would be appropriate for specific courses. Small groups used the activity forms provided to describe new and current practice that address the standards. Participants requested a database of all current activities be made available. There was great satisfaction within the group at the number of efforts already in place. During this time faculty also worked with the facilitators at the computer. They wanted to see several available programs which were unfamiliar and to visit particular web sites that had been demonstrated or described.

An important consideration emerged during this working time. It was sometimes necessary to help participants remember that technology was NOT the focus of the activity. The focus was the content or learning goal as always, but the road to that goal made use of a technology-based experience. There was a strong tendency to focus on what the technology DID rather than how the tool could HELP to meet the lesson objective.

An ongoing element was a shared discussion of major issues to be dealt with as part of program implementation. These included expected topics such as overlap of competencies in multiple courses and ethical and legal use of materials from the World Wide Web. Other issues, unique to our college, such as sessions for adjunct faculty and how faculty and adjuncts would work with the Technology Competency Database also emerged. Following the retreat faculty interest and efforts have continued to move forward. Faculty who teach an undergraduate foundations course have met specifically to think about how they can move forward in this area. In addition one of the facilitators is meeting with individual faculty members on presentation software and using the WWW in their courses.

The Student Strand
A pilot group of 65 preservice students were introduced to the competencies that the ISTE Foundation Standards have set as minimal requirements for all preservice graduates. The college of education plans to put this requirement in place for all graduates of elementary education programs. The Technology Competency Database (http://lrs.ed.uiuc.edu/tcd/), developed by Levin and Waugh at the University of Illinois, is the instrument that has been adapted for use in this pilot (http://192.217.49.150:591/testdb/TCD.html). This instrument provides opportunity for students to identify ISTE competencies they have met and submit evidence demonstrating their competency in that standard. These entries are then
reviewed by faculty. There is discussion of extending the use of TCD into other initial certification programs.

All students in the pilot are graduate students in an elementary education initial certification program meeting in a cluster (or cohort) format. They were introduced to the database for the first time during their initial practicum experience in Fall98. Undergraduate students will begin to use the database during a required technology course Winter99. Opportunities for the development of competencies will be provided in class experiences throughout the program. Students will be encouraged to continually update TCD documentation as they develop greater knowledge of and comfort with appropriate software. Our goal is for the students to place evidence of their technology competencies in the portfolio that is a program requirement.

Conclusion

The success of such projects rests on faculty ownership of its importance for students and student acceptance of the value of these experiences. Ongoing administrative support will be required to maintain the level of assistance faculty will need for several years to come. At the end of this year we will collect data from the faculty to determine what additional support and efforts will be needed to truly institutionalize this integration process in our college. We will also collect information about the development of student competencies. These data will also help us to provide a model that will help other institutions in these same efforts.

As we continue our work this year one-to-one support is available to faculty as needed. They will be provided advice on how to continue the process and how to evaluate technology-based experiences in terms not of content but of meeting the competency requirements as well as opportunities to develop their own competencies. Several meetings of retreat participants will be held during the remainder of the year.

Continuing questions plague this particular endeavor. How will faculty be provided time to learn the various applications available to them? Will there continue to be administrative support of faculty in a consultative role? As faculty become more expert in utilizing technology in their teaching will resources be available for classroom use? Who will oversee new activities developed within each of the courses? Who will oversee that every faculty and adjunct are providing these experiences to the students in their classes?

Additionally, much work still needs to be done in the area of the TCD. Administrative support for the web administration remains a programmatic need. How will sufficient access for all students be provided within the frame of current resources? For faculty there are other questions. Who will introduce the competencies to students and in what context will this be done? Who will accept or reject student submissions? Who will monitor overall progression for each individual student? How will the faculty become comfortable with the criteria for making judgments about student submissions? How can faculty expand opportunities for competence for both themselves and their students?

Endeavors such as ours exemplify opportunities for teacher educators. In this environment faculty can develop needed technology skills as well as learn to integrate appropriate technology experiences into their instructional settings. Through the use of the Technology Competency Database our work also encourages the development of these same skills among the preservice students.

Abstract: America's educational system of the 21st century brings about new challenges for teachers. Integrating technology into the curriculum, developing and implementing effective teaching strategies, and responding to student learning styles are a few of the challenges. Until recently, preservice teacher education, schools, colleges, and departments of education were considered to be lagging behind in meeting the needs of developing technological competencies (Walters, 1992). Consequently, the course Diversity in Educational Settings was designed to emphasize six instructional goals and performance objectives. Throughout the course students engaged in several activities, that fostered the idea of integrating technology into class assignments. Cooperative groups were self-directed and managed. The course expectations challenged students to become creative and explore issues of diversity and technology. Students created materials for a particular audience from K-12. All materials promoted student's engagement, motivation, higher thinking skills, and assessment of their learning.

America's educational system of the 21st century brings about new challenges for teachers: integrating technology into the curriculum; effective teaching strategies, and responding to student learning styles. Until recently, preservice teacher education, schools, colleges, and departments of education (SCDEs) were considered to be lagging behind in meeting the needs of developing technological competencies (Walters, 1992).

Technology competencies challenges are divided into two major categories: 1) strengthening the capacity of SCDEs to prepare teachers to use instructional technologies and, 2) developing models and materials (Abdal-Haq, 1997), as a part of the Teacher Education Programs across the country. Since 1995, the use of technology in classrooms demands technology training of teachers. Teacher Education Programs are responding to the recommendations of the National Council for Accreditation of Teacher Education (NCATE) implementing new unit standards which were recommended from the International Society for Technology in Education (ISTE) which ultimately challenges both teacher preparation programs and K-12 classrooms. These standards addressed content and pedagogical studies for strengthening the capacity of preparing teachers to use instructional technology.

Experiential/Action Learning

EDC 300 and 501 Diversity in Educational Settings are based upon a revision of the Experiential/Action Learning Model (Allen, 1996). This model promotes the infusion of technology while enhancing the students' knowledge and awareness of cultures. Both undergraduate and graduate teacher education students participate in team projects in which they use several multi-media technology to integrate into instructional strategies while learning about issues of diversity.

The model focuses on the learning process that combines concepts from observational learning (Bandura, 1986) and teaching and learning of skills and procedures (Allen, 1996; Beyer, 1987 & 1988). Bandura (1986) postulates four important elements to effective observational learning: 1) paying attention; 2) retaining information, 3) producing and reproducing behaviors, and 4) being motivated. Therefore, it is important for students to observe a behavior and have both the motivation and opportunity to reproduce the behavior (Allen, 1996). Students also need an opportunity to demonstrate an acquired skill through guided practice and receive direct and immediate feedback.
Experiential/Action Learning Model

Students learn best through active involvement. Their retention ability increases if they engage in the following sequence of steps: 1) observe demonstration of skill or usage of skill; 2) be given an opportunity to practice both in group and individually; 3) be given critical/specific feedback; and 4) re-define and/or refine skills and what they have learned before passing on or sharing information with others. Teachers must also become reflective of teaching strategies, learning styles and student assessment which promote effective change in the teaching and learning cycle. These changes suggest altering, enhancing, and developing effective approaches in order to educate students.

Application of the Experiential/Action Learning Model for EDC 300/501 Diversity Course

- Observation of the use of varied technology during class instruction
- Formation of heterogeneous teams
- Designed rationale for their choice of cultural investigation
- Team investigation into the culture with the objective being to gain awareness and understanding of the culture for the purpose of being better prepared to teach students of that culture
- Team work to develop a unit and resource manual of their selected culture. The use of technology was integrated into their presentation
- Created four interactive learning centers for multicultural fair with the use of technology
- Each team taught their unit, learning centers, and presented in the multicultural fair, demonstrating their skills integrating technology into presentation and demonstrating their understanding and awareness of diversity and discovering effective strategies for an inclusion classroom. (This model is adopted from Allen, 1996)

Technology

In EDC 300/501 Diversity course the context goal of technology and education, are focused upon five pedagogical competencies critical to the development of responsive, reflective, effective teaching of teachers: 1) engaging and motivating students in learning; 2) designing instructional experiences that integrate technology into the curriculum; 3) understanding and using technology to access, process and share information; 4) using technology to enhance higher order thinking skills; and 5) assessing student performance (O’Donnell Dooling, 1997). These five competencies can be transformed into classroom instructional goals for the purpose of providing opportunities for students to become technologically literate.

Course Instructional Goals

According to Pina, 1993, to use technology in support of student learning, regardless of access levels, preservice teachers must have sufficient understanding of and confidence in various technologies, assessing and using them effectively for instructional purposes. Consequently, the course Diversity in Educational Settings was designed to emphasize six performance objectives: 1) Understand and use technology to access, process and share information; 2) design instructional experiences that integrate technology into the curriculum; 3) learn to select instructional materials that are free of bias and stereotyping; 4) develop skills to help view other people as having equal worth and dignity regardless of their backgrounds; 5) learn problem-solving skills for effective communication; and 6) learn strategies that address learning styles of students.
Range of Technology Usage in the Class Presentation Project

Throughout the course, students engaged in several activities that fostered the idea of integrating technology into class assignments. Cooperative groups were self-directed and managed. The course expectations were shared with the students, which challenged students to become creative and explore issues of diversity and technology. Students were expected to create materials for a particular audience from K-12. All materials promoted student’s engagement, motivation, higher thinking skills, and assessment of their learning. The groups ranged from high technology literacy to limited technology literacy.

A criterion list of activities and technological use was provided for the students. High tech groups integrated several types of technology usage throughout their class presentation. Three groups in particular demonstrated extremely sophisticated and effective usage of computer technology with their group presentation. These groups used PowerPoint, the internet, and web sites to involve the class in discovery of a country’s macro-culture, language, art, music, location, educational, political and social systems, and many other facts regarding the country. One group also included an e-mail learning center between Cleveland State University and the International School in Cyro, Egypt. Students of the diversity class were able to engage in dialogue between teachers and classrooms in Egypt and those at the university site. Another group created a chatbox site between an elementary school in the Caribbean Islands and themselves. A great deal of cultural exchange took place; students explored philosophies of education and implementation of instructional strategies. The third group connected with a missionary pastor from South Africa who was travelling to the United States and would be stationed with several Lutheran Churches in Ohio. The pastor was invited and accepted the invitation to speak at the university regarding the political, social and education systems of South Africa today. These groups demonstrated advanced technology skills and their ability to assign appropriate use with instructional goals.

The limited technology groups usage ranged from the usage of overhead transparencies to display boards. Most of the groups used overheads to emphasize important facts and information. There was a significant usage of videotapes to either show, explain or stimulate thought regarding a countryside, culture of the people or issues, art and drama and classrooms. Some groups developed videos to document their group experiences while participating in a field trip (i.e. restaurant, museum, city or street tour, church, temple, mosque) and/or an interview with a particular person or people. The class found these tapes to be most rewarding because it was similar to hands-on or self discovery. Audio equipment (tape recorders and CD-ROM) were used frequently. They were used to hear native language(s), national anthems, and different types of music (traditional and contemporary).

Conclusion

A wide range of abilities emerged (high technology literacy to limited technology literacy) from cooperative groups using the diversity paradigm definition to compile heterogeneous groups. A criterion list of activities and technological use was provided for the students. High technology literacy groups produced extremely creative materials with great emphasis on technology, while other groups created projects with the standard/traditional equipment that was most familiar to them. Some groups lacked a basic understanding of effective technology use in the classroom.

TECHNOLOGY AND CHANGE IN EDUCATION: CULTURE IS THE KEY

Joel S. Levine
School of Education
Barry University
U.S.A.
Email Jlevine@mail.barry.edu

Abstract: The benefits of technology in education will not be fully realized without the focus on cultures that may potentially embrace them. Cultures encompass values, norms, and beliefs that normally protect these cultures from being significantly altered or destroyed. Leaders and stakeholders can create structures and collaborative environments to foster learning, innovation and change. These empowering and supportive environments will foster modification of values, norms, and beliefs that will allow its cultural members to effectively integrate technology into their curriculum. Transformed cultures will be able to develop the capacity for change, which leads to beneficial improvements, including those which involve technology.

Introduction

Over the last thirty years there have been numerous attempts to bring about reform or change in educational institutions. Many of these attempts have failed because the focus was on the change itself, not on the needs and outcomes of the institutions and their clients as reflected by their cultures. We cannot continue to promote change for sake of change and we cannot mandate change (Fullan, 1992). In a similar way, we cannot mandate the use of technology in schools and classrooms. Technology has significant benefits for teaching and learning, but we can’t simply utilize technology for technology sake in order to satisfy political agendas that do not benefit students. Once again, the culture of the school is an important key for the acceptance and appropriate use of selected technologies. The technology, which is selected, needs to fit into the cultures’ structure, goals, curriculum, and activities not vice versa.

Culture and Change

The word “culture” has different meanings for different people. The definition of culture in Webster’s dictionary, that most appropriately fits this discussion, reads “the concepts, habits, skills, arts, instruments, institutions, etc. of a given people in a given period.” This definition does indicate that cultures do change, but they also reflect all the characteristics and attributes that make them distinctive. Individuals may significantly represent or display their cultural heritage. The recent focus on culture in social and educational arenas involves diversity issues. Educational institutions are pursuing viable mechanisms and structures for recognizing and accommodating individuals from diverse cultures. These initiatives will usually enhance the existing cultures, but we need to focus, once again, on a culture’s ability to change. This involves both cultures, the one being adopted (the adoptee) and the one that is adopting (the adopter) the other. However, we must not lose site of the pecking order, since the adopter culture must survive at all costs.

There are many other kinds of changes that will impact cultures. These include social, political, economic and technological trends and events. In order for a culture to survive, relief of stress and resistance to change are important concerns (Hodas, 1993). Unfortunately, as Lorsch (1986) has pointed out, the culture of an organization can create an invisible barrier to change. A deeply held set of values and norms often
produce a strategic myopia, meaning that members may miss the significance of external events and may be blinded by their strongly held beliefs (Fung, 1992). As a result, decisions and actions not only reflect the organizations' culture, but are constrained by it (Fung, 1992). Since most cultures are well established, changes that may occur, require commitments, take time, and need to be strategically integrated. Hence the most important changes are the incremental ones (Pogrow, 1996). The effective use of technology in schools throughout the country can only be accomplished if leaders and teachers strategically initiate and support changes to modify or re-shape the existing cultures(s) in their schools.

Leaders, Technology, and Cultural Change

Educational Leaders, especially new leaders, cannot approach technology integration or any kind of change as if the institution had no history, values, norms, rituals and ceremonies (Simpson, 1990). They can facilitate changes in their schools and school districts by re-shaping the cultures of those schools or the school district. This re-shaping involves the modification or changing of people's beliefs and values. It also involves changing school norms, which define what teachers are supposed to be and do, how children are supposed to behave, and what constitutes an appropriate and fair set of expectations for a subject (Eisner, 1992). These norms are sometimes converted and shape attitudes, create inequities, and often reproduce the inequities of the society at large (Apple, 1982, Giroux, 1989). This reflects what Pierre Bourdieu has called "cultural reproduction". Often educational leaders find it very difficult to bring about change, which significantly conflicts with beliefs, values, and norms reflected in the schools' culture or reflected in the culture of the community where the school is located. It is fortunate that technology has finally been accepted as a useful tool in many communities, but often community members and educators are not convinced of its role and benefit in schools.

Leaders need to address the reluctance to change and the need to change as seen by community members and educators. In order to address these issues, leaders need to begin a strategic planning process that would involve all stakeholders. These stakeholders would be asked to discuss educational issues that would result in viable solutions that may alter the current culture, particularly its norms and values. This process would also insure that the leader would not impose his/her values and assumptions on the culture and possible improvements (Schein, 1992). Questions that would flush out these educational issues would include:

Who are we?
Who are our clients?
What are our client's needs?
How can we best provide for those needs?

As discussions and interactions take place, cultural members need to deal with assumptions, perceptions, and expectations that may not be accurate or realistic. In addition, various social, political, and economic concerns will impact the proposal development and implementation of certain educational solutions. Educators and other stakeholders need to review research and understand the possible solutions and strategies to these questions in order to buy into the need and feasibility of these changes. The strategic planning process would hopefully yield valuable information in three critical areas for changing organizational culture:

1.) Content of the change – the vision of the new culture
2.) Leverage points for change – what and how to change
3.) Tactical choices – when and where to change (Nadler, Shaw, Walton 1994).

The strategies and support mechanisms that will enable them to be successful will determine acceptance of these changes. When educators and stakeholders actually see and experience the benefits of these changes, they will officially embrace them.

Educational leaders should guide the strategic planning process to insure that some structures, policies, procedures, and practices will be put in place to support modified norms, values, and beliefs. Educational leaders would then employ strategies to insure that these changes are realized. Most significantly the process of change needs to encourage appropriate structure, collaborative environments, and teacher empowerment (Simpson, 1990, Fullan, 1995, Lieberman and Miller, 1990). First of all, technology can be
effectively integrated into a structure that supports a variety of instructional content, teaching strategies and activities to accomplish a variety of student learning outcomes. These structures support the time and resources for professional development and the subsequent design, development, and implementation of instructional activities. This can involve changes in decision-making committees, developed planning documents, policies, procedures, roles and responsibilities, scheduling, and other functional operations, services, and utilization of resources. Second, collaborative environments allow many different teachers and outside partners to utilize their collective expertise and experience in order to design, develop, and implement instructional curriculum that utilize technology tools effectively. Teachers can benefit from shared experiences, ideas and decisions. Finally, teacher empowerment can allow teachers to become continuous learners, innovators, and experts in the change process within an environment that allows for validation, affirmation, vindication, and self-actualization. An environment free of fear, threats, and anxiety allows for creative and innovative uses of technology in classrooms and schools. Educators need this kind of supportive environment as they accept the challenge to adopt a particular innovation and move at their own pace. They will probably move through eight levels of use (behavior):

1. nonuse
2. orientation
3. preparation
4. mechanical use
5. routine
6. refinement
7. integration
8. renewal (Hord et al., 1987).

In addition, they will probably move through six stages of concern (expressions):

1. awareness
2. informational,
3. personal management
4. consequence
5. collaboration
6. refocusing (Hord et al. 1987).

Educators, learning to integrate technology into their curriculum, will probably move through these stages and levels until they feel very comfortable and confident. Healthy cultural environments, that are maintained and updated by educators in their schools, will foster beneficial changes for students and teachers, including those changes that make beneficial use of technology.

Wrestling with the Bear: A School of Education's Struggles to Comply with Current NCATE Standards on Technology in Teacher Education

R. Bruce Lewis, Ed.D., School of Education, Freed-Hardeman University, USA, rblewis@fhu.edu

Abstract: In late 1997, the NCATE review team strongly encouraged more and varied integration of educational technology into the Freed-Hardeman University's School of Education's courses and into the actual teaching of the courses by the established faculty. Since that time, the author has been charged with the responsibility of integrating a variety of technology programs and projects into our classes, both through the work of the students and as modeled by the instructors. But this has not been an easy task, for while the School of Education has the largest number of majors of any school on campus, the financial commitment toward newer computers and advanced software for education has been difficult to obtain. NCATE seems to be insensitive toward these types of problems, particularly in smaller colleges and universities.

After finishing his dissertation in Instructional Technology, the author was offered the opportunity to work with the School of Education at a small, religiously-affiliated university. Just months previously, the NCATE review team had strongly encouraged more and varied integration of educational technology into the School of Education's courses and into the actual teaching of the courses by the established faculty.

The author inherited a small, out-of-date computer lab of about 15 Macintosh Performa 467s, along with a variety of older Apples, most of which were in the "parts" bin. Soon after the end of the summer term, the Director of Academic Computing managed to arrange for the lab to have 15 new PCs running Windows 98 and MS Office 97. While these new machines were a welcomed addition, they came with a price tag almost out of reach - 10 of the Macintoshes were lost to another lab on campus. The current status of the School of Education's Technology Training Center is 15 new PCs and 5 out-of-date Macintoshes.

As one can imagine, the size of the class that might work in the lab is extremely limited with this type of configuration. No one wants to work on Macintoshes that won't run the newest PowerPC software, such as MS Office 98 for Mac, plus these machines are extremely slow. Clock speeds in the Macs are approximately 25 MHz whereas the new PCs are 300 MHz processors with 32 megs of RAM. Part of this dilemma was solved by working with smaller sections of some of the larger classes and by having comparable software, to an extent, on all of the machines, particularly when designing webpages and researching on the 'Net.

Additionally, it became the author's task to allay the technology phobias and apprehensions of the current tenured faculty, while encouraging them to experiment with the technology in a non-threatening environment. What became immediately apparent in the fall 98 course discussions was that most faculty members were aware of MS PowerPoint as a presentation tool, but had little practical experience using it themselves in the classroom. Further, they did not have the expertise to instruct their students in its use, nor did they have the knowledge of how to evaluate the student's work in this area.

The author's observation that MS PowerPoint seemed to be the almost exclusive technology tool used in the School of Education classes had been observed by the NCATE review team as well. The author, because of his extensive background in Instructional Technology from Dr. Charles Dickens, Assistant Professor at Tennessee State University, Nashville, offered a variety of suggestions of alternative technology components and offered the expertise and the computer lab time necessary to teach these new technologies to the School of Education students enrolled in fall classes, both undergraduate and graduate. These suggestions were readily accepted by the tenured faculty members!
As the various classes have been instructed by the author in the chosen technology components, the response from the faculty has been encouraging. A wide variety of student technology projects have been accomplished and hosted on the web at http://teach.fiu.edu/technology/. The students are becoming more comfortable with the technology and the teachers are seeing the tremendous benefit to their courses of the technology-based projects. Several teachers have acknowledged their lack of familiarity with the technology and have asked for private tutorials from the author.

There is widespread belief among the school of education faculty that the next NCATE team (Nov. 99) will be pleased with our progress of integrating a variety of technology programs and projects into our classes, both through the work of the students and as modeled by the instructors. But this has not been an easy task. Our current plans are to replace the 5 aged Macs with modern Macintosh G3s. We also intend to have a full computer lab of 15 PCs and 15 Macs. Next would come the software necessary to do the technology projects envisioned by the faculty and staff. While the School of Education has the largest number of majors of any other school on campus, it does not control the purse strings and our Dean will earn his pay getting our lab up to full strength, something that NCATE seems insensitive toward, particularly in smaller colleges and universities.

NCATE's Current Standards for Technology and Teacher Education, available online at http://www.ncate.org/projects/tech/currttech.html, lists five areas of accreditation standards with expectations for knowledge and use of technology among students and faculty. In addition to these standards for the entire school of education, NCATE recognizes three sets of technology standards for use in accredited institutions: the International Society for Technology in Education (ISTE), the Association for Educational Communications and Technology (ACET), and the International Technology Education Association/Council on Technology Teacher Education (ITEA/CTTE). Also, new standards for educational administrators, recently developed under the auspices of the National Policy Board for Educational Administration, include specific expectations for the use of technology in instruction, evaluation, and administration, according to NCATE.
The Virtual Learning Technology Community: Creating and Sustaining Professional Development for K-16 Learning Communities.

Mona C. Majdalani, Robert E. Hollon, Susan R. McIntyre
Curriculum and Instruction
University of Wisconsin-Eau Claire
United States
majdalmc@uwec.edu  hollonre@uwec.edu  mcintsr@uwec.edu

Abstract: Two years ago, the University of Wisconsin System, the state legislature and a number of businesses combined resources and provided funds to support regional and local projects to develop self-sustaining professional development models. Through a grant from the University of Wisconsin Extension PK-16 Initiative, a regional consortium of preservice teachers, K-12 educators, Cooperative Education Service Agencies' staff (CESA), and university teacher educators was established. The grant is in its second year and was redesigned to meet the needs of a broader range of K-12 teachers, preservice teachers, and teacher educators.

Historical Context

The Virtual Learning Technology Community (VLTC) is a three-year project in which the goal is to establish and support a community of regional institutions actively engaged in using existing and emerging technologies to support learning by all members. The project includes several phases that are described below. In practice, the phases overlap, allowing for flexibility in establishing and supporting the community.

In Phase I, which coincided with the onset of year one of the project, activities focused on the identification of personnel, the definition of the roles and responsibilities of each member, and identification of the technology needs of teachers in the target region. Also during phase I, the project web site was created to provide visitors (namely teachers targeted but potential interns as well), among other things, access to a listing of a range of technology related graduate course offerings and workshops of interest to the participants. The web site's URL is: http://www.uwec.edu/academic/CI/vltc/vltc.htm At the same time, teacher educators began identifying potential intern applicants to recommend to the respective schools for interviews, and purchasing the technology equipment necessary to support the interns.

In Phase II of the project, attention was directed toward the establishment of links between the VLTC and Regional institutions. At this stage, school sites where teachers were working with technology were identified. Interns were placed with two teachers so the teachers could be released to work on some technology innovations for their respective districts, schools, buildings, or classroom. The interns added some technical expertise, but were also working with the teachers to learn new ways to implement technology in their classrooms. At the same time, teachers, K-12 students, university students, and university educators were developing and participating in courses and workshops in preparation for year two. Those focused on topics such as Instructional Television (ITV and local networks), Computers in Education: On-line Communications and Information Retrieval, Information Literacy, Instructional Design and Development, Technology Gadgets, Creating Multimedia Productions, Distance Learning Networks, and Web Design.

Phase III involved strengthening links among the regional PK-12 schools. It extends and empowers the social context supporting the risks and growth associated with changing teaching and learning paradigms. Through a variety of mechanisms, VLTC participants will share their developing knowledge of current regional projects,
establish communications, and publicize ongoing efforts. These avenues are important because they encourage participants to think about technology as a tool for learning subject matter rather than just learning about technology.

Phase IV will emphasize supporting new projects impacting students in VLTC schools and helping all projects become self-sustaining. Two new projects have emerged as the result of the existing VLTC activities. The Technology Mentors Project (described below) blends staff development in a single large district with opportunities developed for teachers in smaller schools. The Fast ForWord project will bring preservice students, teachers, and university researchers together to examine the efficacy of a web-supported reading remediation program.

Once fully established, the VLTC has a high probability of becoming self-sustaining as members develop shared projects and learn to rely on each other for support. VLTC will support participants' efforts to find new resources, disseminate new knowledge, and extend their expertise to additional PK-12 schools. VLTC will coordinate activities in which participants identify opportunities to continue to work together to develop new and spin-off projects that expand the impact on learners (e.g., parents of students in the K-12 schools, faculty instructors for student teachers and graduate students in the K-12 schools.)

Supporting Staff Development in Rural Schools through Virtual Communities

Affecting change in education requires a change in culture and the consideration of alternatives to the traditional in-service workshop model to teachers and more specifically to those in remote areas. A major goal of the VLTC is to develop distance learning models that are viable for teachers in remote sites. VLTC members have participated in activities ranging from face-to-face hands on workshops to web-supported curriculum design to full-motion distance education courses. The array of offerings included Instructional Television [as a teaching tool (27 teachers at 4 sites participated using the local network)], Computers in Education: On-line Communications and Information Retrieval, Information Literacy, Instructional Design and Development, Technology Gadgets, Creating Multimedia Productions, Distance Learning Networks, and Web Design. Alternative delivery modalities were also explored. Some workshops presented new technologies to the traditional audiences of teachers. Other workshops used traditional workshop formats with traditional audiences of teachers. Some workshops have had blended attendance of students, teacher, and teacher educator participants learning together using traditional workshop format and others with blended attendance using new technologies.

Teachers are putting new knowledge to work in their classrooms. For example, two second-grade teachers are collaborating to build a link between classes separated by 120 miles. They are using Nicenet and video-conferencing to foster an interchange of ideas among students and teachers. Each site's second grade students started by using the digital camera to take pictures of each other to send them to the other end via the web. This example illustrates the extension of the community of learners across schools, regions, and cultures. Additional activities stemming from VLTC supported interactions include the use of the Internet by middle school students to study the Arctic Challenge and first grade project using Distance Education help primary grades students meet their peers in another remote school district.

Through the experiences described above, the cadre of teachers guiding students' activities develop knowledge, skill, and confidence enabling them to serve as role models and support systems for others. Some will adopt other teachers and assume mentor roles. Others will continue developing their own projects to better understand ways in which technology is impacting students in their classrooms.

Emerging Virtual Community Activities

Some VLTC projects are long-term efforts to build new communication structures linking preservice teachers with mentors in the building, university supervisors, and peers in other schools. The Video Conferencing Support for Student Teaching Project is exploring the role of low-cost video-conferencing to increase supervision possibilities and to link student teachers in remote areas to their campus and to their classmates.
Four options for video conferencing are available to the VLTC constituents. They range from low-end (via Modem) to high end (complete Full Motion). One project is using low-end technologies; i.e. high speed modem, to visit student teaching interns in their classrooms at remote locations. Teacher educators use this medium in an attempt to save commute time and as a potential for opening up classroom doors when placement resources are limited. Real-life classroom examples and feedback from K-12 teachers brought into the teacher education classes have proved meaningful. However, connectivity has been an issue at times and participants have been actively working to remediate the problem and accommodate as best they can. A high-end project has been tested connecting two UW System schools at opposing ends of the state. The main issue with this option is the high cost.

The goal of the Technology Mentors Project is to use a multiplier model to establish a building-level support network within a single large district. Teachers with high levels of expertise “the Mentors” will help 2-4 additional teachers develop the expertise necessary to support remaining faculty. In year I (year 2 of the VLTC), six mentor teachers will be identified. The mentors will work with university and CESA staff on issues of adult learning, training models, leadership, team-building, and advanced technology issues. The mentors in turn will adopt two building-level teachers and work with them to enhance their technology skills, help them integrate curriculum and technologies, and prepare them to take on larger technology leadership roles in their respective buildings. In year II, each mentor and building teacher will “adopt” two more teachers and work with them using the same coaching and support model. The overall staff development effort will be supported by the preservice teaching interns assigned to the mentors. The interns will have advanced technological skills and will provide release time and additional support for the mentors and teachers. The activities of the Technology Mentors Project will intersect with other VLTC activities; thus some staff development will involve teachers from many VLTC project sites working together; other activities will emphasize one-on-one coaching.

It is anticipated that the multiplier model from the Technology Mentors Project along with teachers from the other projects contributing and collaborating across districts and regions will reduce the artificial boundaries to student teaching placements and collaboration amongst teachers. It is also expected that the projects that will emerge will be varied in nature and demonstrate creativity. The sharing of ideas and of technology equipment will become second nature to a seamless process.

Evaluation and Assessment

Evaluation of the VLTC focuses on (a) community development and (b) impact on participants. Community development evaluation examines the activities actually used to establish, and sustain the community. Impact evaluation tracks changes in participants’ knowledge, skills, and classroom practices that result from VLTC-supported activities.

Community development evaluation maps the goals of phases I-IV against the activities designed to achieve that phase. Some of the activities are recurrent and/or continuous in nature and thus a decision of where best to place them in the table was agreed upon by the authors. (see table 1 below).

</tbody>
</table>
New initiatives and concerns have emerged as a result of the activities developed at each phase. Those are briefly listed in column three of table 1 and will be summarized here. Expanding the model to other schools, districts, and regions is illustrated by the Technology Mentors Project. New internships have been created to involve additional communities in the Virtual Learning Technology Community. Critical issues in regard to placement have emerged: a) the quality of the experiences that are provided for our preservice teachers, and b) the number of placements at each site in order to maximize supervision. For example, an intern was hired to teach word-processing and keyboarding (low-level tasks) while the teacher worked with higher levels of technologies. In another case, a single placement at a distant location required the supervisor to drive further distances. Another drawback is attracting more interns to distant placements. Inclement weather (ice and snow in spring) is another drawback. Identifying new cooperating teachers with technology savvy, and developing new student teaching placements have alleviated some of the issues. Furthermore, clusters of interns and student teachers are being placed at distant sites to enhance supervisory efforts even though placements associated with the VLTC are further than 60 miles away from campus. The development of an internship fair with a technology boot-camp for those students that will be taking on a technology internship is being developed. Joining forces with already available university resources from Bringing Instructional Technology to Students (BITS) workshops, the project will be able to provide adequate “training” for preservice. Also, trying to involve more university supervisors in the Technology Mentors Project and other potential projects will help integrate a greater variety of technologies in the methods classes prior to the student teaching experience. Finally, a new course was designed that will be delivered using distance technologies to provide skills to K-12 teachers who will become cooperating teachers in these virtual community classrooms.

The impact of VLTC activities on participants is being tracked using pre-post surveys, small-group interviews, project artifacts, and workshop enrollment data. In the following table, items listed in Italics were identified as foci for the future of the VLTC.

Table 2: The Impact of the VLTC on the Different Populations Targeted

Data from a technology needs and practices survey is currently being compiled to build portraits of the knowledge, skills, and comfort levels for teachers in schools served by VLTC projects. In addition, artifacts from workshops, interviews, and classroom projects provide rich qualitative evidence of changes in teacher and student knowledge, classroom practices, and the interactions among curriculum, instruction, and assessment.

The technology needs and practices survey (Hollon and Hartfeldt, 1997) asks respondents to rate their knowledge, use, and student use of 55 technological tools and practices involving hardware, software, telecommunications, and networking resources. The survey also asks participants to rate their knowledge and confidence relative to the ISTE standards for teacher preparation.

Currently, data for 142 teachers are available. These data represent a partial set of pre-project responses. Detailed analyses are ongoing and will be reported separately. Items describing everyday hardware and technology (VCR, overhead projectors, personal computers) received highest ratings of knowledge and frequency of use by teachers. Respondents report much less knowledge about scanners, digital cameras, and image manipulation tools, and seldom require students to use them. Items related to subject specific software, problem-solving software, simulations, networking tools, and curriculum development received low ratings, with groupware, web-authoring software, and project management tools receiving the lowest ratings.

Of particular significance is the difference between teachers' uses of technological tools and their students' uses of those same tools. Our current analyses suggest that, even when teachers view themselves as knowledgeable and comfortable using common tools such as personal computers, word processors, and Internet resources, they use them much more often than they require their students to use them. For example, 82% of the respondents reported that they felt sufficiently knowledgeable about Internet resources to meet their own needs and/or teach uses of the Internet to others. Yet, only 36% reported requiring students to use the Internet more than 5 times per semester. Such discrepancies need to be interpreted cautiously. Some discrepancies are not surprising; not all tools used by teachers translate directly into student use. Additional factors such as limited access to technology resources for students, limited curriculum-technology transformation, and inadequate staff development might account for other gaps in use. Overall, though, the data clearly show that teachers are using technology much more than they require students to use it.

Most survey respondents report that the ISTE standards (ISTE, 1997) are very important goals for preservice teachers; only one standard (of thirteen) related to research and development of appropriate assessment practices was rated as important or very important by less than 90 per cent of the respondents. In contrast, most teachers felt unprepared to help students meet the standards. Only five of the thirteen standards were rated by at least 50 per cent of the respondents as items they felt prepared to help students achieve.

The survey data provide only one view of teacher and student uses of technology. As VLTC projects develop, we hope to see increases in the numbers and types of items rated in the knowledgeable/confident category, fewer items rated as unfamiliar, and smaller discrepancies between teachers and students' uses of the same technological tools.

Analyses of other data continue. Artifacts from workshops show a rich array of products ranging from web sites to communications centers to Internet-supported content instruction. Teachers are quickly developing skill
in using distance education technologies. Barriers between students and teachers are tumbling as comfort levels increase. Student experts are working in formal and informal capacities through web design, coaching peers, offering support and assistance to building teachers, and sharing ideas over the Internet. In short, the community is healthy and growing.

Summary

The process of establishing different phases of developing the VLTC proved effective in that it has opened up lines of communications at different levels. Technology is a “great leveler” as the different constituents of the VLTC work together in the context of changing knowledge and emerging technologies. In this model, K-12 students and teachers and university students and teachers can learn together. Collegial conversations and learning grew directly from teachers’ experiences with their students. Teachers ranged from novices with technology to using it to modify their instructional methods. More data is being compiled as we look onto year three of this project.
The graduate education curriculum: the process of change in an instructional technology program

Abstract: In the Fall of 1998, Curriculum and Instructional Technology faculty undertook the task to revise an existing Masters program to better focus on technology in teacher education. In this paper, we describe the evolution of our program and discuss several important qualities that support programmatic reform efforts. The ideas are relayed as a status report on the change process at the time of this writing. Any errors are the authors' responsibility alone.

Introduction

In the fall semester of 1998, seven faculty members in the Instructional Technology (IT) section convened on several occasions in order to revise an existing Masters program to focus on technology use in teacher education. At Iowa State University (ISU), the Instructional Technology section is located within the Curriculum and Instruction department at the College of Education. Degrees awarded with a specialization in instructional technology at the Master's level include the Master of Education (M.Ed.) and the Master of Science in Education (MS). In this paper, we describe the evolution of our program, discuss issues and challenges we faced, and describe qualities which supported the process of change.

Program History

The history of an educational program conditions the nature of the program and the way in which developments proceed. At ISU, the Masters program in Curriculum and Instructional Technology dates back about 25-30 years and emerged from two groups with different major orientations: a traditional non-computer media group and a computers in education group. The traditional media-in-education group was typical of instructional technology in the 1960s and 1970s and focused on non-computer-controlled technologies, video, and, to a lesser extent, on the traditional instructional design process. The second group emerged in the late 1970s/early 1980s with the development of microcomputers and the possibility of widespread use of microcomputers in education. This group was excited about the educational possibilities
of computers, but, perhaps somewhat uniquely at ISU, came from a teacher education background more than from the traditional media background.

The distinction here is subtle, traditional media was part of teacher education in a programmatic sense, but the focus was more equipment-oriented; while the teacher education focus was more on the learning-teaching process. Two unique factors at ISU were that there was no group strongly focused on instructional design theory and that educational psychology, from which many instructional technology theorists emerged, was housed in the Psychology Department in a separate college. The latter factor tended to reduce collaboration between Instructional Technology and Educational Psychology.

Thus, in the early days, one camp had a lot of emphasis on media and on producing media specialists, and the other camp focused on using the emerging computer technology for learning and teaching. The small number of faculty in the program prevented groups from developing into separate programs of study. In time, these groups gradually merged as digital technologies became the dominant force in IT. As one of the participants described it: "We had the computer people and we had the media people, then we would have these big discussions. It was almost as though we had computer graduate students and media graduate students. Then it was just sort of interesting how that all kind of dissolved as the distinction between computers and media dissolved itself."

Historical Development of the Curriculum

The distinction between the camps influenced the nature of the curriculum. The original curriculum was primarily media oriented. It focused on technologies that produced alternative media (e.g. photography, video, audio) and on the library science aspects of the media specialist position. As the computer camp emerged, courses were added on top of the existing curriculum. Of course, faculty members’ individual interests, the perceived needs of students, and the rapid pace of technology change influenced course development. The content of courses changed as interests and perceived needs changed. When LOGO was a hot topic, a course might focus heavily on teaching Apple II Logo. A few semesters later, HyperCard might be a major topic. The program grew incrementally by adding new courses, but there was no systematic attempt to create an integrative rationale for the program.

The strong need in the state to prepare technology leaders in the schools also played a role in rethinking program revisions. The program accepted a large number of students to prepare graduates to meet this need. While many of these students were primarily practice-oriented, they needed to complete research-oriented theses. The tasks of covering courses and guiding a large number of students stretched the small faculty pretty thin and made the task of rethinking the graduate program seem overwhelming.

Rationale for Change

In recent years, changes in faculty through retirements and new hires led to changes in interests. A faculty member with a strong instructional design theory emphasis was hired. Educational psychology was moved into the C&I Department. The University began a quest to assume leadership among land-grant institutions, and this quest led to the idea that departments needed to focus resources on a limited number of areas that could achieve national and international prominence. Within C&I, teacher education and IT were among the focal areas. A research Center for Technology in Learning and Teaching was established and, because of the interests of the players, developed as its emphasis: technology in teacher education.

The need for a large number of leaders in the area of technology in schools also acted as an impetus for change. Faculty recognized that the existing program did not adequately prepare teachers interested in positions of leadership. All of these changes contributed to the sense that there was a need to develop a focused rationale and direction for the graduate program.

Process of Change

In the Fall of 1998, seven faculty members from a Curriculum and Instructional Technology section at Iowa State University participated in extended faculty retreats to discuss the revisions to the
existing Masters program in instructional technology. While work on this project is ongoing, the process of change was productive and engaging. What follows are descriptions of several areas that facilitated our discussions regarding program reform.

**Collaborative Community**

Perhaps one of the most critical factors in this process was the existence of a collaborative faculty team. A restrictive sense of ownership over individual courses did not exist. One faculty member, reflecting on our discussions, noted, "It doesn't work to say you can do what you want with the rest of it, but don't change [my class] because that's my course." Individuals focused less on making changes to particular courses and more on improvements to the overall program structure.

In addition to a positive working relationship among all faculty members, meetings were organized and had a clear, forward-moving direction. A section leader focused our attention on specific, attainable goals during the meetings and assigned tasks to make follow-up meetings equally productive. While equal ownership in the process was important, one individual focused our attention by structuring meetings and setting the agenda for future meetings. Small group work was highly productive and produced various ways of looking at the program structure. We would leave each meeting with a new assignment and come back ready to discuss our ideas and listen to those proposed by the groups. Everyone felt that change was necessary and that it was important to develop a more focused program.

**Shared Purpose**

During our first meeting, we set the stage by revisiting our program goals to ensure that everyone shared the same goals. One of our initial discussions centered on clarifying who should we serve. We recognized that we could not meet the needs of every potential student. IT attracted interest from students from all areas such as art, agriculture, training and development, and business. However, the interests and strengths of the faculty and the idea of focusing our resources led us to agree that we wanted our IT program to focus on technology in teacher education. Given our history and recent changes in the staff and University, we felt that now was the perfect time to revise the program. The common agenda or focus on technology in teacher education facilitated our discussions.

**Tabula Rasa Design**

In the beginning, C&IT faculty faced one important question. Should we take into consideration the existing courses we offer and build from there? While this seemed to be efficient on the surface, it became clear that if we wanted to design a program to meet our goals, we needed to start with a blank slate in order to design what we believed to be the ideal program for our Masters students. Keeping existing courses in mind at the beginning of this process might have prevented us from focusing on the real task: to develop the "ideal" Masters program. We agreed that it would be better to start over again, determine what we as a team wanted to do, and decide what we wanted the program to look like. Released from having to work within existing constraints, C&IT faculty divided into two small groups to develop proposals for the new program. Succeeding meetings were scheduled to discuss proposals and negotiate through the details of what would eventually become a common core of classes.

**Establish a Common Core**

Prior to making any revisions to the program, the M.Ed. and MS degrees each required a minimum of 30 semester credits of acceptable graduate level work. Of these 30 hours, Masters students in IT were required to take one course each in instructional media, curriculum, educational computing, research design or statistics, and psychology of learning. Students completed the remaining credits for the instructional technology specialization by selecting available courses offered by different faculty members. While seemingly flexible in appearance, the lack of a cohesive course of study presented some areas of
concern: students shared limited experiences, and course content oftentimes contained repetitive elements. A faculty member noted:

"Looking at our existing graduate program, it was clear that while we had a lot to offer, there was a lack of continuity between the courses in the program. What we tended to do was just to add courses without really looking at the entire picture. The problem was that we let the program develop that way and didn't spend a lot of time looking at the entire program. It was like a menu that kept expanding based on peoples‘ interest."

A reconceptualization of the program curriculum as an interrelated set of experiences was needed and a better defined core curriculum served this purpose. With this in mind, faculty members identified and examined several instructional technology programs across the nation. Program data was accessible via information found on World Wide Web sites. During a follow-up faculty retreat, individuals described various program configurations in existence. Our discussions afforded opportunities to examine underlying structures found in different instructional technology programs and allowed us to craft our own structure based on the goals and needs for our program. The most recent draft of the program identifies four major focus areas: research, foundations, applications in IT, and leadership. Table 1 lists courses within the new program requirements.

Table 1: Proposed core course requirements (3 credits each, variable credits shown in parentheses)
Of importance was the decision to increase the number of required credit hours to 36 credit hours. While our initial program required students to complete 30 semester credit hours, a cursory examination of instructional technology programs revealed a 36 credit minimum at many other institutions. The revised program allows some flexibility yet ensures that students experience a common foundation. In addition, the distinction between the M.Ed. and MS degree becomes more apparent.

Meeting Different Needs

Masters students pursuing a specialization in IT mainly fall into two categories. The MS degree was designed for students with an interest in continuing an emphasis on research. The M.Ed. degree was designed for practitioners – full time teachers who come with a different vision of why they want their degree. Initially, the distinctions between the MS and the M.Ed. degree were not clear. The main difference was that students interested in earning the MS degree wrote a thesis and those pursuing the M.Ed. degree engaged in a creative component requirement.

Over a span of several meetings, C&IT faculty discussed how to better serve the needs of both groups. While the four core strands remained the same, efforts were made to address differences (for example, although the research strand is important to both degree candidates, MS students were required to take 9 additional research credits while the research course for practitioners emphasized more practical action research methods). In addition, the new program was designed to give Masters students choices as to whether to write a thesis, develop a professional portfolio, or engage in a creative component. Many Masters students with no intentions to go on for a Ph.D. will have the option to create a professional portfolio or engage in a classroom application project. For the student that not planning to pursue a research area, this serves as a more useful, more practical activity. Students have more flexibility in deciding what would be in their best interests based on their professional goals and future career choices.

Next Steps

At the end of the semester, it was clear that the proposed changes were not superficial but were rather substantial in nature. It is important to note that at this time this paper was written, work on the program revisions had not been finalized. While flexibility is important, clear goals and thoughtful design are critical. We know that our efforts will result in a program that is more focused and better able to meet the needs of our students.
Change Theory for Schools: Some Basic Principles

Kay A. Persichitte
Associate Professor of Educational Technology
University of Northern Colorado
USA
persi@edtech.UNCo.edu

Abstract: There are tremendous pressures on K-12 schools to adapt to a wide variety of expectations (e.g., state and organizational content standards, professional standards, site-based management, technology utilization and integration) that are all related to our capacity (individually and institutionally) to cope with and facilitate change. In general, school reform is inherently dependent upon change. While most administrators have had some exposure to change theories and their application, the large majority of practicing faculty and preservice teachers have no knowledge of these perspectives; nor are they aware of how the theories can be applied to facilitate change at a micro or a macro level. This paper provides a brief, practical introduction to two specific change models: Rogers' Diffusion of Innovation Theory and Hall and Hord's Concerns-Based Adoption Model (CBAM). An extensive bibliography of related readings is included.

Introduction

Change adds an additional layer of complexity to the already overburdened role of the classroom teacher. Offering opportunities to explore strategies so teachers better understand change may bring some relief to the syndrome of 'teacher burnout' and frustration with peers and/or administration. Additionally, it is a given as we approach the new millennium that change has developed into the one constant of our personal and work lives. There is a reciprocal relationship between change initiatives in our schools and classroom teachers--they are mutually influencing. This paper is intended to provide the reader with background knowledge in some basic principles of change and diffusion from Rogers' Diffusion of Innovation Theory and from Hall and Hord's Concerns-Based Adoption Model (CBAM). Key principles are included in this overview from such related theoretical constructs as: adopter categories, diffusion, critical mass, change facilitation, user levels, stages of concern, and other fundamental constructs essential to theoretical application in school settings.

In 1992, Salisbury and Conner wrote, "The increased volume and complexity of change requires educators to develop the critical skill of managing change. Fundamental to the skill in managing is the capacity to absorb change without dysfunctional behavior, operating at the optimum speed of change, enhancing resilience, and understanding the structure of change" (p. 1). Understanding basic principles of change can only serve to help those involved with change to adapt more successfully and with fewer struggles. Some basic principles apply regardless of the change theory or model: Change is a process, not an event; Change cannot occur without disruption of a system and systems prefer to stay at rest; Change causes ripple effects throughout a system; Change occurs as states of disequilibrium transform into states of equilibrium; and Change is typically embedded in ambiguity and risk.

Diffusion of Innovation

Rogers (1995, p. 5) defines diffusion as "the process by which an innovation is communicated through certain channels over time among the members of a social system." Rogers (1995) presents numerous examples of diffusion efforts, all of which have four identifiable main elements: an innovation, communication channels, time, and a social system. In the brief sections that follow, the reader will find abbreviated summaries of key constructs and terminology from Diffusion of Innovations Theory. The reader is encouraged to read Rogers (1995) for adequate treatment of the topic and extensive examples of diffusion research.
Characteristics of Innovations

How quickly an innovation is adopted (or the rate of diffusion) is often affected by the characteristics of the innovation. It is the perceptions of individuals regarding the innovation that will affect the time required to reach widespread adoption. Rogers (1995, pp. 15-16) describes these five characteristics: RELATIVE ADVANTAGE (Is it better than what it is intended to replace?); COMPATIBILITY (Is it consistent with the norms of the social system?); COMPLEXITY (Is it more or less difficult to understand or use than what it is intended to replace?); TRIALABILITY (Can I try it out?); and OBSERVABILITY (Are the results of using it visible?).

Adopter Categories

After decades of research in this area, Rogers (1995) has identified five categories of adopters. Diffusion research verifies that the members of each category have much in common. One should note, however, that each of us will likely fall into a different category dependent upon the innovation and our individual perceptions about the characteristics of the innovation. The categories are distinguished on the degree of innovativeness of the members. Rogers (1995, p.22) lists these adopter categories, followed by the validated statistical percentages of the social system membership that is adopting the innovation: INNOVATOR (2.5%); EARLY ADOPTER (13.5%); EARLY MAJORITY (34%); LATE MAJORITY (34%); and LAGGARD (16%). Diffusion of Innovation Theory provides detailed descriptions of the membership characteristics of each category (see Rogers, 1995, Chapter 7).

Rate of Adoption

"The rate of adoption if the relative speed with which an innovation is adopted by members of a social system" (Rogers, 1995, p. 22). When numbers of adopters are graphed against time, the resulting adoption curve is an S-shape. Innovations that are rapidly adopted are represented by very steep S-shapes, while slower adoptions are represented by lazy S-shapes. A related construct is that of critical mass. Critical mass mathematically occurs at the first inflection point of the adoption curve.

The Innovation-Decision Process

The innovation-decision process can result in either adoption or rejection of the innovation. It is both a process of information gathering and information processing. The process may occur at an individual, unit, or organizational level. Many other individuals (see next section) play key roles in the process when the innovation-decision is made at the system level. The five steps in the innovation-decision process include: KNOWLEDGE; PERSUASION; DECISION; IMPLEMENTATION; and CONFIRMATION (Rogers, 1995, p. 20). There are a number of decision points in the process that may be influenced by the innovation characteristics, the rate of adoption, and the characteristics of the adopter categories.

System-Level Diffusion

Diffusion of innovation at the system level requires careful planning, participation and support of others in the system, and attention to the design of interventions that facilitate adoption. Rogers (1995) describes the characteristics and the roles of the CHANGE AGENT; OPINION LEADER; GATEKEEPER, and the INNOVATION CHAMPION.

Concerns-Based Adoption Model
The Concerns-Based Adoption Model (CBAM) (Hall, Wallace, & Dossett, 1973; Hall & Hord, 1987) is a change implementation model founded on school practice. One of the important perspectives of the CBAM approach is that "there must be an understanding of how the individuals within a school become confident and competent in using educational innovations" (Hall, 1992, p. 884). CBAM has a strong history of research on practice in schools, with teachers and principals, and classroom innovation implementations. The model is comprised of three diagnostic dimensions: stages of concern (SOC), levels of use (LOU), and innovation configuration maps (ICMs). Each diagnostic tool has a unique purpose and is intended for use at varying stages of the change process. Since CBAM focuses on facilitating change and monitoring implementation, it comes as no surprise that the model also emphasizes the use of specialized dissemination strategies, carefully designed implementation interventions, and the role of the change facilitator within the school setting. The reader is encouraged to read Hall and Hord (1987) for a much more complete treatment of the topic.

Survey of Concerns

The SOC is a 35-question survey (Hall, Wallace, & Dossett, 1973) designed for adaptation to use for unique innovations within the school setting. The survey takes about 30 minutes to complete. The instrument is a valid measure (Hall, George, & Rutherford, 1979) of the individual's concerns about the innovation related to self, task, and impact. The survey allows for the development of a Concerns Profile for each individual. The Concerns Profile is a graphic representation of the relative intensity of concern of the individual defined by seven stages (Hall & Hord, 1987, p. 60): Stage 0 AWARENESS (Little concern about the innovation or involvement with the innovation is indicated.); Stage 1 INFORMATIONAL (A general awareness of the innovation and interest in learning more detail about it is indicated. She/he is interested in substantive aspects of the innovation in a selfless manner such as general characteristics, effects, and requirements for use.); Stage 2 PERSONAL (Individual is uncertain about the demands of the innovation. Financial or status implications of the program for self and colleagues may also be reflected.); Stage 3 MANAGEMENT (Attention is focused on the processes and tasks of using the innovation and the best use of information and resources. Issues related to efficiency, organizing, managing, scheduling, and time demands are utmost.); Stage 4 CONSEQUENCE (Attention focuses on impact of the innovation on student in his/her immediate sphere of influence. The focus is on relevance of the innovation for students, evaluation of student outcomes, including performance competencies, and changes needed to increase student outcomes.); Stage 5 COLLABORATION (The focus is on coordination and cooperation with others regarding use of the innovation.); and Stage 6 REFOCUSING (The focus is on exploration of more universal benefits from the innovation, including the possibility of major changes or replacement with a more powerful alternative. Individual has definite ideas about alternatives to the proposed or existing form of the innovation.)

Levels of Use

The LOU concept assumes a range of different types of use of an innovation as well as different amounts of use (Hall & Loucks, 1977; Hall, Loucks, Rutherford, & Newlove, 1975). Levels of Use are operationally defined in eight levels (three nonuser and five user). Two fundamental concepts underlie the LOU as a measure of implementation of an innovation. One, "teachers construct meaning of the innovation and interpret the innovation differently at different times in the change process" (Hall, 1992, p. 892). Secondly, "use of an innovation is not dichotomous" (Hall, 1992, p. 892). The levels and general behavioral indicators are: VI RENEWAL (The user is seeking more effective alternatives to the established use of the innovation.); V INTEGRATION (The user is making deliberate efforts to coordinate with others in using the innovation.); IVB REFINEMENT (The user is making changes to increase outcomes.); IVA ROUTINE (The user is making few or no changes and has an established pattern of use.); III MECHANICAL USE (The user is using the innovation in a poorly coordinated manner and is making user-oriented changes.); II PREPARATION (The person is preparing to use the innovation.); I ORIENTATION (The person is seeking out information about the innovation.); and 0 NONUSE (No action is being taken with respect to the innovation.) (Hall, 1992, p. 893).
Innovation Configuration Maps

CBAM defines an innovation "in terms of key operational components and distinctions are made between the different variations that can occur for each component" (Hall, 1992, p. 886). Consequently, it is the configuration of the actual implementation(s) of an innovation that is of particular importance to the change facilitator. Components of the innovation are often comprised of "a set of operational skills, practices, and uses of resources" (Hall, 1992, p. 887) that influence implementation of the innovation. ICMs are developed to measure implementation at the component level (Heck, Stiegelbauer, Hall, & Loucks, 1981). Clear definition of these components is often made more difficult by attempts to implement bundles or stacks of innovations within narrow timeframes. Time is a necessary requirement for change to occur, but it is not a sufficient condition. Support, holistic perspective, and combined effort are also essential for institutionalized change to occur. The development and formative evaluation of ICMs provide change facilitators a clear strategy for the management and monitoring of innovation implementation.

Conclusion

The demands on our schools and the people who work in them to adapt to dramatic change show no sign of abatement. Given that, and given that some change will have positive results for the system, the challenge for each of us is to be aware enough of some fundamental principles associated with change that we are better able to understand, accept, and help facilitate the individual and collective process. After all, since there is no end in sight, it is the journey that is important.

Abstract: In a project inspired by the Generation Why program, Winona State University College of Education students have begun assisting faculty members as they work to infuse technology into their courses. Along the way, the student interns have learned much about technology, working together to learn about technology, and the struggles and successes that accompany a project such as this. Assisting the faculty in integrating technology into their courses "turned the tables" on the traditional teacher-student relationship. The students learned as much about working with faculty as they did about technology. This paper focuses on their relationships with faculty and the difficulty of fitting into the schedules of faculty who initially look at technology as another "add-on, teaching your teacher, maintaining a human side to technology, and entering a "community of learners."

Introduction

In a project inspired by the Generation Why program, Winona State University education students have begun assisting faculty members as they work to infuse technology into their courses. Along the way, the student interns have learned much about technology, working together to learn about technology, and the struggles and successes that accompany a project such as this.

As in the Generation Why program, interns were not expected to be technology experts, but were expected to accept the challenge of working with faculty as they begin infusing technology into their teaching. The interns agreed to participate in bi-weekly meetings, informal training sessions, and independent study of instructional uses of technology. It was hoped that participating in the program would benefit both the interns—who would gain a more sophisticated understanding of instructional technology—and the faculty with whom they worked—the faculty would also learn about instructional technology and increase the presence and quality of technology in their courses.

The student interns were each assigned to a faculty member. The interns were asked to set up an initial meeting with their faculty member to discuss the faculty member's interest in technology. The interns reported what they learned at the second intern meeting and solicited assistance learning the software or techniques requested by their faculty members. After exploring the software with other interns, working through tutorials, and learning about the software in anyway possible, the interns returned to their faculty members and assisted them in using the technology.

---

1 The interns' names are presented in alphabetical order and do not signify their contribution to this proposal or project. All interns contributed equally.
Although not all of the attempts to infuse technology were successful, many faculty members have expressed a sincere appreciation for the interns. For the first time, many faculty members felt as though they had the support necessary to begin using technology in their courses. And, in the end, the project has resulted in an increase in attempts at using technology. But rather than focusing on increased use of technology in the university courses, we have chosen to focus on what the interns learned by participating in this project.

Besides their newly constructed knowledge of educational uses of technology, the interns learned a tremendous amount from interactions with faculty that might inform future attempts to implement similar programs. Our presentation consists of four presentations by student interns from Winona State University as well as an introduction and conclusion. The four intern presentations will discuss: a) the difficulty fitting into faculty members already full schedules; b) Mentoring their mentors; c) Maintaining the human aspect of technology; and, d) learning from peers. Each of these presentations are described in more detail below.

Faculty Schedules

University faculty members have notoriously busy schedules. Along with their teaching requirements they are expected to serve on committees, conduct their own scholarship, and conduct professional lives away from the classroom. Asking them to add one more thing to the list is, in many ways, asking for trouble.

Fullan has argued that top-down staff development directives will fail. Teachers are resistant to change when it comes as a set of orders. In order to achieve "real" change, he continues, teachers must recognize the need for change and determine ways to address the need. In addition, Cuban has documented a cycle where teachers have been given technology and told to use it. Most times, these efforts have failed and have resulted in "teacher bashing"—something we desperately wanted to avoid. Both of these arguments suggest that getting the faculty to adopt technology and use it in appropriate ways will work only when we address their needs and if something needs to be dropped from their already overcrowded dockets, it is likely that infusing technology into their courses will be dropped.

Many people who are not technologically fluent have remained so because they are intimidated by the idea of technology since it often appears to be much more sophisticated than it truly is and also because it is quite expensive to purchase equipment initially. Those who are seemingly dragging their feet technologically often raise questions which are aimed at technology's shortcomings, such as the possible problems which could result from Y2K and the seeming loss of personal contact which we often find, especially when calling companies and other large organizations. Other justifications these people may use for not learning about technology often include: "Why should I learn about this when the old way works just fine?" And, "by not knowing about technology, I'm saving myself a lot of time that would otherwise be wasted on the learning process, besides, isn't technology always changing? I would constantly be having to update myself." My personal favorite, "it is just easier to not know."

However, those who support technology could counter those questions with their own. Several counter examples may be: "Hasn't the introduction of electronic mail (email), in essence, allowed us to rediscover the skill and importance of letter writing?" And, "while punching buttons in order to direct ourselves through a phone call may seem bothersome and needless, wouldn't many of us rather spend those few minutes punching buttons than paying these companies even larger fees in order to pay an operator to greet and direct each call?" However, my favorite is, "of course you don't have to learn about technology! You simply need to learn those 6 magic words--would you like fries with that?"

In response to those who question the need for technology as a whole, we ask, "Hasn't it been evident throughout history that there have always been people who were satisfied with 'good enough'? However, it has never been those people whom we read about in history books as making a difference in the world around them, but rather it is those who have pushed the boundaries of 'good enough' and stretched them until they broke down and became 'even better.'"

These examples do not even begin to touch the topic of technology and its conflicts/benefits. The real question I am posing, while my opinion may be biased, is "does everyone truly need to be technologically fluent or are their "old school" methods sufficient in today's society?"
Mentoring your mentor

Even when the interns gained access to the faculty’s schedules, they found themselves in a unique situation. They were teaching their teachers. Working with faculty in new ways created new relationships for students and faculty members.

As students, we look up to professors and teachers as mentors. They liberate our imagination by encouraging us to develop through mentorship and empowerment, encouraging us to evolve into scholars, professionals, and independent thinkers. As a result, we often seek to emulate our mentors, often times holding our professors in such high esteem, that we place them on a pedestal, projecting expectations and superhuman attributes onto them that the Man of Steel could not aspire to—“How do they know all this stuff?” This is often the nature of the student-professor relationship.

In considering this relationship, it can be very intimidating to turn the tables and mentor your mentor. Closing the gap between teacher as teacher and teacher as student is disconcerting. We all have something to offer others, but how can we mentor a person that we hold in such high regard? Fear and self-doubt are rampant in the student. Other doubts arise: What if I cross the border of professionalism between student and professor? What is the border? Will I hurt my credibility in some way? What if I do something wrong? The most prevalent question is “do I have the tools and information to teach them the things they need to know.” All questions and fears aside, the students at Winona State University dove in and began the process of trial and error in “The Winona State Technology Internship Program.”

The traditional roles of students and professors working together were soon crossed; WSU students began mentoring their mentors. There were numerous expectations at the start of this program; some held true and others were laid to rest. Difficulties arose for students because of the dissonance created in not having a schema for dealing with situations like this. But being put into this situation led to the construction of new relationships with faculty and a new self-confidence in student mentors as they saw what they could do.

WSU is a unique learning situation, but not so unique that other campus’ cannot implement a program such as ours. Wherever there is a teacher, there is also a student. A teacher is one who models what it is to be a student. A teacher attempts to instill the joy of learning through example.

This program has shown us that our mentors are very well learned, but they don’t know everything. In fact, this experience has probably been a relief. Now they can dress at home rather than in faculty phone booths and become mere mortals once again. In allowing us to interact with them in a non-traditional role, they have taught us more than we could ever have learned in the classroom. They have shown us how to be a graceful beginner, a good student, and what it is to be in the teacher’s chair. More importantly, we have learned that teachers are learning from those whom they are teaching. It is proof that learning never ends, it is truly reciprocal, and that we are always teachers, even when we are the students.

This program has been a great example of reciprocation: the teacher becomes student, and allows the student to become a teacher. Because of this, we all learn, and raise each other to the next level. But success with a program like the WSU Technology Internship Program is dependent on reciprocation and participants being ready to let down their guard and learn from their students. Every one has to want to be involved. With a desire to learn, this program has helped us all to stretch our boundaries of self-discovery and knowledge a little further.

Maintaining the Human Side of Technology

Expectations can be dangerous when it comes to working with people. They can best be described by picturing the person we are supposed to help behind a clear sheet of plastic. We see the person through the plastic, but as we start projecting our expectations on it, our vision of the person on the other side becomes obscured. We must have a clear vision of the person we are to help and train if we are actually going to actually help them. We must make sure that we maintain the human aspects of technology.

Many of us who are proponents of integrating high technology into education feel that technology is the key to creating a better quality of education. This is true, but the computer is not a cure all. The computer is a tool. It is a means for creating more time for human contact and better communication. We must not lose sight of this simple fact. There is no reason for expecting people to integrate technology just
for the sake of technology. In my experience, I have found that technology rarely ever reduces the quantity of work at hand. It has improved the quality, but with the constant upgrade of new programs and new developments in hardware, it is about all we can do as busy individuals to keep up.

Just because a class can be taught through a url address does not mean it is the best way to teach the class. Technology has its uses and place. The computer at its best is a catalyst, a conduit, and a theme. It is a catalyst in that it can bring us together to talk about and learn new things, a conduit because it becomes a means and a channel through which to communicate over time and distance, and a theme because most of us deal with it on a day to day basis and talk about it like the weather—inclement or foul.

My faculty member and I went running for some of our meetings. The key was making the effort to find common ground in addition problem solving in front of a workstation. Relationships should be reciprocal and help us evolve beyond whom we are at the present. The teacher should be open to being a student as well as a teacher. By creating an environment where we can spend a few minutes breaking the ice and finding commonality, technology training was easier to think and talk about. These meetings were very productive in that a technology plan emerged, dated goals were created, and more importantly trust and understanding developed. Because of the trust factor, new ideas were constantly being explored because we were not afraid of looking like a beginner. This allowed us to speak about all kinds of things relating to technology and led to the creation of a protocol for our meetings. We never began the meetings about technology problems. The key to our success was getting to know each other and creating a working relationship through maintaining the human side of technology.

Learning from peers (entering a community of practice)

One major premise of the program was to have the interns work together to solve problems, learn programs, and help faculty infuse technology into their courses. To accomplish this, students met every other week to report on their work and ask other interns for advice. They also participated in a listserv set up to ask questions between meetings.

As the project progressed, the interns began meeting at other times in the education computer lab for informal training sessions. They worked together to share expertise, learn new techniques. In the end, working with each other may turn out to be the most useful portion of the project.

Peer learning occurs all of the time, and is very abundant in the Technology Internship program in which we are involved. Peer learning effects everyone, both the students and instructors. The positive effects of peer learning shine through this program in the computer lab that we maintain and with the interns together. Through this process we are not only learning more about technology, but also developing relationships with other students and instructors.

As we help others in the intern program and in the computer lab, we are developing relationships with more people. We may be known as “that girl who knows about computers” but seeing a regular face is comforting to students who do have questions. We also have the group of interns that are always more than willing to answer any questions that may arise. For example, working through the e-mail program Eudora was unfamiliar, but with the help of another intern it became a more familiar program. He was able to show the different uses of the program and now this information can be passed on once again.

There is a lot to be learned about technology and computers. For example working with the program HyperStudio to make a portfolio was a requirement for an education class. Shannon, the other students and I had very little experience with this program before this assignment. The portfolio included sound, graphics, digitized images, animation and a link to a PowerPoint Presentation. After working through the portfolio and working through the program itself it was becoming more familiar. Working in the lab the night before the portfolio, I found that I was able to answer many questions I did not think I could answer. One thing both of us were unable to do was make the link to PowerPoint, but we learned this through a peer who was working on the assignment and knew. Both of us were really impressed by the student’s willingness to help each other even though time was running thin. One reason we are able to help our peers is because we are able to understand the background of the students.

Students are different with their knowledge of computer software. Younger students, recently graduated from high school, seem to have more experience with technology having learned it in school. Returning and non-traditional student generally seem to have less experience and more apprehension when it comes to technology. With my experience with computers I am able to see what younger students have
questions with. Before this program word processing was about as far a technology went for me. I can understand frustrations and confusions these students have because I have been there before. Shannon is a returning student and with the same experiences as myself is able to understand what both the younger and non-traditional students might be having problems with. We are only two of sixteen interns with unique backgrounds in technology.

It is sometimes easier for students to ask their peers for help for mainly two reasons. The first is that the instructor has limited time and peers are able to ask each other questions faster than getting the instructors attention. Another reason is that peers may be less apprehensive to ask each other questions than asking an instructor. Either way, learning from peers has had a positive impact on the effectiveness in our computer lab. Both peers are able to learn something new whether it be how to link a PowerPoint presentation or how to check e-mail.

Conclusion

Through their participation in this project, the interns and faculty members learned more then new technological procedures or processes. Students developed new relationships with the faculty members and learned--and sometimes developed-- appropriate uses of technology in teaching. As a result of this project, the interns will be able to use technology in more sophisticated ways when they enter their own classrooms and the faculty at Winona State University have become more proficient with technology as an instructional tool. We conclude our presentation with a short look at the future by raising the question: Now that faculty members have increased the amount and quality of the technology used in our courses, what role will the interns have in the future?

The Pivotal Role of the Department Chairperson in Infusing Technology into a Teacher Education Program

F. Thomas Scappaticci
King's College
United States

Nicholas Holodick
Kings College
United States
naholodi@kings.edu

Abstract: The importance of the department chair’s leadership cannot be overestimated. (Bennett and Figuli 1990). This is a key, because the chairperson must simultaneously provide leadership to the faculty and supervise the translation of institutional goals into academic practice. (Tucker, 1992). These two functions must be balanced if a successful change is to take place. This paper deals with how one chairperson was able to lead the effort to integrate technology into it’s teacher preparation program by a balanced approach of providing leadership to the faculty and representing the administration in carrying out institutional goals and long term plans. It deals with how the role of the chair was used, how workload assignments were reworked to satisfy both faculty and administration, how technology was tied in with improved college teaching, how conflicts that arose were managed, and how department goals and long term planning were utilized to get limited resources.

Background

We need to be aware of the report issued by the Office of Technology Assessment entitled Teachers and Technology: Making the Connection, which stated that technology was not central to the teacher preparation experience in most colleges of education in the U.S., and that too many teachers were graduating with only limited knowledge of the ways that technology could be used in their professional practice. (U.S Congress, 1995). Colleges of education are now attempting to deal with the issue of infusing technology (Drazdowski, 1995, Fox and Thompson 1994) but their attempts are not without problems. One important way that has been successful in addressing the problem and accomplishing this infusion has been to include the entire department in the plan in a concerted effort (Drazdowski, Holodick and Scappaticci, 1996). While this paper recognizes the important roles of all department members in the process, it deals more specifically with the pivotal nature of the department chair’s role in the process. (The term department chair in this paper is a broad designation to include all heads of undergraduate teacher education units, whether the formal title is chairperson, or some related designation).

A Balanced Approach Between Faculty and Administrative Needs

At King’s College the faculty handbook states that faculty department chairpersons are considered regular faculty members who assume certain necessary administrative functions, and as such are not
considered as part of the regular administration. As chairperson I had to work within these parameters. I view my role as faculty chairperson primarily as advocate for the education department and the education faculty. However, in no way does that preclude the best interests of the students and the college, and that is precisely why I call it a balanced approach.

First, in order to carry out any kind of positive change effectively it is imperative to have a consensus among the education department faculty that a change is necessary. In this particular case the change we are referring to is an infusion of technology into our Teacher Education Program. I met with the members of the department individually and collectively on this issue. Fortunately, the faculty was of one mind and all agreed that we needed to make a major effort in this area. Additionally, we agreed that we had to have one member of the department with technological expertise to assume an important leadership role in this area. Once the department was fully behind the concept of infusing technology into the Teacher Education Program, my next step was to broach the administration with our perceived need, since it would mean an enormous financial commitment of limited resources. Without the full support of the administration and its administrative prerogatives, any plan to infuse technology into the Teacher Education Program would be futile.

Our college is nationally recognized for its work with strategic and long range planning, so the first thing I had to do was to tie our requests in with the colleges strategic and long range plans. That would be the best way to get the administration's attention. There were two specific existing college goals that I referenced. The first was, "The college will develop and implement an action plan to make the computer an effective learning tool for students." The second was, "The college seeks to develop a Teacher Education Program which is of the highest quality and most innovative in Northeastern Pennsylvania." Our request fit neatly within the parameters of both of these goals, and as a result the college agreed to review our plan to infuse technology into our Teacher Education Program. I do not think that I could overestimate the importance of couching our request in terms of the existing college plan. That was absolutely key. We were on our way.

Some Undefined Roles of the Chairperson

As chairperson, I could not miss an opportunity to promote our infusion of technology plan every chance I got, both formally and informally. It is the informal that I would particularly like to emphasize. It is difficult to quantify the results of all the informal interactions, but I am certain that they were essential in keeping the importance of the plan at the forefront of all of those people who had input into the funding of the program. As chairperson I was in contact with people who could be influential in providing and prioritizing funding, and I never missed an opportunity to promote our program. If I were in the company of the vice-president for finance, I would remind him of our department's extremely positive cost/revenue ratio, and how necessary the infusion of technology would be for us in order to continue to attract students in the future and to maintain our newly achieved position as the largest department in the college. When I was in the company of the vice-president for academic affairs, I would remind him of how this plan to infuse technology into our Teacher Preparation Program was a direct outgrowth of strategic and long range planning, and how it would directly affect the quality of our teaching, since our plan called for each of the education faculty to include in our teaching the very things we were proposing to teach to our student teachers. With the vice-president for technology, I pointed out the absolute need for our student teachers to be on the cutting edge of technology, since they would be exporting it to all the school districts in the area, and it would reflect back on the technology program at King's in a most positive manner if they were all prepared to utilize the latest technology.

Was it politicking? Was I using my long time association with colleagues in influential positions to promote our program? The answer is a resounding yes. but it was a cause worth promoting, and as advocate for the education department, I felt no qualms about it. I believe it was necessary. The end result was our program for infusing technology into the Teacher Education Program was approved.
Reworking Faculty Assignments and Work Loads

The model of management that I personally utilize is one of open communication and shared responsibility. (Hackman and Oldham, 1976). I believe that faculty who enjoys open communication and shared responsibility in the business of the department respond with increased motivation and commitment. As such, our department meetings dealt with the education faculty’s role in this whole process. The first thing we decided was that the faculty member with the greatest knowledge and interest in technology had to be the primary change agent. Then we began redefining our respective roles in light of this new technology being infused into the department.

The faculty member who was functioning as the primary change agent was taking on enough additional work to require an adjustment. He opted for an overload contract rather than released time. That being his judgement, it was my responsibility to try to accommodate him. When I pointed out to the vice president for academic affairs that an alternative to granting an overload for our change agent faculty member would be hiring an outside consultant which would not only more expensive, but also much more cumbersome and a lot less convenient, he agreed to the adjustment. The rest of the faculty did not feel that they warranted an overload contract, but they did want support for learning what had to be learned in order to incorporate the new technology into their classes. Support came in the form of funding from a Teagle Grant and workshops sponsored by the college.

Our primary change agent in consultation with the rest of the faculty came up with our wish list. The argument posed to the administration was that our education faculty would need state of the art personal computers for their offices and workstations for their classrooms that included computers, LCD panels, cable and internet hook-ups. The problem that arose here was that that requests of this nature crossed over several bailiwicks and that is always problematical. My role as faculty chairperson was to guide the requests through proper channels and to massage the process in the most expeditious manner, always maintaining the balance between the different vice-presidential areas. Fortunately we were successful and the requests were honored.

Conclusion

Our plan to infuse technology into the Teacher Preparation Program was successful. The education faculty and the administration came to agreement with regard to our respective roles in the process. It was a rewarding experience, since it was cooperative and not adversarial. The request for the major change emanated from the faculty, but we were careful to use the means that the administration had in place for change, namely strategic and long range planning. By working in concert we were able to accomplish a major change. There is an old French proverb which states, "When it comes to change, people like only those that they make themselves." In order for the change to be successful, all parties, from the individual members of the education department to the various members of the administration had to feel a sense of ownership in the plan. I believe it was my challenge to remind each of the major factions of the importance of their respective roles. By utilizing an open communication and shared responsibility model, I believe we were able to accomplish it. That is not to say that we did not have our problems or that we do not expect to have problems in the future, but as long as we can maintain a model of open communication and shared responsibility, I believe that we can meet the challenges of the future by continuing to make a concerted effort to be a part of the solution and not a part of the problem.

Abstract: This progress report delineates processes and procedures in assessing changes in teacher attitudes and behaviors as they utilize Internet for the first time in curriculum development and delivery. The setting is a north Texas rural district serving 1320 students. The sample includes 66 teachers in the middle school and high school. Quantitative data on the Stages of Concern are elicited electronically at three stages in the semester. Quantitative data on the Levels of Use are elicited in face-to-face interviews at the same three stages. Concurrently all teachers participate in a project listserv which provides structure for professional colloquy and qualitative data for analysis. The model provides a framework for the study of change processes relating to various innovation configurations.

Conceptualization of the Problem

Standards

The problem on local, national, and international levels is to use technology as a tool for learning within meaningful contexts to support learning (Kozma & Shank, 1998). National, state, and local standards identify the need to integrate technology into learning processes in our classrooms. In Texas, the standards reflected in the Texas Essential Knowledge and Skills (TEKS) (Texas Education Agency, 1997) include the computer competencies which the learners must demonstrate in the state learning assessment, the Texas Assessment of Academic Skills (TAAS) (TEA, 1997). Thus Texas students are assessed specifically on technology competencies for which teachers and administrators are held accountable.

The State of Texas not only mandates computer competency standards; it also requires districts to submit a three-year technology plan for approval. The Texas Long-Range Plan for Technology 1996-2010 addresses: (1) teaching and learning, (2) educator preparation and development, (3) administration and support service,
and (4) infrastructure for technology. The state offers sizable Technology Integration in Education (TIE) grants to support district efforts. As schools move from first generation of using technology to the second generation of thinking with technology, computers are moved from labs into classrooms. Increasingly, Internet becomes available there.

**Internet in the Classroom**

The most significant change in the classroom today is not just a computer, but also direct access to the Internet. This practice is congruent with the four goals in the national long-range technology plans and the goals supported by Texas TIE grants. Access to the information superhighway stimulates dramatic changes in the classroom just as it has in millions of home and businesses. Such innovation calls for significant professional development for teachers at all grade levels and all content areas.

**Teaching**

Research suggests classroom teachers are under-prepared or unprepared to utilize existing electronic resources effectively (Brownell, 1997; Buhendra, 1996; Clawson, 1996; Fisher, 1997). Basic technical productivity skills are not enough. With the increase in the amount of information available, both students and teachers need advanced skills in analysis, evaluation, and synthesis as the new technologies are integrated into the learning process. The teacher no longer holds all authority over knowledge. She/he must work in the information age to support the development of self-directed, meaningful learning for all students. Experienced classroom teachers must not only become technically literate but also must reexamine fundamental beliefs about traditional classroom approaches now being questioned due to expanded opportunities (Dede, 1998).

Much teaching has been largely dependent on the structure and resources provided in the teachers’ guides that accompany the selected texts. This assumes that the teacher dispenses the knowledge through texts and the resource choices that he or she makes. In the Information Age, many of our traditional resources are outdated. Today all need to know how to access the knowledge, check the validity, organize, evaluate and synthesize. Thus, the teacher’s instructor role becomes more that of a guide. This role may utilize Socratic questioning that leads to higher levels of critical thinking. Such roles are congruent with the constructivist philosophy that requires a tremendous amount of adaptation and flexibility on the part of the teacher.

**Evaluating Change**

Change is complex and cannot be forced from the top. The individual is the primary focus of change (Fullan & Miles, 1992; Little, 1993). As state and districts set new learner expectations, as the teaching environment is enriched by new opportunities, and as appropriate professional development supports professional growth, teachers do change. This model addresses the changes in concerns and usage behaviors as they relate to the utilization of the Internet as a tool for learning.

Change is not finite, not an event. It is a *process*. This research focuses on the *change process* as teachers change in their attitudes and usage behaviors as an innovation is attempted. In education, study of change has been well established in the Concerns Based Adoption Model (CBAM) (Hord, Rutherford, Huling-Austin & Hall, 1987). Twenty years of research with teachers, administrators, and professors have substantiated the reliability and validity of the two instruments: *Stages of Concern Questionnaire (SoCQ)* and *Levels of Use (LoU)*. These instruments are utilized in relationship to the Innovation Configuration (IC) which defines the innovation central to the change being studied.

In this study the Innovation Configuration revolves around Internet access in the classroom and its use by teachers to develop and deliver curriculum. The research collects quantitative data electronically on the SoCQ and by individual interview on the LoU. Electronic teacher discourse is examined qualitatively in order to identify patterns of concerns and usage. The *Nudist Qualitative Analysis Software (NQAS)* provides a research tool to analyze these qualitative data.
The Research Problem

As national and state standards establish goals supporting use of technology as tools for thinking, the philosophy of classroom teachers and traditional classroom methods are being questioned. This ongoing research evaluates the changing of teacher concerns and usage behaviors as they use Internet in their classrooms for the first time in the spring semester of 1999. District training is designed to support the changes, and electronic teacher discourse is established and supported by researchers. The Concerns Based Adoption Model (CBAM) provides two tools to collect quantitative data (SoCQ and LoU). Qualitative data drawn from the electronic teacher discourse provides interpretative and contextual data and is analyzed with NQAS.

Research Design

This descriptive study of changing attitudes and behaviors toward an Innovation Configuration (IC) examines the experience over one semester of 66 classroom teachers in middle and high school settings. The research collects quantitative data on the SoCQ and LoU at three checkpoints (January, March, and May). Qualitative data are collected from teacher electronic discourse through participation in a listserv related to the project. The first four Hypotheses use SoCQ data to address changes over time of the whole faculty and by three groupings (grade level, school level and content specialty). The next two Hypotheses use LoU data collected in individual interviews to assess changes in usage behavior over time and possible relationships to home Internet access. Hypothesis 7 assesses a possible relationship between stages of concern (SoCQ) and home Internet access. Hypothesis 8 uses path analysis is used to track the relative influence of components of the innovation configuration during the first year of adoption.

Hypotheses

1. No significant changes in teacher SoCQ attitudes are evidenced from the beginning of the semester, mid-semester and end of the semester.
2. No significant changes in teacher SoCQ attitudes by school level are evidenced between the beginning of the semester, mid-semester and end of the semester.
3. No significant changes in teacher SoCQ attitudes by grade level are evidenced between the beginning of the semester, mid-semester and end of the semester.
4. No significant changes in teacher SoCQ attitudes by content area at middle and high school levels are evidenced between the beginning of the semester, mid-semester and year end.
5. No significant changes in teacher LoU behavior ratings are evidenced between the beginning of the semester, mid-semester and end of the semester.
6. No significant correlation between home Internet availability and LoU behavior ratings is evidenced.
7. No significant correlation between home Internet availability and SoCQ attitudes is evidenced
8. No significant correlations will be attained among path vectors of the predicted models of change dynamics.

Sample

The census sample (n=66) includes all middle and high school classroom teachers in one small rural Texas school district. Little Elm Independent School District (LEISD) enrolls 1350 students, of whom 45% are designated at-risk, and 22% are minority students. Approximately 120 teachers are employed as classroom teachers in the four schools: primary, intermediate, middle, and high schools. All middle school teachers (n=27) and high school teachers (n=39) had Internet available in their classrooms for the first time in Spring of 1999. LEISD is one of eleven district partners in the Community Collaborative Professional Development Centers (CCPDC) sponsored by Texas Woman's University. These eleven districts include two urban, three suburban, and six rural professional development sites. This CCPDC entity encompasses the entire TWU undergraduate teacher education program and university liaisons work with each district.
Instruments

The Stages of Concern Questionnaire (SoCQ) consists of 35 items that use a seven point Likert response form. Analysis of the data results in placing the subject at one of eight levels of concern: (1) Awareness, (2) Informational, (3) Personal, (4) Management, (5) Consequence, (6) Collaboration, and (7) Refocusing (Hall, Wallace, & Gossett, 1973). The measure was developed at the Research and Development Center for Teacher Education, University of Texas at Austin, and has been heavily used in the change literature (Fullan & Stiegelbauer, 1991; Fullan, 1993a; Fullan, 1993b, Hord et al, 1987).

Hall, George, and Rutherford (1979) assessed the reliability of the 35 items on the questionnaire. They used Cronbach’s alpha to examine internal reliability. They report alpha coefficients ranging from .64 to .83 on the seven scales. Test-retest correlations taken two weeks later used the Pearson r correlations and ranged from .65 to .86. The lowest correlations in both analyses occurred in the Stage Zero scales.

The validity of the questionnaire was ascertained from intercorrelation matrices, judgments of concern based on interview data, and examination of concerns in relation to the amount of time of involvement with the specific innovations. Hall and George (1980) determined that the correlations on the 195-item questionnaire were higher near the diagonal. This finding supported the theory that each scale was more like the ones immediately surrounding it than those farther way (Hall & George, 1980). Reliability and validity have both been examined in subsequent studies and the original suppositions have been supported.

The Level of Use (LoU) data are collected by individual interviews. A detailed manual developed by Loucks et al. (1975) supports the focused interviews used to assess the level of use of innovations. A detailed guide establishes a list of objectives and questions but the interviewer is provided latitude within the framework guide. Approximately 1680 interviews were conducted during the validation period. Interrater reliability was established using the detailed examples in the manual, and it was fairly simple to reach 70% agreement or more.

The Innovation Configuration (IC) specifies the dimensions of the innovation so that all subjects are focused on the same concept as they share their concerns or level of use. The configuration is clarified in the first training and repeated in every data collection. In this study the IC is the access to Internet in the classroom and the ways and degree that the teachers use it in development and delivery of curriculum.

Demographic Data such as gender, teaching experience, certifications, and degrees will be used to describe the sample. Grade level and content specialty will be used to address Hypotheses 2, 3, and 4. Home Internet availability will be utilized in Hypotheses 6 and 7.

The Nudist Qualitative Analysis Software (NQAS) in not an “instrument” in the classical sense, but it is a contemporary software tool designed to support qualitative analyses and/or content analysis. This important addition to this exploratory study provides vital background for designing a larger research effort.

Data Analysis

The seven developmental stages of the SoCQ are transferred to a seven-digit number for facet analysis. Hypothesis 1 (changes over time), Hypothesis 2 (time by school groups) Hypothesis 3 (time by grade level, and Hypothesis 4 (time by content area) are be addressed in these analyses using three-digit configurations from the profile to assess initial, middle, and advanced concern concentrations. Change in these configurations will be separately assessed through t-tests for adjacent time periods and repeated measures ANOVA across all three time periods. Facet mapping of changes in the overall profile will also be conducted.

The ratings developed from the LoU interviews are converted to ordinal data for testing of Hypothesis 5 (changes over time) using Wilcoxin’s matched-pairs signed-ranks test. Hypotheses 6 data (relationship of LoU
behaviors to home computer availability) are examined using Spearman Rho correlation coefficients. Hypotheses 7 data (relationship of SoCQ attitudes to home computer availability) are examined using ETA correlation coefficients.

Hypothesis 8 will be examined by a path analysis used to track the relative influence of components of the innovation configuration during the first year of adoption. Components to be tracked include (1) access and usage of the classroom computer, (2) participation in the LEISD professional development, (3) home Internet availability, (4) school access to and usage of the Internet, involvement in electronic discourse, (5) beginning SoCQ and LoU profiles, and (6) ending SoCQ and LoU profiles. Strength of influence along vectors will be examined through correlation coefficients.

Qualitative studies are increasing in education. Its advocates believe that depth of understanding of human phenomena is founded on these data. The electronic discourse among teachers will be examined over time. Changes in content themes and value connotations of procedural statements will be charted.

Procedures

1. In August and September, Human Subject Review forms were completed and filed at the University Research office. LEISD administrative approval was obtained at this time. The Principal Investigators (PIs) met with administration in the LEISD central office to plan training schedules and clarify procedures. Installation of technology was delayed and thus limited the study to middle and high schools.

2. In October, the PIs placed the SoCQ on a website for electronic collection of data. Since every teacher will have access in his or her classroom, all data on this measure can be collected anonymously and electronically. The data are imported into the Statistical Package for the Social Sciences (SPSS) for analysis of quantitative data.

3. In November, the PIs and GRA explored the NQAS software for the analysis of teacher discourse. SoCQ and LoU concepts are used as a foundation for content analysis but possible patterns were left open for discovery.

4. In December, the PIs and GRA prepared for the January inservice and the first collection of SoCQ data. Plans were made for dissemination at the Society for Information Technology in Teacher Education (SITE) international conference in March in San Antonio.

5. In January, during the University break, the PIs and GRA participated in the teacher inservice, held in Little Elm. Interviews for LoU were conducted. The first set of SoCQ data was collected electronically and first analyses in SPSS were completed. The LoU data was entered into SPSS for analysis. Thelistserv was established and the collection of teacher electronic discourse data began.

6. In March, the midterm SoCQ data were collected electronically and the GRA completed the second set of interviews for the LoU data. The PIs prepared and presented a progress report for CCPDC personnel, and for the SITE 99 conference. The GRA continues analysis of teacher discourse.

7. In May, GRA completes third set of interviews on LoU. The last set of SoCQ data are collected electronically. The GRA completes data analysis available through SPSS. Qualitative analyses continue through June. PIs plan with LEISD officials for fall inservice and data collection.

8. In June, preliminary findings are offered on the WEB through CCPDC and PI web pages to other CCPDC districts, to professional associations and government agencies.

9. In July, The PIs complete qualitative analysis using the NQAS, and prepare the appropriate research report.

10. In August, PIs and GRA prepare for inservice at LEISD to share first-year results and project research extension to primary and intermediate schools, as they are equipped for the Internet.

Significance

This study has practical value for education practitioners. Importantly, it also promises contributions to the change process literature using technological configuration as the innovation. The research values are
bifurcated: (1) an important study of change process with a contemporary technological innovation, and (2) findings from the qualitative study drawn from teacher electronic discourse.

Change facilitators intervene appropriately as levels of concern are revealed to them. Meeting the needs of the professional, like meeting the needs of our students, helps these professionals advance developmentally in their attitudes and behaviors. Both the quantitative and qualitative analyses provide a strong foundation for effective change facilitation to support the professional development process.

The changes in attitudes and behaviors of these LEISD teachers cannot be generalized because it is a census sample, not a random sample from a specified population. However, the changes in attitudes and behaviors of these LEISD teachers are of significant interest to teachers in other small districts. More than one million Texas students are enrolled in such schools in isolated areas. Internet offers these students and their teachers global access to information and colloquy with their peers in near or distant locations. The Texas Woman’s University preservice teachers placed in Little Elm ISD gain unique insights into the use of Internet technology and the changes instituted in the use of Internet for curriculum development and delivery.

Acknowledgments

For contributions to the implementation of this project on the various campuses, Drs. Vera Gershner and Sharla Snider would like to express appreciation to Dr. Linda Monaco, Assistant Superintendent of Little Elm Independent School District; Marvin Beaty, Principal of Little Elm High School; Suzanne Woodard, Principal of Little Elm Middle School, Kathy Kazanski, Principal of Little Elm Intermediate School, and Linda Lammers, Principal of Little Elm Primary School. Dr. Donna Crenshaw, Director of the CCPDC Program and Dr. Sondra Ferstyl, Associate Dean of Research, are applauded for their ongoing support of this project. Funding was provided through a University Research Enhancement Grant of $5991.
Technology and Innovation in Michigan K-12 Schools:
Findings from the NextDay Teacher Innovation Grant Research Project

NextDay Research Team*
Michigan State University College of Education
East Lansing, MI 48824

Project Overview: Introduction to the Michigan NextDay Research Project

Program Goals

1. Identify and share best practices among grantees and other educators in Michigan and beyond
2. Encourage and document sharing and learning among grantees
3. Encourage and support action research of grantees
4. Document and analyze the impact of the grants on teaching practices, learning outcomes, and school culture of technology integration

Overarching Research Questions

1. What impact does the program have on the grantees in terms of technology proficiency, technology integration, attitude, and most importantly teaching practices?
2. What impact does the program have on the learning outcomes of students in the classrooms of the grantees, as a result of the change in teaching practices and introduction of technology?
3. What impact does the program have on the culture of technology integration in the schools/districts of the grantees in terms of changes in other teachers and the school or district?

NextDay Proposals
Research Design

Three Level Design

Level 1: All grantees (115) participate at this level. We will:
- Examine the grant applications submitted by each grantee
- Conduct three surveys among every grantee to inventory their computer attitude, computer use (projected and existing), computer proficiency, self-efficacy, pedagogical beliefs, and teaching practices
- Facilitate and observe electronic communications of participants throughout the year on a list server and on a Web-based forum
- Collect monthly electronic journals throughout the project
- Collect bimonthly panorama pictures of the classroom or a classroom activity and descriptions of the activities

Level 2: Thirty grantees, selected to represent diversity in subject area, grade level, geographical location, technological level, district size and type (urban, suburban, or rural), and student SES, participate at this level. In addition to level 1 data, we will:
- Conduct two face-to-face interviews (one at the beginning and one at the end of the project) and three electronic interviews throughout the year
Level 3. Twelve grantees, selected to represent diversity in grade level and subject area, participate at this level. In addition to level 1 and level 2, we will:

- Visit and observe classrooms frequently (once-a-month)
- Interview teachers frequently
- Interview students and parents
- Survey other staff at the school

Research to Practice: An Online Connection

Sean J. Smith & Linda Mandlebaum, Bowling Green State University, USA

Abstract: The infusion of technology into pre-service teacher education should be a major priority for teacher education programs across the country; especially in the area of special education where technology integration can be beneficial to student development. Similarly, teacher education programs need to prepare students to bridge the gap between teaching and research. This presentation describes how we have begun to integrate the Internet and world wide web into pre-service teacher education method instruction in hopes of expanding the instructional use of technology in special education classrooms while integrating best practice (based on effective research) across the curriculum.

The infusion of technology into pre-service teacher education should be a major priority for teacher education programs across the country; especially in the area of special education where technology integration can be beneficial to student development (Carnine, Bean, Miller, & Zigmond, 1994; Hasselbring & Goin, 1991; MacArthur & Malouf, 1990). This presentation will describe how we have begun to integrate technology across the Special Education Methods Block. We have organized the discussion to illustrate various ways faculty members can provide models of appropriate use of computers for instructional purposes. Although not exhaustive, the examples are meant to illustrate ways higher education can prepare both pre- and in-service teachers to integrate the Internet and problem-solving software into their K-12 classroom instruction.

Specifically, we will illustrate how the Internet provides a way to help bridge the gap between teaching and research. We are all familiar with teachers' often justifiable complaint that research is something done and read by professors in ivory towers. This attitude is a response to the difficulty many teachers have in interpreting research methods and results that are written to satisfy the rigorous standards of research journals. Yet, in our own experiences, we have found pre- and in-service teachers to be quite receptive to the idea that research should be used by teachers in their classrooms.

Effective teachers (i.e., those whose students have greater measured outcomes than other students) are researchers, whether they recognize themselves as such or not: They analyze their students' levels of performance; they make instructional changes in response to those levels of performance, and; they evaluate the effects of those instructional changes. Sometimes this is accomplished through the use of pre- and post-tests analogous to studies using statistical procedures to evaluate the effects of interventions; other times it is accomplished through repeated measures of baseline and intervention data analogous to single-subject research methods. One goal we have is to make it more evident to teachers that they can and should be researchers (i.e., prove that the techniques they choose to use are effective) by exercising more deliberate control over their data-collection procedures and instructional decision-making processes. At the same time, we must convince them that they don't need to "reinvent the wheel" or rely solely on other teachers' personal experiences and anecdotes to deal with every behavior and learning problem they encounter. There is existing research with direct classroom applications in libraries, and increasingly in cyberspace, waiting to be found.

This presentation will illustrate how we employ these resources in special education method instruction. We will share with participants examples of a research-based online component that offers teacher-educators access to online research-based resources.

Our specific objectives include:
- Discussion of strategies to incorporate technology across curriculum and methods instruction;
- identify ways faculty members can model the use of technology in teacher education preparation;
- model ways the Internet and multimedia applications can be used to bridge the gap between research and practice; and
• demonstrate how students are currently developing an online research-based resource for special education teachers.

Learning Schools Programme: Developing Teachers' Information Communication Technology Competence In The Support Of Learning.

Peter Twining, School of Education, The Open University, UK. Email P.Twining@open.ac.uk

Robert McCormick, School of Education, The Open University, UK. Email R.McCormick@open.ac.uk

Abstract: The UK government has initiated a massive information communication technology (ICT) staff development programme: LoFTTI (Lottery funded Teacher Training Initiative). The aim of this programme is to train all practicing teachers in state schools within the UK so that they can make effective use of ICT as a tool to support their children's learning. The Learning Schools Programme is one of the consortia that are intending to provide this training. The paper sets out a brief history of key developments in ICT use in UK schools over the last 25 years and the requirements that have been set down for LoFTTI. The content, structure and support mechanisms for the Learning Schools Programme's training is then described, with reference to relevant literature.

A Brief History - 1970 To 1998

The use of ICT in UK schools goes back over two decades. In the early 1970's the UK government founded the original National Council for Educational Technology that had the brief of evaluating and encouraging the development of educational technology. Since then there have been a large number of centrally driven initiatives relating to the use of ICT in schools. For example, in the early 1980s the Department for Trade and Industry funded schemes to put a computer into every school (in England). At around the same time the Microelectronics in Education Programme was funded to provided a focal point for staff development in the use of ICT in schools and developed a substantial base of support materials. A large number of similar schemes were rolled out over the 80's and 90's.

In 1990 the UK government introduced the National Curriculum for state schools in England and Wales. Information Technology (IT) was included as part of the Technology curriculum. In 1995 a revised National Curriculum was introduced, in which IT appeared as a subject in its own right as well as being included as part of the general requirements for every other subject except PE and RE.

Despite all of these initiatives, and the expenditure of hundreds of millions of pounds on the development of IT in schools, there is considerable evidence that in the majority of schools IT is not being used extensively nor in ways that enhanced children's learning (OFSTED, 1997; Underwood & Monteith, 1998).

McCormick (1992) identified two common failings of these initiatives as being a lack of provision of training and a focus on the level of the classroom rather than the school as a whole. Additional problems, which Maddux (1994 p.130) identified with early schemes in the USA, also apply to the ones in the UK, namely that the Government was mandating the use of technology in schools and that there tended to be an emphasis on computer literacy which suggests that learning about computers per se is the main aim.

When the new Labour government came into power in 1997 a major part of their platform was to increase the level of 'basic skills' achieved by children in the UK. Prior to their election, they had commissioned a report that stated that "if the next government does not take steps to intensify the use of information and communications technology (ICT) in our schools, a generation of children - and a generation of adults as teachers - will have been put at enormous disadvantage with consequences for the UK that will be difficult to reverse." (Stevenson et al., 1997 'Our Vision'). Thus, with the aid of the relevant government departments, they introduced a number of 'educational' initiatives in 1998, including:

1732
• The National Grid for Learning (NGfL), which is a web-based initiative, focussed on education. (See http://www.ngfl.gov.uk/ and DfEE, 1998a).
• Funding to connect every school in the country to the internet and to provide additional computer equipment. This funding now stands at £700 Million over the period 1998 to 2002.
• The ‘Literacy hour’ for schools in England. This requires that all primary aged children spend a minimum of one hour per day studying English and prescribes a detailed English language curriculum and teaching methodology predominantly based around whole class teaching.
• The ‘Numeracy Programme’, which will be implemented in September 1999. This will involve a detailed maths curriculum and a teaching methodology largely based around whole class teaching.
• A national curriculum for initial teacher training (DfEE, 1998b). This included requirements for ICT, which every trainee teacher has to achieve in order to become a qualified teacher.
• An IT audit, known as ‘the Needs Identification’, which is due to be carried out by all existing teachers in state schools in the UK early in 1999.
• The Lottery funded Teacher Training Initiative (LoFTTI). (See below)

These initiatives, like many of their predecessors, represent a power-coercive model of curriculum development. They are being imposed on UK teachers by the government at a time when they have already been swamped with centrally imposed changes, many of which have served to de-motivate and de-professionalise teachers.

An Overview Of LoFTTI: The Lottery Funded Teacher Training Initiative

LoFTTI is a £230 Million programme to train practicing teachers in UK schools to use information and communications technology (ICT) in their subject teaching, starting in April 1999. This initiative, at least implicitly, recognises that:

• ICT has the potential to enhance learning across the curriculum (Scrimshaw, 1997);
• the majority of schools within the UK are not harnessing the potential of ICT effectively (OFSTED, 1997) or to quote Stevenson et al (1997 Summary) “the state of ICT in our schools is primitive and not improving”;
• "Teachers need to know not only how to operate the systems in a technical sense, but also what educational possibilities they have, and the consequences of their introduction both for teaching strategies and for curriculum planning." (Scrimshaw, 1997 para 17);
• incorporating ICT in teachers’ professional practice represents a significant innovation (e.g. Hoffman, 1996; Kerr, 1991; Maddux, 1994; Ridgway & Passey, 1995; Somekh & Davis, 1997);
• “innovation involves winning people over to change the way they do things, and this can never be achieved without adequate and appropriate professional development.” (Somekh, 1998 p11).

In addition, LoFTTI has recognized that previous attempts to train teachers to use ICT, which have been focused on relatively small numbers of teachers and have often used a cascade model, have not worked. Thus this initiative aims to train every single practicing teacher in state schools in the UK over a three-year period. This represents around 450,000 teachers in England, Scotland, Wales and Northern Ireland. In order to achieve this ambitious target an invitation to tender as an approved training provider was issued in September 1998. This set out in great detail the purposes of the planned training and the outcomes that were expected. These outcomes, which are largely the same in each of the four countries, consist of pages of competencies that teachers should have, both in the use of ICT in the teaching of other subjects and in their knowledge and understanding of ICT itself. The focus of the training is very much on developing teachers’ skills in using ICT to support the development of children’s learning in other subject areas.

The total training budget of £230 million pounds, which amounts to approximately £460 per teacher, will be devolved to schools in the form of vouchers that can only be used to buy ICT training from approved providers. The approved training providers will thus operate in a competitive market in which schools can choose which provider to use (with variations across the four countries about the role that their local educational authorities will play in the process of selecting providers).
The Learning Schools Programme

The Learning Schools Programme is being developed by a consortium of organisations, who together applied to become an approved training provider. The consortium consists of a partnership between the Open University (OU) and Research Machines (RM), plus associate organisations including Education Authorities employing approximately 320,000 teachers across the UK as well as other professional bodies, organisations and individuals. The OU provide expertise in relevant curriculum and research areas as well as in the development of effective supported self-study materials. RM is one of the most significant suppliers of ICT equipment and services to UK education and provides extensive support networks and excellent links with schools and education authorities across the UK.

The Learning Schools Programme (LSP) will provide staff development across all four countries in the UK. There is one core course for primary school teachers (K-6), which focuses on the use of ICT in literacy, numeracy, science, and cross-curricular work. This will be supplemented by additional material for use in Northern Ireland and in English speaking schools in Wales, as well as a version of the course with material originated in Wales and presented in Welsh. There are 14 core courses for secondary school teachers (for students aged 11-16), each focused on the use of ICT in supporting teaching in one of the national curriculum subjects (e.g. English, Maths, Science, History, etc.). In Wales, the Welsh language as a subject will also have specifically produced material. Thus we are combining a generic cross-country approach with a country-specific one. In addition, all the courses are linked into a UK wide accreditation framework, which contributes towards postgraduate qualifications such as a Masters in Education.

The Learning Schools Programme is adopting a school based, supported self-study model of staff development that is based on a constructivist view of learning. This has a number of implications for the ‘courses’, which are discussed below.

A School Based Approach

Being school based is crucial because the conditions and factors that impede professional development of teachers who need to learn skills for teaching with technology reside in the culture of the school (Barnes & Hall, 1998). A culture change is needed for schools to become learning organisations in which teachers see their own learning as part of their professional role (Lieberman, 1995). As we noted earlier, the school needs to be the focus for professional development, allowing a balancing of the needs of individuals and institutions. The importance of leadership in any change effort is widely recognised (e.g. Barnes & Hall, 1998; Fullan, 1986; Hoffman, 1996; Hopkins & al, 1994; Lieberman & Miller, 1990; Louis & Miles, 1990; Miles, Saxl, & Lieberman, 1988). Part of the reason for the importance of leadership is the key role that ‘leaders’ play in providing pressure and support for any given initiative. Pressure and support are both necessary for the successful implementation of change in education (Fullan & Stiegelbauer, 1991, p. 91) and a key element of this is an “expectation from the institution that effective educational technology be used” (Topp et al., 1996, p. 58).

There are also more practical issues relating to basing training on the resources available within the school. Taking teachers out to special centres has limited effectiveness, not only in exposing them to equipment that is not available in school, but also assuming a cascade of change from these teachers to those who remain in school. Thus the LSP courses will include materials for a school organiser as well as external support for them (see A supported approach below). The programme is intended to link in closely with school development plans, and the school materials reflect this, as well as including elements to assist with the administration of the Programme. The need to include the whole school community is recognised through the provision of materials (e.g. videos) aimed at parents, governors, staff and children. A communal library of books about the management of change and ICT use in schools is also provided within the school-level materials.

In recognition of the importance of access to equipment (e.g. Topp et al., 1996; Twining, 1998) the LSP had intended to provide portable computers as part of the school-level materials. However, the rules governing LoFFTI funding did not permit funding to provide any hardware.
A Supported Self-study Approach

There is a great deal of evidence that one of the most important ways in which teachers develop their ability to use ICT in their teaching is through time spent at home (e.g. Hoffman, 1996; Stevenson et al., 1997). Adopting a self-study approach also provides greater flexibility for teachers in that they have more freedom to work on the programme when and where they wish than would be the case with other modes of study. However, the importance of support for a significant staff development programme at a range of levels is crucial (e.g. Hoffman, 1996; Fullan & Stiegelbauer, 1991). Within the LSP support is provided at all levels and in a number of different ways. Thus school organisers and teachers working on the programme are provided with:

- structured course materials using a range of media (e.g. paper, multi-media and the Internet);
- in-school support from peers, their school organiser and their regional advisor in the form of face-to-face meetings and computer-mediated communication (email and conferences);
- access to the National Grid for Learning (NGfL), which contains extensive support material for teachers provided by other organisations as well as access to teacher discussion fora;
- technical support in the form of a telephone help line operated by Research Machines.

In addition the regional advisors, who support staff in schools, are provided with face-to-face training as well as electronic support conferences designed specifically for them and moderated by staff at the Open University.

A Constructivist Approach

The LSP is in full agreement with Lieberman (1995) when she says that staff development cannot be thought of as bite-sized packages of knowledge to be transferred to teachers. Thus, though we are providing materials that encapsulate ‘bite-sized packages of knowledge’ we see it as being crucial that these are contextualised and debated locally by individual teachers. We believe that if they are going to “really change the way they work - then teachers must have opportunities to discuss, think about, try out, and hone new practices. This means that they must be involved in learning about, developing, and using new ideas with their students.” (Lieberman, 1995 p.593). Thus LSP encourages teachers to:

- engage with resources that encapsulate models of teaching using ICT and raise issues about the implications of such practice;
- enter into an iterative process of planning, implementing and evaluating activities that are relevant to their own contexts, incorporating ICT where appropriate;
- act as reflective practitioners (Schon, 1987) and share their experiences with colleagues.

A Long Term Approach

There is substantial evidence that indicates that any programme that aims to integrate ICT in teachers’ practices requires a long time frame (e.g. Hoffman, 1996; Ridgway & Passey, 1995 p67; Somekh, 1998; Topp et al., 1996). Thus the LSP allows teachers to work on the programme over a period of up to six months and provides continuation mechanisms and strategies to support teachers after the end of their formal enrollment on the programme. The Programme is built round an action plan supported by a professional development record, which we hope will continue after the initial training is completed. Indeed, the possibility of continuing electronic conferences and access to the internet, should encourage teachers to move from a focus on ICT as the subject of their professional development, to ICT a means of their development across the range of professional issues.

A Subject Oriented, Problem Solving Focus

Throughout the programme our approach focuses on the real issues facing teachers who are trying to teach their subject(s), in line with the suggestion that the best way forward is to "drop all consideration of increasing the use of technology for technology's sake and approach change from the perspective of developing solutions to problems." (Willis & Robinson, 1994 p.15). This approach also recognises and builds upon the expertise of...
teachers rather than adopting a deficit model (Rhodes, 1989). We hold a strong belief that ICT is an effective tool for education and agree with Willis that in these circumstances "a problem-focused change effort will include {new technologies} as an element of solutions even though technology was not an initial target." (Willis & Robinson, 1994 p15). This needs to be combined with activities and outcomes of the programme that are seen as being of practical value by the teachers concerned (Somekh, 1998). Hence, we have aimed to follow Ridgway and Passey's advice that: "Early stages should focus on achieving desirable goals which are hard to reach in other ways (such as supporting problem solving groups, developing writing skills, inculcating modeling skills), while providing positive classroom experiences for teachers and students. These stages should be attainable without a massive investment of time by the teacher. They should lead onto pleasant classroom experiences, which actually make teaching easier, and the educational gains by students should be judged to be valuable by the students themselves, by other teachers, by parents, and by people outside the school community." (Ridgway & Passey, 1995 p.66).

A Differentiated Approach

The LSP aims to cater for a large number of teachers, covering a broad spectrum of levels of confidence and competence in their own personal use of ICT as well as in its use within teaching. Thus differentiation is a key issue for us. Indeed, it is important that we build on the individual outcomes that teachers have achieved from their ‘Needs Identification’ audit (see under A Brief History above) both politically and because “innovations are likely to fail when they challenge fundamental values and practices, ... ignore the starting points of the individuals involved, fail to monitor progress, and adapt the programme appropriately” (Ridgway & Passey, 1995 p.66). We aim to achieve differentiation by providing a range of starting points and end points with clearly defined routes between them. However, we have utilised some of the flexibility that electronic media provide to allow teachers to fit the material to their own needs and interests.

Summary

The LSP has been developed in the light of past research into staff development and the implementation of ICT in schools. It is adopting a school based, supported self-study model of staff development that is based on a constructivist view of learning. However, despite the fact that the LoFTTI initiative clearly reflects the recommendations made in the synoptic report on the evaluations of the Education Departments Superhighways Initiative (Scrimshaw, 1997), there is inevitably a tension between any centrally imposed innovation and the approach to staff development that the Learning Schools Programme aims to adopt. For example, whilst the Learning Schools Programme aims to empower teachers to use new technologies in ways that serve their own needs, the need to use ICT to enhance their teaching is being imposed upon them. Similarly, the LSP’s aim is to build on the expertise that teachers have and yet LoFTTI takes as its starting point the Needs Identification, which will have identified the areas where teachers lack necessary skills. The extent to which we have succeeded in reconciling these tensions and the degree of effectiveness of our approach remain open questions; the first teachers are due to start working on the LSP in April!

Abstract: This paper is a report combines the findings of a study conducted on how, three North Carolina school districts created a representative consortium of rural schools to construct methods to identify when and how technology impacts school reform and the changes necessary if technology is to impact education reform efforts. The Technology Activity Gage or TAG instrument is being piloted to identify how technology is used in schools. The TAG instrument can be used in a similar fashion as thee CEO Forum’s 1997 School Technology and Readiness (StaR) Chart. This approach incorporates prior research on technology implementation conducted on the Rural Technology Challenge Partnership, with emphasized professional growth of teachers, students exposure and development of technology skills, and accountability to all involved.

Introduction

Beginning in 1998, three North Carolina school districts created a representative consortium of rural schools to construct methods to identify when and how technology impacts school reform. Currently this endeavor is being accomplished through program evaluation and the use of the Technology Activity Gauge instrument. The Technology Activity Gauge, or TAG, is based on Cronbach’s (1983) functional model of design, which states that each school, even within the same district, differs in the areas of political, social, and resource structures, and helps us to understand why technology focused models of school reform fail to be replicated from school to school successfully. TAG’s technical approach is based on establishing uniformed instrumentation to identify three levels of technology-use indicators and student-learning indicators. Reported indicator levels reveal a classroom’s TAG level. TAG levels consist of low (1), medium (2), high (3), or target tech (4). The TAG instrument can be used in a similar fashion as thee CEO Forum’s 1997 School Technology and Readiness (StaR) Chart. This approach incorporates professional growth of teachers, students exposure and development of technology skills, and accountability to all involved.

Two types of technology indicator levels are associated with school reform. TAG incorporates both Indicators of Use and Indicators of Learning Activities. Means (1994) argues that technology can support exactly the kinds of changes in content, roles, organizational climate, and activities that are the center of the education reform movement. It is the goal of indicators of use to determine how often and in what ways technology is utilized in the school

Whether technology and education begin to develop a partnership in the reconstruction of conventional education will depend on whether or not educators develop and sustain a set of instructional goals that promote learning, and then find appropriate ways to use technology as a tool to achieve those goals. Technology must no longer be viewed as a goal to be achieved in and of itself, but instead a support for the learning process (Sheingold & Tucker, 1990).

Teachers who use technology in the classroom do so because they believe it will support more complex and challenging forms of learning. The reform efforts of the past have taught us that to improve the quality of instruction requires the transformation of learning environments into those that are conducive to learning. Educators and psychologists agree that in order for students to achieve higher order thinking skills we must shift from our paradigm that focuses on the transmission of information and skills through listening, to a paradigm that considers learning to be a participatory process where students construct knowledge through experiences, inquiry, and a variety of other resources. Table 1 illustrates the changes that must occur for this constructivist paradigm to become the guiding force in our schools (Roehrig Knapp & Glenn, 1996).
The introduction of technology has the potential to promote the changes that are necessary for school restructuring. First, technology encourages the recognition that learning is a lifelong process. Because technology continues to rapidly change teachers realize that they must constantly evaluate and manipulate information. Second, technology promotes collegiality between teachers. Because technology is new to many teachers it becomes necessary that they interact and exchange information regarding its use to promote teaching and learning. Third, technology provides teachers and students opportunities to engage in problem solving activities, and lastly technology changes the roles and relationships in the classroom by distributing expert knowledge throughout the classroom among teachers and students. This changes the role of the teacher from that of “keeper of knowledge” to that of a facilitator of learning (David, 1991).

Changes Necessary to Restructure Education

<table>
<thead>
<tr>
<th>Element of Change</th>
<th>Conventional School Characteristics</th>
<th>Restructured School Characteristics</th>
</tr>
</thead>
<tbody>
<tr>
<td>Learning</td>
<td>Students learn by absorbing information and skills through listening, lecturing and textbooks.</td>
<td>Students learn by constructing knowledge through inquiry and experience.</td>
</tr>
<tr>
<td>Teaching</td>
<td>Teachers introduce information and skills, and then assign exercises to encourage the memorization of the content.</td>
<td>Teachers engage students in activities that promote critical thinking, problem solving and the development of questions. Teachers are facilitators, coaches and a resource.</td>
</tr>
<tr>
<td>Curriculum</td>
<td>Emphasizes the mastery of skills through a curriculum divided by content area and ability level.</td>
<td>Emphasis is on inquiry designed to engage students in solving real problems that are interdisciplinary.</td>
</tr>
<tr>
<td>Classrooms</td>
<td>Isolated settings that are teacher centered. School work is typically individual and competitive.</td>
<td>Multipurpose rooms where school activity is collaborative and focused on cooperation and team building.</td>
</tr>
<tr>
<td>Assessment</td>
<td>Focused on short answer and essay tests that demand the simple recall of facts and fragmented pieces of information.</td>
<td>Focused on the ability of the students to demonstrate their knowledge and skills. Students are allowed to self assess. The purpose of assessment is to allow for continued improvement and more complex learning.</td>
</tr>
<tr>
<td>Technology</td>
<td>Traditionally have included pencils, paper, chalkboards, textbooks, manipulatives and other resources that help develop basic skills.</td>
<td>Variety of tools to create knowledge and skills by supporting research, analysis, problem-solving, and communication.</td>
</tr>
</tbody>
</table>

Table 1: changes that must occur for this constructivist paradigm to become the guiding force in our schools' technology implementation (Roehrig Knapp & Glenn, 1996).

Means and Olson (1993) in their study of school reform and technology literature identified that technology: stimulates teachers to engage students in more complex tasks and materials; provides teachers a context to become learners, and to share their ideas about curriculum and instruction; motivates students to engage in more complex tasks, and to focus more on the quality of their work; while allowing them to solve problems in ways that adults do in the real world. As teachers gain access to the use of technology in the classroom it can often be overwhelming for them. Often they question what role technology will play in their classroom, what professional implications are involved in using technology, how technology will
impact student learning, and how they will integrate technology in all content areas (Roehrig Knapp & Glenn, 1996). The first question teachers ask is what role technology will play in their classroom? The TAG initiative addresses this question by providing teachers professional development both in and out of the classroom. Teachers receive technology instruction and work collaboratively with The Center for Technology Education & Assessment staff to develop ways to use technology in developmentally appropriate ways that promote learning. The second question teachers ask is what implications technology will have on them professionally? Means and Olson, 1993; Cotton, 1991; Bialo and Sivin, 1990; and Sheingold and Hadley, 1990 all suggest that using technology effectively in the classroom will enable teachers to be more successful in meeting the needs of their students. Teachers who instruct with technology: have higher expectations for student work, engage students in more complex and challenging activities, are able to meet individual needs of students, are more innovative in instructional practices, and experience a greater sense of professionalism about their role as a facilitator in the learning process.

As the importance of technology increases in U.S. schools educators must focus on creating environments that promote its effective use. Sheingold and Hadley (1990), and Means and Olson (1993) have identified characteristics of a technologically favorable teaching and learning environments. The essentials include: access to use technology when and where it is needed in instruction; teachers must be experienced in how to use the technology; support must be provided to teachers; school administration must support instructional practices that differ from traditional approaches.

The School Technology and Readiness (STAR, 1997) report shows how far our schools are from creating the best environment for technology to become a key factor in the restructuring of education. STAR profiled schools current use of technology, and categorized them according to their hardware capabilities, connectivity, content, and professional development activities. Their findings indicate that 59 percent of American schools have either no technology or poor, inadequate technology for their students. There were less than 3 percent of schools who were considered on the high level cutting edge of technology integration. The first category, low technology schools typically have limited access to modern computer technology, and limited access to computer networks. Fifty nine (59%) percent of American schools fall in the low technology category. The second category, mid technology schools, have moderate access to modern computer technology, and computer networks. This category contains 26 percent of schools. Only 12 percent of schools were placed in the third category, high technology schools, characterized as having significant access to modern computer technology, and networks. The last category, target technology schools, included only 3 percent of American schools. This category boasts the highest level of computer technology and network access for students with typical ratios of 3 students per computer, and 4 per multimedia computer.

The President’s Committee of Advisors on Science and Technology (PCAST, 1997) also highlighted concerns about access, but more importantly focused on how technology could most effectively be used to enhance learning. This report recognizes that in order for technology to maximize it’s potential in improving teaching and learning, a shift must occur in the view of technology as a tool to more efficiently perform traditional instructional practices, to a constructivist view or paradigm that views technology as a tool to sustain a classroom. In the constructivist paradigm the teacher’s role becomes that of a facilitator in the learning process and students are helped to construct knowledge through interaction, and experiences. The notion of “teacher as expert” is no longer the guiding philosophy of the classroom environment. PCAST (1997) represents a national perspective recognizing the importance of a constructivist model to enhance the teaching and learning that occurs in American schools.

"Before you become too entranced with gorgeous gadgets and mesmerizing video displays, let me remind you that information is not knowledge, knowledge is not wisdom, and wisdom is not foresight. Each grows out of the other and we need them all." —Arthur C. Clarke

Abstract: This study was conducted to examine the impact of an intensive professional development program on teachers' growth as educators. The researchers analyzed teachers' reflections on their attempts to integrate technology into their teaching and teachers' perceptions of their growth at the conclusion of the three-year project. In this study, echoing Clarke's viewpoint, the researchers investigated teachers' understandings of their journey and transformations in teaching, rather than multimedia hardware and software, per se.

Background

Research shows that successful professional development takes place over an extended period of time (Fullan 1991). Additionally, it provides for distributed learning/implementation to foster systemic change (Fullan 1991). Male (1994) suggests that successful classroom implementation of practices provided in professional development requires: theory, demonstrations of appropriate uses, opportunities for immediate practice and feedback, time to adapt curricula to technology, coaching, and periodic review. In a recent study, Cleland, Zambo, Wetzel, Buss, and Rillero (in press) reported on a successful professional development featuring (a) modeling of pedagogical strategies, (b) providing time for participants to implement their new understandings, and (c) providing opportunities for reflection.

Well-designed preservice teacher preparation programs and inservice professional development programs should provide opportunities for individuals to reflect on their teaching. Reflective teaching, critical evaluation and review of teaching for the purpose of improving practice, has played a prominent role in teaching and teacher education programs since its advent in the early 1980s. For example, since Schon's (1983) seminal work on reflective teaching practice, entire teacher education programs have been designed around this concept. Subsequent work by Schon (1987, 1991), Peterson and Comeaux (1989), and others attests to the richness of the reflection process. As a result, pre-service teachers are frequently asked to engage in systematic, reflective practice during their pre-service preparation through specific course requirements such as journaling, "reflection papers," and so on.

Although practicing teachers also engage in reflective practice, albeit on an intuitive, non-systematic basis, much less is known about the effect of reflection on the daily teaching of in-service teachers. Nevertheless, Cranton (1996) cogently argues that reflection is fundamental to the professional development of educators. In particular, Cranton (1996, p. 76) notes, "If educators are to develop their practice, a process including both personal and professional growth, then critical reflection on practice will be central to learning. ... [further] development requires moving beyond the acquisition of new
knowledge and understanding, into questioning our existing assumptions, values, and perspectives.” It is clear that new knowledge such as that acquired during “professional training” can provide “grist for the reflective mill.” Moreover, when teachers are confronted with how to apply this new knowledge (e.g., technology to aid science instruction) to their classrooms, they must stop to consider how this information can be incorporated into already existing instructional units, materials, and activities, and/or how they might change their teaching.

Such critical reflection can lead to transformations in teaching practice, what Cranton (1996) calls transformative learning. Transformative learning occurs when there is a revision of basic assumptions, beliefs, or perspectives. Thus, for example, when a teacher revises her teaching perspective to incorporate a problem solving orientation rather than merely teaching an array of isolated algorithms in mathematics, she demonstrates transformative learning.

Project Overview

In this paper, we report the progress of 54 teachers who participated in a collaborative College of Education/Southwestern school district staff development program funded by a National Eisenhower Grant. Teachers from two elementary schools participated in three years of after-school workshops as well as extended summer sessions.

The goals of the project for participants were: (a) to develop teachers’ technological skills to use applications for production, presentation, and telecommunications; (b) to develop teachers’ pedagogical strategies; (c) to develop content-rich, real-world thematic units that focus on mathematics and science using the tools of technology; and (d) to apply technological and pedagogical skills from the professional development workshops to classroom situations. An additional goal was that participants' student would develop skills for using the applications listed above as part of their daily classroom activities as teachers implemented the new instructional strategies. It was anticipated that in working toward these goals teachers would change the nature of their instruction.

To effect a change in the instructional culture of a school is no simple task. To help make technology integration a topic of daily discussions among teachers as they implemented new instructional materials and strategies, several elements of effective professional development were incorporated into the design of the program.

Specific schools were targeted over the three years of the project to achieve a high teacher participation rate at each site. This concentration of participants at two sites encouraged teamwork and collaboration between teacher participants.

Teachers were given incentives to fully participate in the workshop activities. The incentives included stipends, computer equipment for their classrooms, and the opportunity to earn university graduate credit.

The project incorporated an extended format of instruction over a 10-month period each year. Weekly school-year workshops focusing on the learning of new material were coupled with intensive summer workshops during which teachers could consolidate their learning and apply it to the production of integrated units/lessons. During the instructional segments of the workshops, leaders modeled pedagogical strategies that were to be incorporated by teachers into their classroom instruction. Teachers were able to implement the newly learned material in their classrooms between workshop sessions.

The project provided extensive opportunities for teacher reflection. During each workshop session teachers discussed orally the successes and challenges they had encountered during the school week as they attempted to test strategies and materials they had learned about in the workshops. At the end of each
workshop session, teachers were encouraged to reflect on what they had learned during the session and how they might use the newly acquired in their classrooms over the following week.

In addition to the reflective opportunities that were a part of each workshop. Teachers also maintained a written journal between workshop sessions. This allowed teachers to record their endeavors in a timely manner, as well as encouraging them to reflect about their teaching with technology on a daily basis.

Data Sources and Data Analysis

To describe the project teachers’ growth as educators during this professional development program, data were collected from multiple sources: participants' weekly journal entries, weekly workshop feedback forms, and open-ended questions answered at the completion of the three-year program. As the researchers read and re-read journal entries, workshop feedback and final responses, categories emerged. The data were then coded using these emergent categories: teachers’ struggles, technology-using teacher, integration of technology in the classroom, transformations in teaching, and emphasis on higher level thinking skills. As the study progressed, related categories were merged to facilitate interpretation and reporting.

Findings

Teachers’ Struggles

As teachers attempted to implement new classroom projects in which students used technological tools, they were working out the answer to: “How do I teach with technology in my classroom?” Examples of their concerns included:

- “Kids worked in groups to create a stack based on what they found on their insects. Each child did a page. This is a slow process. How do other teachers utilize their time on the computers?” Sue, 4th grade teacher
- “Internet exploration with a group during class doesn’t work because it takes too much of my time while the other groups need attention too.” Mary, 5th grade teacher
- “Am I guiding too much when I anticipate possible stumbling blocks? I don’t want to give them answers, but I also don’t want them to become sidetracked or distracted on unnecessary problems that will discourage them.” Jen, 7th/8th grade science teacher

Sue and Mary express concerns about organizing students to use one or two computer stations in the classroom, managing such a new arrangement, and noticing that students are working slowly and taking too much of their time. Jen voices her concern about the appropriate amount of scaffolding to provide for students attempting to solve problems using technology tools.

Every week participants discussed many different issues and problems. Through the workshop discussions, trainer modeling of lessons, and reflections on practice, teachers began to work out their own unique solutions to their quandaries. The mix of new information, social support, and time for individual reflection enabled teachers to try new ideas and technologies in their classrooms, question practice, deal with obstacles, and grow.

Teachers' Growth as Educators
The researchers asked the participants to describe their growth over the course of the three-year staff development program.

**Technology-integrating Teachers**

The project leaders noticed that participants became more comfortable with the integration of technology in the classroom as a result of sustained opportunities to learn, practice and reflect. For example, teachers said,

- "I feel perfectly competent and at ease with computers and technology in the classroom . . . I use technology as a standard and it is integrated into the curriculum." Tim, 7th grade teacher

- "One thing I would like to point out . . . teaching us to learn to work out the problems has been such a great idea. We have to learn to troubleshoot for ourselves and I think this has been one of the reasons I feel that the program is a success. I have learned, through the help of the trainers, how to handle many of the situations that come my way, on a daily basis." Kelly, 8th grade teacher

- "I am especially proud that I could use this technology in a Kindergarten classroom. I am able to have students create books, reports, and projects using the technology. I was a little concerned about how I was going to use the technology that was given to me. Frankly, (now) I need more!!" Nancy, kindergarten teacher

- "I am currently involved with the National Geographic Society working on “What’s in Our Water? as a test site. Because of my experience I feel I am better able to deal with this project.” Margarita, 4th grade teacher

We believe that the professional development program encouraged teachers to address problems encountered by writing about the problems and articulating the specific concerns, making connections between the modeling provided by the leaders of the workshops and their classrooms, and orally sharing problems and solutions as part of the workshop format.

**Transformative teaching**

During the project a number of teachers transformed their teaching from didactic, whole group instruction to project based learning with cooperative groups, hands-on projects, and student presentations. Such transformative teaching is exhibited in individual teacher's stories that follow.

- "I have made many changes in my teaching over the past three years. When I am writing my lesson plans or working on a unit, I think about how the computer will fit in. I don't just limit the use of the computer to free time or if the students have their work done. I encourage them to work together to solve (problems) and to use the (student) computer "experts" in the classroom." Jorge, 6th grade teacher

- "I recently interviewed for a job at another school. One of the questions I asked was what technology they could offer me at their school. When I was told that what they could offer me was a jack in the wall for a phone line, I honestly had less enthusiasm for working there! I felt an incredible loss not having my Mac, TV/VCR/laserdiscs player, all my software . . . So, in answer to your question, as an educator, I have come to EXPECT technology to be used in my classroom to do everything, when before, it was something that only the teacher used to word process notes going home to parents.” Kathy, kindergarten teacher
"I see a greater need to teach kids problem solving in math. I used to do a lot of computational math and not a lot of higher level thinking. I am now using more problem solving and weaving in computation as necessary. I enjoy using some of the (technology) programs we have in both science and math." Lisa, 4th grade teacher

Discussion

Our analysis suggests participants entered the project with different teaching styles and levels of technology literacy. Because they had diverse backgrounds, their reflections revealed differing amounts of changes in confidence with technology use, integration of technology in the classroom, and teaching style.

During the course of this intensive professional development, some teachers initially doubted the value of technology integration and related teaching practices. Later, as teachers became more comfortable with using technology, they reflected on their own teaching practices. This questioning process was facilitated by providing opportunities for reflection including: (a) discussion of successes and challenges of their own attempts at technology implementation, (b) reflection on training sessions, and (c) written journals maintained between workshop sessions.

In conclusion, for transformative teaching to occur, professional development programs must provide substantial and systematic opportunities for reflection. These practices must be sustained over a period of years. Further, teachers must receive encouragement to try out new practices, discuss them with leaders and colleagues, adapt lessons based on work with students, and reflect on their attempts in relation to their own teaching practices.

Technological Diffusion within Educational Institutions: Applying the Technology Acceptance Model

Stacy Wolski and Sally Jackson
Department of Communication
University of Arizona
United States
Stacy@u.arizona.edu

Abstract. Expectancy models of behavior such as the Theory of Reasoned Action and the Technology Acceptance Model offer guidelines that aid efforts to facilitate use of new technology. These models remind us that both acceptance of and resistance to technology use are grounded in beliefs and norms regarding the technology. Although the Technology Acceptance Model is widely used to model user acceptance of technology, we suggest that the model fails to capture all of the relevant components to technology acceptance in the context of educational organizations. This paper discusses the application of expectancy models to educational institutions and we identify relevant aspects of technology use that are accounted for by the Theory of Reasoned Action.

Introduction

When technology offers improvements over existing processes it seems reasonable to expect that the improvements will be readily embraced and incorporated into practice. However, adapting to new technology is rarely this simple; some users will resist change entirely, and even among users who embrace change, the new technology may not be used to its full potential.

Resistance to change is a widely recognized problem in the study of organizations. Resistance is manifested in two behavioral outcomes: either the user fails to incorporate educational technology altogether, or the user fails to use the technology to its full potential (Markus, 1984). The causes of resistance are cognitively based. Because resistance depends partly on the individual's openness to learning and change (Diamond, 1993), we might expect that educators (experts in learning) might be more receptive. However, recent experience with new instructional technology suggests that change in educational organizations is as problematic as change in any other organization.

Five years ago, a deliberate decision was made at the University of Arizona to position a group of early technology adopters as "change agents" on campus. A large interdisciplinary group of faculty recruited by the Provost as a "Faculty Development Team" was assigned the task of preparing the faculty for the use of new technology in the classroom. Specifically, the Team's job was to define training and technology requirements for "student-centered" teaching. Later, this task was handed off to a consortium of instructional support units (the Faculty Development Partnership, formed as a coordinating body for the Library, the Computer Center, the Teaching Center and other units), taking new learning technologies as a defining element of its membership and mission:

The primary mission of the Faculty Development Partnership is to enhance the undergraduate learning experience at the University of Arizona. Strategically, the Partnership promotes employment of successful teaching models facilitated and strengthened by new learning technologies. Tactically, the Partnership works closely with faculty across the curriculum to create General Education and advanced courses through which students acquire foundational as well as lifelong skills. The Faculty Development Partnership assists campus improvement initiatives, actively supporting ongoing classroom renovations while preparing to implement an Integrated Learning Center (http://www.facpartner.arizona.edu/partners.htm).

Given the specific intention of promoting the use of new technology, and the underlying assumption that new technology will be understood as an enhancement of instruction, the Faculty Development Team and Partnership have undertaken a variety of initiatives to support faculty in technology adoption. At Arizona as at many other educational institutions, two main strategies have been used consistently: incentives and training. These programs have been effective in stimulating some creative projects, but many faculty remain reluctant to consider...
the use of new technology and largely unacquainted with its applications to education. State-of-the-art equipment in newly renovated classrooms remains unused, and rich resources for technology-enhanced learning remain underexploited.

For both practical and theoretical reasons it is important to understand resistance to change within educational organizations, and in particular to understand why educators are reluctant to adopt technology advances. The purpose of this paper is to explore theoretical perspectives on technology adoption and to apply those perspectives to common strategies for promoting change.

### Reasoned Action Models for Technology Acceptance in Education

One theory with potential utility is the Theory of Reasoned Action (Fishbein & Ajzen, 1975), which has recently been elaborated as a Technology Acceptance Model (Davis, Bagozzi, & Warshaw, 1989). The basic idea behind the Theory of Reasoned Action (TRA) is that people take the practical and social consequences of action into account in deciding what to do, building an overall “behavioral intention” as a complex function of value-bearing beliefs about the outcome of the behavior and the beliefs about others’ evaluations of the behavior.

TRA predicts acceptance or rejection of certain behaviors from attitude and normative influences on the intent to perform those behaviors. A person’s attitude toward the behavior is assumed to be made up of beliefs about its outcomes and evaluations attached to those outcomes. Attitude toward the behavior may be strongly positive or strongly negative; however, attitude toward the behavior is only one potential determinant of the behavioral intention. People also take into account a “subjective norm” made up of beliefs about how others important to them will evaluate the behavior and motivations to comply or not with others’ influence. According to TRA, intentions are formed as weighted combinations of attitude and subjective norm, and behavior depends most directly on intention.

**Figure A: Theory of Reasoned Action**

The Technology Acceptance Model (TAM) is a specialized adaptation of TRA to technology implementation contexts. This model is used to describe the antecedents to technology use (Davis, et al., 1989). TAM suggests that both technology acceptance and technology resistance are forms of reasoned action, and both are in some sense rational for users. A central theoretical assumption is that technological resistance depends on end-user perceptions (that is, on faculty perceptions in the case of educational organizations). TAM describes the relationship between users’ beliefs about technology and their “behavioral intentions” (what they actually intend to do with or without the technology).

The specialization of TRA to the technology acceptance context results in two special features of TAM. First, TAM omits the subjective norm component that, in TRA, combines with attitude to determine intention. The development of TAM as an explanatory model led Davis et al. To an empirically-grounded judgment that technology acceptance does not depend on normative beliefs. Second, TAM centers on two specific beliefs that have been shown to influence acceptance of or resistance to technology: perceived usefulness and perceived ease of use. According to TAM, the likelihood of technology use is high for users who believe that it will lead to improved job performance and who believe that it is easy to use, but low for users who either doubt its benefits or perceive it as difficult.
Although specifically tailored to explaining technology acceptance, TAM may or may not adequately represent the factors affecting technology acceptance in educational contexts. Omission of the subjective norm component seems reasonable enough in some organizational contexts (e.g., for-profit corporations). However, in educational contexts, where technology is a potential influence on teacher/student relationships and where individuals identify themselves closely with expert communities of fellow practitioners, it does not seem plausible to assume that the decision to use technology is made without reference to others' approval or disapproval of its use.

Moreover, the two specific beliefs identified by Davis et al. do not offer a straightforward fit with the practical circumstances of faculty workload. At a minimum, the underlying belief set needs expansion to take account of the common faculty problem of balancing investment of time between two or more budgeted activities (teaching, research, and other duties). While faculty undoubtedly consider the impact on the quality of teaching in deciding whether to adopt new technology, they also consider how investment in teaching improvement affects the overall balance of success they might have in teaching and research. Particularly in Research I universities like Arizona, the rewards for improved teaching are thought to be much less certain and much less tangible than the rewards gained from conducting research.

In the tradition of theoretical and practical research following from TRA, the underlying belief set and the weighting applied to various components is generated empirically. Because we doubt the generalizability of TAM to educational organizations, our own attempts to model faculty acceptance of technology include measurement of a much broader set of potentially relevant beliefs, including normative beliefs, as shown in the survey below (http://emma.comm.arizona.edu/techuse.htm).

Strongly Agree = SA  Agree = A  Neither Agree nor Disagree = N  Disagree = D  Strongly Disagree = SD

Learning to use WEB based instruction would be difficult for me.  SA  A  N  D  SD
It is easy for me to become skillful at using WEB based instruction.  SA  A  N  D  SD

Designing Strategies for Change

How might TRA, TAM, and similar models guide efforts to promote change in educational practice? Regardless of specific situational adaptations, these reasoned action models remind us that both acceptance and resistance are grounded in "reasonings," and change in behavior must be associated somehow with these underlying reasonings. A model that adequately represents the relationship between the decision to use technology and the underlying attitudinal and normative components can help us to target beliefs and perceptions that make a difference to what faculty actually do. In this section, we consider two pervasive faculty development strategies, using TRA to illuminate the process by which these strategies might affect behavior, and then use the model to generate new strategies that are not so obvious.

Incentives

One common strategy for encouraging the use of technology is to provide direct incentives for doing so. During summer 1998, the Faculty Development Partnership offered the incentive of a loaded laptop computer to recruit faculty members teaching General Education courses into one-week workshops on new technology and new teaching strategies (http://www.fcii.arizona.edu/gened). These workshops have been wildly successful, drawing many more recruits than can be served and generating rave reviews from faculty (e.g., http://www.fcii.arizona.edu/gened/may_18_participant_comments.htm). Yet the incentive offered is very modest relative to the time commitment required of the faculty members. We should not suppose that incentives work only through direct change in beliefs about outcomes of behavior (that is, by linking the acquisition of some good, like a laptop computer, to the performance of a behavior).

Incentives have complex functions. Besides their potential to directly affect beliefs about the outcomes of behavior, they may also indirectly affect other beliefs by providing direct experiential evidence on issues such as the difficulty of using technology and the impact of technology use on workload. However, incentives serve a more important and often overlooked function in educational institutions: They provide information on what it is the institution and its leaders value. Very small incentives often draw faculty effort out of all proportion to their practical value, in part because these incentives are frequently the only clear clues faculty have for figuring out the institution’s current priorities. For this reason, over the past two years our Faculty Development Partnership has
been very explicit in linking any incentive offered to a statement of institutional objectives. The laptop program has been explicitly represented as a form of administrative support for General Education faculty, and our yearly internal grants program has for each of the past two years issued Calls for Proposals that incorporate a specific support agenda (such as building infrastructure for distributed learning—see the current CFP at http://www.facpartner.arizona.edu).

Training

A straightforward implication of TAM is that acceptance of technology can be increased by attacking the ease of use. One obvious way to do that is through training, and this has been a mainstay of Faculty Development at Arizona through both the volunteer phase (in which training was organized and offered by the Faculty Development Team in symposia, showcases, and other special events) and the Partnership phase (through which training has been offered mainly as workshops and individual consultation by the Library and the Faculty Center for Instructional Innovation).

Again, however, the relationship between strategy and behavior is complex. Training does often succeed in persuading people of the benefits of new technology, and it also often succeeds in overcoming beliefs about the difficulty of using new technology. As with incentives, however, training also provides normative information as a side benefit. Participants in the laptop program appreciated being introduced to new possibilities and helped with new skills, but they expressed real surprise at the value of interaction with their own peers. Comments by workshop participants are open on the web (http://www.fcii.arizona.edu/gened); a few of the norm-related comments are shown below:

1) I wish this opportunity could be available to all faculty members. The increased sense of community I feel and commitment to our common mission of teaching is amazing.
2) Having the opportunity to work closely with other faculty members from across campus has greatly increased my understanding of how, we as individual instructors, can collectively impact the education of our undergraduate students. As we shared our lessons and talked about writing in each of our courses, the big picture came together for me.
3) Apart from increasing my awareness of the new instructional possibilities technology opens up, the sense of community engendered among the participants was revelatory. The commitment to teaching on this campus is far greater than I and I gather others in the group had suspected.

Neither incentives nor training are designed specifically to take advantage of normative influence. On the contrary, incentives are usually conceptualized as a way to make the outcomes of the behavior more rewarding (leading to a more positive calculation of the behavior's consequences), and training is usually conceptualized as a way to overcome resistance associated with perceived difficulty, i.e., incidental lessons are associated with the information participants get about how the institution or the expert community values behavior. This suggests some less obvious avenues for promoting adoption of technology in education, relaying directly on well-understood structures for peer review.

Activity Reporting

In TRA, the powerful influence of what is recognized among children as "peer pressure" is modeled more generally as the subjective norm component. We believe that faculty are much more sensitive to normative influences than is suggested by the TAM, that strategies commonly understood as operating through the attitudinal component are effective partly because of incidental normative information, and that sensitivity to normative influence can be used to develop additional change strategies within educational organizations. Specifically, creation of structures that require or seem to require that faculty pay attention to their own use or non-use of technology establishes technology use as important to the expert community and as subject to normative evaluation.

Arizona has recently undergone comprehensive revision of its Tenure and Promotion guidelines. Use of technology is not explicitly linked to positive or negative decisions. However, the newly adopted reporting formats include sections for reporting of technology use and other forms of instructional innovation (http://w3.arizona.edu/~vprovac/f&v/section6.html), and the simple occurrence of a reporting opportunity of this kind makes technology use a matter of normative influence. Not only does the reporting formation represent technology use as important to the faculty role, but also, the content reported by any faculty member becomes important normative information for any colleagues who review the dossier. Many faculty interpret the inclusion of
a reporting category of technology as a sign of institutional approval of technology use. TRA and its theoretical spin-offs suggest that one powerful form of support for change is creation of stronger normative beliefs—exploitation of peer pressure. Even without linking of the activity to outcomes, faculty who believe that their peers will be impressed by reported activity are more likely to engage in that activity.

Conclusion

To ameliorate faculty use of technology, we need better representations of why some adopt technology and why some resist it. This is the purpose of such models as the Theory of Reasoned Action and the Technology Acceptance Model. Working from detailed pictures of the determinants of technology use, our attention is directed to factors that influence intentions and behavior. In particular, these models direct our attention to often overlooked normative influences that may have powerful persuasive effects within educational organizations.

Abstract: From interview data with 17 teachers who wrote competitive project grants we conducted a preliminary analysis. From this sample, we selected 4 teachers to study in depth using interviews and observations to analyze how teachers used technology projects to restructure schools at the classroom level. Themes that emerged in all of the interviews included how curriculum, pedagogy, student learning and assessment changed in the restructured environment and challenges teachers faced with technology infusion.

1. Introduction

TIPS (Technologies in Pedagogical Strategies) is a collaborative partnership among the College of Education and Graduate Studies at the University of Wisconsin-River Falls; the Hudson, River Falls, and Prescott School Districts; St. Bridget Elementary School; and their respective communities. The funding for this project comes from the Wisconsin Department of Public Instruction Goals 2000 funds, University of Wisconsin-Extension, AT&T, and University of Wisconsin-System PK-16 Initiative. A key component of the partnership involves meaningful curricular integration of technology, so teachers and students may use this tool to foster higher-level thinking.

Our study focuses on one segment of the TIPS: teachers' curriculum integration projects. Last year, TIPS supported 35 teachers' individual or team projects to implement technology in their classrooms. Our goals in this research were to 1) document the kinds of technology being used to restructure schools at the classroom level; 2) identify some of the best practices and highlight specific projects that have been designed and implemented by teachers; 3) analyze the growth of respective teachers' experiences with technology integration and 4) identify challenges teachers face when infusing technology. A team of two faculty and four graduate students in the Teacher Education Department at the University of Wisconsin-River Falls reviewed 17 competitive project grants from 35 teachers and selected four projects for in-depth study and analysis.
2. Background

In the first year, twenty-three PK-20 faculty participants met on a monthly basis for specific instruction in using technology. During year two, thirty-six PK-20 faculty participated and a technology consultant worked in the schools with teams of participants and monitored individual teachers. For year three, sixteen PK-12 teachers, working with 18 university interns, provided technology mentoring and training to colleagues in their respective buildings in two school districts. During that year, the project supported 35 teachers' projects to implement technology in their classrooms, and interview and observational data from those teachers' projects form the basis of the research on which our proposal is based. Most recently, during the fourth year, 27 teachers and 27 interns in three school districts and a private school assisted others with the instructional integration of technology and supported 50 projects from over 100 teachers. Many states are providing grants to teachers to encourage technology integration. This research may provide some insight as to how teachers are changing teaching practices by introducing technology, and the effects of this pedagogical change on the learning outcomes of students in these teachers' classrooms.

2.1 How Technology is Being Used in Classrooms

Technology is infused in different ways at different degrees and styles across various content areas and grade levels. Schools have differing internal structures that support this endeavor, and each teacher is confronted with differing challenges. The future of technology in the classroom will depend on continued research and efficient support systems for teachers who are exploring new ways of teaching and of promoting learning. This research attempts to enhance our understanding of this complex process.

Our description of the projects will be summarized in accordance with four categories by which technology is used in the classroom: Instructional software, Instructional support tools/hardware, Telecommunicating/telecomputing/networking, and Multimedia [Forcier, 1996; Jonassen, 1996; Means, 1994; Newby, Stepich, Lehman and Russell, 1996; Roblyer, Edwards and Havriluk, 1997].

2.1.1 Instructional Software

This involves word processing; spreadsheets; simulations; tutorials; drill & practice; desktop publishing; CAD; problem solving games; test generator; instructional games; photo editing; Hyper Studio; and C-maps. Another category of instructional software is used to aid teachers in maintaining records of students' grades and other work. First grade students learn to use Hyper Studio software to construct an electronic portfolio. These portfolios are continued in subsequent grades so that students, teachers and parents have a multimedia record of the elementary education of individual students (see 3.1 Hyper Studio Electronic Portfolio Project). A new zip disk and an existing Alpha Smarts Program allow teachers and 2nd grade students to tackle large writing projects. An interactive laser disc simulation program is used in a middle school science class to promote math and problem solving skills as students figure out what caused an accident and other real life problems.

2.1.2 Instructional Support Tools/ Hardware

This refers to the physical or technological inventory contained in the learning environment. Examples include at the base level: computers; monitors; scanners; CD-ROM's; printers; LCD's; RGB-TV converters; audio speakers; modems; overhead projectors; closed circuit televisions; and calculators. At a more specialized level examples would include: CBL's, GPS's; digital cameras; digital video cameras; and zip drives. A high school calculus teacher has students using Global Positioning Satellite (GPS) Instrumentation to survey a practice field and snow fence. Students use the GPS, a traditional transit, and calculus applications to measure angles and curves and to plot coordinates of latitude and longitude. A high school biology teacher incorporates Calculator Based Laboratories (CBL) to examine how various pH levels affect reactions, to test the effectiveness of different strains of yeast, and to study the effects of various levels of exercise on heart rates.
2.1.3 Telecommunicating/Telecomputing/Networking

This category comprises software and hardware which facilitates communication via technology utilizing e-mail; bulletin board systems; Internet; teleconferencing and video teleconferencing. These foster the linking of diverse databases, information sources, geographic areas and populations. Second graders are involved with an on-line project called "Journey North" where they track the growth of tulips with other students around the country. A middle school teacher relies on a subscription to the education web site which includes an author chat line to motivate her middle school English students. A 5th grade teacher assigns a famous woman to each of her students. The students use the Internet, Grollier's CD-ROM Encyclopedia, and the school library to do research on their assigned woman. The students fill out forms asking for specific information and present their findings to the class as a poster presentation. A 5th grade teacher has her students use the Internet to research the Civil War and specific topics of interest. Students create projects to show what they had learned, and they present them during an activity day where there is a re-enactment of a Civil War campsite among other activities. A middle school teacher uses e-mail and digital cameras for a project in his science class. The students pick out a variable (i.e. weather, height, etc.) and take a digital picture of the change from month to month. The students send their pictures to key-pals in a neighboring school. The teacher also has the students take a GPS home and send their key-pals the latitude and longitude of their family's homes. A social studies teacher's students select a WWII event; access primary documents such as diaries, newspaper articles, or photographs from the Internet and communicate their projects via participation in a teleconference (see 3.3 WWII Internet Project). A high school English teacher challenges her students to become critically aware of Internet sources. She teaches her students specific skills in examining electronic resources and encourages students to incorporate these and other resources into encompassing projects or term papers in the English classroom. (see 3.4 Evaluating Information Technology Project)

2.1.4 Multimedia

Multimedia is a computer system product that involves the integration of more than one medium into a form of communication by incorporating text, sound, pictures/graphics, and/or video. Digital cameras are used to record classroom activities, and later the information is inserted into Power Point for presentation to parents or other students, submitted to school newsletters or local newspapers, converted to VHS format for "video yearbooks," incorporated into individual classroom projects, or e-mailed to students at other schools. Electronic portfolios, which include representative samples of students' work across the content areas, are shown to the class through a Power Point presentation and later are taken home in VHS format. CBLs, which are connected to graphing calculators, allow students to collect data that is later presented to the class on an overhead projector; students discover information on their own while manipulating numbers on the calculators. A high school biology teacher has her students study organisms indigenous to the Kinnickinnic River basin. The students use digital cameras to make a field guide of the local flora. Through research on the Internet and library resources the students compile a final project on their organisms that are presented in a Power Point format (see 3.2 Kinnickinnic River Biology Project). Video cameras and advanced editing equipment allow students in a high school journalism class to make commercials and create newscasts of extracurricular and classroom activities for the school's broadcast.

3. In-depth Study of Four Projects

Follow-up focused interviews were conducted regarding the projects of one elementary and three secondary teachers (science, social studies and English). After presenting descriptions of each project, we summarize interview information about the changes teachers experienced in curriculum, pedagogy, student learning and assessment, as well as the challenges they faced integrating technology use in the classroom.

3.1 Hyper Studio Electronic Portfolio Project
The elementary teacher is a 1st grade teacher who is engaged in an ongoing five phase electronic portfolio project that is in its first phase. The goals of the project are threefold: 1) to help students become comfortable with computers and technology, 2) to provide students with a technology based project, and 3) to have students create an electronic portfolio that records their academic and extra-curricular achievements throughout their elementary school experience. The students are instructed in the rudiments of Hyper Studio software. The teacher used laminated cards in class to teach the children examples of Hyper Studio screens, keyboard functions and how to use a mouse. Students then worked in pairs to practice the Hyper Studio functions on the computer. After students learned to use the software, they worked independently on their computers to design their electronic portfolio. Students selected items from their hard-copy portfolio as well as current work samples to incorporate into their electronic portfolio. Students designed their electronic portfolio from start to finish.

3.2 Kinnickinnic River Biology Project

With the introduction of block scheduling, the science teacher wrote and implemented a new curriculum for a biology class that involved the Kinnickinnic River which is indigenous to the town of River Falls. The course was designed to allow students to research a macro and microorganism individually on the Internet as well as work collaboratively with other students in the class. Students were encouraged to tie in all the factors related to the ecosystem through food webs and by studying the ecosystem roles and plant life and insect life of the river. Components of this project included: poster presentations; sampling and identifying the actual macro invertebrates of the Kinni River basin; use of the CBL (Calculator Based Laboratories) such as testing the pH, oxygen content and temperature of the river to make conclusions on water quality; designing a food web; capturing images of the flora using a digital camera; and creating a Power Point presentation.

3.3 World War II Internet Project

Using an already existing course called World War II, the social studies teacher infused a technology based project with the goal of sharpening students' intellectual ability. Students were to choose a World War II topic and research it by accessing diaries, photographs, and documents off the Internet and participated in teleconferences. Eventually students were required to also relate Internet resources to print materials, articles, and books about the same event and make comparisons. One goal was that students would be able to critically analyze resources from the Internet. The second goal was for students to use a variety of methods of technology for the final project such as a scanner, quick camera, and camcorder to name a few. The end product differed from student to student ranging from a newspaper, teleconferencing, Power Point presentation and research paper.

3.4 Evaluating Information Technology Project

The English teacher infused technology into the classroom through a project that challenged students to assess and evaluate information technology. The unit required students to pick resources for a specific research topic and then decide if the resources were reliable, valid and appropriate. Topics ranged from Social Security to "beat" poetry of the 1950's and 1960's. Students were instructed to collect sources (text, electronic and human), list the strengths and weaknesses of the sources, rank the sources including a written explanation for the ranking, and develop a criteria the student deemed necessary for determining the appropriateness of sources. The students composed a "Works Cited" page and performed a concluding presentation to the class.

4. Findings

4.1 Curriculum

All four teachers commented that the technology projects required them to rethink what they teach in general while providing them an opportunity to think about what material to include in the curriculum more
specifically. Three important points brought up by three of the teachers included: 1) depth versus breadth, 2) factual content versus process, and 3) change in focus.

Regarding depth versus breadth, the social studies teacher stated that teachers may eventually move away from covering every single part of the curriculum to provide the "big picture" but rather turn to a project based pedagogy in which the project ends up dictating the content of the course. He said, "We let the big picture go and we concentrate on learning the smaller part of the picture well and not worry about covering all of the content."

For factual content versus process, the English teacher stated that in order to incorporate new tools (technology), some instructional time was used to address technology techniques and issues. Therefore, rather than focusing on the English content curriculum, she said she focused more on how students are processing the information.

Similarly, change in focus deals with the idea that teachers are starting to focus on skills they want students to develop in order to become independent learners who can access information on their own instead of focusing only on "what" we want to teach them.

The elementary teacher stated that curriculum and content were not significantly altered. However, she has been using hard-copy portfolios and students are already learning computer skills in their regular computer lab time. She said that this project was a very convenient way to combine those two preexisting activities.

4.2 Pedagogy

All four teachers stated that they have adopted a constructivist style of teaching that is student-centered and project based. They went on to say that they were able to address the variety of learners better in this setting, have moved away from a “teacher knows it all” model and have become much more reflective about their teaching style. The science teacher said,"... you really have to have quality projects planned out there (Kinni River) and they need to be projects that engage the students right away and require them to gather meaningful data, whatever that might be." She went on to state that without her involvement in the Kinni project she would not be questioning herself and her educational philosophy as critically. She said she is constantly trying to refine and develop her pedagogy. The English teacher said that this experience has forced her to rely more heavily on her students who are experts, and therefore she designs units that are more relevant to individual student ability and interest.

4.3 Student Learning

Consistent with the philosophy of a student-centered pedagogy, teachers said that students were taking more responsibility for their own learning, though at times students expressed frustration over the increase in responsibility. Students also developed analytical skills that required them to evaluate material obtained from the Internet for reliability and validity which was often assumed to be present for print material. Students were more focused on the process of learning rather than the end result, though most students were excited and felt very proud of their end products. The teachers stated that the students expressed that it was challenging to adjust to a new way of learning. Student motivation seemed to be more intrinsic and student learning generally more positive.

The elementary teacher stated that several of her students who are not academically strong experienced many opportunities for success while engaged in the Hyper Studio electronic portfolio. The following are two examples from the elementary classroom. "One of my poorest readers read her story. She practiced forever and it's wonderful. I laugh every time I hear it." "He couldn't find much academically he wanted to put in but he played the guitar...into his portfolio...this success encouraged him to find other examples of his work which were academic in nature."

4.4 Assessment

The three secondary teachers said that the general structure of how they assess their students' learning did not change but modifications were made based on the nature of the task. For example, the social studies teacher stated that traditional quizzes, discussions, essays and oral presentations were used in general and performance tests were used for teleconferencing or Power Point presentations. Even in the case of performance assessment, he said"...you look at their regular research in the library of print media.
and articles and you look at what they got off the Internet and assess their project, choices and their questions about the assignment." However, as the project evolved the idea of assessing higher order thinking became the central focus of the assessment.

The science teacher said she also used fairly typical written tests throughout the term. She administered weekly vocabulary quizzes that dealt with scientific terms and terminology, compilation of daily or regular data sheets twice a week, other daily assignments, projects and labs. She went on to say, that in an applied class like hers, projects like constructing the food web become good assessments of student learning. In order for the students to construct the web properly, students have to master certain concepts about flow of energy in the ecosystem and understand the definitions of the different ecosystem roles. She went on to say more student exchange occurred during this project than during other projects which she thought represented learning and higher order thinking amongst students.

The English teacher also stated that this project did not change her views about assessment in general. However, she felt that her views on assessment have changed gradually over the 24 years as she moved away from using tests to focusing on students' ability to demonstrate expertise.

The elementary teacher said that she did not think this project changed how she thought about assessment. She said at this level and with this type of assessment, watching them do their work through observations and looking for a successful portfolio was her main concern. She also noted that the students who had been academically challenged were producing more and providing better products at times. She did not provide an explanation for the cause of this observation at the time.

4.5 Challenges

There were general challenges and specific challenges related to infusing technology. Some of the general challenges included: making sure everybody stayed busy, not knowing if students were on task, decreasing the human contact with students, struggling with technology that did not cooperate, spending time teaching technology rather than using it for content instruction, overcoming one's own fear and resistance about using technology, and not establishing objective and controlled ways to assess your own practice.

Specifically, the elementary teacher saw the continuation of student portfolios throughout the subsequent grades as a challenge. One of the significant challenges she saw was how other teachers will become a part of this continuation especially if they lack computer skills. The science teacher noted that complex projects, increased student autonomy and variability of tasks which produced a challenge for objective and efficient methods of grading. The social studies teacher said that one of the main concerns he had was students' lack of necessary background knowledge needed to engage in higher-order thinking, which he envisioned would be the result of this project.

5. Conclusion

The projects implemented by the four teachers have been an avenue by which they were challenged to rethink "what" they teach and "how" they teach. Technology alone can not explain, nor can it become the sole answer for our exploration about changes in curriculum and pedagogy at this present time. Naturally, when a new idea, method or way of doing things is introduced, the tendency is to become more aware of how one does things. Whether novelty of a new method of teaching has caused the changes we observed or technology itself has been the primary cause warrants additional study for us to draw further conclusions. However, teachers' thinking about what they teach and how they teach have been positive outcomes related to these projects nonetheless.

Teachers have moved to a student-centered pedagogy allowing for more ownership and responsibility of student learning. There is still much to learn about how technology infusion changes our way of thinking about assessment and our assessment practices. Despite the many challenges these teachers faced, their innovative ideas and pioneering spirits have encouraged us to explore how classrooms can be restructured through the use of technology.

TELECOMMUNICATIONS -
GRADUATE, IN-SERVICE
& FACULTY USE
As we move into the 21st century, technology has grown in schools so much that it is now a vital part of our children's education. In fact technology is just as important to our students and teachers as any other discipline. The challenge for many teachers at all grade levels is how to keep up with the fast growing pace of new and expanding technology while maintaining a learning environment for the students. Integrating technology into the everyday curricula is the most productive way for teachers to expand the learning levels of the students. One such way to allow integration in the classrooms is through the Internet. There are many ways to involve students with the Internet. This paper will discuss the following four ways to integrate computer-mediated communication into the K-12 classroom: keypals, electronic mentoring, tele-field trips, and online collaborative projects.

KEYPALS
Many of the uses of technology resemble the ways that teachers did things in the more traditional. One of the first ways in which people used telecommuting in their classrooms was to write letters to other students over the internet much the same way that they wrote to pen pals and sent the letters through the mail. Keypals allows individuals to “talk” electronically to other individuals, or individuals to talk to groups or groups to talk to other groups. It is still one of the most popular types of electronic telecommuting activities.

Since “keypals” require access to the Internet for individual students most teachers use one email address to facilitate this activity. LISTSERVs, newsgroups or Internet-connected bulletin boards can also be used as the common contact for exchanges. Keypals can be a very rewarding activity for many students. They are often stimulated educationally through these exchanges with other students. Another benefit can be the exchange of ideas with people their own age but from a different culture. Some examples of keypals may include a call for letters to exchange information from different towns in the USA.

One of the main problems with keypals is the management of this activity. Since each student needs to use an email address and be on the Internet, many teachers may not have time to devote to this type of activity. An easier activity to manage for the classroom teacher may be a group to group exchange also called global classrooms. In the global classroom activity, two or more classrooms located anywhere in the world may exchange information or ideas on any subject that is of interest to them. Group to group exchanges often
address current issues and problems that are more open ended so that students can express their own ideas on the issue. One example of a group to group exchange is asking high school students around the globe in commemoration of Earth Day to respond to Robert Frost's and Maya Angelou's poems read during Bill Clinton's 1992 Inaugural Day ceremony. As teachers collect the responses they can use them in their classroom discussion. Also many teachers feel that if they facilitate young people coming together from different, often distant places, to share ideas on the world's problems, real solutions may be implemented as these students grow into adulthood.

One specific population that is positively affected by the use of keypals is the rural districts that criss-cross this country. Students living in rural areas of our country are often isolated from other populations in America and the world. They rely on electronic communication to expand their perspective on current issues and educational ideas. They may be influenced to expand their horizons when considering career choices. Many rural school districts have to make tough decisions regarding the issue of scarce resources to fund Internet access for their students, but most rural districts have been pleased with the results of such investments. School administrator Bruce O. Baker (Baker & Hall 1994) has stated that using the Internet to connect students in his district and others can help overcome the disadvantages of geographic isolation. The problem of funding as the technology changes is an issue for not only rural districts but also all schools districts in our country.

ELECTRONIC MENTORING
The concept of the mentor has a long past, ranging from that of a trusted guide to the modern meaning of mentor (Roche 1979). Mentoring has been used to help individuals develop psychologically, occupationally, and cognitively. Educators have found that pairing students interested in a particular topic with educators who have expertise in that topic is an effective learning relationship. Widely known as instructional mentoring, students can gain specific knowledge from experts in a field when they have exhausted traditional resources for information (e.g., the teacher, encyclopedia). In addition, an instructional mentor can personalize the information for the student, often making the content more meaningful. With the invention of electronic communication, the definition of mentor has been broadened to include experts who know the student through electronic means alone (email or the WWW). Teachers are matching their students with online instructional mentors to give their students an additional resource when studying a specific topic in the curriculum.

Many universities around the United States have programs that teachers and students can join to become connected with subject experts from all around the globe. For example, The Electronic Emissary Project (Harris 1994), based at the University of Texas at Austin, is a service that helps connect teachers and students to experts in different disciplines. The experts are found by posting announcements to selected Internet-wide LISTSERV groups. The experts post their areas of expertise that they would be willing to share with K-12 students to an interactively-accessible online database. The information that the prospective mentor enters is then searched by topic, by classroom teachers wanting to request "matches" for their students.

Many students from K-12 have used the Emissary to find experts to answer specific questions or just communicate with via electronic email. Second grade students in Reading, Massachusetts studying magnetism were connected with a physicist from Arizona State University. Fourth grade students in Fort Worth, Texas communicated with an astronomer and planetarium coordinator from Louisville, Kentucky about specific questions they had about the solar system. Ninth grade students in Hart, Texas communicated with an engineering professor from Boston University about waves and wave phenomena. Twelfth grade students in Atherton, California communicated with a computer scientist about their individual projects in cosmology. Consequently students from all grades have benefited from electronic mentoring.

TELE-FIELD TRIPS
The ultimate objective of today's school is to provide students with a well-rounded education, and one of the ways many schools accomplish this ultimate goal is through field trips. Field trips provide students with the opportunity to communicate with the community. Many organizations such as NASA, Houston Lighting and Power, and other industries are happy to open their doors to teachers and students so that they
can explore what is going on. Although fieldtrips provide the best form of student to community communication, sometimes they are inconvenient, expensive and not feasible. Through sophisticated technology, all schools can have the opportunity to take fieldtrips.

Tele-field trips involve the sharing of information gathered by expert teams, teachers, or students with others all over the world via the Internet. For example, if class A goes to the local city zoo, they can post what they saw for class B that is in another part of the country where the closest zoo is five hundred miles away. Also, class B can email questions to class A about their fieldtrip to the zoo. Also, tele-field trips involve various experts such as explorers and scientists posting their many findings on the Internet for teachers and students to see.

A school district in Springfield, Illinois is heavily involved with tele-field trips projects such as a cow's eye dissection, a walk along the Nile, the Oregon trail, live from the stratosphere, Maya Quest, the Titanic, the journey North, adventure online, dinosaur dig, and much more (http://www.springfield.k12.il.us/resources/webprojs/fieldtrips.htm). Some of these tele-field trips consist of extended year curriculum, photos, movies clips, dialogue, etc.

Some of the above tele-field trips are sponsored by various expert teams; for example, The Adventure Online tele-field trips feature various expeditions such as running the Nile, global adventure, Arctic challenge, and project Central America. The running the Nile tele-field trip is sponsored by a team of kayakers, and the project Central America is sponsored by a team of mountain bikers. These individuals have diverse backgrounds ranging from educators to global adventure travelers.

There are many tele-field trip projects available at no cost, but some require a subscription fee or site license fee. These fees can range from about ninety-seven dollars per password or subscription and higher, and some sponsors offer a group discount for the purchase of several subscriptions or passwords (www.houston.isd.tenet.edu/techinst). So teachers who want to participate in tele-field trips have a wide range of options available.

ONLINE COLLABORATIVE PROJECTS
Online projects usually require collaborative work within a team and take the form of hypermedia. They have many benefits over traditional projects, including searching, handling of dynamic information and team working. Online projects provide students with equal opportunities to get to know what research is and how it is conducted. It is meaningful in terms of fostering students' scientific thinking and behavior. Since information is in abundance on the WWW, it is impossible for each student to exhaust all the links listed under a project. Teamwork is then a natural solution to the problem. Each student has a chance to play a role in order to get the job done. In addition, a lot more freedom doesn't guarantee learning. Students may learn to discern what kind of information suits their topic, and which one should take priority over others. Therefore, online projects cognitively facilitate collaborative and discovery learning.

To get started with collaborative projects there are some things that need to be kept in mind. Teachers should examine lesson plans and review the curriculum to identify activities that could be enhanced if re-engineered into an online collaborative project. It would be a good idea to visit several online collaborative project sites (examples are listed below) to see how others have organized their project. Also contacting the site webmaster (an e-mail address is usually listed on the site's home page) and asking questions about conducting online projects would be a valuable use of the teacher’s scarce time. Once a project is decided upon the teacher should outline the specifics of the project, including information such as the name of the project (give it a "catchy" title), the curriculum objective it addresses, the grade level(s) that it is for, etc. Then the teacher can post a "Request for Participants" in several educational listservs and newsgroups. Once the participants are enlisted, the teacher is ready to begin.

Samples of Online Collaborative Projects:
Elementary (Grades K-5)

Each project is a directed exploration of a site on the World Wide Web and includes a comprehensive lesson plan and a printable blackline master. Project topics cover a variety of subject areas ranging from language arts to social studies to mathematics and natural science.

Monticello World Wide Web Lessons (http://www.monticello.org/Matters/people/plans.html)
Learn about Thomas Jefferson and his life at Monticello. This web site contains a lesson plan, an activity, and a teacher answer key.

Project ScienceSpace (http://www.virtual.gmu.edu/)
The purpose of this project is to explore the strengths and limits of virtual reality (sensory immersion, 3-D representation) as a medium for science education.

Global SchoolNet Foundation (http://www.gsn.org/project/index.html)
This site contains a variety of links to online projects.

NickNacks (http://www1.minn.net/~schubert/EdHelpers.html)
This site contains links to interactive projects.

The JASON Project (http://www.jasonproject.org/front.html)
The purpose of the JASON Foundation is to excite and engage students in science and technology, and to motivate and provide professional development for their teachers through the use of advanced interactive telecommunications.

Secondary (Grades 6 – 12)

Mars Academy (http://www.marsacademy.com/)
An educational collaborative project in which participants will design and simulate a manned mission to the Red Planet.

Encyclopedia of Women’s History (http://www.teleport.com/megaines/women.html)
Collectively provides a celebration of Women’s History for students, as well as provides a starting point for further research.

European Schools Project (http://www.esp.educ.uva.nl/)
This project supports teachers and students in participating in the world of Internet-based Computer Mediated Communications and in using the Internet’s Information Resources to improve learning and teaching. A project listing can be found at: http://www.kc.kuleuven.ac.be/esp/prtitles.pht
Some examples of current online projects include Human Genetics, “Down the Drain” water consumption project, and “Me and Media”.

The World Band Project (http://co-nect.bbn.com/WorldBand/Pages/WorldBand.html)
This project involves realizing musical activity electronically, both locally and over the Internet. Emphasizes learning to collaboratively create music with partners at other sites.

Global Schoolhouse (http://www.gsh.org/project/index.html)
This site contains a listing of secondary-level online collaborative projects, including Holocaust/Genocide Project, MathWorld Interactive, Global Cultural Shock, and “To Exam or Not To Exam”.

Possible Problems of Online Collaborative Projects
Flexibility is one of the online projects’ strengths; however, it may possibly lead to some difficulties due to inconsistency. Since those recommended links in a certain online project are prepared by other teachers, they may not suit your students’ particular learning style or your intended instruction. If you just let your students go with that online project, inconsistency of format or content might occur. It is always a good idea to identify your teaching content before you start using any online project for your class. When necessary, select certain parts of an already existing project and add your own desired material.

Teaching and Learning with the Internet: Issues for Training Special Education Teachers

John Castellani
Center for Human disAbilities
George Mason University
United States
jcastell@wpgate.gmu.edu

Abstract: This paper is a report on the findings of a study conducted on a graduate level course for teaching and learning with the Internet for high school teachers working with students having severe learning and emotional disabilities. Qualitative interview data was used to explore issues throughout the course as teachers used information in their classrooms. The results indicate that ongoing inservice education needs to be specific to identified classroom needs. Teachers integrating technology into the special education classroom face an extremely diverse student body. There should ongoing development for teachers as they work through teaching and learning with the Internet in their classrooms. Results also indicate that it is important to realize how special education teachers can use the tool in their classrooms, understand why they use the Internet, what it accomplishes for their own personal teaching and learning needs.

Introduction

Inservice staff development for technology has historically consisted of school district courses designed to instruct teachers on emerging issues for teaching and learning within the classroom. These courses are generally brief, short term, and range from one day to a series of three or four days across a semester (Claxton, 1996). Courses designed in such a way do not meet the recommendations made in the literature for continuous, ongoing inservice technology-based staff development training (U.S. Department of Education, 1997). Many of these courses do not deal effectively with the integration of new teaching ideas into the curriculum because of the quality and quantity of training necessary for teacher growth. Given recent innovations in technology and teacher practice, many inservice staff development efforts have not changed. As a result, the potential benefits for innovative teaching methodologies and tools, such as student directed learning and the Internet are not fully understood. Ongoing research is currently needed to identify the development role of the teacher in a high technical classroom and keep this role as clear as possible (Rogers & Mahler, 1992).

The role of the classroom special education teacher has changed due to a variety of forces that have been effecting the field of teaching. Laws in special education are requiring the consideration of assistive technology in the Individualized Education Plan (Behrmann, 1998). There is an increasing amount of money available for schools to purchase technology and the social context for 21st century schooling is quickly evolving. Also, there have been advances in our understanding of how people learn (Doyle, W., 1979). Additionally, standards have been developed by the federal government, state educational agencies, local school boards, and within national teaching organizations (International Society for Technology in Education - ISTE, Council for Exceptional Children - CEC) to encourage
effective technology practice. Access to the Internet has greatly increased and teachers are changing classroom curriculum to accommodate new information tools. All of these forces combined place the special education classroom teacher in an exciting yet difficult position. In order to facilitate the position of teachers, ongoing support and training is necessary.

The purpose of this study was to question the development of teacher attitudes and practices of the Internet through elements within a university course designed for technology integration. These questions are critical because of the increasing presence of the Internet in schools, but more specifically, because of the necessity to assess pedagogical beliefs and experiences with new forms of learning (Dede, 1998) while exploring the way learning environments are changing because of access to the Internet (U.S. Department of Education, 1995; Benton Foundation, 1997).

An inservice university training course developed for special educators learning to integrate the Internet into classroom instruction. The goal of this course was to expose teachers to emerging technologies and innovative forms of teaching as well as provide the teachers with the information, skills, and problem solving methods to critically think about the integration of technology into the special education curriculum. The broader scope of this study answered questions about issues for teaching and learning with the Internet for high school students with severe emotional and learning disabilities and the context of special schools and new technology tools. An additional question included in this study provides the specific focus of this paper:

How do high school teachers working with student having severe emotional and learning disabilities report using the Internet after participating in an inservice training course designed for technology integration?

The Study

Data was collected from 5 course participants in course EDSE600 - Technology Integration in the Classroom during the 1997-98 school year. The course was contracted with the Training and Development school, a non-profit organization serving students with severe emotional and learning disabilities in a level 5 restricted facility. There were 24 teachers selected to participate in the course that were currently working within each of the four schools. Two of these teachers were male and three were female. All of these teachers were within their first two years of teaching within their school, although each had prior experiences working with students having severe emotional and learning disabilities. In addition, all of these teachers were working on ED/LD certification during this time period.

As part of a research study, data was collected from course participants to answer questions about the issues for teaching and learning with the Internet in their classrooms. Data was also collected to explore how school and student context influences special education teachers' use of new technology tools and to analyze how teachers integrate new knowledge of teaching innovations throughout an inservice training course. Data consisted of interviews, a teacher post-survey, electronic course discussions on Townhall (an electronic discussion group), individual teacher journals, and teacher lesson plans.

Administrator and teacher interviews were the primary mode of data collection for this research question. The teachers were selected mid-point in the semester and interviewed twice, once during and once after the course was completed. Two out of the available eight administrators were chosen for interviews based on time restraints and availability. Interview
data was explored using qualitative analysis methods (Miles & Huberman, 1986 & Maxwell, 1986). Emerging themes and ideas were used to justify research questions and to synthesize and report issues related to teaching and learning with the Internet in their schools/classrooms. A post-survey was used as one method to triangulate interview data and collect teacher reports on the last day of class.

Findings

The impact of an inservice training course for high school special education teacher of students with severe emotional disabilities is multidimensional. An analysis of the data reflected many issues teachers face for instructing these students and the potential uses and limitations of the Internet as a tool for teaching and learning. Teachers of students with disabilities have additional factors to consider when planning for the Internet. It is therefore important to know why and how teachers are using the Internet to facilitate the integration of the tool into the classroom. The dialogue between the instructor and teacher during this course was important for developing knowledge about what was working in the classroom as well as the content/skills teachers needed in the course to continue their development. A synopsis of teacher responses and an item from the post-survey are reported in the following sections.

Teachers Working with the Internet

Teachers responded differently to taking students into the computer lab. When the issues of risk and whether or not teachers thought there was risk involved in taking students to the computer lab, Teacher D was the only person who was too "nervous" to take them into the lab. Other teachers expressed various levels of frustration while working in the lab on the Internet. Some of the frustration had to do with the "amount of printing that students do" and the fact that they did not "know how to trouble shoot". Teacher A expressed that he did not have the time to plan for Internet activities and Teacher E stated that he liked using the computer lab, but that he could never go in there (the lab) without having a clear idea of what he was going to do. "Every time I have done that, it causes problems and everybody wants to print. I guess the reason why the Internet doesn't bother me because you really don't have to worry about student work getting erased. Something crashes or you log-on and it is busy and you can come back later and it is there".

Teacher B liked using the Internet because she could integrate it into her teaching style and how she thought students learned:

Interviewer: Have you made any conclusions about how kids learn differently in class?

Teacher B: Actually, I think that the Internet helps them...because it provides that type of accomplishment in their own time and with their own abilities and their own pace. Either they discover the web-site themselves, or I introduce it to them as they go and what they need to do, at the rate that they can do it. You know, and even though the computers are all there together, it is not like you are sitting there and worrying that these kids are finished, because they go looking for something else.
And if it takes them a few weeks to type up their report, other people are still doing web stuff and it is in their own time frame and it is less intimidating that way.

Teacher C was enthusiastic about her time in the computer lab and working with students on the Internet. This seemed based on how she thought students would engage in activities. It also reduced her individual stress because the use of the Internet was a motivator for students to complete assignments:

Teacher C: For me it is easier when I know that I have the computer lab in my schedule in the afternoon. It is easier for me to plan for the computer, because I can see that the whole afternoon is going to be relaxed. So the kids usually behave. I understand that in regular schools that issue might not matter because they don't have the problems that I have working with these students. It is nice that they are motivated by the Internet, because in the morning I can say that if we don't finish what we have to do, we will not be able to go to the computer lab and they finish their classwork.

However, Teacher C continued to be reluctant to allow students to have e-mail and to interact with other students on the Internet. She did believe that interacting with other students on the Internet would be a good form of learning, but she did not feel comfortable giving them the freedom to 'interact however they want':

Teacher C: I'm still thinking I should give the kids a pen pal, but I haven't made a decision about that yet. (The students) would probably get excited about the idea...but I wouldn't try it and I am afraid it wouldn't work right. Even when they went into the translation site on the Internet, they get excited, but the first thing they start writing is all the bad words in English, and you cannot get them back on task.

Teacher A specifically liked using the Internet because of the resources it provided him as he prepared for his classes:

Teacher A: I didn't have a lot of resources as it was, so to have the Internet, where I was doing everything from current events to looking up experts. Instead of having to worry about getting the morning paper, all I have to do is get on the Internet and we go to the Washington Post. Or in the case of my health class, there is always something I can do with the information available on the net.

Teacher D never took his classes into the computer lab to work with the Internet, but would send students to the librarian to look for materials. At one point, the only access within the school was the librarian's computer. After the school was "hooked-up", Teacher D continued to use the librarian as a resource for the Internet. He liked being able to send students to the librarian to work independently. When President Clinton went to Gambia, Teacher D thought that he could use the Internet with his students; however, he could not find the site that followed Clinton's travels. He became frustrated with searching the Internet and said, "I felt like I missed an opportunity and that really bothered me".

Teacher A, Teacher B, and Teacher E also express negative aspects of the Internet, especially the amount of time that it took to preview sites for students when planning specific
activities because he thought the Internet was so "wide open". They all felt the need to view materials before integrating the Internet into their daily activities:

Teacher A: I used (the Internet), I found it to be a great learning tool, but it's time-consuming from the standpoint of a teacher using it to checkout what's there. I've learned the hard way that you really have to preview the stuff to know where everything is.

Why Teachers Use the Internet

Teachers responded to questions on a post-survey. One of the questions specifically addressed why teachers used the Internet. Their individual responses are reported in tallied format as "frequency of response", for a total of five teachers.

Considerations for faculty working with Special Education Teachers

Teachers felt that their knowledge of teaching and having time to develop an inventory of lesson plans was important to their success in the classroom. There were several first year teaching issues related to 'time and priorities'. Teachers needed more time for developing lessons and adapting to a new teaching and learning environment. Apart from school context issues and personal teaching pressures, teachers needed extra time to implement a new "technology innovation". Teachers did not have lessons developed, so they were not integrating the Internet into existing instruction, they were developing new instruction that included Internet integration activities:

Teacher A: As a first-year teacher, and because this teaching situation is so overwhelming, I did spend a lot of time calling parents and asking teachers other questions...Since this is my first year of teaching, I don't have many of the resources that they do. There is this other teacher next to me who has worked in the field for a few years and uses the Internet. She has a wealth of projects that she has already done. I would have the same if I had remained in teaching. But I didn't so I have
been trying to rely on the resources that I have. If I decide to stay here next year, I
will spend some time over the summer trying to develop some plans... I think
technology has a great ability to enhance teaching...and I think people will develop
better ideas about teaching and learning over the next few years.

Since many of these teachers were working on their certification during this course,
inservice efforts were necessary to help them meet certification requirements and develop the
skills needed to work with technology. Teachers attempted to collaborate with each other but
there was limited time during the school day. During class sessions, there was an
opportunity for teachers to work collaboratively on academic projects. As a result, teachers
shared information and had time to merge new ideas about the Internet within their daily
classroom activities.

Conclusions

Ongoing support was necessary for these teachers as they attempted to work with the
Internet during instructional activities. These teachers struggled with how to use the Internet
with their students. During the span of the course, 4 teachers left the Training &
Development schools. Out of the five participants in the study, only three returned for their
second year of teaching. For these teachers, the majority of their knowledge about teaching
and learning, technology were developed during this course and based on their prior
experiences working with these students. In order to increase support for teachers working
with these students, inservice education needs to provide teachers with the ideas, time, and
support to enable integration of technology into the curriculum. Individuals creating and/or
delivering such programs need to think about several things.

First, in order to deliver inservice training specific to the use of the Internet, it was
necessary to realize how teachers were using the tool in their classrooms. Teachers
expressed that they continue to use the Internet primarily as a search and retrieval tool,
however, the methods they used to structure their classrooms and deliver these lessons
became more student oriented and directed. Although students were not interacting on the
Internet in communication forums, teachers used the information on the Internet to adapt
content to individual reading levels and personal capabilities. Teachers expressed difficulty
working with the identified texts for their curriculum. Teachers needed to consistently
explore new forms of content to deliver to the students. Teachers need to be aware of the
literacy opportunities on the web for students with disabilities. Teachers of students with
disabilities need to consider how technology can be integrated into their curriculum.

Secondly, it is important to understand why teachers want to use the Internet in their
classroom and what it accomplishes for their own personal teaching and learning needs.
Teachers felt that working with students on the computers and with the Internet was
applicable to student learning, allowed students to work for longer periods of time, increased
individualization. Using the Internet both reduced stress and increased stress depending on
how familiar teachers were with the computer. Teachers ultimately responded on many
different levels in response to using the computer lab and the Internet. Some teachers
responded that they liked using the computer lab, worked with their students on a daily basis,
but felt uncomfortable with their technology skills. Teachers liked using the Internet because
students were often "better behaved". However, when there was a crisis involving technical
difficulty, students did not have the patience to wait and give teachers a chance to resolve the
issue. Other teachers seemed to be less concerned with knowing where to go and how to
trouble shoot. Still others were too concerned about having technical difficulties and
therefore did not make use of the lab. They also used the Internet for accommodating their
students, working with real-life materials, and being less teacher-directed while working with
the computer. Students seems to respond to teaching and learning more directly in the
computer lab and it seemed to take some stress off of the teachers. However, it added
additional stress to some teachers because they felt it "took more time" to develop lessons, or
made them nervous because they had difficulty controlling "where students were going".

Third, ongoing development for teachers working with students having severe emotional and learning
disabilities is important because they may not have the fundamentals provided in methods courses at the
preservice education level. A portion major portion of learning happens after they have received a teaching
assignment. As a result, one-shot methods for instructional development, especially with technology, may not
have lasting influences on classroom instruction.

This course ran over a period of eight months. At the end of the eighth month, there were teachers
who still did not know how to complete basic computer functions and were not integrating the Internet into their
instruction. In some cases, it wasn't until after the course was over and the last round of interviews were
completed, that two of the research study participants started to use the Internet (during the extended school
year session). The teacher burnout rate in these programs can be high. Training and "retaining" these teachers
can be difficult. It is important to realize how teachers were using the tool in their classrooms, understand why
teachers use the Internet in their classroom, what it accomplishes for their own personal teaching and learning
needs, and how it "fits" with prior knowledge. Inservice courses that do not meet their specific needs may not
influence classroom instruction. Knowing how special education teachers are using the Internet in their
instruction, why they are using it, and the open discourse necessary to work with these teachers in the classroom
is extremely important.

Conducting an Interactive Workshop Over the WWW

Susan Gay
Professional Teacher Education
University of Nebraska at Kearney
USA
sgay@unk.edu

Abstract: An inservice workshop was conducted over the WWW to evaluate several interactive components designed for the course. The workshop evaluated a web-based threaded discussion application, e-mail, shared workspaces, and an on-line participant contribution page for resources. Despite a wide range of participant computer experience, the teachers rated the on-line web course very highly. Participants evaluated the interactive web components of the workshop very high and e-mail less useful even though they were more familiar with e-mail at the beginning of the course. With the availability of web teaching software packages increasing, further study and evaluation of the effectiveness of teaching with the interactive features on the Web should be conducted.

Introduction

Many people exploring the effectiveness of delivering instruction over the Web. This delivery format is evolving and providing fertile ground for experimentation and evaluation. Numerous software packages that allow instructors to create a web course and teach it electronically are appearing on university campuses nationwide. Incentives for creating web-based courses are being offered to faculty willing to experiment with this form of instructional delivery. The web teaching software packages are including more and more interactive features to design instructional experiences and activities for students. Features such as interactive testing and feedback, video conferencing, chat rooms, threaded discussion boards, shared work spaces and e-mail are all being used as instructional strategies in these on-line courses.

This paper describes a workshop for inservice teachers. The workshop was conducted over the Web during the summer of 1998 and the resulting evaluation of that workshop. The workshop course design attempted to incorporate interactive components of web instruction rather than passive, text and graphic only materials. Evaluation of the quality and usefulness of information or experiences provided through these interactive web features should be conducted to determine the most appropriate use in web-based instruction. As the number of web-based courses increases, more information about effective design and best practices in this new instructional field should be collected.

Course Design

This workshop was advertised throughout a midwest state to recruit K-12 teachers as participants. This state contributes to the support of a K-12 Internet access system which has enabled K-12 teachers across the state to participate in workshops of this nature. The course materials and field study were funded by a grant, therefore, the only expense to participants was the optional graduate tuition. Thirteen K-12 teachers from both urban and rural school districts in the state enrolled, participated, and completed the workshop.

The three-week long workshop was designed to incorporate both web-based and face-to-face modes of instruction. Concern over the completion rate of many other web-based prompted the combination of modes of instruction. Participants met face-to-face for an orientation and training day. During this day, the participants were introduced to the course web site, and a sample teaching lesson from
the course was modeled for the participants. The teachers were allowed to practice navigating the web site and received help with such items as telnet to access their school e-mail accounts from remote locations. The participants returned home to work on the course for the next two weeks. The workshop concluded with three-day field study trip and two days in the computer lab to develop a web-based K-12 classroom lesson that the teachers completed by the end of the workshop.

Two textbooks, an interactive CD-ROM program, and the web site were used to deliver the content information for the workshop. The web site included lesson pages that used a variety of formats to deliver the information. The interactive features included a web threaded-discussion forum, e-mail, and interactive pages with shared work areas and information contributions posted by participants for the group. There were nine content lessons on the Web during the workshop. Two or three content lessons were made available every four days during the workshop. The content lessons required the participants to use the web site, the texts and CD-ROM materials, as well as other web resources that were posted on the resources page. Participants, during the course, posted web resources they had discovered to share with the group. E-mail messages to the entire group provided announcements regarding the progress on the availability of the content lesson links.

The threaded discussion application allowed the participants to respond to questions over the content lessons and to questions posted by other participants. The web resource contribution page and the shared workspace page were dynamic web pages that were supported by a FileMaker Pro database running in the background. These pages allowed the participants to enter information and post it or save it to make further changes as they worked. The shared work spaces allowed the students to log in and view the work others had done, add, delete or edit the work, and then upon designating it completed, post it to the page for display. All facets of the workshop were evaluated with special attention focusing on the on-line portion of the workshop.

Findings

Participants viewed all of the workshop components positively. The web-based instruction was consistently rated highly as well. A preliminary survey of the participants revealed that only one third had any prior experience with distance learning, correspondence, or on-line course work. Participants were most comfortable with e-mail and half of the participants reported only an average confidence level with a web browser or a threaded discussion application. In the final evaluation, a five point Likert scale was used with five being high. The participants rated the web features of the workshop at 4.75 for both quality and usefulness in the workshop. The on-line content lessons were rated 4.42 for quality and 4.25 for usefulness. Finally, the threaded discussion application was rated 4.42 for informative, 4.6 for usefulness, and 4.6 for ease of use.

The final evaluation also asked participants to identify the average amount of time spent on-line for the course. All of the participants reported different amounts of time spent on-line with no pattern. The participants were also surveyed as to the frequency of use for the on-line portion of the workshop. Eleven of the thirteen participants reported using the on-line features everyday or every two days during the on-line segment of the workshop. And even though participants reported being most comfortable with e-mail prior to the start of the workshop, only five reported a high frequency of use for e-mail during the course. All participants said they would recommend this web-based workshop to other teachers.

Conclusions

This workshop format of combining the orientation day, field study trip, and the web-based instruction worked very well for the K-12 teachers who participated. All of the teachers completed the workshop even though only half registered for graduate credit. The participants reported a positive experience in the web-based workshop and most reported increasing their computer skills as well as increasing their content knowledge as a result of participating. The high ratings by the participants were somewhat surprising as there were some computer glitches experienced by the participants. The participants thought technical support would have been helpful, but realized the distance between their physical locations made it impossible to provide that type of support. The participants also noted the flexibility of asynchronous scheduling made possible by the web format was very helpful to them. The
variety in the answers about the average length of sessions spent on-line would support the fact that the participants all worked in a variety of personal schedules during the course. Combining both face-to-face sessions and web sessions in this workshop was successful.

In light of the fact that the course was advertised statewide and all expenses were paid, the small number of participants that actually enrolled might raise some questions about the teacher’s interest in using the Internet for instructional delivery or in distance learning courses. More information would need to be collected before it could be determined what role computer literacy and skills of the K-12 teachers at the current time would play in determining enrollments for web-based courses. The teachers found the web-based components of the course to be very user friendly and used them in place of e-mail although they were more familiar with the e-mail applications at the beginning of the workshop.

The workshop provided an opportunity to use interactive web pages for instruction. During the course of the workshop, it became evident that other interactive designs would be useful as instructional strategies over the Web. Some of the interactive strategies to be incorporated into the workshop for the next time it is taught include:

1. Small group e-mail discussions, which result in a consensus reply to the discussion forum.
2. Use of the shared work areas for teachers to develop group responses to issues or debates.
3. On-line web directed instruction using two browser windows to direct instruction and keep the learners "on task."
4. On-line office hours by the instructor, who would be available for e-mail, chat or phone conversations.
5. Participants (individually, with a partner, or in a small group) could create their own web page illustrating their perspectives and post it for discussion and response by the group.
6. Participants submit a web page with a series of links and images to verify or illustrate their responses to information or issues.
7. Participants can use on-line tools to generate maps, diagrams or graphs as responses to discussions or issues and post those for other participants and the instructor to review.

These additional design features would keep participants actively involved in the course during the time they are working from home. They will also be included with the hope of developing a network or community among the participants so they will get to know one another better and rely on each other for ideas and content help after the course has ended.

For Further Study

The World Wide Web has great potential for interactive communication and eliminating distance issues that might have previously prohibited people from participating in classes and workshops. By offering courses and workshops over the WWW, universities will be able to reach a new segment of potential students. It also means increased competition if a student can enroll and take a course from any institution on-line. Further research will be necessary to determine the effective components that should be included when designing instruction for the Web.

Instructors need to know if survey and research results are measuring the novelty of the new found convenience students are experiencing by taking on-line courses or are they truly measuring the effectiveness of the instructional value of the features used as teaching strategies in these courses. Courses might be offered and conducted through two differently designed web sites that would allow a comparison of the instructional features. The Web also requires the examination of two issues that should be measured separately. Both synchronous and asynchronous instructional strategies can be useful in web course design, and the value of each is relative to the task it is being used for in the course. Understanding the instructional design and the effectiveness of that design relative to web-based instruction is essential to developing a model of best practices for educators and students.
An Electronic Professional Development Center  
and 
The Chicago Systemic Initiative 

By 
Todd Hoover  
Loyola University Chicago  
United States  
thoover@luc.edu 

Abstract: Beginning with 1994, the Chicago Public Schools began a substantial initiative to improve and integrate mathematics, science and technology instruction [Chicago System Initiative or CSI]. This effort resulted in a major, continuing grant from the National Science Foundation. Initially, the project was to focus resources to the local school building by offering many different opportunities for teachers to develop their knowledge and skills. Today, the grant still offers these same kinds and types of services to the local building level and to the teacher. It should be pointed out that the Chicago Public Schools consist of more than 575 individual buildings and more than 26,000 teachers. During late 1996, CSI began building their web page to provide resources for teachers essentially focusing on lesson plans, teaching activities and other ideas. This paper focuses discusses a major revision to the CSI web page and to a major rethinking about staff development. 

Background: 

Beginning with 1994, the Chicago Public Schools began a substantial effort to upgrade the skills and knowledge of teachers. The focus was on skills and knowledge related to teaching science and mathematics while at the same time beginning to add technology to the curriculum. Substantial work has been accomplished to distribute the content and processes to teachers. The basic model included direct materials distribution to the individual schools. This was largely due to the logistical problems of sending things to buildings with just a handful of professional and support staff. Once the distribution network was established, more individual buildings were contacted to participate in the program with more than 160 schools currently participating in this distribution network. The network is used to distribute supplies and equipment related to science and math. In addition, as technology is becoming available, schools are being connected to the "internet" network. But, much more than the distribution of materials is involved; There is teacher training and development. The general model for dissemination of ideas and teaching processes appears in Figure 1. 

Figure 1: CSI Staff Development Model
A brief explanation is in order to help the reader understand the key features for each of the three elements. On the left, the Central Office staff for CSI consists of the Co-directors, Associate Director and three key professional staff including a person focusing on special projects, a math specialist and a science specialist. In addition, there are a couple of professional development specialists. The middle box includes the key people who are actually in contact with individuals within school buildings. Each of the twelve "regional coordinators" is responsible for about fifteen CSI designated school buildings. Their roles include direct work with teachers by holding staff development activities and assisting the building level CSI representatives with their work. The right hand box corresponds to the individual school building. Within each of the designated CSI participating schools are two individuals responsible for working directly with teachers by providing peer based assistance. These people are the building level CSI representatives. In summary, the model appearing above is a traditional dissemination model (includes the element of train the trainer where the regional coordinator work with the building representatives) and has worked well given the constraints of a large organization. Schools all over the United States use similar organizational approaches to staff development. It should be noted that the initial efforts for technology integration were limited because the Chicago Public Schools had not begun the actual widespread technology installation within the schools until fairly recently. However, much planning has been done to serve a complex system consisting of 575 buildings.

Staff Development:

With the CSI as a background, the paper now focuses specifically on staff development. The National Staff Development Council (NSDC), founded in 1969, is the largest non-profit professional association committed to ensuring success for all students through staff development and school improvement. The NSDC can be contacted by way of the web at www.nsdc.org. It is interesting to note that the "NSDC will provide one-, two- and three-day workshops on effective staff development practices." Certainly, this important resource is one to consider when thinking about and conducting any type of staff development activity. The list of topics, presentations, and consultation areas NSDC can provide is extensive. Figure 2 provides a listing for many of the topics.

- Implementing standards-driven professional development;
- Developing a comprehensive long-range staff development plan;
- Implementing a successful follow-up program;
- Improving student achievement through staff development;
- Making effective presentations;
- Providing staff development to support school improvement;
- Implementing a training of trainers program;
- Facilitating school improvement planning;
- Facilitating school-based decision making through group development, consensus decision making, and effective meeting management;
- Effective staff development practices;
- Evaluating staff development programs;
- Motivating adult learners;
- Implementing change;
- Staff Development 101;
- Resolving conflicts;
- Understanding the changing role of central office staff;
- Maintaining the momentum of improvement efforts;
- Facilitating effective meetings;
- Tools for change.

(source: http://www.nsdc.org/services.html)

"Figure 2: Staff Development Resource"

The above Figure shows how extensive Staff Development efforts have evolved during the last thirty years. All kinds of services are available to schools ranging from resolving conflicts to implementing a trainer
the trainers program. This is a wonderful resource for school people along with other professional organizations in the pursuit of improved teaching practices and improved curricular materials.

The problem with the staff development models is that they are labor intensive. That is, this model requires, or even mandates, that school systems spend enormous amounts of resources in the form of professional school people working with professional teachers. There is the direct cost associated with providing staff developers and the cost of teacher time since teachers have to be taken from the classroom. The alternative is to conduct workshops after school and that usually means paying for time to attend the workshop sessions. Figure 2 clearly suggests the nature of this labor intensive business. On top of all of this is the often heard complaint by teachers as to the inappropriate content or that the content does not meet teacher needs. As a consequence of additional funding, the Chicago Public Schools in cooperation with Loyola University Chicago began constructing a world wide web site intended to provide teachers with web based information. The guiding principal was to locate and display as many quality mathematics and science resources as possible which teachers might utilize as part of their teaching. The web page was obviously organized along the lines of math and science resources. In addition, and consistent with parent involvement practices, the web site also provided resources for parents as well. Finally, many high quality student sites were located which were presented to teachers for possible in-class use. To date, more than 40,000 “web hits” have occurred. But, this is only the beginning because until recently few Chicago teachers were web capable in their individual buildings or in their own home. We anticipate substantial increases in the “web hits” over the next year because we are changing the web page, because of increased interest in the use of the web pages by teachers, and better methods for letting teachers know they have their own web pages for important sources of information. As a small but important testimonial, the CSI web page for mathematics was recently cited among the best in the nation ["Road Map To The World Wide Web III" by T.H.E. Journal, 1998, http://www.thejournal.com/].
their schools. Because of the falling prices for competent computers, teachers are buying new machines with fast modems. As such, the next generation of the CSI web page will emerge with more graphics.

**Future of Staff Development**

Since there is a major change in the quality and price of the computers and their related equipment, the CSI professional staff and the author started thinking seriously about how to organize the content of the CSI web pages differently. We also thought about how teachers should use the web pages and how staff development might look in the future. An important resource written by George Piskurick focuses on twenty-one trends for the future of training and developing the American workforce. Among the future forces are three that appear to have important relevance to school people. These three forces are:

- Individual responsibility for personal development has become the new philosophy of development specialists. This vast need for programs and opportunities that can be employed on an individual basis will be met through the use of technology development, implementation, and administrative systems.

- Self-directed learning theory will challenge and assist those who work with technology to develop an integrated implementation format that will combine the suitable amount of technology and nontechnology-based learning interventions to meet the needs of learners who have lower and higher levels of internal self-directedness.

- Web-based training through both internal and external Nets will continue to develop and become a standard for technology-based training as problems with bandwidth and speed are solved.

The above three points are important because they help us to re-focus our thinking about staff development. Perhaps the future will place a major responsibility on teachers for their own staff development rather than depending on the school system to provide the service. The notion of self-directed learning is especially appealing - perhaps the notion of "just in time training" might be appropriate here. Finally, bandwidth will improve which means that teachers can work from their home machines to receive a host of learning resources ranging from recorded video programs, on-line libraries to locating examples of academic standards.

As summer 1998 approached, the thinking about the web page began to emerge. Part of the change was because of the realization that this web page was intended to serve 26,000 teachers rather than just those who are more or less computer literate. Questions emerged addressing the issues of how best to modify and how best to enhance the web page for teachers. It is obvious that the web can provide the most current information for teachers and it is the most accurate information. More importantly, we began thinking in terms of the future staff development needs.

The use of the web is emerging as the primary source for consistent, standard and accurate information regarding standards-based education in the context of mathematics, science, and technology integration as witnessed by the plethora of web-based sites addressing these points. By the time you read this, the next generation of the CSI web page will be online and available for teacher use. It will not be complete but, it will be the beginning of the new thinking about web-based technology and staff development. The obvious but significant focus here is the use of technology to deliver staff development to those responsible for math, science, and technology education. The appearance of the newest version of the CSI web page is found in Figure 4.

Changing the way we think about the web enabled us to change the way teachers can utilize the web. More specifically, the new web page can be thought of as a "just in-time" resource. Namely, the most current information is always available for any teacher who has the need at any moment in time. This is an important advantage provided by the World Wide Web. We also thought about the new web page as being a "Electronic Professional Development Center." This metaphor is taken from the professional development centers run by
many school districts. The concept is, of course, that one of goals of development centers is to provide current information to teachers including curricula, materials and ideas. The "Electronic Professional Development Center" will certainly achieved this important goal.

The concept is, of course, that one of goals of development centers is to provide current information to teachers including curricula, materials and ideas. The "Electronic Professional Development Center" will certainly achieved this important goal.

The "Electronic Professional Development Center"

There are a number of important features that will be added in the future. Most noteworthy will be an effort directed toward "on-line" courseware for teachers. Establishing a "Best Practices" location where teachers and facilitators can locate suggestions. An effort will be directed toward building a monthly "spotlight" on a CSI designated school and their respective faculty as well as other similar ideas. Moderated distribution lists/discussion groups have been constructed which enable professionals to send email to their respective specialized groups. For example, principals will have their specialized distribution lists to enable them to share ideas and suggestions about such things as how mathematics, science and technology can be integrated. Similarly, distribution lists for other groups will be developed to encourage the sharing of ideas and suggestions.

While an urban area appears to be relative small in geographical miles, it interesting to note that an individual teacher can feel particularly isolated in a professional sense. This is especially true when one considers that there are so many teachers involved in an educational enterprise known as the Chicago Public Schools. Therefore, the first goal for the "Electronic Professional Development Center" is to provide current and accurate information. The second goal of the "Electronic Professional Development Center" is to become an electronic meeting place for the exchange of ideas and approaches to educating children. Both of these goals will be presented in the context of the "just in time" model for professional development of teachers. The information is available when they need the information. Further, the professional educators can meet using the "electronic town hall" concept to discuss and exchange points of view and ideas. The third goal is to move to "on-line" learning which begins to addresses George Piskurik's ideas. The third goal will be the most challenge to achieve.

One of the primary criticisms of the "Professional Electronic Development Center" will be the lack of an actual person to talk with and to discuss ideas. This might be true, however, we think that this might be offset
by two dynamics. First, we think that dollars will be saved with an "electronic" form of the professional development center. Second, we think that the information provided to the various groups as represented by the different “Centers” will be of highest quality. Consequently, the professional educator will be somewhat more willing to overlook the lack of a specific contact person in favor of consistently good material as we teachers move toward being responsible for our own continuing education.

Summary

The Chicago Systemic Initiative is just beginning their work toward the new concept for delivering staff development services and we recognize there will be many important and significant concerns expressed by the teachers. Further, we recognize that this effort will be incremental in nature. Maybe it might be best to look back from the future to see what this will look like. Just to name a few things, the teacher will be able to focus their own learning relative to staff development. These activities will range from colleges and universities offering and delivering new kinds of courses sent right to the home of the teacher [time and environmentally friendly]. The teacher can meet on-line regularly and, in person. The teacher will have access to the most current district standards and policies. The teacher will be as well informed as any official of the public school system or any other peer which helps to eliminate the sense of isolation one experiences within the context of a large urban setting. The teacher will be provided information for parent relative to his/her students which parents can use. This new form of staff development is a completely flexible system that can be custom designed to meet the specific needs of the teacher exactly when the teacher needs the information. But, we should not be misled. With this flexibility goes responsibility for one's own destiny. That means the teacher must work to set learning goals and performance standards to improve their own teaching. It will not be an easy time as there will be many criticisms. As a benefit of this work, the new staff development system will produce substantial improvements in student outcomes and learning.

This article has highlighted a different way of using the World Wide Web. In particular, the web is being used to serve as an "Electronic Professional Development Center" which provides high quality and accurate information for professional educators. It can also serve as a "town hall" where folks with common interests can meet and exchange questions, solutions and ideas. Much more work remains. But, this effort represents a new way to look at the delivery of professional development services to the classroom teacher. It is anticipated that next year, a report will be available describing progress toward the goal of using technology for purposes of staff development. It is an exciting time and requires individuals with the most imaginative and creative ideas.
The After-Training Support: Using Internet Technology to Help and Connect In-Service Teachers in Their Teaching and Professional Development

Jun Hu

Abstract: For the last decade, the movement of bringing computer technology into the classroom has been a focal point for many institutions and organizations. In summary, the mainstream of this movement has gone through the first two phases of obtaining equipment and the computer literacy training (Hunt & Bohlin, 1993; Marcinkiewicz, 1994), and is currently undergoing a third phase of technology integration training (Hu & Nelson, 1998; Lan, 1998). This paper is to discuss another phase that follows the integration training: the phase of the after-training support -- how important this phase is to ensure the success of the aforementioned three phases to be carried on into everyday teaching, how to use Internet technology to implement this key phase, as modeled in the website of Health and Sciences Technology Academy, and the effectiveness of the implementations.

The Four Phases of Technology Integration
Bringing computers into the classroom started with introducing computer hardware and software into schools, and providing teachers with computer literacy training. There is a strong growth in use of technology by schools, and the expanded penetration of computers in schools is continuing, in forms of adding equipment and developing connections to the national information infrastructure at a high rate (1996, Glennan & Melmed). Early technology-related training to teachers was limited on the computer literacy training. The focuses were on how to operate computer, and how to use general-purposed software such as word-processor, spreadsheet, e-mail and web browsers.

In the past 3 years, as the technology integration movement outgrew its infant stage, more and more attention has been paid on technology integration training, which differs from the computer literacy training in that integration training focuses on appropriate usage of technology in content area curricula rather than on general usage of computer hardware and software (Hu & Nelson, 1998). Every year, especially during summer sessions, groups and groups of teachers go through technology training workshops to learn how to use computers in their teaching. Typical workshops are intensive training that lasts for one to four weeks. Such training is enthusiastically welcomed by the teachers, and post-test survey results are usually very encouraging: teachers reported that they had learned a lot, they had networked with other teachers, and they were planning to integrate the knowledge and skills they acquired in training once they got back to school. But a disturbing question for many training providers is “what happened after that?”

In many cases, most of those positive results of the workshops dissolved soon after the teachers left the training session. What went wrong? Why the positive attitudes were not sustained? Why planned projects were not carried out? Why the full potential of the program did not get realized?
The reasons behind such a phenomenon are from many aspects. In earlier stage of technology integration, we attributed the failure to the lack of equipment when there were not hardware and software in place for teacher to use. Yet the proliferation of equipment in recent years did not bring the corresponding increase of technology integration. The RAND/CTI workshops on professional development and technology-assisted effective schooling suggested three common requirements for continuing professional development: (1) adequate time for teachers to acquire skills and to plan the program and activities; (2)
assistance that is keyed to the needs of the teachers and provided at the times when they need it; and (3) a clear vision concerning the purposes and the educational goals that guide the program of the school and classroom (1996, Glennan & Melmed).

The second requirement is in accordance with our notion of emphasizing the after-training support, which is one of the key issues that need to be addressed to ensure the positive effects of the technology training to sustain, and the knowledge and skills teachers obtained in the training get utilized in their everyday teaching. It is time to add another phase -- the phase of the after-training support -- after the third phase of technology integration training.

Some well-designed technology training programs have already started to implement the after-training support. It can be done in different fashions such as on-site visit, mailing, listserv, e-mail, phone troubleshooting, and tele-mentoring, etc (Lan, 1998). This paper is to discuss the use of various Internet technology to support and connect in-service teachers in their teaching and professional development after the training sessions, as modeled in the Health Sciences and Technology Academy Program, which is affiliated with Robert C. Byrd Health Sciences Center of West Virginia University.

The HSTA Program and Its Special Needs for After-Training Support:

The Health Sciences and Technology Academy (HSTA) reaches out to 9th-12th grade under-represented students and follows them to college and towards professional school to help them prepare for health care careers. Our goal is to nurture the ambitions of talented students who, for economic or other reasons, might not ordinarily achieve these career goals. HSTA is a partnership among the numerous units of West Virginia University and many Appalachian communities.

The program brings minority and disadvantaged students and their teachers to campus each summer for clinic, laboratory, and classroom training and enrichment activities, then provides the infrastructure and support for community-based science projects mentored by teachers, health professions students and volunteer community leaders during the school year. HSTA aims to share the resources and talent of the University, to encourage public school teachers' and community leaders' mentoring of students.

The ultimate goal of HSTA is to increase the college-going rate among under-represented students in the Appalachian region, to improve science and math education, to empower communities through leadership development of their youth, and, ultimately, to increase the number of health care providers in West Virginia's currently under-served rural communities.

Currently HSTA is in 20 counties of the State of West Virginia, involving 460 students and 48 middle and high school teachers. 100% of the graduating 4th year HSTA students applied to college and were accepted. For professional development, 5 HSTA teachers graduated with a Master degree in secondary education in 1997 through HSTA, and over the next two years, 8 more such teachers will graduate.

The challenge of HSTA teacher training and professional development is that the only chance for face-to-face sessions are the 4-week summer workshop, and a two-day fall workshop each year. The workshops are focused on how to integrate technology into teaching and HSTA club activities. For the rest of the year, teachers are located across the state in their local HSTA clubs to facilitate student projects related to health sciences and technology. How to provide support to the teachers in their teaching and professional development, and how to connect teachers and students across the state become a key issue for the successful operation of HSTA program.

Goals of the After-Training Support Website:

Through task analysis and interviewing with teachers and field site coordinators, we defined the major goals for this support website is to

1. Provide quick case-based tech support for teachers on computer hardware/software problems.
2. Provide guidance and suggestions on curriculum and activity design and technology uses.
3. Build a cyber-community for the HSTA participants. Provide a forum for teachers, students and field site coordinators to network with each other, with content experts in health science and education, and with the HSTA central administrative office.
4. Provide selected quality resource links on the Internet related to health sciences, science education, and technology integration.
5. Showcase teacher projects as well as student projects. Reinforce the sample curriculum and activity design and the appropriate use of technology.
Internet Technology Used in the After-Training Support

**Asynchronous and synchronous communication:** The WebBoard software by O'Reilly is an excellent tool to facilitate asynchronous and synchronous communications. These two types of communications are usually hosted by separate software. Bulletin board is used for asynchronous communication in which users log on to the bulletin board and post messages, waiting to get a response from other users when they log on to the board and read the message in a different time. Chat software is used to facilitate the synchronous communication in which users log on to the chat room at the same time, and communicate back and forth by typing messages. WebBoard is a seamless combination of both: it can be used as a bulletin board where users can access in different times and locations to post and response to messages to the board, and it is also used in many sites as a chat software, including major sites such as NBC.com Forum, Dell Talk, and ZD Net. WebBoard combines both features by using conference rooms. Each conference is a posting board with its own topic, and a chat room is attached to each conference. The combination of the posting and chatting features makes the online communication easy to use and to manage.

In HSTA website, we set up conference rooms for four categories of topics. One for curriculum and club activity development, topics in this category include air quality, concept mapping, generic engineering, health career experiences, human nutrition, inquiry and discover activities, science projects, tobacco and health, water quality, and UV radiation. Another category is for tech support for software and hardware, such as Tips and Tricks, and Tech Support, where messages on how to make better use of software/hardware, and Q&As on software/hardware problems are posted. The third type is for management, such as announcements, and conference for field site coordinators where they can discuss administrative tasks, and the fourth type is used for supporting graduate courses provided to HSTA teachers for professional development through College of Human Resources and Education of West Virginia University.

Another feature of WebBoard is that more than one board can be set up. In HSTA site, we have one board dedicated for the teacher use, and we are in the process of setting another board for student use. The student board will allow students to log in and communicate with others in project collaboration. Separating the two boards makes management of the posting and chatting easier. Moderating features for the posting and chatting are available if necessary.

Besides these two boards for different user groups, other boards have been used for specific collaborative projects. The current project board is the one dedicated to the UVB project, facilitated by one of the HSTA curriculum coordinators, Jenny Bardwell. In this project entitled "UV Rays and Global Change" ([http://nt-hsta.hsc.wvu.edu/health/uvproie/nebulae.htm](http://nt-hsta.hsc.wvu.edu/health/uvproie/nebulae.htm)), students of the HSTA clubs across the State of West Virginia gather daily data on UV-B intensity, and post the daily readings to the WebBoard. The data are then entered into the database for future analysis, and currently the curriculum coordinator is working on putting the UV-B readings on the West Virginia map so that the map can be used by TV stations as part of their weather reports. Other related discussions to the UV rays and collaboration activities are also hosted on the board. The future direction of this project is to network with the teachers and students from other locations across the nation, or even across the world to collect and analyze the UV data. WebBoard can be used to facilitate the online communication of large-scale collaborative activities.

**Connect Teachers, Students, Health Science Professionals, and Other Content Experts.** The HSTA website is not just a tech support site for instructional technology and science and health education, it also serves as a connecting mechanism that brings the expertise and knowledge of the teachers and other professionals together by using database-generated web pages.

In the process of facilitating the student-centered science projects, one of the issues that trouble the teachers most is their worrying about “what if the topic of investigation is out of my scope of expertise?” “How much time I have to spend to research for the answer?” “Where can I find help?" An “Ask the Expert!” website is a possible solution to those questions. This website listed profiles of volunteered health science professionals from the medical school of West Virginia University, and other experts in science education and some other areas. The profiles have a brief introduction to the experts, including the specialty areas and the current research interests of these experts, as well as their e-mail address. When teachers and students run into questions in their investigation, they can look up the profiles, and find experts specialized in their problem area. By contacting the experts through e-mail, they can get suggestions back from them soon.

Because the expert list keeps growing and changing, updating the expert web pages becomes a time consuming task for web site management. Each time when a new expert comes in, a web page has to be
created for the individual, and a new entry has to be added into the index which is sorted according to the
last name of the expert, and by the keywords of their specialty areas. To make fast, easy and accurate
update of expert profile web pages, Microsoft Access is used to help with creating the web pages. When a
new expert turns in the application form provided by HSTA, all the information on that form is entered into
an Access database. The database is programmed by the website manager so that HTML code of the
webpage for the new expert is automatically generated, and is added into the site. This use of database
makes site management more efficient. It is not only applicable to the update of the expert record, but also
makes the change on webpage layout design more flexible. For example if one link has to be added on each
expert’s page, instead of going to each expert page and add that link, all the site manager needs to do is to
adjust one line of code inside of the database and click an "update" button. Each of the expert web pages
will be updated to use the new format in a snap. Using database in webpage creation makes update and
expansion of the “Ask the Expert!” feasible.

With similar approach, currently a new database is being built to create a site called “Ask the Teacher!”.
This site aims to create connections and encourage collaboration within HSTA clubs. A webpage is created
for each HSTA teacher, highlighting the teacher’s specialty areas and the projects the teacher facilitated.
We hope this will help teachers to share valuable experience and information with each other and with the
HSTA students.

Other highlights of the support site include the showcase of student projects, lesson plan posting, resource
links on technology integration and science education, and annual science fair organizing.

**Evaluation:**

HSTA is currently in the process of design surveys on teachers’ use of the HSTA website. Based on the
five goals of the HSTA website, the questionnaire will ask the teachers in what degree the website achieved
the five goals in providing support for their teaching and professional development. The questionnaire will
also include open-ended questions to collect suggestions from teachers on how to make the HSTA website
more useful and user-friendly for both teachers and students.

What Really Happens in Classroom Internet Projects

David M. Marcovitz, Ph.D.
Education Department, Loyola College in Maryland, Baltimore, MD, USA
Email: marco@loyola.edu

Abstract: One of the difficulties with Internet projects is finding out what actually happens in real classrooms that participate in the projects. Generally, we hear the hype about the project but not the reality. Projects that sound good might have few participants or no participants, or they might be poorly coordinated. This paper presents preliminary results of an ongoing study in which teachers whose classes participated in Internet projects are asked about the successes and failures of the projects for their classrooms.

1. Introduction

Teachers use Internet projects with their classes for a variety of reasons. Some have broad objectives, such as adding a technology component to their curriculum or motivating their students. Others have specific curricular objectives. In many cases, broad or specific objectives are met by Internet projects, and in many cases they are not.

In this ongoing study, I am communicating with teachers who have participated in Internet projects with their classes. The classes range from K-12 and include public and private schools, single-grade and multi-grade classrooms, and regular classroom teachers and resource specialists. I am specifically looking at three Internet projects: The World Weather Watch (http://youth.net/weather/), Signs of Autumn/Signs of Spring (Signs, http://www1.minn.netkschubert/ssf/), and Global Learning and Observation to Benefit the Environment (GLOBE, http://www.globe.gov/). Each has students observe the environment as the seasons change. World Weather Watch and Signs require little or no training and a minimal commitment of time and effort on the part of participating classes. GLOBE requires teachers to attend training for five days, requires daily measurements that conform to scientific protocols, and requires approximately $500 of equipment.

In World Weather Watch, students gather sunrise/sunset times, high/temperatures, and a general description of weather conditions each Wednesday during the project. This information is shared with all participants. Additionally, each class is paired with a partner class in a different climatic zone, and partners email their data to each other. A discussion board is provided at the project web site for group discussions. World Weather Watch is open to students in grades K-12, but over two-thirds of the participants are in elementary classrooms.

In Signs, students make weekly observations about the changing seasons for four weeks in the fall or spring. Observations, stories, and pictures are sent to the project coordinator who compiles an electronic magazine (e-zine) each week. Students compare their seasonal changes to others by looking at and discussing the e-zine. The project also suggests several extension activities to supplement the observations made. Signs is open to students in grades K-12, but over two-thirds of the participants are in elementary classrooms.

In GLOBE students collect one or more types of data on a daily basis according to specific scientific protocols. Weather data, for example, must be collected at solar noon each day, including weekends and holidays. The data is posted to the GLOBE web site and can be viewed by participants in various formats, including scientific visualization software. Participating teachers are given an "Implementation Guide" with a variety of learning activities and protocols for collecting and using the data. GLOBE offers opportunities to discuss the project with scientists who are using the data. GLOBE is open to classrooms in grades K-12 and includes lesson plans and activities appropriate for all grade levels.

Overall, participating teachers were very happy with the projects. Most reported that their objectives were and they hoped to participate in the project again. Nearly all teachers reported some problems. Some of the problems were viewed as obstacles to overcome and others interfered with some or all of the objectives of the project. In this paper, I describe some of the obstacles and successes that the teachers encountered.
2. Methods

This informal qualitative study involved sending electronic mail surveys to participants in each of the three projects studied. The questions were modified for each project to include one or two questions that related to the specific project. The questions asked of GLOBE participants were: "How did you find out about the project? What were your objectives for participating in this project? Were they met? Did you have any problems? What did you do with the data that was collected from your class and from the entire project? Did you participate in any of the Learning Activities? Have you participated in this or other Internet projects in the past? If so, which projects? Did your students benefit from the fact that the data was being used for real scientific purposes, or would it have been just as beneficial to have participated in a data collection project that was not linked to scientific study? Was the project worthwhile for your class?" As results were received, each respondent was sent an electronic mail message of thanks, and some respondents were asked follow-up questions.

For World Weather Watch, 5 out of 9 teachers surveyed responded. World Weather Watch includes approximately 70 classrooms each session. World Weather Watch was used as a pilot for this study. I was concerned that teachers would be disturbed to receive unsolicited email. I was pleased to find that no one who responded complained about unsolicited email, and many were pleased that I had found their work on the web (and disappointed that more people had not sent them email about their project).

For the Signs Project, 12 out of 29 teachers responded to my survey.

For GLOBE, 59 out of 237 teachers surveyed responded. GLOBE includes hundreds of teachers from the United States and all over the world. About one-third of GLOBE participants in the United States were surveyed. No participants from outside the United States were surveyed.

The respondents to the survey do not reflect a random sample, and the responses are not used for any statistical analysis. Those responding are more likely to be technically savvy (at a minimum, they must have entered correct email addresses for the project, and they must have read and responded to an email message). Many of the respondents were excited to share their success stories so those who were unsuccessful with the projects might have been less likely to respond. Responses from participants were analyzed for common themes as well as unique stories to serve as a roadmap for the possibilities and the pitfalls a classroom teacher might encounter when undertaking an Internet project.

3. Obstacles, Issues, Problems, and Successes

The vast majority of teachers reported that the project in which they participated was successful, meeting or exceeding their expectations. As one GLOBE teacher reported, "The GLOBE program has surpassed my original expectations, which were to have students participate in a project that would represent real science, doing what real scientist do.... The extra benefits we have reaped: my students have participated in GLOBE chats with the real scientists, we have downloaded information from our own archives which has enabled us to see patterns about how the earth's systems are connected, we have also used our data to make predictions concerning El Nino weather patterns."

Most teachers reported problems along the way. Some of these problems were obstacles that were overcome while others limited how well the objectives of the project were met. Problems fell into five categories: time and management, technology, curriculum, communication, and other. These categories are not strict and many overlapped, but they help give a sense of the kinds of problems teachers encountered.

3.1 Time and Management

Time and management problems were the most commonly reported problems. These included problems of not having enough time for the project, not having the appropriate time for the project (e.g., temperature readings needing to be taken at a certain time that did not coincide with class time), and general issues of managing students as they did the project.

Both World Weather Watch and GLOBE required readings to be taken at specific times (temperatures at solar noon, for example) or on specific days of the week. In addition, GLOBE weather readings were required every day, including weekends and holidays. This was a burden for many teachers. As one GLOBE teacher
reported, "It has also been difficult at times to collect data on the weekends. Students are not always able to come in since their families have other activities on the weekends (like soccer games that are also occurring at solar noon)." Another GLOBE teacher who could not have readings taken over the summer was disappointed because she thought the summer readings would be beneficial.

While many teachers reported problems with collecting data regularly, some viewed this as an opportunity to teach responsibility. One teacher, whose class missed very few days over a two year span of taking measurement for GLOBE, reported that her success was due to her emphasis that science included making sacrifices. In addition, she offered extra credit for weekend and holiday measurements. Other GLOBE teachers found that using more experienced students and parents as helpers alleviated the burden on the teacher: "So that we don't all have to go out to the weather station each day, I have trained two former science students, upper classmen, who come to my two Earth Science classes and take two kids out to the weather station to do the measurements, then to the multi-media lab to enter the data.... It works perfectly. During the summer, I train parents to take over, so I can take a break. On weekends during the school year, I record the data, since I live only 3 miles from school." One GLOBE teacher found that this helped raise the self-esteem of the student who was helping out.

Other teachers reported a more general concern for lack of time, fitting the project into an already packed day. As one GLOBE teacher stated, "My only problem has been finding enough time! (Isn't that everyone's complaint?) Our schedule is so packed (5th grade) and there are so many extra programs they are supposed to participate in: DARE, Jr. Achievement, Here's Looking at You 2000, H.E.A.T., Ropes, etc."

Because of the flexibility of the curriculum, many specialists and resource teachers found Internet projects to be worthwhile, but specialists had the problem that they did not see the students regularly enough.

Many of the time and management problems limited the impact of the project, often to a few students. This was due to schedules that did not coincide with the time for taking readings and the fact that an entire class does not need to go to a weather station to take a single temperature reading. Some teachers used rotating schedules so different groups of students took readings each day. In one case, more than one group took readings each day, but only one group's readings were "official" and used for the project. Other teachers simply limited who could participate in the project. A GLOBE participant responded: "The major concern I have involves the actual number of students who participate in the program. I begin the year training all of my students how to perform the atmospheric protocols.... The protocols must be completed during solar noon. Only three of my five classes take place during the prescribed time.... My other problem is that it doesn't take 30 students to perform the protocols."

Management problems were not limited to managing individual classrooms. Many schools or grade levels that tried to use a project with several classrooms had difficulties in managing groups of teachers. One school tried to integrate the GLOBE project into four fourth grade classrooms. This created some problems because not all the teachers were interested in the program. One teacher reported that "not all teachers felt ownership and therefore not as invested; some teachers believe too difficult for 4th graders; some teachers believe too difficult to manage; some teachers believe too time-consuming (GLOBE plus regular science curriculum)." This teacher found solutions to problems for her own classroom, but teachers who were not as interested in the project were not as willing to find creative solutions.

3.2 Technology

Problems and difficulties with technology were common. However, teachers chose to participate in the projects with a basic understanding of the technological needs of the project, so technology problems were mainly obstacles that teachers found ways to overcome. None of the projects required computer technology more advanced than simple email and world wide web access. Problems included a lack of an Internet connection in the classroom or school and difficulty transmitting information in the appropriate format.

In World Weather Watch, information was exchanged with partners via email. One teacher's partner class chose to send an attached file with the students' messages. This teacher could not read the attached file. Solving this problem took several weeks to solve. This limited the class's ability to establish an pen-pal relationship.

A participant in Signs had difficulty submitting pictures, "My main problem was my inability to know how to send pictures. The computer technician at my school put them onto a disk for me to transmit from home, but they never got to wherever they were supposed to go."

Many teachers reported that their classrooms were not hooked up to the Internet. Most solved this by finding other computers in the school to send data or by sending data from home. This worked out well for the
technical needs of the project, but some teachers found that it separated their students' from the project. One Sign teacher reported, "I went into the project knowing that our school didn't have Internet access in any place except the principal's office. I knew that that I would be responsible for uploading the information from home and that was okay. I thought we would have more time to examine other schools' work in the central office but it took so long to do this that we could only view our own work twice and we didn't view the work of other schools at all. So I guess the children felt a kinship with other students completing the project knowing that they were part of the group but they never saw the other students' work."

A GLOBE teacher reported that he found the students got more out of the project after the classroom was hooked up to the Internet, "Last year I was taking the data home and sending it on my home computer. This year we are on line at school..... The students have much more ownership this year. Each child gets to enter the data and then we print out a copy of the completed sheet for them to take home to show their parents. They are amazed that their data is instantaneously sent to Boulder, Colorado."

While entering data at home worked well for some teachers, one GLOBE teacher could not always keep up with the data entry, "I did not have a computer with the Internet in my classroom and have had to enter the data by myself. I was not able to do it consistently even though the data was being taken."

Some teachers found that students could help them with technological problems. For example, "The first year I taught GLOBE I had two wonderful students who were very strong in science (they also were good on the computer). They were helping me log on. They read the instructions and figured out which number was our code and which was our password."
the real benefit of the projects. "Previous to GLOBE our school had participated in a weather data collection project sponsored by a local television station. The station uses the data for forecasting and reports which school is supplying the data, but the students felt that the GLOBE program had a larger impact due to the greater number of schools and people involved."

A kindergarten teacher found that Signs could help her teach concepts that are difficult for her students, "Everyone is not having the same weather at the same time. Kindergarten children have a hard time with concepts like that."

3.4 Communication

Issues of communication were a problem for some teachers. This was true World Weather Watch in which classes were partnered with other classes. Partnering provided great benefits to participants with active partners, but those benefits were limited in some cases by partners that did not keep up their communication.

A World Weather Watch participant commented that communication, including an electronic discussion board and email with the partner school were beneficial, although not all schools took full advantage of them, "It was nice that she included a partner school and a place to share. You always hope that people take advantage of the sharing, but this is a new medium for teachers."

The organizer of the World Weather Watch project expressed her concerns about participant sharing. She was hesitant to match classrooms with partners, but she felt that the benefits outweighed the risks, "As with any free endeavor, there was a certain amount of attrition. In many instances, I was informed via email that a class would not be able to continue and I was then able to rematch their partner class. In other instances, the class left high and dry chose not to be rematched but rather to just use the weekly data on the page for their in class activities. I spent many hours trying to decide if I wanted to match classes for this very reason and decided that with having a partner school came a little more commitment." Since the project was free and easy to join, not all schools felt the same commitment that they might if they had paid to join the project or paid for expensive equipment. This created some frustration when partners dropped out of the project.

3.5 Other

Many other problems occurred for some of the teachers. Projects had fairly strict timeframes and schedules, as do schools. When these schedules are disrupted by problems, Internet projects might not work. The most serious problems were expense and equipment security. Although none of these projects had a registration fee, the GLOBE project required approximately $500 worth of equipment to take proper data readings. Many teachers found support from their schools and districts. Others sold popcorn.

Security of the equipment became a problem for many teachers. Even locked equipment was occasionally stolen or vandalized, as one GLOBE teacher reported, "Another problem we encountered was vandalism. Our station is locked, but one of the students didn't lock it securely and another student took one of the thermometers and hid it.... This year our rain gauge was smashed even though it was within a brick wall."

For every problem with Internet projects, some teachers find it limits the usefulness of the project and others find solutions or view the problem as an opportunity. Almost every teacher reported some kind of problem with every project, but most of them found ways to be successful despite (or sometimes because of) the problems.

3.6 Successes and Interesting Solutions

While many of the teachers found that the basic requirements of the projects were enough for their classes, many teachers found creative ways to use the projects. One Signs teacher reported:

Rather than measure weather patterns and temperatures, etc., I had my students observe specific sites around the perimeter of our school. By focusing their attention on specifics, they could observe changes in those things with the possibilities in how the changing weather or other variables affected them. We photographed the individual areas on our initial nature walk and took notes about what we observed. Subsequent walks were usually photographed...and...documented.... I used a digital camera to photograph
the walks/sites and students' artwork and uploaded the pictures to my classroom computer, edited them and put them into a looped slide show. I put the computer in the school hall outside my classroom to share our work with the rest of the school....

After our walks, we would draw our illustrations (if not completed in the field) view our photographs, then share our work with each other as we held conferences about what we had observed.... Problem solving skills were used to predict future expectations based on what had been learned....

Long after the completion of the project, on a sunny June day as we marched around the block in a Flag Day celebration, my little scientists were still calling out to me things like, "Look, Mrs. G.! The rose bush is now in full bloom and I see bees landing in it for a drink!" And, "Oh, look! The bird nest is falling down and is empty now." A positive sign for a happy, successful learning experience.

In the GLOBE project, data is collected and used by scientists around the world. Almost all the teachers in GLOBE reported that it was beneficial that real scientists used the data. It helped to motivate students, to give them a feeling of real purpose, and to make them take pride in their work and be more careful in taking accurate measurements. This was true for gifted and talented students as well as underachieving students. "I think it has been a real motivator. As with the other field study projects we're involved in, students take on a more serious demeanor and have a high proud factor as they collect data for a purpose.... At least with my students who are gifted and talented, just doing an exercise without any purpose is a real turn off." "I feel they have a sense of responsibility and that they have contributed something worthwhile in a way they never could before.... Just being able to participate has bonded my students, who have heretofore felt worthless and incapable in academic areas, together to provide a sense of pride, belonging, and contribution to society."

Of course with an attitude like this, it is hard to fail: "All my involvement with ... technology-related work in the classroom for students is worthwhile, even if the project doesn't work out. I like to explore new challenges and opportunities in these areas to take risks and see if the chances I take (academically) can make me a better teacher.... Mistakes are challenges to be overcome."

4. Conclusion

Technology can be very beneficial, and it can be intimidating and difficult to use. Anyone who attempts to participate in an Internet project is sure to run into problems. Simple projects, like the World Weather Watch and Signs, and more complex projects like GLOBE had their share of problems. The Internet does nothing for education on its own. Creative and dedicated teachers find ways to use the Internet to expand their classrooms and enhance their curricula. Obstacles with time and management, technology problems, mismatches with existing curricula, personal communication, and expense can all be overcome to create a powerful learning environment. But teachers must understand that it is their hard work and dedication that will be necessary to overcome these obstacles. This paper provides a guide to some of the problems and successes that several teachers encountered while expanding their classrooms to take advantage of telecommunications projects.
EDUC 541 Goes On-line

Abstract: This paper focuses on graduate students' responses and reflections on the required use of the Internet to complete assignments for an on campus research course. Students' responses to feedback forms, email assignments, and conversations with the instructor were analyzed. Materials and activities are gradually being designed and developed to enable the entire course to be delivered over the Internet. Students enrolled in on campus sections of the course during the Fall and Winter quarter are providing feedback for the further development of the course materials.

State and university initiatives to develop distance education courses, encouraged faculty to identify courses to be delivered using either compressed video or the Internet. Once courses were identified, summer grants were available from the University to facilitate faculty in the development of courses for distance delivery. One of these grants was used to begin the development of web-based materials to place EDUC 541 - Introduction to Graduate Study and Research on-line. It was proposed that the materials for the course be developed over the summer of 1998, field tested during the Fall and Winter quarters (1998-1999) using students enrolled in on campus sections of the course, and further refined over the summer of 1999 with the intent of offering the complete course on-line in Fall 1999. This paper chronicles the field testing of the materials during the Fall 1998 quarter using students' email messages, responses to on-line feedback forms, and personal conversations with the instructor.

Development of the course materials followed the instructional design stages advocated by Willis (1992) which include: design, development, evaluation, and revision. As the materials were designed and developed, care was taken to lessen the chances of students becoming lost in the hypertext on the screen (Jih, & Reeves, 1992; Park, 1991; Saga, 1992). This was an important consideration because it was anticipated that the students would have a variety of technical skill levels and prior experiences with the Internet. Once students successfully access the materials, they must develop mental models of the content to understand how the material is presented in the hypertext environment (Jih & Reeves, 1992; Park & Gittelman, 1995). Students who do not develop an adequate mental model of the web site can become confused and disoriented as they search the hypertext documents.

Well designed on-line course materials can promote improved student learning by appealing to students' learning styles, providing flexible learning, and encouraging learning in a variety of ways (Owston, 1997). Web sites can provide stimulating, interactive course materials, such as links to course-related sites and sample tests to take. Projects and activities that students can complete at their own pace and at their convenience give students flexibility in their learning. Further, Owston contends that web based learning enables students to learn using critical thinking, problem solving, written communication, and collaborative activities.

The development of the course materials involved a team approach, as advocated by Hoffman and Ritchie (1998), to assure a variety of technical expertise as well as a support system. The first author contributed the course content, while the second author worked on the design and technical aspects of the web based materials. However, as the collaboration continues these roles become less distinct.

Barriers to accessing on-line course materials include: malfunctioning hardware, configuring software to access the Internet, slow or down servers, busy signals, lack of access to computers (Owston, 1997; Ross, 1996). Hence, technical support from the instructor and the university is an essential
component of an on-line course. Barriers encountered when accessing and using the on-line materials cause students to become frustrated and may interfere with their learning content.

Methodology

Students enrolled in the course were required to access the course web site to examine course materials, link to course related sites, download files, and complete feedback evaluation forms.

Participants

The sample consisted of 16 graduate students enrolled in EDUC 541 during the Fall Quarter of 1998. They ranged in age from 22 years to mid 50s; including 9 females and 7 males. All of the students were working on masters degrees; four students were working on degrees in health and wellness; seven students were working on masters degrees and teacher certification; two of these seven had retired from other professions and recently started teaching.

Instruments

Instruments used to collect data included researcher developed pre- and post-feedback forms, email messages, and student conversations. Feedback Form I consisted of seven questions. The first five questions dealt with information on the computer system and Internet browsers students were using as well as how they were accessing the site. Question six dealt with the ease of finding materials on the site, and question seven asked if they had taken any other courses requiring them to use the Internet.

Feedback Form II contained the same questions as Form I with 12 additional questions. These additional questions focused on difficulties they encountered, usefulness of the content, ease of use, would they take another course requiring web access, and would they take this course completely on-line. Students were asked to elaborate on their responses to these questions.

Students were required to complete four email assignments. Email assignments one and four were to send the instructor email stating that they had completed the feedback forms. The results of the forms were sent to the second researcher, and the results were not viewed by the first researcher until grades were submitted. Email assignment two required students to access the course pages, examine the links to APA reference sites, and comment on the usefulness of the sites to the course. Email assignment three was a progress report on their research proposal. Field notes recorded after conversations with the students were also examined to determine the impact of the web based materials.

Procedure

During the summer of 1998 an instructor web page was created with a link to a course web site. Some course materials for EDUC 541 were converted to HTML documents using Adobe PageMill and Microsoft FrontPage. The materials were divided into several broad categories which include: course objectives, course requirements, grading scale, course calendar, instructor information, and feedback forms. The first five categories contained information from the syllabus used in the class. Under course requirements were links to the university library and the ERIC database. The course calendar provided links to handouts used in class, course assignments, links to course related sites, and supplemental materials to facilitate the development of the research proposal.

Students enrolled in EDUC 541 during the Fall quarter were encouraged to participate in the project by accessing the course information on the web and completing four email assignments. Students were introduced to the site and told where to go on the site to access instructions for the required email assignments. Email assignment one required them to browse through the site, complete Feedback Form I, and send the instructor email indicating they had completed the form. During the quarter students were referred to the site to search for materials that would be useful as they completed their research proposals.
and to download examples of the Human Use Committee forms that were to be included in the research proposal appendix. Often, this is the first course students encounter that requires them to use APA format for their papers. Hence, links to APA sites were added to the course web pages. For email assignment two students were asked to access two links to APA reference sites and comment on the perceived usefulness of the sites as they worked on their research proposals. Email assignment three asked for a progress report on their proposals. During the last week of class, Feedback Form II was placed on the web site for students to provide feedback on the web based course materials. Once students' grades were turned in, the results of the feedback forms and the email messages were collected and analyzed.

Data Analysis

Questions one through seven on Feedback Forms I and II required multiple choice and “yes/no” responses. On Feedback Form II questions 8 through 19 consisted of questions with “yes/no” answers followed by spaces for comments. Percentages were used to analyze the responses to the multiple choice and “yes/no” questions. Responses to the feedback forms, email messages, and personal conversations provided multiple sources of data. These multiple sources provided structural corroboration that enabled the researchers to examine recurring themes and draw conclusions (Eisner, 1998). Additionally, consensual validation (Eisner) was obtained by having the researchers independently examine and interpret the data.

The data obtained was coded and constant comparative data analysis was used to compare data codes within and across categories. Categories were compared and contrasted to determine similarities and distinctions among them as relationships were discovered (Leedy, 1997). The open ended responses, email messages, and personal conversations were examined to determine patterns in perceptions about the web based course materials across students’ responses.

Results

Responses from the feedback forms, email messages, and personal conversations were analyzed to determine the impact of the web based course materials.

Results from Feedback Forms I and II

Fifteen responses were received to Feedback Form I and Feedback Form II. However, all sixteen students reported via email assignment one that they had completed Feedback Form I. Only one student did not report completing Form II. Questions one through five on both forms asked students technical information about their computers and Internet access. On Feedback Forms I and II 27% or four of the students indicated that they did not know the screen resolution or their monitor screen color. Two students indicated that they accessed the Internet via a modem at a public school, which corresponds with the two teachers who mentioned in class that they had Internet access at their schools. When completing Form I, 67% of the students indicated they accessed the web site from home and 74% indicated home access on Form II. Since most of the students in the class have full time jobs very few of the students were on campus on a regular basis, so accessing the web site was easier to do from home than from the university network. On Form I 47% indicated they had taken other classes requiring Internet access for course related materials and on Form II 40% indicated they had taken such courses. This indicates the possibility that two students completed only one of the forms.

Questions seven and eight on Feedback Form II asked about ease of use of the site and all of the students indicated that the site was easy to use and that they were able to access the information without assistance. The remaining questions on Feedback Form II asked students to elaborate on their responses to the questions posed. Question 9 asked if they had encountered any difficulties accessing the on-line materials, and question 10 asked them to briefly describe any difficulties. Student responses indicated that 27% encountered difficulties; however, none of the students elaborated on the difficulties. Some difficulties were mentioned in conversations, phone calls, and email messages. One student had difficulty configuring his home computer to enable him to use his university email account. He called one evening to chronicle his failed attempts to transmit the first email assignment. Technical assistance was provided over the phone
by the son of one of the researchers, and shortly thereafter his first email message was received. However, during the last two weeks of class the following was tacked on to email assignment three: “I am still having problems getting on line with E-mail.” No mention was made of the specifics of the problems, and the student did complete all the email assignments. Some attempts to access Feedback Form II resulted in messages such as: “I completed email #4, but this appeared on the screen once I submitted the form: HTTP/1.0 501 Not Supported

Does this mean that it was not received? Let me know if I should resend my answers.”

Upon receipt of this and similar messages from other students, the problem was corrected and students were emailed that the form was working and to try submitting their answers again.

When asked in question 11 if they were able to find what they were looking for in a short period of time, 93% of the students indicated that they could. In response to question 12 students did have suggestions for making the site more user-friendly. These suggestions included:

“For the teacher to use the same terms in class that appear on the website. For example, if she says in class to click on the course requirements on the website, then there should be a place on the website that states course requirements.”

“Once you have chosen a link . . . make it easy to get back to the home page.”

“Study guides on the Internet.”

Students’ comments will be incorporated into the revisions of the web based course content for the Winter quarter.

When asked if the web site made the research class any easier, 73% indicated that it did. Only 10 students used either their own email account or a spouse’s, indicating a lack of access to the web site which may account for those who did not find the web site useful. Or perhaps, the materials provided were not useful to these students. Students responses included:

“Course requirements and the APA section. Also it was good to know that I could always e-mail my Professor and get a timely response.”

“The links to the reference sites.”

“It helped me in the literature review of my research proposal.”

Responses to question 15 about the least useful part of the site included: course objectives, grading scale, and course schedule. Overwhelmingly, 80% of the students indicated in response to question 16 that they would take another course that required them to access the Internet. When asked to explain their responses, students wrote:

“I spend so much time on the computer anyway that I might as well get credit for doing something I love doing.”

“Getting on the Internet lets me get answers on-line rather than having to call the Instructor.”

“The Internet is very convenient for me because I can access it at any time (especially late at night).”

“The more I have to use the Internet, the easier it is to access the information needed.”

“The Internet is the tool of tomorrow. If you do not learn to use it properly then you will be left behind.”

Some students found the integration of the Internet into the class enjoyable, convenient, important to learn, and useful.

Students who would not take another course requiring Internet access offered these comments:

“I am not on-line yet and don’t live near campus.”

“I just don’t feel comfortable using a computer. I would rather do it the old fashioned way.”

The university is located in a rural area and local phone service ends just beyond the parish boundaries. Hence, students who do not live near campus have to pay long distance charges to access their free university email accounts from home. Some students would have to drive for an hour or more to use the computers in campus computer labs.

When asked in question 18, if they would take the course completely on-line, 27% indicated they would and 73% indicated they would not. Students who indicated they would take the course completely on-line offered these comments in question 19:

“yes only if i was on-line. i know access is offered through the college but i don’t live near campus.”

“The required usage of the internet has helped me to overcome my fear of the Internet.”

One student indicated willingness to take the course on-line, but then commented:

“Education 541?????? No way. It was always good to have Dr. Matthew close by if I needed help.”

1796
Reasons for students not being willing to take the course on-line included the lack of human contact and interaction, needing face-to-face, one-on-one guidance, and the teacher. “There is too much, i.e. citation problems and reference problems, that can usually be only handled face-to-face.” “Sometimes I need to talk to the instructor one on one.” “I think the class interaction is useful and helpful.” One student cognizant of a preferred learning style commented: “I learn better by hearing the information.” Hence, further on-line development of the course will have to assure access to the professor in person and interaction with classmates for students who feel that this is needed for the successful completion of the course.

Results from Email Messages

Email messages were examined to 1) determine whether or not the students were using their own email accounts, 2) corroborate responses to open-ended questions, and 3) discover themes not addressed in the responses to the open-ended questions. Based on an examination of the email addresses used and student comments, it was determined that 9 of the 16 students had their own email addresses. One student used a spouse’s address and the remaining 6 students used friends’ or parents’ email addresses. Three students used university email accounts. Another student tried repeatedly to get her university email account to work. After approximately two weeks of visits and phone calls to the computing center, she opted to use her boyfriend’s account with a local Internet service provider.

Email assignment two required the students to access two APA links and comment on their usefulness for writing their research proposals. Reviews of the APA sites were mixed and included the following:

“I have completed the second email assignment. The APA FAQ page was particularly useful and easier than finding what I needed in the book.”

“I just figured the APA site out. It seems like it would be pretty helpful. I especially like the section under APA on references. I have a hard time with references and I hate having to go back and flip through the book trying to figure out which to use. This way, I can just go here and the different types are clear. I going back now to search on that APA journals section. I just wanted to let you know that I found it.”

Email assignment three was a progress report on their research proposals which elicited a range of responses:

“My research proposal is coming along fine. still have a few bugs to work out and need to finish the introduction.”

“The proposal seems to be going very slow. I think I’ve found all of the articles I need, but I’m having trouble putting it all together. The limitations section has me ‘tangled up in blues’ as does the basic assumptions.”

Students encountered a variety of problems when using the Internet. Whereas some of the students were quite resourceful and persistent about finding Internet access and completing their email assignments by the deadline, one student elected to just wait until her classroom Internet access was available. Three days after the quarter ended, I received the last three email assignments from her. Email assignment two read:

“I did browse the APA web site suggested. I wish that the internet would have been working for me to have used that site in my research proposal. I think that it would have made the paper a bit easier. Lincoln Parish Schools Internet services were repaired today.”

Only two students went beyond the required email assignments and used email as a means of communicating about their research proposals. One student submitted a rough draft of his proposal abstract. Then, he inadvertently wiped out the inbox in his email account and was not sure if I had responded or not. This was his only attempt to submit a draft via email, and he backed it up with a print copy as noted in his email message:

“Dr. Matthew - I didn't get a chance to check if you had sent me an e-mail before it was all erased. If you had please send it again....if not I'll check again later.
Thank you – (Student’s Name)
p.s. I'm assuming you got the copy I left attached to your office door.”
Another student wrote requesting assistance on locating references for his proposal: "I am beginning to really become concerned about the state of my review of literature. The articles that I ordered through inter-library loan are not coming through. I've tried the Carl Un cover system but the articles that I need are in journals that say this journal does not allow faxing of its articles." Any suggestions? I am going to go to LSUS and look for anything today. If you've got any other ideas would you e-mail me back. I'll check my mail intermittently through out the day, so any suggestions you might can offer would be greatly appreciated. Thank you again for all your help.”

This message was received three weeks before the proposal was due and fortunately, later that week his inter-library loan articles arrived.

Within 24 to 48 hours of sending messages, students received a reply stating that their message had been received. When additional comments were written or questions asked, the students frequently did not respond. One reason for this could be the fact that many of the students were using borrowed email addresses.

Conversations with students before and after class indicated that the Internet requirement for the course had impacted them beyond the course requirements. One student commented that the required email assignments forced her to get an email account. Once she acquired the account, she began using it to email several friends who live out of state.

Conclusions

As anticipated the students had a variety of technical skill levels and prior experiences with the Internet. Students’ responses indicated that the site was easy to navigate; however, they did have suggestions for improvement. As site development continues, their suggestions will be implemented. Students indicated that they enjoyed the convenience of being able to access the web as needed and being able to contact the instructor by email. They encountered the same barriers as mentioned in other research studies such as, configuring software, down servers, and lack of access to computers.

Requiring students to use the Internet is not a common practice in the College of Education, hence, there was some concern about the implementation of the Internet in this course. Only minimal use of the Internet was required during the Fall quarter. The Winter quarter will require the students to access more materials from the Internet and will include group activities to be completed outside of class time using Internet resources and email. Students positive responses to the use of the Internet are encouraging. However, their concern for a lack of human contact and interaction in an on-line course will need to be addressed as the materials and activities for the course are developed.

If we built a discussion list, would they come?

Alex C. Pan
The College of New Jersey

Abstract: With the Internet gaining its popularity among teachers, an effort was made to engage teachers in actively communicating via discussion list with each other between two groups of teachers from New Jersey and Wisconsin. Although most teachers considered the discussion device useful, they did not actively participate in the discussion activities. Several factors were identified to slow down the communication among teachers. This paper describes the discussion activities among participating teachers and attempts to analyze various factors that may contribute to the successful communication in the discussion activities. Finally this paper makes suggestions about how to enhance such an experience in the future.

A discussion list for teachers from two states

The Internet is rapidly growing into the education world each day. However, the Internet does not seem to have changed the teachers' nature of being isolated. With ubiquitous Internet access from home or school, more teachers than ever have experiences of using the World Wide Web (WWW). These teachers learn to use local computers to access the Information Highway and locate valuable resources they desired. However, many Internet-using teachers that we know are passive information receivers. They neither contribute to the development of the new Internet resources by creating new information or applications, nor do they share resources and experiences with other teachers. The isolation among these teachers still exists.

Long-distance correspondence via e-mail is a popular use of telecommunications in schools. The correspondence can be used for several different purposes in the learning of many subjects or in connecting a group of people for consultations or idea sharing. To promote the use of the Internet to connect teachers with each other and to minimize the isolation among teachers, an effort was made to encourage teachers to use the Internet not only to find information but also to share resources and experiences via the listserv discussion. The listserv is an e-mail mailing list that distributes mail to all participants on the list and to which any participant can publish mail. During the summer of 1998, 31 teachers from New Jersey and Wisconsin joined a private listserv discussion. Through two separate computer courses offered from The College of New Jersey (TCNJ) and the University of Wisconsin at Whitewater (UWW), participating teachers were introduced the listserv discussion service and were also strongly encouraged to participate in the joint discussion activities between the two groups. The goals of the joint class discussion list were as follows:

- Familiarize teachers with the discussion list technology as a means to communicate with other teachers.
- Identify factors that obstruct teachers from effective participation in the discussion.
- Explore strategies to engage teachers in actively participating in discussion list activities.
- Model the use of discussion list to support teaching, learning, and communication among teachers.

This paper also intends to explore the following issues.
- If teachers are taught how to use the listserv, will they adopt it and find it useful?
- Will teachers be able to learn from each other via the listserv?
- What kinds of behavior and performance are visible as teachers communicate with each other?
- What kinds of difficulties exist in using the listserv for teacher communication?
- How can we motivate teachers to use the listserv as a tools for classroom instruction enrichment?

The discussion list activities
The following information about the discussion list activities includes an initial survey of students' background information, a series of observations of participants' performances, interviews of participants, and analysis of the participants' messages over one full-week period during the summer session.

The profiles of the participants
Thirty-one inservice and pre-service teachers participated in the listserv discussion activities. All 21 participating teachers in the UWW were inservice teachers while five out of nine NJ students were preservice teachers with limited school experiences. The WI participants were more computer-experienced than the NJ participants, in that most of WI participants had taken one or two computer courses prior to this course and most WI participants had some prior listserv discussion experience. In contrast, most NJ participants were the first-time listserv users and this computer course was their first computer course in the program. Most of NJ participants did not have e-mail access from home so that they could only send and read messages while attending the class. Although many WI participants had e-mail access, most of the e-mail messages were sent during the class.

Participant's perception about the list
From the initial survey, all teachers considered the discussion list a positive device to communicate with other teachers. They appreciated the learning of such a device and hoped to get much out of such an experience. After learning how the discussion list operated, they were encouraged to use it as a means to communicating with each other and to acquiring new information. Most participating teachers confirmed that this was a wonderful opportunity for them to learn about how teachers from another state used technology for their work. Until the end of the semester, most participating teachers still considered the discussion list a useful tool to communicate with one another.

Also there were some second opinions regarding the list. While most NJ students were excited to have an opportunity to join the discussion with others, a few of them did not feel comfortable about communicating with people they could not see in person. Some NJ participants commented that they did not know what to say and what to ask. Other participants considered the summer session an inappropriate time for teachers to engage in such an activity because people were busy with their course work and they did not have urgent issues to discuss at this point.

Many participants shared their perceptions about the discussion list in the post interview. They believed that listserv could be a useful device to engage conversation and to acquire information, even in their own class. They also realized that it might take a while before their students would be able to use such a device because their schools were not fully equipped with fast access to the Internet yet. The biggest advantage for the discussion list, as many of them pointed, was the ubiquitous access of e-mail which allows us to use it any time and anywhere so that people do not necessarily have to be on-line at the same time and still can get the discussion moving on. They also learned that once a message was sent to the list, everyone would get it. This feature alerted them to modify and maintain desired behavior during the communication, they became more careful about their writing. They also agreed that Netiquette issues and proper language issues should be addressed seriously in their own class.

Instructor involvement and student participation requirements.
The instructors of the courses acted as facilitator of the learning and services as well as participants. The instructors from both campuses provided basic listserv instruction, set up the discussion list, coordinated the discussion activities, and encouraged the participants to put in their best effort to learn from each other via e-mail exchange. NJ students were taught the procedures of subscribing to the listserv and were required to send at least two message to the list. The WI participants were encouraged but not required to send or respond any messages to the discussion list. The participation of WI students in the discussion list is on a voluntary basis.

The messages from the discussion list
Throughout the entire discussion activities, a number of questions were raised regarding various topics, including, “security of purchasing on the net”, “suggestions to do electronic portfolio”, “criteria of selecting good web sites”, “how parents and teachers can prevent kids from getting lured into certain web sites”, “copyright issues on the net”, “sites of on-line tutorial on web page development”, and many others. There were 55 messages altogether, with 27 from WI and 28 from NJ as shown in Table 1. The messages can fall into four categories: inquiry and issues, response to inquiry and issues, self-introduction, and information sharing. The nature of the messages was mostly inquiry, issues, and responses. WI participants seemed to have made more responses to the messages than NJ participants. However WI participants responded more messages only to their home group, discussing issues such as their class schedule and assignment.

Difficulties encountered

Two kinds of difficulties occurred in the discussion list activities: technical difficulty and adequate access to the Internet.

1. Mechanical difficulty. All the students were able to log in and subscribe to the discussion list through the listserv and send messages to the list. However, many new Internet users got confused about the listserv and discussion list. For example, they were puzzled by the fact that once they had subscribed to the listserv, they should send discussion messages to the discussion list and they should get off the discussion list by sending a request to the listserv. It took some explaining and hands-on activities to make them fully understand the operation and feel comfortable about the process.

2. Time and access to the Internet. Most of the NJ participants did not have access to the Internet at home. They would have to rely on the access in the computer lab and during the class time. Two NJ students were overwhelmed by the number of messages they received and felt uncomfortable in sending more messages because they thought it was too time-consuming for them to handle the discussion list.

Inadequate communication

Throughout the entire discussion activities, many shortcomings other than the technical difficulties were observed. The communication seemed less interactive than intended. During the discussion list activities, most students focused on the things they were most interested and neglected other people's messages. Most participating teachers tended to ask questions or shared information about what they know and what they have found on the Internet rather than responding to other people's inquiry or issues. This is probably because they did not have a good knowledge and skills to answer the questions being asked, or they were reluctant to respond to people they did not know well. The language used in the e-mail messages seemed rather informal and contained many spelling and grammatical errors. The information or advice offered by individuals usually seem too shallow to answer other people needs. Also, many people tended to communicate only with people from their home group and were indifferent to the other group. Still a couple of people sent personal message to the discussion list by mistake.

Respond now or never

Most participants tended to read messages and respond immediately. Because they use either the VAX or UNIX e-mail system, it takes time for them to go back to check older messages. If they didn’t respond
immediately, they were not likely to go back to read and respond to the messages later, especially during the tight summer schedule.

Getting started with a simple self-introduction
Since this discussion was established for two class groups where members did not know each other. Many people started by sending a self-introduction message followed by questions or comments. This had proved to be a useful strategy.

Students' comments about the listserv activities
The following are some comments that students made regarding the discussion list activities.

“It's a great feeling to see someone that you don't know responding to your message.”

“It can be a frustrating experience when nobody answered your inquiry for a long while. However, if you don't hear from others, that suggests that the topic you raised did not catch their eyes or maybe they just didn't have an answer.”

“Some possible reasons why we received too few responses could be, 1) The listserv might be too new to some of us; 2) The number of participants is too small; and 3) most participants are not very knowledgeable about other people's area.”

“I wish I knew enough to respond other people's questions or comments. I simply don't know what to say to others.”

“Listserv is a good device for teachers to communicate.”

“I believe this is a good opportunity to find out more about what other teachers do with computers. I also think the listserv discussion may help reduce teacher isolation.”

“Posting questions or message without getting responses reduces the value of a listserv and is also frustrating.”

“If we can get our schools connected to the Internet, our students can exchange e-mail with each other like what we are doing here.”

Discussion

If teachers are taught how to use the listserv, will they adopt it and find it useful?
In spite of the frustration in the slow e-mail communication, most of the participants did consider the discussion list a feasible and useful tool. Through the entire discussion list activities, participating teachers had exchanged ideas by posting questions and responding to each others' message. Teachers who had learned to use the listserv discussion are likely to continue to use it and learn from other people. From the initial survey and post interview with participants, most teachers considered this a beneficial device for themselves as well as for their own classes.

Why didn’t they take advantage of the listserv?
The participating teachers did not seem to have optimized the list discussion opportunity to communicate with each other. As analyzed from the observations and interviews with the participants, the possible reasons are 1) participants did not have enough access time to participate more often, 2) it's a bad timing during the summer with intensive course work and no time to ask questions, 3) participants did not posses enough knowledge or skills to make appropriate comments or responses, 4) they had been shy about communicating with strangers, 5) there was not enough incentive for some participants to play an active role because the WI instructor did not mandate required participation for all participants, 6) most of these teachers
were not working during summer and did not have immediate needs to solve any particular problems or to discuss about certain issues, and 7) the courses were ill-structured for such kind of activities. If the courses were designed with the same goals and similar themes and connected the discussion list to the content learning, the results could be significantly different.

How can we engage teachers to use the listserv as a tools for self or instruction enrichment?

From the experiences learned in this study, several strategies may be used to increase the participation in discussion list activities.

- Set minimal requirements about participation. Based on the nature of the discussion activities, participants should be encouraged to use the listserv and send messages at an early stage. Once they become familiar with the discussion list, it will take time for them to find the value of using it.
- Assign duties to participants so that they will become active discussion leaders, instead of being passive information receivers. After they start taking leadership in the discussion, they may become appreciative about getting messages from other people.
- Identify relevant contents for discussion. In most cases, the discussion activities turn boring or fruitless because participants do not have input about what they want to talk about. When discussion issues are clearly defined, participants may prepare questions or information for the discussion. In this way, they will be able to focus on the same discussion issues and conduct some research work for their discussion assignment. The results will become more meaningful.
- Relate discussion topics to participants’ own experiences or interests. Sharing participants’ personal experiences may help maintain and further extend discussions.
- Encourage the use of self-introduction detailing one’s specialty areas, prior experiences, and interests to help break the ice for discussion.
- Remind users to use formal languages and watch Nettiquette issues.

Conclusion:

The discussion list has provided a unique channel of communication in education. Teachers, having long been considered isolated, may use such a channel to communicate with each other. This paper describes an effort to connect teachers from NJ and WI via the discussion list from two separate computer courses. These teachers were taught how to use the discussion list and were encouraged to participate in the discussion. Although many teachers did not take advantage of the listserv or made contributions to the discussion activities, most of them believed that the discussion list was a useful tool for themselves and for their own class. This paper also identifies some factors that affected the teachers’ participation, including, timing, access, personality, knowledge and skills, and structure of the courses. Based on the analysis of these factors, some suggestions were provided for future practice.
Telecommunications As an Object And a Tool for Teaching and Learning

Irina Rozina, Foreign Language Department, Rostov State Pedagogical University, Russia, rozina@edu.donpac.ru

Clark Germann, Metropolitan State College of Denver, Colorado, USA, germannc@mscd.edu

Abstract: This paper provides an overview of a collaborative project in progress involving mixed traditional and on-line teaching, flexible independent learning and psychology assistance for Russian students. The project is educational, methodological and researchable in nature and involves the distance course "Technical Writing" delivered by Metropolitan State College of Denver to students of Rostov State Pedagogical University in Russia. Features of this project are discussed, followed by issues facing Russian educators.

Telecommunications is a very attractive area for innovators from all levels of education. The main trends for an application of educational telecomputing are widespread communication for professional and learning purposes and rapid access to important subject information. Communication is a necessary element for effective instruction and methodology training of preservice teachers in higher school. Active pedagogical, educational contacts are the main means of providing assistance in accomplishing the instruction tasks in traditional school. Simply put, computer telecommunications allows ample opportunities for these contacts to professionals, educational associations, and social-psychological group collaboration using numerous services of global networks as e-mail, mailing list, WWW, news conference, videoconference etc. Use of e-mail and the web to deliver coursework is the object of study. The structure of teaching doesn't change in this case, but communication is somewhat limited between student and teacher. Nevertheless telecommunication applications used in this manner are preferable in Russia because of slow connection and expensive commercial account for more educational institutions.

Use of videoconferencing and other advanced methods can result in more innovational approaches. On-line or distance learning is used now for different subjects. But in Russia, preference is given to interdisciplinary collaboration of Informatics or Information Technologies and subjects such as English Language, Management, Technical Translation etc. Distance education is desirable because of the lack of prepared specialists and students at many universities. The computer and telecomputing skills of many students at Russian Colleges and Universities are not satisfactory now but grow year by year thanks to home computers and commercial courses offered in Russia.

The most potential for on-line teaching and learning uses Web technology. It can be used as sources for educational and science information, search engines, bases of data etc. Depending on the educational tasks, suitable URLs or search engines can be used for finding sources of information. Both online and traditional teaching are right for passive and active students. But the success or failure of these methods depends on the educational tasks and outcomes desired. The ways the primary information is delivered and received is not as important as the educational product and content delivered made by them and possibility of the resultant increase in communication. Thus on-line teaching is often desirable, but not always possible to carry out today, and this is the focus of our project.

Rostov State Pedagogical University (Russia) and Metropolitan State College of Denver, Colorado (USA) began the joint project based on the distance course "Introduction to Technical Writing" delivered from Metropolitan State College during Fall 1998. For Russian students, the project means mixed learning by traditional (lectures and practice in computer and telecommunication classrooms), independence (home and work at classes) and innovative forms (on-line and collaborative learning). In this way telecommunications and networks are presented as the means for traditional and as the tool for online teaching and learning (the part of independent and innovative forms). For Russian and American tutors and instructors it means use of more flexible methods of teaching For getting a success and a benefit from this and other foreign courses, it's necessary to have a good command of language (in our case it is English language) and computing skills. All Russian students participating in the project study at the Foreign Language Department and were tested on an
English language level before participating in the on-line course. Their computer skills were tested as well and advanced by individual lessons with instructors and independently in computer classes if it were necessity. The third limitation is that of telecomputing skills, which is not an obstacle in this case because of the inclusion of the introductory lectures, practices and independence learning in traditional computer classes and because of full access to Internet. Introductory lectures included the review of global networks and Internet, popular telecommunication services as e-mail and WWW, digital equipment as camcorders, etc. Practice lessons include work with e-mail programs and browsers. The fourth limitation is mental or psychological obstacles for getting study by distance for Russian students. We made some psychological tests for Russian students before the distance study and will make ones at the end of our project. In the opinion of the Russian author, psychology assistance is the necessity component for foreign on-line study because of lack of traditional visual and audio contacts and language and social obstacles.

The project is both educational/methodological and researchable in nature. For Russian educators the goal of this research project is to produce knowledge and skills in the area of on-line teaching for Foreign Languages Faculty of the University for future active innovation in instruction.

The distance course used in this project uses personal computers instead of the traditional classroom/lecture setting to conduct the course material for both American and Russian students. Purposes of this course are:

- to acquaint students with the names and content of various types of technical reports used in business, industry and government;
- to acquaint students with some basic formats used in business, industry, and government;
- to make students aware of some basic differences between material written in a technical style and that used in other types of writing;
- to give experience in preparing technical reports for a variety of audiences;
- to give experience in preparing written and oral technical presentations for a person in a decision-making capacity.

Content and requirements for this course are the same as for the traditional classroom version of Metropolitan State College of Denver's COM 2610 which uses the textbook authored by Markel [1996].

The Web page with course materials can be found at http://clem.mscd.edu/~2160 and consist of follow sections:

- Course syllabus
- Course schedule
- Assignments
- Using Search Engines for Research
- Resources for technical Writers
- Ideas and Topics for Papers and Projects
- Meet the other students in the Class

Forms of Synchronous Dialogue Resulting from Web-based Professional Development

Paul G. Shotsberger
Department of Mathematics and Statistics, University of North Carolina at Wilmington, Wilmington, NC USA, e-mail: shotsbergerp@uncwil.edu

Abstract: This paper provides a consideration of ways in which synchronous dialogue can contribute to a program of Web-based professional development. Online chat transcripts were analyzed using a framework for classifying forms of dialogue in a telecommunications environment. Synchronous dialogue behaviors emerging from the analysis were classified into four over-arching categories: Instruction, Inquiry, Conversation and Debate. Portions of transcripts provide a notion of the context in which these behaviors arise. Synchronous dialogue is contrasted with asynchronous communications typically found in online learning environments. Unique aspects of synchronous dialogue center on the dynamic nature of the interaction, which can result in simultaneous strands of dialogue as well as the presence of debate in interchanges.

Background

Distance learning networks are changing the face of education and training in ways that could not have been imagined even ten years ago, thanks largely to the ubiquity of the World Wide Web. Universities in particular are discovering that “Distance learning networks can be used for all forms of education to improve the reach of programs, stretch education and training dollars, and deliver just-in-time educational content to learners anywhere, anytime” [Chute, Sayers & Gardner 1997, p. 76]. The Department of Mathematics and Statistics at the University of North Carolina at Wilmington has developed a World Wide Web site called INSTRUCT, which stands for Implementing the NCTM School Teaching Recommendations Using Collaborative Telecommunications (http://instruct.cms.uncwil.edu). INSTRUCT is designed to support inservice school mathematics instructors as they implement the National Council of Teachers of Mathematics Professional standards for teaching mathematics [NCTM 1991] in their classrooms.

The literature on distance learning networks and teacher professional development agree that interaction represents a powerful method for engaging learners [Chute, Sayers & Gardner 1997; Scardamalia & Bereiter 1993; Guskey 1986], yet too often this aspect of distance education and training is either forgotten or given only passing consideration. INSTRUCT’s design intentionally integrates aspects of groupware, or software intended to support group interaction, to expand its use beyond being simply a storehouse of instructional material. INSTRUCT provides the option for users to communicate synchronously or asynchronously, as appropriate, as a primary resource for establishing and maintaining group integrity [Mandviwalla & Olfman 1994].

[Cohen, McLaughlin, & Talbert 1993] asserts that “The only way we change our teaching is to talk to people who are also changing” (p. 93). INSTRUCT participants are given assignments to carry out in their own mathematics classes in order to promote teacher active participation in and application of online training materials. An intentional by-product of these assignments is the need for sustained interaction and collaboration among participants. The standards material includes notions of what constitutes worthwhile mathematical tasks, ways of establishing a classroom learning environment that promotes student discourse, and methods for self-analysis of teaching and learning events that can enhance classroom instruction. For each of six standards, teachers have the opportunity to be engaged in two synchronous meetings, one to discuss the hypermedia material and brainstorm ideas before implementation, one to reflect on implementation attempts and future applications.
Theoretical Framework

[Blanton, Moorman, & Trathen 1998] proposes a classification scheme for the forms of dialogue that can occur in a telecommunications environment. The authors' classification research focused on analyzing asynchronous dialogue contained in e-mail discussions. The classification scheme is shown below (Tab. 1).

<table>
<thead>
<tr>
<th></th>
<th>Convergent</th>
<th>Divergent</th>
</tr>
</thead>
<tbody>
<tr>
<td>Critical</td>
<td>Instruction</td>
<td>Debate</td>
</tr>
<tr>
<td>Inclusive</td>
<td>Inquiry</td>
<td>Conversation</td>
</tr>
</tbody>
</table>

Table 1: Classification Scheme for Telecommunications Dialogue

For the purposes of this classification scheme, the authors define Convergent situations as those in which participants assume one correct answer, as opposed to the Divergent condition in which multiple interpretations are possible. Critical situations are defined as those involving some kind of analysis, questioning or perhaps skepticism, and this is contrasted with an Inclusive environment in which each participant's contribution is valued and accepted. The classifications therefore represent intersections of pairs of these situations: Instruction (Convergent-Critical), Debate (Divergent-Critical), Inquiry (Convergent-Inclusive), and Conversation (Divergent-Inclusive). As a result of their research on asynchronous dialogue, the authors found evidence for three of four of the classifications: Conversation (the pre-dominant mode), Inquiry and Instruction. The authors found no indication of Debate playing an important role in the asynchronous communications that were analyzed for their studies.

The Study

The purpose of the present analysis is to attempt a classification of the types of synchronous dialogue INSTRUCT participants engaged in during their online meetings. Chat transcripts were analyzed from online meetings held during Fall semester 1997 among 13 participants and three facilitators. Participants were primarily high school and middle school mathematics teachers. Analysis focused on the portions of the chat transcripts that dealt specifically with some aspect of the Professional Standards training materials. The following categories of synchronous dialogue have emerged from initial analyses (an example of each is provided in parentheses):

- Affirmation of another participant's efforts (“I like that ....”)
- Belief about teaching/learning (“I think that a group needs half and half strong [students].”)
- Concern about implementation (“The really smart kid may talk too much like a teacher...and turn the weaker kid off.”)
- Current practice (“I use groups on the average of once a week...it is not my main thing.”)
- Desire to implement (“I also want to do some on line researching for some things that I don’t have time to search for now.”)
- Intent to implement (“I had planned to use the scoring sheet and their scores as part of the analysis.”)
- Question about implementation (“Does everyone else sit [students] in rows and then move to groups or are your desks in groups?”)
- Result of implementation (“My other 2 groups with the exception of a very few that are full of raging hormones really work well in groups.”)

The Blanton, et al. classification scheme detailed earlier is intended to encapsulate telecommunications dialogue generally; therefore, it seemed reasonable that the classifications might be used to capture forms of
synchronous dialogue as well as asynchronous. Based on analyses done for the present study, the categories of dialogic behaviors identified from the chat transcripts would seem to lend themselves to being grouped according to the proposed framework as indicated below (Tab. 2).

<table>
<thead>
<tr>
<th></th>
<th>Convergent</th>
<th>Divergent</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Critical</strong></td>
<td><strong>Instruction</strong></td>
<td><strong>Debate</strong></td>
</tr>
<tr>

</tr>
</tbody>
</table>

Table 2: Categories of Synchronous Dialogic Behavior

Results from analyses confirm the adequacy of the Blanton, et al. classification scheme for use with synchronous dialogue. Notice that the categories of Belief and Concern actually span both Instruction and Debate, depending on whether participants simply reported their personal beliefs/concerns or if they actually argued for or against expressed beliefs/concerns. The presence of Debate appears to depend to some extent on the personalities of those involved in the dialogue. A sample exchange follows in which Teacher 2, who possessed both a strong personality and a highly practical view of teaching, took on the role of spoiler in a discussion of a classroom activity implemented by Teacher 1.

<Teacher 1> One of the games my students really enjoy is basketball. I actually shoot baskets into the trash can using paper balls. We divide the class into two teams and play until everyone has had three shots. Then I use data from shots to teach ratio and proportion.
<Teacher 2> That’s a great idea. I just hope the principal doesn’t come to observe my class during the basketball lesson.
<Teacher 3> ...I echo that.
<Facilitator> ...I dare say he would be impressed.
<Teacher 1> I have that fear too.... It would take a lot of explaining!
<Teacher 3> ...mine calls that “Stepping out of the box.”
<Teacher 2> Unfortunately mine would call it 24 students off task for twenty minutes.

Therefore, unlike the results of Blanton, et al. for asynchronous dialogue, it was possible to classify aspects of synchronous dialogue under Debate. Examples of Instruction and Conversation are provided later in this section as simultaneous strands of dialogue during a single chat. Inquiry and Conversation include some overlapping behaviors (Affirmation, Question). However, Inquiry differs from Conversation in the convergent nature of the comments, which generally have to do with the Desire or Intent to implement a particular method or activity. An example of Inquiry follows:

<Teacher > ...I plan to use this [geometry scavenger hunt activity] for my last standard, is that acceptable?
<Facilitator> Depends what kind of analysis was used, I guess....Could they possibly do a reflection writing piece on their experience...?
<Teacher > That’s an idea. I had planned to use the scoring sheet and their scores as part of the analysis.
<Facilitator> What I found, why it’s important, etc....I think it would be great for writing.
<Teacher > I’ll follow through with your idea...and send you some of the papers I get.

Unlike asynchronous dialogue, which tends to follow specified threads based on the subject of a particular posting, simultaneous synchronous dialogues may emerge due to the dynamic nature of the environment. An example follows of two qualitatively different dialogues which took place simultaneously during a single chat session. Strand 1 can be characterized as Instruction dominated by convergent expressions of Belief.
and Concern, whereas Strand 2 is a Conversation primarily containing divergent Current practices and Results of implementation. The comments from the strands have been staggered to indicate the order in which they came up in the overall dialogue, and words or endings of words have been included in brackets to clarify comments.

**Strand 1**

<Teacher A> Dare I ask if anybody had a chance to look at the section regarding "stories?" I found this very interesting, especially in light of all the chat regarding writing and journals. What a wonderful way to take care of a multidiscipline requirement.

<Facilitator> Expand on that....

<Teacher A> ...just before entering the chat shop, I looked over the Standards, for Tools to Enhance Discourse. Well, under Using Stories as a Tool, a [teacher] has a lesson plan for using writing stories that lead to a conclusion which is a given math equation [or] solution. I think I could modify this for my 5th graders.

<Teacher C> A lot well is great if it [is] the right areas that are tested [on the state End-Of-Course, or EOC tests].

<Facilitator> I know our Alg 1 teachers are trying to teach to the objectives instead of going straight through the book.

<Teacher B> I'm not really going straight through the book either, so sometimes I wonder if I've missed something!

<Facilitator> They are also trying to incorporate applications since the EOC is based that way now.

<Teacher E> ...one time I read my eighth graders the book "The Dot and the Line" a geometry love story. Then they chose math symbols and wrote and illustrated their own love stories. They loved it and I felt they really learn[ed] from the activity.

<Teacher B> ...I agree with you completely. Oh for the good ole days when we could just teach without having to worry about 1001 objectives!
<Teacher C> I am in block and will only cover what is on the EOC test, concentrating on the higher percentage areas. I think it is wrong, at least for my Algebra B students, but the EOC seems to be all that matters.

<Teacher B> That [is] my concern too....

<Teacher D> I agree...!

<Facilitator> ...do you still have any of the samples of what the students wrote?

<Teacher E> I think I do. I will look for them.

<Teacher C> I don't know how English teachers stand it. When I read my students writing it makes me ill.

<Facilitator> ...I am with you. I can't imagine grading a term paper or even an essay by my students.

<Teacher E> I think stories would be difficult to use at the high school level but I used them all the time in middle school.

It is interesting that except for Teacher C's comment at the end of the first strand, these two substantive dialogues were carried out simultaneously by two separate groups of participants involved in the same chat. Further, it is important to observe the role of the Facilitator (a teacher who had previously been through INSTRUCT training) who acknowledged comments and encouraged contributions during both strands. As noted in [Shotsberger 1997], "...given the text-based environment of many conferencing or discussion tools and the resulting lack of cues that tend to regulate social interaction, the task of mediating group activity while promoting some kind of kinship among learners is challenging in the extreme" (p. 104). Yet, this kind of interaction, if properly cultivated, can come to be viewed by teachers as a natural environment for the exchange of ideas and experiences.

Implications

Unique aspects of synchronous communications identified in the INSTRUCT transcripts appear to result from the dynamic nature of the environment, which can produce simultaneous strands of dialogue as well as the presence of debate in interchanges. As online facilitators better understand the dynamics of synchronous communication, this rich form of interaction has the potential to make Web-based training an important component of teacher professional development. Unfortunately, due to time/place constraints, real-time chats do not currently play a significant role in most online education and training efforts. To address this limitation, INSTRUCT offers two meeting times per week, one in the afternoon and one in the evening, to encourage teachers to participate from school or home. This flexibility has turned out to be a key element of teacher satisfaction with INSTRUCT.

INSTRUCT participants are encouraged to use both synchronous and asynchronous means of communication, yet it was synchronous dialogue that was crucial in providing teachers a "...rich, safe and self-sustaining environment for implementing changes in instructional practice" [Shotsberger in press]. Participants from Fall 1997 each submitted responses to an online survey at the end of the semester-long program. When asked what they enjoyed most about using INSTRUCT, the majority of respondents included some comment about the unique impact the chats had on their experience. Sample comments from three participants follow: "I enjoyed chatting and sharing ideas with other teachers the most. I don't feel so alone when I know others are experiencing the same things I am;" "I truly enjoyed the online chats weekly. I think the ability to discuss weekly with other teachers that are working on the ideas that you are trying in your classroom was the most valuable;" and "I thoroughly enjoyed the opportunity to gather at a
regular interval with my fellow teaching professionals. We shared our experiences and served as a peer resource for others for the overall improvement of not only our friends and fellow teachers but also improved the teaching of math concepts in so many schools and minds.” The quality of professional interchange and collegiality reflected in these comments and in the sample chat transcripts is impressive, even in comparison with face-to-face professional development. Moreover, bear in mind that these participants were communicating using a text-based chat program, with all of the incumbent challenges of getting and staying online, perhaps being a marginal typist, and attempting to express oneself in a largely expressionless environment. The growing affordability of computer technology, coupled with more reliable network connections and improvements in synchronous communications such as desktop video conferencing, make Web-based training a viable alternative for current and future teacher professional development programs. Developers and facilitators of Web-based education and training are obliged to think seriously about the critical role interaction plays in learning and how synchronous communications tools might best be employed to foster that interaction.

Abstract: Web-based instruction has become a powerful tool in recent years. However, WBI utilizing a Constructivism theoretical framework has not been explored. A database-driven WBI is the solution for this implementation. Another critical issue is the difficulty encountered in creating, editing and maintaining WBIs particularly for those lacking experience in HTML creation. EMC 598 Internet for Teachers, a hybrid televised and Internet course, is designed with the integration of database-driven instruction. The database manages student publishing, an online grade book, a final project...etc. This program does not require the instructors or the students to be familiar with web page creation.

Introduction

The integration of web-based instruction (WBI) into classrooms has been one of the most important instructional designs to be developed in recent years. Web page design has become the most popular strategy for the delivery of information and communication among educators and students. Creating web pages is not a critical issue for most instructional designs. However, updating and maintaining are the most critical tasks encountered in WBI design. It is very common to see web pages that haven't been updated or maintained. The primary reasons for avoiding updates are that editing HTML codes is time-consuming, and teachers and students are not familiar, or are uncomfortable, with HTML editing. With a database-driven strategy, these two issues can be resolved.

Theoretical Framework

Improving instructional design is not the primary reason to use a database. Conceptually, Constructivism is the theoretic basis of distance education (Jonassen, 1995). Remote access to online databases may facilitate the construction of knowledge. Retrieved information can be used to support positions in a computer conference discussion, for elaboration on a particular topic, or for satisfying personal curiosity. Knowledge construction is fostered through the intentional searching process and by linking information to the learner's own schema. Merely locating information in a database does not necessarily lead to learning. Critical to the knowledge construction process is the articulation of the learner's behavior while performing a database search. This search facilitates and strengthens connections between elements of information and results in higher-order thinking and meaningful learning. A database learning environment requires learners to reflect upon personal knowledge, state learning intentions, and publish ideas to a communal database, thus producing cumulative, progressive results for the group.

A Database-driven Graduate Course

EMC 598 Internet for Teachers is a graduate level course offered through a distance education format utilizing a combination of television and Internet technologies. It utilizes FileMaker Pro, a web-compatible database by Claris Work, to enhance the instructional design. This database-driven design includes student publishing, course management, and final project management.
Assignment Database

The online assignment database is an important aspect of database design. Student publishing has been a very powerful strategy for instructional design. Teachers and students confront the issues of web page creation and maintenance by student publishing on the web. Frequently, teachers and students spend a tremendous amount of time and energy on web page creation, resulting in an inability to focus on the instruction and content. The purpose of student publishing is not learning how to create web pages. When teachers and students are able to achieve the creation of web pages, the student publishing normally is not well organized and is not searchable. It simply provides static information and limited interaction. Web page creation is only the first critical issue in student publishing; the second issue is the FTP (File Transfer Protocol) barrier. Unless teachers and students understand FTP, another learning necessity is created which is not the intention of student publishing.

An online assignment database can be the solution for web student publishing. In this reaction paper assignment database, students compose their assignment on a word processor, then copy-paste the response to the web browser, and submit it, or simply compose the assignment on the browser directly (Fig.1). Students paste their assignment to the proper web fields, such as the title field, the body text field, keyword fields for the title and the target audience, and submit it. When students submit their assignment on the browser, the assignment is converted into an HTML format and a searchable database because the keyword fields are created at the same time. Students and teachers can search the database on the web by keyword, title, author, or subject, etc (Fig.1). This assignment posting doesn't require students and teachers to be familiar with HTML creation and editing. After students have posted their assignments, an editing page allows them to update or edit the assignments they have posted. This design provides students with more interactions through the database, and reduces the maintenance, editing, and updating duties for teachers.

Online Grade Book Database

An online database can be applied to class management; for example, an online grade book can be created. Since the teacher can review student assignments on the web, grading is done on the web as well. Teachers post the grades and feedback on the web without HTML or spreadsheet work. Students' grades and feedback will be available for the students to view when posted by the instructor. The total points earned to that point is also computed after the teacher enters the new grade (Fig.2). When the grades are entered, the students will be notified via an automatic e-mail generating function. Teachers are not required to compose separate e-mails to notify students that their grades have been posted. Teachers also have different formats to view students' grades and feedback, individual student view, and a list of students. This gives teachers an improved, flexible method to manage their class. In the student online grade book, separate from the teachers' grade book, but using the same database, students are required to enter their student ID number to obtain their grades and feedback. This design provides a high level of interaction and personalized information immediately. Students can view their previous grades and feedback, thus obtaining a comprehensive status report.
The final project database is the most complicated design in this course. It contains several sub-databases, which provide different functions and management. In this course, students created a web-based instruction and FTP on a web server. The process requires students to post project titles, URL, keyword on subject, and keyword on audience. This process is completed on the web (Fig.3). A web page allows students to view the list of project titles with hot links to the students' web sites. Students are also able to make updates, edit, or change the information they submit. The self-management feature is utilized throughout this database. Peer evaluation is employed in the final project. Students are asked to evaluate five other students' final projects by using an online evaluation form (see fig.). Students can work at their own pace to complete their final project evaluations. This evaluation form contains four criteria. Basically, students follow the criteria to give scores and feedback. In the evaluation form, the project author's name and evaluator's name are required. This gives the instructor the opportunity to determine who has provided evaluations of whom, very important information for the instructor. After finishing the evaluation, students click the submit button to submit their evaluation to the database.

The second part of the final project database is viewing the evaluations. After students provide their evaluations on other students' final projects, they are able to view their score and feedback right away. Students are able to see all of their evaluations immediately, after they have been submitted. A number with a paragraph, which explains the evaluation status to the students, is located on the top of the page. This gives students a very clear picture of the evaluation status, and they have the opportunity to know how well they are progressing constantly. Eventually, students should be able to see all five evaluations. The results of these evaluations provide scores, feedback and the total score and average score of the five evaluations. The same process is used to view the instructor's evaluations with the total score and average score (Fig.4).
The third part of the database is its most powerful element. The scores shown in the student and instructor evaluations are connected to the grade book database. Whenever someone submits a score to the final project database, the students’ final project score will be updated immediately with a pre-scripted calculation. For example, the students evaluation is 50% of the final project score and the instructor’s evaluation comprises the remaining 50%. When the final project score is updated from evaluations, the students’ grades are updated immediately. Since this is a pass/fail course, the students will see their grades with their status. The final-project is an excellent example of self-contained management in a database-driven instruction (Fig. 5).

Security

Security is another reason to use a database. If the database is running on a server, it will be automatically backed-up on a regular basis. In other words, it is safer than on the teacher's computer, which is rarely backed-up. Although the database is running on a web server, a regular backup can be scripted on the FileMaker Pro to backup the important database and files. The access log is another security feature. Whenever the database has been accessed, it will be kept in a log file, which can provide a reference for statistical analysis. If security is extremely important, the database can be scripted to a limited access location, such as an identifying IP address.

Software and Hardware

The database utilized in this class does not require extraordinary software or hardware. The central piece of software, FileMaker Pro 4.0, was installed on a PowerMac 7200/100 with 32 MB RAM and a constant Internet connection, which is not a web server. Two HTML editors, Claris Home Page and Page Spinger, were used to create HTML pages. HTML editor is not required to produce database-driven instruction if the person plans to use codes. However, Claris Home Page provides seamless integration with FileMaker Pro on the HTML creation.

Hardware requirement (FileMaker Pro, 1998) for installation of filmmaker Pro is:
MAC
A Macintosh or Mac OS computer with at least 8 MB of RAM (16 MB or more recommended)
A CD-ROM drive
System 7.1 or later, or Mac OS 8 or later

PC
An Intel-compatible 486/33 PC or higher with 8 MB of RAM (16 MB or more recommended)
A CD-ROM drive
Windows 95 or Windows 98, Windows NT 3.51 or later, Windows for Workgroups 3.11, or Windows 3.1

A constant Internet connection is highly recommended for web publishing. A dial-up connection works but it may not be as efficient and reliable as a constant Internet connection. The number of users is another important issue to examine in terms of hardware requirements. If the database will be accessed by large numbers of users, a more powerful computer is recommended. There were about thirty students in EMC 598, the PowerMac 7200/100 was efficient enough to process all student data, requests and accesses.

Discussion

This database-driven course instruction will be expanded to a full-scaled database-driven course in the future. Course schedules, all assignments, course content, class announcements, joint database with other courses, integration with CGI/Perl will be included in future iterations.

A course schedule database will allow instructors to create, edit, and update course schedules interactively. HTML coding is not required. The schedule will embed with hyper links to make it more interactive.

Assignment database will be applied to all assignments. This will increase student-publishing power and enhance critical thinking and information searches. After several semesters, the database will contain a large amount of searchable information. Students will be able to benefit from this instruction with easy access, not complicated by the necessity of learning more technology.

Course content database will assist instructors in developing and organizing the content of their course(s). Currently, most instructors have their course content in computer files on the their hard drive without any connection. This disorganization creates difficulty for instructors in joining their content. With a content database, instructors can very easily assemble course content, particularly for individual learning instruction. Instructors are aware of the importance of individual learning instruction; but it has never been truly implemented because of the time required. With database design, instructors should be able to design an instruction suited for individual student needs in a timely fashion, a minimum amount of searching would coalesce the content.

A class announcement database is a good tool for class communication. Instructors provide the announcement with a date and post it on the browser. With database scripting, the announcement can be controlled by the instructors' wish. For instance, with minimal scripting work a new announcement will be seen by the date designated by instructors and retired on the date specified. Updating and deletion of the announcements is not required. Instructors can prepare all of the announcements for the entire semester and post them at the beginning of the semester. This feature will help instructors to remember all announcements.

A joint database with other courses will increase the power of database-driven design. It simply expands the size and amount of the database.

With the integration of CGI/Perl or other programming, the database will be more useful, interactive, and secure. However, with programming integration, the concern will be creating more advanced skills for teachers or instructional designers. A database-driven course design doesn't require teachers to have a great deal of familiarity with technology. However, it creates a tremendous amount of work for the database designers or instructors. Filmmaker Pro provides user-friendly interfaces to anyone that has some basic HTML and database design experience. Involvement with web programming creates different issues of design. It is suggested that if someone is planning to integrate a database into their instruction, several questions must be answered in advance: What do I want from a database-driven instruction? Why do I want it? How much do I want it? How much time and support
Database design can be extremely expensive and frustrating without thorough planning. The concept of a database is planning and taking advantage of it later. Anything involved in redesign or restructure of a database can be very costly.

FileMaker Pro is not the only database available. In terms of the scaleable issue, other products, such as Oracle or Sybase, may provide a more thorough, secure, and scaleable program. However if cost is a major, FileMaker Pro is inexpensive, unlike Oracle or Sybase.

**Conclusion**

Database-driven course design is a new way to manage and re-examine our instruction designs. Critical thinking, constructing knowledge, learner-center instruction is a new paradigm for instruction design. In the past few years there have been multiple developments in educational technology. Instruction design should take full advantage of database technology to provide a more interactive learning environment.

TELECOMMUNICATIONS - PRESHIERVICE APPLICATIONS

Dr. Jerry R. Aschermann
Department of Education
Missouri Western State College
United States of America
asher@mwsc.edu

Abstract: Prospective employers and external accreditation agencies today expect preservice teachers to fully document their success in a teacher education program. Missouri Western State College moved from the "scrapbook" portfolio to the WEB delivered electronic portfolio in three years. This paper explains why MWSC chose to bypass the CD delivered portfolio and move directly to a portfolio that is created using Netscape Composer. The paper discusses problems encountered with the electronic portfolio and how MWSC chose to resolve those problems.

Why portfolios?

Several years ago the Department of Education at Missouri Western State College (MWSC) began hearing about portfolios. Students were urged to begin making a portfolio. Initially, "portfolio" was associated with a scrapbook that included "things" that had been saved and which could eventually be shown to a prospective employer. The early portfolios lacked organization and structure but they were used by prospective employers to help select beginning teachers and MWSC graduates did gain employment because they had a "portfolio."

Eventually the "things" became more refined so that an organized three-ring binder would include a resume, references, letters of recommendation, transcripts, educational philosophy, classroom management theory, personal goals plus lesson plans, unit plans, printed technology examples, assessments and personal reflections. Many portfolios included photos to illustrate examples of lessons and the congruency between what was being said and what the student teacher actually did in the classroom. Again this refined portfolio was informally done and was used only for employment purposes. Doty and Hillman (1997, p. 776) explain the early development of the preservice teacher technology portfolio.

What is a portfolio?

The MWSC faculty also began to refine the definition of what a portfolio really is. An excellent description is offered by Paulson, Paulson, and Meyer (1991). They describe a portfolio as "A purposeful, integrated collection of student work showing student effort, progress, or achievement in one or more areas. The collection is guided by performance standards and includes evidence of students' self-reflection and participation in setting the focus, selecting contents, and judging merit" (p. 295).

MWSC welcomed the idea of having students develop a teaching portfolio. It was believed that the completed portfolio would be a tangible collection of a student's best work that was a result of a complete and full teacher education program. The student portfolio would provide both faculty and school administrators with examples of what a student could do rather than merely rely upon a transcript of grades or formal evaluation forms. Though an examination
of the portfolio an evaluator could begin to easily determine if there was a connection between philosophy and practice. 

The department could assess the strengths and weaknesses in the teacher education program with student portfolios. Prospective employers could use the portfolio to help select first year teachers.

Early it was learned that the notebook portfolios were not ends in themselves but a working tool that students could use when reflecting about their knowledge, skills and attitudes about teaching. The new portfolios included the above items as well as an explanation of how and why each item in the portfolio illustrated good teaching. Exceptional student teachers simply began documenting their successes in the classroom and the college campus. The development of the teaching portfolio easily became part of the MWSC field-based, performance-based, reflective model of teacher education.

A new meaning for "portfolio" was developed when it was learned that accreditation agencies as the National Council for the Accreditation of Teacher Education (NCATE) issued new guidelines for teacher preparation and would be using the new standards to assess the strengths of the MWSC Department of Education (Thomas, 1994). Associated with the new guidelines was the idea of the electronic portfolio. Several major issues arose with this new use of the portfolio:

- where would the department store all of the three ring binders
- how would the department deal with the students who wanted to take their lesson plans, unit plans, assessments, etc. when leaving MWSC

The "notebook" portfolio no longer would be suitable for the new uses of the portfolio. Jackson (1997, p. 698) explains the trade-offs of the traditional portfolio vs. the electronic delivered portfolio.

How are portfolios produced?

Technology. "Why don't we just put the portfolios on a CD?" An easily stored electronic portfolio would solve all of the storage problems, allow the students to take their materials with them and could then be used by the students for employment purposes. Programs as HyperCard, SuperCard, Multimedia Director or HyperStudio could be used to develop non-linear links for the electronic portfolio. The CDs could be archived and easily used by external evaluators. The electronic CD portfolio would meet the needs of the department.

Reflection soon indicated, however, that the CD ROM electronic portfolio created as many problems as it solved. Once made, it would be difficult for a student to update the portfolio if the student no longer had access to the college provided software and hardware. Licensing or purchase of production software plus the necessary hardware would be very expensive. Incompatibility between the equipment at MWSC and the equipment in the area schools would make the CD useless to many students. Questions arose as to how many copies of the CD portfolio a student might need. Jackson (1997, p. 700) highlights the limitations of creating an electronic portfolio on a CD.
The idea of the CD electronic portfolio was quickly replaced with the WEB portfolio that could be developed using the HTML editor found with Netscape Communicator/Composer.

**Netscape Composer** was selected as the appropriate software because all computers in the departmental computer lab already had this gratis program. All students at MWSC already have a free Internet account through the college so each student has a place to house the electronic portfolio. Many students are connected to the college account via a modem so the electronic portfolio can be developed any of twenty-four hours per day. Netscape Communicator is a free program that can be downloaded so students can continue to update and revise the electronic portfolio after leaving the college. Other html editor programs might make it possible to produce a more elaborate WEB page; but, availability of the program after leaving MWSC again was the concern. With little technical knowledge a person can produce a very acceptable WEB page with Netscape Composer.

Earlier the idea of a floppy disk portfolio had been rejected because of the limited storage capacity of a disk. As the portfolios become more sophisticated and include video clips, the 1.3MB floppy definitely would not meet the needs of students.

A WEB based portfolio also would eliminate the problem of "how many CDs should I make?" An employment scenario might go like this: student visits a school superintendent with a brief resume that lists the URL [WEB location] of the electronic portfolio. The superintendent calls a school principal or department chair and says, "I think we have a person we might want to look at in depth. Please look at this candidate's WEB pages that contain the portfolio." Without the WEB portfolio the candidate must leave a CD and the school personnel must then shuffle the CD from one office to another or from one side of town to the other side of town. This can take several days. The WEB based portfolio eliminates the need to produce five or fifteen CDs that might be needed for employment purposes. The WEB delivered portfolio is available within minutes to prospective employers and on a twenty-four hour basis.

External program evaluators will also be able to review student portfolios prior to the arrival on campus, in their hotel room or when they are on the MWSC campus. Again, the Internet delivered portfolio reduces the need to orchestrate the moving of CDs from one evaluator to another.

All elementary education students at MWSC are required to take an instructional technology course. During this course students create two WEB pages: one using the manual inserting of html tags into a document and one using the HTML Netscape Composer editor. Production of the above WEB pages require students to become familiar with basic WEB page production and composition, image transfer, FTP, scanner software and digitization of photographic images. [Secondary education students, however, are not required to take the instructional technology course.]

The production of the WEB based portfolio becomes a logical extension and real-world application of skills previously learned in the required elementary education technology course. Many students are able to adapt previously developed WEB pages to the final electronic portfolio or they merely create a hyperlink to the earlier WEB pages.
The above plan was implemented during the fall semester of 1998. All fall student teachers were required to complete the electronic portfolio before the end of the semester. The secondary student teachers quickly and easily were able to complete the project using Netscape Composer. Composer eliminates the need to learn all of the necessary html tags.

As compared to the earlier "three-ring notebook" portfolios, it appears that the quality of the electronic portfolios has moved to the positive side of the ledger. The electronic portfolio has the potential of being viewed by a greater number of people. Thus, greater effort and pride was taken to create a public document. Today most prospective employers are interested in assessing a candidate's technology skills. The electronic portfolio easily allows this to happen.

The appropriate WEB pages that illustrate the Missouri Western plan are located at the following URLs:

- http://www.mwsc.edu/~edtech/webpage98.html

Results of the required electronic portfolio assignment

About the time we think one or two problems are solved new ones develop.

One major problem faced by the faculty was the idea of the electronic portfolio itself. Students had been told for several years to develop a "notebook" portfolio. Some students resist doing things a new way and saw the electronic portfolio as an infringement upon their time during a busy student teaching semester. Immediately the required elementary instructional media class will be adapted to insure that the basic format and structure of the electronic portfolio is completed prior to the student teaching semester. It was further noted that the required electronic portfolio required students to make a direct connection or integration of the knowledge and skills learned in the earlier technology class to a finished product that was part of another class. Earlier students had failed to connect "technology" to anything but the technology class. New ways of thinking had to emerge.

Students who did not have a home computer or who were student teaching a far distance from campus found it difficult to complete the final electronic portfolio. The assignment for these people required trying to get into a computer lab during the evenings or weekends. For the majority of the students, however, the WEB based portfolio was easier to complete when compared to a CD portfolio that used less available hardware and software.

Early in the semester "privacy" became an issue. Several students strenuously objected to having personal data, letters of recommendation, evaluations, etc. in the public domain or on all computers in the world. To counter this concern it was suggested that the student create a subdirectory that used a very unique name for the electronic portfolio URL. The URL would be available to only those people that the student chose to give it to.

Competition for employment can be very challenging. Several students expressed a concern about having their peers simply copy, wipe and paste html codes from someone else's electronic portfolio to a "new portfolio." The more technically skilled or motivated students
had a concern that the seemingly open portfolio would jeopardize their employment possibilities.

Computer literate students asked about aggressive search engines that can find almost any web page. Unless a student specifically registered a WEB page with a search engine it may take several months before the existence of the page is known to the world. [And by that time the student will be employed.] Because of the "privacy issue" no MWSC student produced WEB portfolio is available for viewing.1

The issues of privacy and plagiarizing will be resolved for the spring semester of 1999. Entry to all electronic portfolios will require a protected password.

For whatever reason it may, some students might zap the electronic portfolio before it can be viewed by program assessment evaluators {NCATE and Missouri State Department of Elementary and Secondary Education}. To insure availability two or three years in the future, all electronic portfolios will be converted to a CD that will become part of the departmental archive. A trained workstudy student is able to burn a CD in less than five minutes.

MWSC students have 5 megs of computer space for housing both email and WEB accounts. Some of the produced WEB pages are very elaborate with many graphics. This has resulted in several students exceeding their computer space allocation. After graduation the student loses this free account. The lack of space and the closing of the account were unanticipated problems. Each problem will be solved when the Department of Education sets-up its own server before the spring 1999 semester. The department will be able to store several years of electronic portfolios on the new server. MWSC will be able to continue to provide a service to its graduates by making the electronic portfolio available to prospective employers.

Students were encouraged to use photographs to visually present various parts of the portfolio. The department purchased digital cameras for this purpose. Digital cameras were quickly replaced with the student owned 35mm cameras and film. {Most students could not predict exactly "when" the best time to take pictures of classroom activities would be.} Thirty-five mm film can be developed and digitized for less than $10 per roll. The photos can then be ftped to the student web page file. Using student cameras eliminated the problems of not having enough digital cameras, record keeping, not having the camera right day and the eventual problems of having cameras used by so many people. Students with advanced computer skills can enhance photographs with programs as Photoshop.

Success

Three years ago the idea of "portfolio" caused alarm in our department. As the semesters go by we will continue to deal with additional problems that are yet to be faced. For the present time, however, the electronic portfolio created by Netscape Composer seems to have provided solutions to what seemed to be an insurmountable problem.

An overview of the MWSC Web Portfolio can be found at

1 Preservice and Inservice Teaching Portfolios can be viewed at http://curry.edschool.virginia.edu/curry/class/edlf/589_004/sample.html
A word of caution: there is a distinct difference between an electronic portfolio that might be used by a student for employment purposes and the portfolio that will be required by NCATE and/or state agencies who are interested in program review. The production processes can be the same. A student might elect to duplicate some of the basic content but in all probability the majority of the portfolio will contain different information. The similarities and differences between the two types of portfolios are beyond the scope of this paper.

A Constructivist Approach for Introducing Pre-Service Teachers to Educational Technology: Online and Classroom Education

Anne K. Bednar, Eastern Michigan University
Michael T. Charles, Eastern Michigan University

Abstract: The goals for our preparation of pre-service teacher educators in educational media and technology include the development of pedagogical ability as well as technical knowledge and skills. Pedagogically we adopted the goal of teaching the students to use technology to facilitate a constructivist approach to teaching and learning. We have developed a classroom-based and online courses in which we immerse students in educational media and technology. In this paper we provide accounts of our experiences in the implementation of these constructivist learning environments.

Eastern Michigan University prepares more educational personnel than any other university in the country. Along with cars, the state of Michigan exports teachers to the rest of the country. Standards recently adopted by the state for pre-service teachers state that new teachers should be able to use technology effectively in teaching/learning and as a personal and professional productivity tool. The state's Council for Pre-service Technology has adopted a framework for teacher preparation and educational technology. Carl Levin, U.S. Senator from Michigan, is sponsoring activities aimed at establishing Michigan as a national leader in the infusion of technology into classrooms throughout the state.

It was in the midst of this serious discussion of pre-service teacher preparation and technology that we undertook to create a new course for EMU students to address pedagogical and technical skills to use infuse media technology throughout their curriculum as teachers. The guiding principal in the development of the course was that pre-service teachers realize the potential that technology has to facilitate constructivist, student-centered learning environments. It was essential that we create a learning environment for our students to learn about media and technology that would reflect how we hoped they would later use technology to facilitate learning in their own classrooms. In order to achieve that goal we have developed parallel student-centered learning environments, one classroom-based and the other online, in which we immerse students for their training in educational media and technology. The purpose of this paper is to share our experiences in the development and implementation of these constructivist learning environments.

Constructivists believe that the way we learn is by interpreting our experiences based on our prior knowledge, constructing meaning and later revising our understanding by reasoning through new experiences. Knowledge must be constructed, not transmitted (Jonassen, Peck and Wilson, 1999). In a constructivist learning environment, students should be engaged in activities and assignments which are authentic tasks embedded in rich, real world contexts. When possible the audience for those tasks extends beyond the classroom, and assessment is performance-based and reflective. The relationship between the instructor and the students is one of cognitive apprenticeship, in which the instructor models problem solving, engineers learning experiences, provides scaffolding as students attempt tasks, and encourages reflection. Working collaboratively and using original source materials when possible, students constantly confront multiple perspectives on the content being learned: their own, other students' and multiple experts' including the instructor's. Students are encouraged to reflect on their experiences and their learning as it progresses.

To implement these concepts, we designed a new professional education course as part of our elementary and secondary teacher education programs, one focusing on pedagogy of teaching with educational media and technology. Since construction of new knowledge rests on the bed of prior knowledge, prerequisites
include a basic skills computer course and a curriculum methods course. The course itself is a simulation, with each student being hired as a teacher at a specified grade level and in a specified content concentration if the grade level is grade six or above. Tasks require that "teachers" participate on a school-wide committee to create a weeklong, school-wide, thematic unit on a decade of the twentieth century (Sandholtz, Ringstaff, & Dwyer, 1997), to demonstrate instructional planning for technology infusion. At the classroom level, students create a variety of media/technology products such as a PowerPoint presentation and a multimedia, self-instructional lesson. As a member of a district-wide committee, the students confront an ethical issue which arises related to internet usage by students in the district and, working collaboratively, make recommendations about district policy and staff development. Students reflect on their learning in a journal and, using their work from the course, create a professional electronic portfolio documenting their knowledge and skill in using technology in teaching and learning.

The online version of this course (http://www.emunix.emich.edu/~abednar) has been taught twice by one of the presenters, with that same presenter teaching the classroom version once. The classroom version has also been offered two more times by the other presenter. By way of comparison, both presenters have taught multiple sections of earlier media and technology courses which were not built on a student-centered constructivist model. We collected data from each of these course formats in order to analyze student products and reflections from the new course and examples of student assignments and course evaluations from the earlier courses. In addition, we have analyzed our personal reflections about the progress of the course and of individual students and groups in which they participate.

The question we are seeking to answer ultimately is whether there is a difference qualitatively in the ways students choose to use technology in the classroom when they learn to use educational technology in a constructivist learning environment. As with many questions in teacher preparation, the answer lies in a long-term study in classrooms of the future when these pre-service teachers mature. Meanwhile we can make observations contrasting their performance in class to that of previous classes. We would not characterize our findings so much to be an endorsement of a particular approach or medium as much as an inquiry into the strengths and weaknesses of a new approach.

Interestingly enough, the two faculty teaching the course had rather different experiences with their first teaching of the new professional education course. In the following they will both discuss their experiences and then hypothesize explanations for the differences.

**Faculty Member Number One: Anne**

I developed both the online and in classroom syllabus for the new course. This semester I taught two sections of the new course (one online and the other in the classroom) and four sections of the older non-constructivist media course. Some of the key constructivist elements, which I tried to include in the new course, were:

- Authentic tasks – assignments based on real world tasks that students will eventually perform as teachers for their classrooms, schools and districts, using technology and software that they may expect to find in state-of-the-art schools technologically.
- Collaborative work groups akin to school committees for curriculum development and problem solving activities.
- Reflective thinking to synthesize readings, individual and group projects, and the perspectives of peers, instructor and various experts.
- The instructor’s role as a resource, to structure and guide learning experiences and model task performance.

Of these elements, only the first is in any sense an element of the non-constructivist media course; that is, some of the products that students create in the media course are similar to products assigned in the new course but without the unit context as a focus.

From early in the semester I noted differences in my classroom section of the new constructivist course as compared to the sections of the other media course. The constructivist course met twice weekly, and from
the first day I had them assigned to collaborative work groups; they were representing a committee of teachers in a curriculum development project and were divided into interdisciplinary groups were at the elementary, middle or secondary level. The majority of early class sessions were team meetings either to get started on the unit development project or to assist each other with challenge assignments as they developed new skills with technology. I occasionally did a demonstration in front of the whole class, but more often coached them as they worked to achieve goals as a small group.

In the media classes, the class was taught as a body of the whole; when small groups were used, they were for a single class period only. The dominant pedagogical approach was demonstration while students worked hands-on at their own computer stations to follow along with me. Interspersed with demonstration were mini lectures/discussions to link the technical skills, which were being developed to pedagogical approaches.

At one point, about four weeks into the semester, I used a similar computer-based draw/paint group activity, one involving generation of masters for an overhead transparency and overlay, in all the sections of both courses. I expected the media sections to do better on the project, because I had devoted more direct teach, in-class time to developing draw/paint skills in that course than in the new course. The opposite occurred. The only class to finish the problem was the new course, and all four small groups within that class finished with a high quality product. No group in the media sections finished; they had difficulty figuring out how to start the task, and when faced with a false start they could not adjust but rather needed to start from the beginning again. My interpretation was that the students in the media classes were unable to work independent of my demonstration; they needed to be told each next step to do.

Later, when the homework assignment related to this in-class small group activity was due, all but one of the students in the new course successfully completed the assignment and many were high quality products that I would be pleased to use in a classroom. About a fourth of them also included technically complex graphics at this early point in the semester. In the media course, many more students (4-6 per section) achieved the product only by successive approximation, that is, submitting a product, receiving feedback, and resubmitting the product at least a second time. Out of twice the number of students, only two used complex graphics on their transparencies.

The other characteristic of this product (again, the first assignment of the semester) was that the products turned in by students in the new course were good choices of real ways in which to use transparencies in the instructional process, while often those turned in as part of the media course were the minimum required to meet a passing grade and did not represent materials that most teachers would choose to use in actually teaching the content covered. The students in the new course had been required to create a product, which could be used in the teaching of the interdisciplinary unit they were developing. They had already worked fairly extensively to identify resources for the units and to set the unit goals and objectives. In contrast, the students in the media class had been required to create a transparency with at least one overlay that they might use in teaching a content they might teach in the future. Several of these transparencies from the media course were artificially divided into two parts to meet the requirement of an overlay with little thought about the actual teaching. I credited this difference to the reflections required of students in the new course but not included in the media course. In these reflections, the in-classroom and the online students in the new course were asked to reflect on questions critical to the use of technology in the classroom. We had already discussed in depth the various rationales for use of technology in schools and had developed a decision framework requiring that technology be used only when it enhances learning rather than just for the sake of using technology. As one student reflected: "The teacher must know before hand if the use of technology will boost student learning and achievement. I will approach lesson planning with the most emphasis on what is important for my students to know rather than what video or other use of technology fits into this unit. Assessing student learning will determine if I choose to include this type of technology again."

I saw evidence of these contrasts between students in the two courses frequently throughout the semester. For example, when preparing their multimedia lessons near the end of class, quite a few students in both the new course and in the media course found that their scanned images required so much memory that they could not save them on their disk as part of the lesson. Two students from the new course recalled that
I had said JPEG files from the Internet required less memory than other, more dense, graphic formats. Instead of asking the lab assistant how they could solve the problem, they asked for help in saving the scanned image file as a JPEG. At the beginning of the course neither of these students used a computer for anything other than word processing and neither had a home computer. They seemed to take the problem as an opportunity to learn rather than a reason to give up. I did not see this kind of attitude generally in the media class where problems were likely to result in defeat until specific solutions were given.

Another characteristic which is generally different between the classes is the pride which students in the new course, both in the classroom and online, show in their work. At times I tried to discourage fairly lofty goals anticipating problems they would cause along the way. Students in the new course insisted on going ahead, however, and have been extremely proud of their ability to get things they way they wanted in spite of limitations of technology. One several occasions they have commented on using work from our course in another course as well and the success of their work to that extended audience.

Of course there were some excellent students in the media courses and some less capable students in the new course, but generally I was more pleased with performance in the new course. I wondered whether my observations were biased, but a colleague who visited the course several times also noticed the difference between this group and students in my previous media and technology courses he had visited.

Reflecting upon these differences as we moved through the semester I concluded that the students in the new course were: more independent as learners, more confident in their ability to handle challenges while using technology, and more conscious of the applications of the things we were learning in a school context. It occurs to me that two possibilities exist: either EDMT330 has influenced these groups of students to talk about and work with technology and its use in schools in a much more mature way than my other undergraduates, or I have simply had exceptional groups of students (20 in the classroom and 20 online) in this first semester of the course.

Faculty Member Number Two: Mike

I taught the classroom version of this course for the first time this semester as I began my second year of teaching at the university following a decade and a half of teaching in K-6 schools. This semester I taught two sections of the constructivist course (with approximately 20 students in each section), using a syllabus that was developed from and similar to Anne’s. Both of these sections were classroom courses (i.e. I did not teach the course online), taught in fifty-minute sessions, one period after another, in a class that met twice each week. I was also teaching much of the same content in an introductory course in our educational media and technology graduate program. I did not teach any sections of the older non-constructivist media or computer courses this semester, so I could not directly compare work between the two courses.

Like Anne, I tried to incorporate key constructivist elements in the new course. An emphasis on authentic tasks meant that assignments were all related to a thematic unit about one of the decades of the 20th Century. Students did much of the work for that unit in collaborative work groups. Opportunities for reflective thinking to synthesize readings, projects, and different perspectives were provided, though not as frequently or with as clear a focus as was the case in the Anne’s section of this course. Likewise her emphasis on relating to the students more as a resource, with less of an emphasis on direct instruction was not something that was pursued with the same energy. My focus frankly was more on figuring out how to put together these two courses that had taught separately in a less-constructivist fashion into one course that could be taught successfully in a more-constructivist way.

So perhaps it is not surprising that our experiences in teaching the course were rather different. Anne has described a marked difference in the quality of the work she received from the constructivist course compared to the non-constructivist course. Most notably she found evidence for what some might call more learning with less teaching (Papert, 1993). But I was much more discouraged by my experience in teaching the constructivist course. According to student reflections, they built a stronger bond of community through their group work. But generally speaking, I did not see better quality work from the students in this course.
One of the first warning signs came in the opening weeks of the course. Students were to choose a decade from the 20th Century, and write a list of unit objectives and a content outline that pertained to the content from that decade they decided to teach. The quality of objectives and content outlines that I received varied greatly, with more than a third of the groups receiving very low scores and notes to revise and resubmit their work. Even the revised work was not particularly strong. Students were required to have taken a curriculum course prior to or in conjunction with taking this course, so unit design was not supposed to be new. But for some this did not come easily at all.

As the semester continued, several students made individual appointments with me, asking if they could complete some of the individual assignments for the course (such as software evaluation) apart from their decade. They had not understood that the whole course was structured around the unit despite my instructions. When they began to do materials evaluations of various media and computer programs, they did not want to be limited to looking only for materials that pertained to their decade of the 20th Century. I allowed them to look at other materials that they specified from their own major. In fact I announced that for the software review, they did not have to limit themselves to their decade, since decade-specific software is rather hard to find. But this created a more serious problem that persisted throughout the course. In fact even up to the last class session, as students were working on various assignments such as creating a newsletter or a Hyperstudio presentation, I was asked, "Does this have to relate to our unit?"

One place where the difference in our experience came most clearly into view is in the overhead transparency assignment described earlier in this paper. We first did an in-class exercise of using a draw program to create a volcano and using a paint program to create a castle. This activity and its accompanying step-by-step directions were well received by the group. Some of them did not need such specific help and I encouraged them to use their prior knowledge of these programs to complete their work. But in the second session, few of my students were able to complete the draw/paint group activity of preparing a sample multilayered display in class. Then the overhead transparencies turned in as independent work, relating to the unit, again varied greatly in quality. In particular, a number of them (about 4-5 per section) were simply unusable due to either the size of the font or graphics or the way they were constructed. Some of these had to be revised and resubmitted several times in order to receive credit. This is precisely the same experience Anne had with her students...but in the non-constructivist course!

By the end of the course, I was particularly concerned about how well the unit plan idea had worked with our students. I asked for some direct feedback about this aspect of the course, noting that this was my first semester teaching the course and I wanted to improve it in the future. In an electronic bulletin board environment, I asked them to discuss the strengths and weaknesses of using the thematic unit approach to tie together the assignments for the course. I then asked them to suggest any ways that this unit approach could be improved in future offerings of the course.

The reflections of all forty students can be summarized in three points:

- The students really enjoyed working cooperatively in groups for the most part, with the only problem being getting together outside of class in a "commuter" university.
- The assigned decade approach was not so strong because it limited the applicability of the material that they prepared for future use. The decade scenario, though interesting, seemed too unlikely for future use. There was one group in particular, however, who really thought the decade approach worked well; they consistently did among the best work of both classes.
- In the future, allow groups to choose their own unit topics that could relate to other courses they are taking or would relate more closely to topics they will teach in the future.

As the professor in the course, I was honestly pleased at how many of the students, despite their criticisms, also mentioned that they thought the course was very valuable (though labor intensive). My own impressions of the student's experience had not been so positive. I did not realize that the groups seemed to function as well as they did, though this is perhaps in part due to the fact that one group in particular had serious problems that required a great deal of my energy to resolve. Also, this was my first time teaching this course, and I believe that I taught the second section much better than I taught the first section by virtue of simply having a better understanding of the content and pedagogical issues.
There were areas in which I did see better work this semester. In my course, I ask for fewer student reflections than Anne, preferring instead for them to read two articles with divergent views about the promise of educational technology (specifically computers) in the schools (See Oppenheimer, 1997; Starr, 1996). They wrote a summary and response to the arguments of the articles. The papers that I received for this assignment were among the best I have read to date. Many more students understood the subtle points of agreement between these two positions while locating the clear points of departure between the two. In addition, more of the students supported their own responses to the articles with factual statements taken from the text, in contrast to merely stating their own opinions without support.

So in a sense, my students seemed to have a positive experience with at least two of the constructivist elements mentioned initially by Anne: Collaborative work groups and reflective thinking to synthesize readings. They had serious questions about the authenticity of the thematic unit task in the long run, questions that are not without merit. But the most striking difference between our class was in the question of the instructor’s relationship to the students. I had occasion to visit Anne’s constructivist class section several times during the semester. I was impressed with the level of independence of her students in comparison to other classes that I have taught and in comparison to other classes I have observed her teaching. I vividly recall the day she met me in the hall, noting just how well the students had understood a particular computer application and just how little direct instruction she gave them. Working in groups they solved the problems that came up. As she stated earlier, the students in her course saw problems that came up more as opportunities to learn than reasons to give up.

Ownership and Authentic Tasks

Creating opportunities to learn is a main focus of a constructivist learning environment, and, while we have learned many things this semester, the experience of teaching the constructivist course has resulted in the opportunity for future exploration of many more questions. One of the main questions is that of ownership as it relates to authentic tasks: in whose eyes must the task (in our case, the unit plan) be authentic, the instructor’s or the students’? We are exploring ways to maintain the collaborative group structure while devising a way to allow students more freedom in the choice of their unit topic.

The question of ownership has a second side, that of ownership by the instructor of the course they teach. We found clear evidence that the most successful activities in either of our courses were the activities we individually had worked to structure and for which we felt both ownership and commitment, the reflective paper for Mike and the challenge activities which helped reinforce the independence of the students for Anne. The partner issues of authenticity and ownership impact the motivation of students to learn and instructors to teach – two critical elements in any learning environment.

Jeannine Hirtle will speak to the historical, theoretical and pedagogical background of computer mediated communication and the ways in which computer systems have and are redefining concepts of learning and teaching and the communities in which learning and teaching processes occur. At issue are the ways computer-mediated communication (CMC) affects the learning communities that shape knowledge in the classroom. How do these cyber webs of personal relationships support learning? Do these cyber discourse communities have the potential to contribute to the teaching and learning process?

In order to support students in providing learning experiences that have the potential of transforming their cultural reality, providing discourse opportunities is an imperative. One of the prime goals of our current work is to determine if the quality of discursive collaboration is enhanced by the connectivity provided through computer-mediated discourse. Studies which have reported the impact of computer-mediated discourse include ProjectH (Sudweeks & Rafaeli, 1997, www.arch.usyd.edu.au/~fav/projecth.html), a research project conducted over a twenty month period among investigators who had never met personally, but communicated and included 15 countries, numerous universities and commercial or industrial firms, and over 100 scholars. Twenty-three subsequent studies resulting from Project H have been conducted. (www.arch.usyd.edu.au/~fav/projecth/publications.html)

Larry Walker will describe the World In 2020 project and web site (http://wi2020.conroe.isd.tenet.edu), a secondary school based science project which uses threaded messages board for recording remote asynchronous communication between project participants, and the recent 1998 NCSSSMST Student Conference. Walker will describe the organization and structure of the threaded message boards and the processes involved in the construction and management of the communications system. In addition thee will discussion on the nature of the data that can be gathered from the threaded message boards.

Peter Cooper will outline a proposed project to extend the work of these studies by focusing specifically on the pedagogical impact of CMC within secondary and post-secondary educational environments. We seek to understand if technology can enhance the learning environment that provides those opportunities. In particular we ask the following questions:

- What are the effects of computer-mediated communication on the learning process.
What impact does educational-oriented computer-mediated communication have on student attitudes toward technology?
How does language, and specifically the language of our students when mediated by computer assisted communication, create or disrupt community?
What is the impact of computer-mediated communication on student attitudes towards communication and collaboration?
What impact does computer-mediated communication have on student attitudes towards learning?

The proposed project would employ both quantitative and qualitative tools utilizing a variety of data collection methods including:

- Computer-mediated communication, primarily in the form of threaded messages. The threaded message board provides the opportunity for sequenced multimedia communication in both asynchronous and semi-synchronous modes. The content and structure of communication through the threaded message boards will be analyzed to ascertain how the process impacts both learning and teaching.
- On-line interviews of participants during the data collection phase will be conducted to elicit data on participant reactions to the CMC experience.
- Qualitative data concerning participant perceptions of the value of the computer-mediated communication learning process.
- A quantitative pre-post analysis of participant attitudes toward technology (Cooper, 1997) will be performed to identify changes in attitudes as a result of exposure to learning-oriented computer-mediated communication.

References
Like baby ducks imprinted to follow their mama, students who are spoon-fed knowledge in teacher-centric learning environments are trapped in limited repertoires. They may perform a limited number of academic behaviors, but their capacity for independent and inter-dependent thinking is seriously diminished.

The pervasive emphasis on using educational technology for DELIVERING information imprints students as passive learners (isn't television bad enough?). Where and how do we teach students to be independent learners who can find, assimilate, and apply information on their own? Where and how do they learn to create new information and insights?

Four years ago, we began testing an asynchronous Internet software collaboration system, FORUM (www.foruminc.com). This presentation demonstrates some of our uses of FORUM for individual and group work that goes beyond “imprinting the ducklings.” Illustrated are examples of how to stimulate insight, creativity, and ability to organize and apply information.
Expanding The Horizons Of The Classroom

Pameolin K. Nelson, Eckert Intermediate School Aldine ISD, USA  pamnel@flash.net
Monique Micheaux-Gordon, Technology Department, Houston ISD, USA  mmicheau@swbell.net

Abstract: Telecommunication expands the horizons of the classroom, opening doors to real audiences and exciting interactive activities from locations around the world. Teachers will discover how to integrate telecomputing within existing curriculum framework using the components of the Internet. They will gain insight into ways in which to locate lesson plans, simulations, online and pen pal projects, listservs, newsgroups, and virtual tours via the Internet. Examples of sample lesson plans and student projects will be displayed.
Transmission of Teacher Dispositions: A New Use for Electronic Dialogue

Susan M. Powers
Department of Curriculum, Instructional and Media Technology
Indiana State University

powers@indstate.edu

Abstract. This paper describes a project where three teachers served as virtual guest speakers to preservice teachers through an email-based electronic discussion group. One goal of the project was to integrate technology into the daily classroom activities of the students. However, one unexpected byproduct of the project was the modeling by the guest speakers of dispositions of effective teachers and their public reflection on teaching. The success of the project has led to a larger program, supported by grant funds, with 32 teachers and teacher education students from across the state.

Introduction

Imagine a professional development school and teacher education program where the teachers play an integral part in the preparation of future teachers. Each teacher has the opportunity to impact the learning and preparation of hundreds of future teachers and each pre-service teacher has the opportunity to interact with multiple veteran teachers. During these interactions, teacher education students can ask the experienced teachers burning questions related to current issues and practices in education. The teachers in turn have the opportunity to reflect upon their professional practice and share their professional development with future teachers, teacher educators, and their peers.

Although this may be happening at some professional development schools (PDS) and within the associated teacher education program, it is difficult to achieve the level of involvement without the inclusion of multiple teacher education programs and multiple PDS systems. The logistics of that task would be enormous. Fortunately, with the use of simple information technologies such as electronic mail and the World Wide Web (WWW), that type of K-16 learning community can be developed.

Recent articles in the Journal of Technology and Teacher Education have described the power of placing the voices and experiences of teachers online. Bosworth, Haakenson, and McCracken (1997) describe the use of a web publication to distribute teacher viewpoints to pre-service teachers and how these students grew in their understanding and comfort in dealing with various issues. Denise Johnson (1997) details a project where preservice teachers developed a greater understanding of reading philosophy through electronic dialoguing with practicing teachers from around the country. The relay of information can be an important outcome of electronic communication, as well as the demonstration of practical, integrated uses of the technology. However, can more be obtained and gleaned from these electronic dialogues? Can these electronic dialogues serve to not only have teachers use more technology while learning about the teaching profession, but also become more reflective practitioners and understand more about the dispositions that are an integral part of being a teachers (INTASC 1998; IPSB 1998).

Background

In order to understand the project described in this paper, and to envision the possible future forms of the project, it is equally important to understand the purpose behind the use of a virtual guest speaker program. The research presented here examines the literature behind the premises of technology use, reflective practice and dispositions.
The National Council for the Accreditation of Teacher Educators (NCATE) issued a report recently entitled Technology and the New Professional teacher: Preparing for the 21st Century Classroom (1997). This report describes the need for teachers to be able to understand the impact of technology on society. It describes how teachers need to adopt new roles which allow them to use technology to become more reflective and critical consumers, and that teachers must participate in activities that are delivered via informational technologies. Building upon this last point, the literature points to the potential of information technology to enhance learning productivity as larger numbers of students are able to be reached at a lower incremental cost, and how technology allows faculty to accommodate individual differences (Massy & Zemsky 1995). Kozma and Schank (1998) posit that information technologies will increase the use of effective project-based learning by allowing students to converse with experts from around the world. Vicki Hancock (1997) concurs with that position through her evaluation of six classrooms that are actively using information technology to create self-initiated learning projects. These types of programs, that bring the technology directly into the regular activities of teacher education students, create an atmosphere which moves students from knowledge consumers to knowledge producers while at the same time moving from technology that is an adjunct to instruction to technology that is central in the delivery of course content (Pellegrino & Altman 1997). In this manner, the teacher education program as a whole is better able to increase the instructional technology skills of its students, while transmitting important pedagogical information. This transformation to technology-rich teacher education classrooms is new and the efforts are still experimental, but the importance of using technology as a vehicle for delivery of information is apparent.

One of the questions that emerged with the project is whether or not the process of learning from and through technology can be translated to another level of learning and professional growth, such as the development of reflection? Thoughtful reflection is a difficult process that must be developed and nurtured (King & Kitchener 1994). Donald Schön (1983 & 1987) identifies the important role that reflection plays in professional development and growth. A number of researchers in addition to Schön have discussed how reflection takes place on a variety of levels (Zeichner & Liston 1987; Zimpher & Howes 1987; van Manen 1977). The lower levels of reflection concern the reporting of factual information or descriptions of what took place during a situation. The higher levels are where actions and behaviors and the impact those actions had on others are examined. King and Kitchener (1994) provide a number of ways that reflection, which leads to a critical analysis of performances, can be fostered. Examples include the creation of multiple opportunities for students to examine different points of view reflectively, development of a learning climate that promotes thoughtful analysis of issues, and opportunities for students to make judgements and explain what they believe. The process of reflection is also closely tied to dispositions in that teachers (in-service and pre-service alike) must want to act up on their reflections to change behavior (Kottkamp 1990) and that the teacher is ultimately in control as to whether or not they have the desire to reflect (Dewey 1933). Given that dispositions are an integral part of newly developed teacher standards and principles (INTASC 1998, IPSB 1998), if technology can enhance reflection, can technology also be used to model and perhaps enhance dispositions?

Dispositions of successful teachers are not as elusive and unapproachable as might be imagined. Dispositions and attitudes are not new to teacher education. Researchers and practitioners have been examining those characteristics in the literature (Robinson, Noyes & Chandler 1989; Brookhart & Freeman 1992; Pajares 1992). The difficult question for teacher education programs is how to make these dispositions real and demonstrable to preservice teachers. Davis-Blake and Pfeffer (1989) describe the dispositional approach as one that examines those stable traits that influence our affective and behavioral actions. Holland (1985) took this argument even further by saying that these stable traits or personality types impact vocational choices, satisfaction and success. Unfortunately, this position then assumes that a person cannot change their dispositions, or can't be taught a different dispositional stance. This research would indicate to teacher education programs that successful teachers and candidates could be detected by some pre-measures. Research supporting this assumption has been done as a predictor of success for urban teachers (Haberman 1993). A number of theories contrast this notion of stability and suggest that group climate, social influence and social networking can impact attitudes and behaviors, and in turn, possibly dispositions (Festinger 1954; Deutsch & Gerard 1955; Slancik & Pfeffer 1978; Pfeffer 1983). It is therefore a possibility that the dispositions outlined in the various standards are dispositions that could be "taught" to students. Alternatively, at least students might be able to become more aware of and able to adopt appropriate dispositions by being in situations which bring them into social contact with teachers exhibiting appropriate dispositions.
Project Description

This paper describes a pilot project that brought together three teachers from different parts of the country with sophomore teacher education students through an electronic discussion group in the form of a moderated listserv. A moderated listserv means that all messages are first sent through a moderator (in this case the course instructors) who determines the relevance of the message to the topic, or possible redundancy of the message. Therefore, the moderator may choose to not post a message that has little to do with the topic or is in questionable taste. The moderator may also choose to combine a number of messages that pertain to the same topic and thereby reduce email traffic flow. The role of the moderator is not to determine "worthiness" of the message except in those instances where a message is blatantly in poor taste or irrelevant to the topic.

Each teacher spent two weeks online, using email, answering the questions of teacher education students. The expected outcome was much like what has been discovered by the authors exemplified above: teachers and teacher education students alike would grow in their appreciation and understanding of the instructional uses of technology, and teacher education students would grow in their knowledge about what practicing teachers do. These outcomes did take place. However, what was more powerful and far more unexpected was the transmission from teacher to teacher education student of the dispositional stance of a successful teacher, and the display of open, honest, public reflection on teaching.

The Conversations

The electronic discussion group begun much as would be expected. Three teachers were used and each teacher was online with the students for three weeks. Teachers submitted an opening statement to the students about who they were, where they worked, how long they had been teaching, etc. Then the discussion group was opened for questions and answers. The first several days, the discussion was tentative and general. Questions and responses focussed largely on issues that students were also learning about in class. One such question focussed on interdisciplinary teaching and elicited the following response:

"I've not done a lot of integrated teaching because I haven't had my own classroom for awhile. But these are my observations: 1) Everyone has to be philosophically on board if a team is going to do it, I don't mean that everyone has to accept the concept without reservation, but they have to be willing to give time and energy. 2) The content teachers must know what the major concepts that the kids need to master are in their curriculum. You might be surprised how many teachers can't identify the BIG IDEAS in their curriculums because they rely on textbooks. Once the major concepts or big ideas are in mind, then the teachers have a framework to keep in mind when planning. 3) It's easy to forget when planning an interdisciplinary unit what skills and types of thinking the kids' needs to have in order to complete projects and assignments. For example, sometimes we ask kids to compare and contrast without making sure that they know what the words mean or whether they have strategies for comparing and contrasting." She continues:

"At my school, we are now asking ourselves three questions when we plan: 1. What's the content (e.g. concepts, big ideas, etc.--what do the kids need to know) 2. What skills and processes do the kids need (what do the kids need to be able to do--narrow down a topic, use a variety of resources, etc.) 3. What types of thinking do kids need to be able to do--summarizing, analyzing, etc. Once these questions are answered, we have a better picture of how to structure the unit." 

Then, a little over a week into the discussions, unexpected and tragic news hit the national media in the form of the Jonesboro, Arkansas school shootings. Suddenly the students were filled with questions about safety and student searches. The teacher online at that time began exposing her feelings and her attitudes to the students, and the students came to understand that these were important qualities in a successful teacher and that they were heretofore not consciously aware of these dispositions. Within 24 hours of the shootings, the following two questions were posted:

"I was wondering if teachers are nervous for their OWN safety due to the recent outbreak of violence in schools? Has anyone in your school talked about taking extreme steps to prevent student violence? Do you think anything can be done?"

"With all of the news about students bringing weapons such as guns and knives to school, do you feel threatened as a teacher, or do you just not think about it?"

The teacher responded in an honest and open manner without any pretense:

"I do not feel threatened at school and still would wade in and break-up a fight. We have had weapons at school, and we have unstable students. But then again, I have some unstable neighbors--so I do not allow
myself to get agitated. Violence is not a daily occurrence for me--if it was I don’t think I would stay. We have peer mediation and civil rights groups operating in school. They’re small steps--we have a long way to go in creating a situation where each student feels he/she has an advocate here, and I think that would help keeping an escalation of violence at bay. However, it is an issue that is not going to go away."

The conversations continued in this manner for the remainder of the six-week period that the three teachers were online with the students. Conversations focused on topics emerging from class information (e.g., teaming, interdisciplinary curriculum), experiences students had in the field (e.g., classroom disciplines, faculty meetings), and items from the news (e.g., school violence, public grieving). Some of the topics were predictable; others came from out of the blue and demonstrated the level of student concern and consideration.

Teacher Educator and Student Reflection

As might be expected from this project, the discussion group elicited some reflection. One student who did not actually ask any questions, but was apparently absorbing the information offered the following:

"I have been very interested in both the questions asked and the answers given. I know that there are a lot of things I do not know [a lot] and this has been a way for me to learn about things that I didn't even think about before!"

The public reflection of both teachers and students opened doors for this student that had been previously unconsidered.

At the same time the public reflection occurred, the dispositions of those individuals on the discussion group were being modeled; the teachers were being plain about how their attitudes toward various aspects of their jobs make them successful and satisfied.

The power of the electronic discussion group also surprised the teacher education faculty, as demonstrated by the following comment:

"Questions about Jonesville that Jill got; questions about national certification to Karen; and magnet school questions that Jane fielded--all three stick in my mind. I believe, from my vantage point, that your participation, as three active and involved professionals was the major cause of this level of quality. Indeed, you elevated the level of discourse for a number of reasons: students recognized that you were a committed professional; students have, and we in the department have come to understand this much better this semester, a need to talk their concerns and questions out; the security of a non-face-to-face interchange brought about a different level of conversation; and the length and tone of your responses was also a major part of this effort; the depth of detail that you went into--about everything--and the up-front honesty that framed all of the responses contributed to this."

This faculty member honestly felt that the level of student reflection he saw rose as a direct result of the discussions. Additionally, the technology became an "honest" classroom tool that achieved results beyond mere utilization, rather, the technology furthered the instructional goals of the class. Finally, his students grew to understand the importance and relevance of reflection and dispositions to the teaching profession.

Next Steps

This pilot project was a success from the standpoint of the teacher educators, the teachers, and the students. Funding obtained through internal, university grant sources allowed the teachers to receive a modest stipend for the time they spent online. The success of the pilot, the interest of faculty, teachers and students made the question arise as to whether or not a similar project could play a bigger role in teacher education. In other words, could more students participate, as well as more teachers?

During the Spring of 1998, a grant was written to obtain funding from the Educate Indiana Preservice Grant Program (Goals 2000) to develop a series of statewide electronic discussion groups. Starting in the Spring of 1999, 32 teachers from around the state, representing different grade levels and disciplines, will be online with teacher education students from all over Indiana. Three different listservs will be in operation, dealing with three different sets of teacher performance standards. As data is gathered from faculty, teachers and students, it will be interesting to discover if other elements emerge beyond the reflection and modeled dispositions. Through the experience gained with the project described here, it is fairly apparent that the results will extend beyond mere technology integration. Pellegrino and Altman
(1997) provided a challenge to teacher educators to find ways to allow the technology to be a tool that delivers unique and higher-levels of learning and teacher development. This project demonstrates that it is possible, and that such a situation might occur if it’s allowed to develop.

Abstract: The ability to locate, retrieve and evaluate information resources from the World Wide Web is rapidly becoming one of the foundational skills for information literacy. This paper presents a framework for introducing these skills to preservice teachers. Key concepts presented include differences between databases such as online library catalogs or ERIC and the web, keyword searching using Boolean logic, effective use of search engines, directories, and metasearch engines, frameworks for evaluating web-based information, and the location and use of pathfinder pages.

Introduction

In a recent editorial discussing “The State of the Net,” Dr. Sylvia Charp (1998) made the following observation: “With all of the enthusiasm on the use of the Internet for teaching and learning, some concerns must not be overlooked. One of the most often repeated complaints is that students are not taught how to locate or access the required information.” (p. 4) Perhaps students are not taught location skills because their teachers haven’t had the opportunity to learn these skills themselves. In informal conversations with preservice teachers, many express great confidence in their ability to locate and retrieve information from the web. Yet, when presented with a relatively simple task such as finding lesson plans for elementary school science or social studies, these formerly confidant students are unable to locate any relevant resources. This paper presents a sequence of skills and concepts used to introduce basic web searching skills to preservice teachers.

Introducing web searching to preservice teacher educators begins with a discussion of hyperlinks, contrasting the traditional linear organization of information in books with the hyperlinked, webbed nature of information on the World Wide Web. Using Netscape or Internet Explorer, the concept of a browser is introduced next, emphasizing navigation and organization tools (such as the Go Menu, History, and Bookmarks or Favorites). The Official Netscape Guide to Internet Research (Calishain & Nystrom, 1998) provides a very helpful overview of Netscape’s capabilities.

Our experience indicates that students often have a very naïve view of the amount of information on the web, and they are frequently confused about the characteristics of online indexes and databases versus information found on web pages. To help students understand the difference between searching in a controlled environment (like an online library catalog or the ERIC database) and web searching, students are introduced to the concept of searching with controlled vocabulary versus keyword searching (Basch, 1998). This naturally leads to a discussion of the power of searching using Boolean logic with keywords, which is demonstrated with Venn diagrams. Students are also presented with information about other power searching techniques such as the use of truncation and wild cards. Students learn how to broaden and limit their searches using these techniques. Barrett (1997) provides a table listing many of these techniques, and also goes on to discuss the
advantages and disadvantages of beginning with a general search or a specific search. Barrett stresses the importance of persistence in the search process, which can easily be modeled for students as sample searches are performed in class. The Eisenhower National Clearinghouse for Mathematics and Science Education (1998) presents much of this information in a clear and sequential web tutorial.

Searching Tools

The majority of this sequence of instruction centers on the use of web searching tools. These tools can be grouped into three categories: directories, search engines, and metasearch tools. Directories, such as Yahoo! <http://www.yahoo.com> or LookSmart <http://www.looksmart.com>, are the most library like search tools. Essentially hierarchical lists of subject categories, directories can be searched by category, title or name. Search engines such as AltaVista <http://www.altavista.com>, InfoSeek <http://www.infoseek.com>, or Ask Jeeves! <http://www.askjeeves.com> use spiders or bots to build a database of web pages, which the search engine then uses to conduct the actual search. Keyword searching, fundamental to all of these search engines, is stressed, however students are also introduced to advanced searching techniques available with different search engines. Finally, students are acquainted with metasearch tools, such as Metacrawler <http://www.metacrawler.com> and DogPile <http://www.dogpile.com>, some of the newest and most powerful search tools available today. (Abilock, 1997; Find it on the web, 1998) These power tools use several different directories and search engines simultaneously and provide the searcher with the intersection of the search sets. Through a demonstration, students are shown how the same search yields very different results with each search resource. Especially revealing are the different results from the different search engines that would appear to return identical sites. This leads to a discussion of the concept of relevance ranking, emphasizing that only the end user of the information can truly determine the relevance of any item retrieved. Additionally, students begin to become aware of the importance of matching the kind of information sought with the appropriate search tool. Students are provided with suggestions on how to make good matches.

The importance of evaluation is stressed throughout the instruction. All educators need to realize that all information is not available for free from the web, the information that is available can be hard to find, once located it can be difficult to determine the quality of the information, and even after the information has been located, it may not be there when you try to find it again. Many authors (Abilock, 1997; Ackerman, 1997; Basch, 1998; Evaluating web resources, 1998; Rettig, 1996) have outlined key features to examine in evaluating the quality of information on the web. Ackerman (1997) provides several tips for locating information about the authors of web pages, including visiting the home page of the institution the author is affiliated with and searching newsgroups for additional information about the author. Abilock (1997) also suggests the use of DejaNews (http://www.dejanews.com) to locate the information about web authors.

Pathfinder Pages

While learning how to search the web is important, it is also important for students to realize that they should make use of resources compiled and maintained by others. At this point, students are often overwhelmed with the search tools and techniques available on the web, so an alternative method of information access is presented: the use of pathfinder pages. Pathfinder pages are lists of links on topics that are collected and maintained by someone who has both interest and expertise in an area. Basch (1998) refers to these as “guru pages” (p. 85), and likens guru pages to very specialized subject catalogs. Basch compares finding a guru page to “striking gold” (p. 85) and suggests bookmarking and using these pages frequently as part of effective searching. Kathy Schrock’s Guide for Educators <http://www.capecod.net/schrockguide/> and David Levin’s Learning@Web.Sites <http://www.ecnet.net/users/gdlevin/home.html> are both examples of general education pathfinder sites: lots of links to many different curriculum areas that are well maintained by conscientious educators. Once students realize the power of pathfinder pages they are encouraged to locate a pathfinder that “works” for them.

This scope and sequence of web searching concepts and skills, when followed by guided and independent practice, has proven to be an effective way to quickly improve the searching skills of preservice
teachers. While we present these concepts in a preservice technology use in education survey course, they could easily be adapted to any content area. Activities that allow students to practice their new and improved searching skills can be developed to match virtually any instructional objective. Once students have the skills and strategies they need to search the web effectively, they are usually eager to apply these skills to locate relevant information.

Facilitating Critical Reflection
About Field Experiences on E-Mail:
Emancipatory Teaching in Cyberspace

Joan L. Whipp
Department of Educational Leadership and Policy Studies
Marquette University
United States of America
WHIPPJ@vms.csd.mu.edu

Abstract: This paper reports findings in a study of an e-mail discussion activity in an undergraduate methods course. Critical interpretative methods were used to examine levels of reflection in student e-mail discussions and the degree of support for critical reflection offered in the e-mail activity. Findings suggest that the e-mail activity promoted some reflection among the participants and that as the discussion developed, joint interpretations of field experiences by the participants increased; but critical reflection was rare. In light of the findings, suggestions for increased structural supports for critical reflection are offered.

There has been a move in recent years to use telecommunication networks and electronic mail in teacher education courses, especially in conjunction with field experiences (Blanton, Moorman, & Trathan, 1998; Hoover, 1994; Schlagal, Trathen & Blanton, 1996; Thomas, Clift & Sugimoto, 1996; Wizer & Beck, 1996; Yan, Anderson & Nelson, 1994). Although there have been considerable description and argument about how such electronic dialogue can enhance student teacher learning, there has been little systematic study of precisely how to structure the e-mail activity to achieve particular learning outcomes. And yet several studies have suggested that the design of the e-mail assignment may be critical (Harrington & Hathaway, 1994; Schlagal, Trathen & Blanton 1996; Thomas, Clift & Sugimoto, 1996).

In this paper I report on a study of my use of electronic mail as an activity to foster critical reflection on field experiences for preservice teachers. My studies are grounded in critical pedagogy in teacher education (Harrington, Quinn-Leering & Hodson, 1996; Hatton & Smith, 1995; Liston & Zeichner, 1987; Scering, 1997; Smyth, 1992) and social constructivist theory (Blanton, Moorman & Trathan, 1998; Rogoff, 1990; Wertsch, 1985). Critical pedagogy in teacher education focuses on the teacher's role as facilitator of questioning and analyzing taken-for-granted assumptions about the status quo from multiple perspectives that include social, political and ethical frameworks. Teachers are viewed as emancipators and agents of change in schools. To take on such roles, teachers need to look beyond their own personal and subjective ways of looking at educational situations to develop skills of critical analysis and moral decision-making. Social constructivists maintain that learning is negotiated within socio-cultural contexts. Through guided support and activities within a social context, learners are scaffolded from their present and more egocentric ways of knowing to more complex ways of understanding.

Context and Method of Study

I teach at a large private university where the majority of teacher education students are young white females who do much of their field work and student teaching in a large urban school district. For most, experiences in these urban schools are their first in a multicultural context. In the course where I conducted these studies, all 23 students were Caucasian; all but three were female; all but three were 22 years old or younger; and all but six had limited experience in multicultural contexts. The course, Teaching in the Middle School, is required for middle school teaching certification and is usually taken during the semester before student teaching. In addition to a class focus on adolescent development, middle school curriculum, and pedagogy, students do twenty hours of clinical work in a middle school where we also hold some class sessions. Located in the center of a large urban area, the school's student
population is 75% African American, 15% Hispanic, 5% Asian and 5% Caucasian. Although teachers in the school vary considerably in teaching style, philosophy, and experience, for field placements I have attempted to identify teachers who enjoy teaching at the middle school level and who enjoy engaging university students in conversation about practice.

Beginning in the third week of the spring semester of 1997, I asked students to contribute an e-mail message to the class discussion at least once every two weeks. They could write on any topic suggested by their field experiences or related class discussions and readings. The only requirements were that messages fill at least one screen and that messages reflect reading and hearing other students' messages. To study what happened in these e-mail discussions, I asked these questions: 1) To what extent are students thinking critically about their field experiences? 2) To what extent does the structure of the e-mail activity and my own pedagogy support critical inquiry on e-mail? Primary data sources were a transcript of all e-mail messages written by 23 students and me (189 pages of text) as well as written surveys about the e-mail activity completed by students at the end of the semester.

To analyze the nature of the analysis and reflection in the student e-mail messages as well as the level of support for critical reflection, I used critical interpretive methods (Lincoln & Guba, 1985) for analysis. Hatton and Smith's (1995) levels of reflective writing were used to code the student e-mail messages. Hatton and Smith distinguish "descriptive" writing where students interpret "in light of personal worries and previous experience" (p.46) from "dialogic" writing where students step back from events, weighing competing claims and exploring alternative perspectives. Only then, they argue, can reflection move into a "critical" mode where ethical criteria, based on social, political and cultural considerations are used to call into question the status quo. Two graduate students coded all messages and then negotiated coding to 100% agreement. To analyze to what extent the structure of the e-mail activity and my own pedagogy on e-mail were supporting critical inquiry, I focused my analysis on an extended discussion that emerged during the semester about the significance of cultural differences between teachers and students. I also analyzed my own e-mail messages and the written surveys completed by students. I used social constructivist learning and critical teaching principles to develop criteria for critique of my own pedagogy on e-mail as well as the structure of the e-mail assignment. Is there evidence that the e-mail discussions and my pedagogy facilitate student analysis of assumptions or beliefs about emerging problems and situations? Does my pedagogy on e-mail push students to think beyond their subjective interpretations to consider multiple perspectives? Does the activity structure of the e-mail discussions and/or my pedagogy seem to be promoting or modeling use of broader socio-political and moral frameworks to critique the status quo?

Findings

Levels of Student Reflection about Field Work

Analysis of the student e-mail writing revealed that that students engaged in extended discussions on a variety of problems and situations that offered opportunity for critical discussion and reflection. They talked about: low teacher expectations, socioeconomic and cultural gaps between teachers and students, vandalism in classrooms, school suspension and expulsion policies, social promotion of students, the uneven quality of substitute teachers, student rudeness toward teachers, lack of student interest in the curriculum, and how issues of sexual identity might be handled in the curriculum. In addition, they shared stories and problems that arose in their first teaching experiences with young adolescents. Using Hatton & Smith's (1995) framework for different types of reflective writing, I found that early in the semester about half of the students were largely at a level of "descriptive" writing; they were simply telling stories of their field experiences along with a description of their personal feelings about the experience. One student was "sad" when a girl called another girl "an ugly rag." Another student wondered how she would deal with the math class she observed where half of the students were absent due to suspensions. Another student reported her shock over two students making calls on their cell phones in the middle of class.
As students read each other's messages, they began to jointly pose alternative interpretations for what they were seeing. One student described an eighth grade class where the students seem to have no interest in what is going on and concludes: "It is too early to tell whether or not it is the lack of classroom management or if it is the students." Another student contrasted that class to a situation in an eighth grade computer class where the students are very social: "I am not sure whether this is a sign of immaturity or simply a higher interest in and curiosity for the subject matter." In reply, another student working with eighth graders suggested that their behavior can be explained "because they rule the school and bring an attitude into the classroom." Still another student argued that it's hard to separate seventh and eighth grade behavior: "I think it just may be the luck of the draw."

During the first five weeks of the semester, only four students reached what Hatton and Smith would call "dialogic reflection." One student puzzled over a half-empty algebra class due to the fact that many of the students are tutoring in a nearby grade school. She weighed the pros and cons of their absence: they need to learn math, but tutoring "helps the students' self-esteem and confidence. They think they are making a difference." Another student told the story of coming to a computer lab where students were supposed to be typing up final drafts of a one page writing assignment that they had been working on for three days. He noticed that many students were just beginning their paper and pondered a number of possible explanations: poor classroom management, low student motivation, uninteresting curriculum. Later in the semester, however, about half of the students moved into this "dialogic reflection." Their messages demonstrated "a stepping back from the events... a "mulling about, [a] discourse with self" (Hatton & Smith, 1995, pp. 48) about alternative explanations and analyses of situations.

Only on three occasions in the semester, however, did individual students approach a level of critical reflection where they were considering events or problems "located in and influenced by ... historical and socio-political contexts" (Hatton & Smith, 1995, p. 49). For example, one student told a story about a student who was caught with drugs and expelled. The student was an honor student and this was a first offense. She questioned a school system that throws kids out when they make a mistake: "Isn't school the place where students should get a second chance? Schools are there to help kids learn from their mistakes and to help them to succeed." Another student agrees, making reference to the historically poor treatment of children by American institutions, and continues the conversation at a critical level: "Children definitely deserve second chances but many of the institutions for remediation don't provide a helpful support system for change.... What becomes of problem children? It really makes me wonder when the school system simply dismisses a 'problem' child rather than addresses the underlying issues behind the events leading to expulsion.... children need to be treated differently than hardened adult criminals.

Level of Support for Critical Reflection

The students' move to dialogic reflection in the e-mail discussion in the middle of the semester came after a series of dramatic stories: the student who asked for help in reading but who got into a gang fight and was expelled; the girl who bit part of a boy's thumb off after he bit her in the breast; the boy who was called a "wimp" by a classmate after he had gotten roughed up in the bathroom. Then one student raised the question of whether she was capable of effectively teaching children with backgrounds so different from her own and particularly whether she could effectively teach African American children. That e-mail message led to a two week debate on the subject of cultural competence in teaching. These excerpts are representative:

I agree that white teachers will never have the same experiences as their black students. The same goes for black teachers and their white students. Still, this issue is entirely irrelevant. Because I am white, does this mean that I can relate better to the experiences of all white students? No! For most of my life, I've lived in an affluent...suburb inhabited for the most part by white Jewish families. With this background, I don't see how my 'whiteness' would aid me in teaching poor white students in a Kentucky mining town.
or wealthy, spoiled white Hollywood students....

I know we come from different backgrounds but that does not mean that I cannot learn from them and they learn from me. I know that growing up in an all white community has made it hard for me sometimes to relate to the students in the city schools, but I know that with experience and hard work I can be a good white teacher to my Black, Korean, Chinese, Native American and Japanese students.

If a black teacher who was raised in an urban environment came into a central city school he/she would in some ways have an easier time adjusting to the environment there than I would. However, just because something is difficult does not mean it is impossible. I think that Mr. [who is white] has great relationships with his students. On the other hand, there is a middle aged African American man... [who] just screams... at the students.

I realize I have a lot to learn about the environment that the children come from because their background is different from my own... However, I do not see the difference between this and trying to reach any classroom of white students. I will have to take the time to get to know each one as an individual. I believe that I can teach any child who wants to learn.

In this extended discussion students were jointly presenting multiple perspectives on the issue of cultural conflict and competence in the classroom. The discussion generated a variety of beliefs and assumptions about good teaching, culture, and student-teacher relationships. On e-mail students seemed less inhibited than in class to challenge each other's beliefs and assumptions. But the students were doing little to question or critique their own assumptions about these topics. They drew largely from their joint personal experiences to support previously held positions. Nowhere in this thread of the e-mail discussion did students draw from the variety of critical frameworks (e.g. Anyon, 1981; Delpit, 1995; Noddings, 1994) we read in class to suggest alternative ways of looking at issues or to consider issues within larger socio-political and ethical frameworks. Furthermore, in the final surveys about the e-mail discussions, only three mentioned "reflection" or the opportunity "to think more fully" as a benefit. More typically, students cited the opportunity to "hear what other students were doing in their classrooms," get advice, and realize that others were having similar experiences.

Looking at the transcript of my e-mail messages to the students, I can see that on e-mail I was less active as a critical teacher than I was in class. I did not model critical pedagogy. I did not pose critical questions which could have disrupted usual ways of thinking about teaching, learning, and the unjust ideologies and values perpetuated by schools and other societal institutions. Instead, my e-mail messages were typically about directions, assignment procedures, and reminders. Consequently, I missed opportunities to guide the student discussion to a critical level. For example, at one point two students reported on a lesson they had tried to teach on the importance of police officers. They expressed their shock that their class of predominantly African American students did not share their own value of the police. Despite my students' efforts to get their students to say something positive about the police, most refused; only the white student in the class was willing to write a positive comment and then she made sure that no one else could read her paper. Instead of remaining silent, I should have posed questions here to help students critique the incident beyond their personal frameworks: Why were student perceptions of the police so divided along racial lines? Why do some people feel alienated from the police? Would Ogbu's (1983) theory of "involuntary immigrant" or Delpit's (1995) discussion of "cultural conflict" help make sense of this situation?

**Discussion**

The transcript of the conversation and the student surveys suggest that the way that I structured the e-mail assignment with focus on field work experiences and freedom to select topics encouraged students to hear and voice diverse views on a variety of subjects. This exposure to multiple viewpoints and questions from
peers seemed to move many students from descriptive reporting to a higher level of "dialogic" reflection. E-mail made it possible for students to take the time to reflect on hard questions, say what they wouldn't say in class, and consider multiple ways of coping in what one student called "an unpredictable world." This study suggests, however, that to move to a consistent level of critical reflection about their field experiences, more structural supports in the e-mail activity would be needed. First of all, both the object and goal of critical reflection must be much clearer to students. Secondly, students must have a much clearer understanding that critical reflection requires using multiple perspectives, including socio-political and moral frameworks to identify and question their own beliefs and assumptions about teaching, learning, and problems in schools. Finally, students need more models of how to identify and question their assumptions and how to utilize socio-political and moral frameworks to do so.

In the future I can see that if I want to support critical reflection on e-mail, I will need to:

1) Help students identify problems and issues that emerge from their field experiences. Instead of keeping the discussions completely open-ended, I should pose critical questions for debate and ask students to utilize particular social, political, cultural and/or moral frameworks for analysis and support. For example, from the inevitable nightmare classroom management stories that often emerge in such discussions, students could be asked to evaluate their school's suspension policy from the vantage point of Noddings' (1994) ethical caring or Anyon's (1980) "hidden curriculum."

2) Clarify expectations for critical reflection. A rubric that defines precisely what students must do in their e-mail entries could be helpful.

3) Take a more active role as facilitator in the e-mail discussions. I need to model how my experience "can illuminate and enhance our understanding of academic material" (hooks, 1994, p. 21). At the same time, I need to model how class readings can inform critical interpretations of field experiences and pedagogy. This could be done on e-mail much in the way that Dillard (1996) writes journals with her students. She uses her journal entries as places where she can "re-introduce topics, dilemmas, and questions which arise in their collective journals" and "place them back into the classroom context for critical examination from students' multiple perspectives" (Dillard, 1996, p. 14).

4) Integrate the e-mail conversations with what goes on in our face-to-face meetings. One idea would be to consider the transcript of the ongoing e-mail conversation as a class text. Periodically my students or I could prepare summaries of the e-mail discussions that include selected excerpts from them. These summaries could become the basis for face-to-face class discussions.

5) Continually monitor and support the joint negotiation of meaning that goes on in these discussions. Many students need individual support on e-mail, especially students who are struggling with critical issues, students who assume leadership roles in the discussion, students who are ignored and students who are silent. I must take greater care to insure that all have equal and ample opportunity to participate and critically reflect on their experiences.

Abstract: This study was designed to determine the effects of online mentoring on the professional growth and development of preservice teachers and their mentors. These web and email based interactions provided assistance and support to the preservice teaching experience and validated the importance of both effective mentoring and effective use of technology in teacher education programs. Mentors and their assigned preservice teachers reflected positive growth from this program. The implementation of this online mentoring model emphasizes the need for both practice and continued professional support of preservice teachers.
Theoretical Framework

Mentoring is the passing of advice and knowledge from a respected, experienced person to a less experienced one. Glickman, Gordon, and Ross-Gordon (1998) identify the mentoring experience as effective among alternative professional development formats. They describe the process as one in which an experienced teacher is assigned to a novice for the purpose of providing individualized, ongoing professional support. Selected criteria for the mentor should include years of experience in the school system, effective teaching performance, interpersonal skills, past commitment to the profession, flexibility, and willingness to spend time helping beginning teachers. The National Commission on Teaching and American’s Future recommends that teachers continue to teach while taking on other roles that allow them to share their knowledge and promote continued skill development related to clear standards (Wise, 1996). Practice is moving toward teaching as collegial-characterized by sharing, working in teams, observing peers, and studying with colleagues. The intellectual, social, physical, and psychological challenges that preservice teachers face require the understanding, skills, and insights which may be provided by effective mentoring (Hawley, 1997).

Too often in schools, teachers are isolated from one another so that they cannot share knowledge or take responsibility for overall student learning (Wise, 1996). Teacher preparation has traditionally encouraged preservice teachers to work alone in an environment that rewards autonomy. With few exceptions, most assignments are individual efforts (Holland, Clift, Veal, Johnson & McCarthy, 1992). Mentoring programs may help teachers with the transition from their formal schooling to teaching, providing a bridge between theory and practice (Morrison, 1997). Through mentoring the preservice teacher may incorporate a more collaborative way of thinking into their professional work.

As educational leaders engage in practices that are directed toward improving teaching and learning, the use of technology must be included. Integrating technology into educational coursework for preservice teachers is important (Stuhlmann, 1998) and can become a real catalyst for change (Drzadowski, Holodick, & Scappaticci, 1998). Electronic dialogues in preservice teacher programs have provided ongoing opportunities for declarative and procedural knowledge to be discussed and examined. Communities of practice have created forums for problem solving and lessened the isolation of teachers (Greene & Zimmerman, 1996). Preservice teachers have been studied using technology for social and emotional support (Thomas, Clift, & Sugimoto, 1996) and for general exchange of ideas (Schlagel, Trathen, & Blanton, 1996).

This online mentoring program will integrate technology with mentoring preservice teachers providing valuable support in order to facilitate professional development and the community of practice. Technology can ameliorate time, distance, and isolation barriers and establish a connection between preservice teachers and their mentors. Institutions including the University of Massachusetts Lowell have set up mentoring programs using computer-based communications such as “Teacher Helping Teachers” and “Teacher Talk.” Limited studies have explored the potential of this telementoring application (Agresto, 1989; Ruopp, 1993). Telementoring has been defined as the use of e-mail or computer conferencing systems to support a mentoring relationship when a face-to-face relationship would be impractical (O’Neill, Wagner, & Gomez, 1996). Reflecting, sharing, and growing together will enable all participants to establish a vital learning community via technology.

Purpose

This study was designed to determine the effects of online mentoring on the professional growth and development of preservice teachers and their mentors. These web and email based interactions provided assistance and support to the preservice teaching experience and validated the importance of both effective mentoring and effective use of technology in teacher education programs.
**Methodology**

**Setting**

The setting for this study was a rural area of western North Carolina. The preservice teachers were completing an internship prior to beginning student teaching. The doctoral students were in their second year at a local university.

**Participants**

The participants in this study were 1) seventeen preservice elementary teachers completing an internship followed by student teaching, 2) five doctoral students who functioned as mentors, and 3) the university supervisor of the preservice teachers.

**Procedures**

Each online mentor maintained a reflective journal sent to a listserv, which was used as an initial resource for the online experience. Each mentor communicated with their designated preservice teachers at least once a week through a web page consisting of two web boards and email links to specific faculty members and the mentors. The regular communication between the online mentor and the preservice teacher was in response to the preservice teachers’ regular communication with their preservice teachers, the mentors responded to others when their expertise was requested. Communication between the designated mentors and the preservice teachers was shared outside of their one-on-one relationships only with the consent of the preservice teachers. Trustworthiness and authenticity were thus assured (Lincoln & Guba, 1985; Erlandson, Harris, Skipper, & Allen, 1993).

Since the researchers specified neither the main variables nor a specific research hypothesis before data collection began, the process toward the discovery was, therefore, inductive. Grounded theory procedures (Glaser & Strauss, 1967; Strauss & Corbin, 1990) which call for findings grounded in specific contexts and in real world patterns (Patton, 1990) were used to identify emergent categories from the data. Data included the listserv, web boards, and email messages. All electronic correspondence was compiled and coded. Pre and post attitude surveys about mentoring were completed and reviewed.

**Results**

**Pre Post Surveys**

Answers to the pre and post surveys about mentoring were very similar on questions of mentor definitions and programs. On the pre surveys, preservice teachers expressed the common theme of anticipation of gaining knowledge from an experienced individual. This anticipation shifted from knowledge to more practical answers such as needing help for goals, problems, advice, and even reciprocal teaching on the post surveys. Comments such as, “I will take my mentor’s suggestions and comments and apply them to my classroom”, “Mentoring opens your mind to other points of view in education, which is never a bad thing”, and “I will definitely try to find a mentor when I begin teaching” were written on the post surveys by the majority of students. One preservice teacher wrote that the mentor seemed to be a burden and that her cooperating teacher gave better, immediate feedback. Two wrote that the mentoring program was a good idea, but emailing mentors seemed like an extra task on top of an already hectic schedule. One preservice teacher suggested that the mentors’ identity should not be secret. She wanted to meet her mentor face-to-face and have a better idea of who she was receiving advice from.

**Email Messages**

Thirty email messages were sent to mentors from preservice teachers within a six-week period. Written interactions between mentors and preservice teachers covered many topics and ranged from positive
Email messages to mentors from preservice teachers had one of three common themes. First, there were discussions of communication. Preservice teachers observed the lack of communication from students to teachers. Teachers were speaking to students but there was a question of whether or not they were listening to their students. An inability on the part of the preservice teacher to express his/her opinions to the cooperating teacher was repeatedly discussed. A preservice teacher wrote, "My cooperating teacher has made it really hard for me to know what her expectations are...on Monday morning my teacher really made me feel like I was a burden to her by some of the comments she made..." A final topic in communication emerged as preservice teachers showed their inability to carry out their role of teacher outside of the traditional classroom. When preservice teachers were approached by students in settings such as the cafeteria, hall, and playground, they discussed the problems of answering questions as a teacher. A student mentioned that he thought the preservice teacher wanted gum to kiss her boyfriend. The preservice teacher was so stunned she could not respond. She wrote her mentor that she was "dumbfounded".

Second, preservice teachers expressed their concern about observing and not participating within their classrooms. As preservice teachers began critically observing and participating in their classrooms, judgements began to be made about incidences in reflections and there was a clear desire to move from observer to participant. As one preservice teacher wrote, "Like any other work, (my teacher) shows them exactly how to do the artwork. In the words of the immortal 'Anne of Green Gables', she doesn't leave any scope for imagination. I do not agree with this." The preservice teacher reflects the desire to move into the participant role by asking her mentor, "How can I encourage the students to be creative without undermining my teacher's authority?" Some preservice teachers revealed a hesitation to move from observer to participant. After learning that her cooperating teacher would be absent all week, she wrote, "I'm basically in charge and I have to teach all week. I'm looking forward to this but of course I'm scared to death. The only real teaching I've done in class thus far has been on an individual basis."

The last theme was one of conflict of values and philosophical differences. Through all of these observations and comments regarding what the teacher is doing and their participation in that activity, they critically question their core beliefs and philosophical underpinnings. Questioning which leads to reinforcement of core beliefs is evident in the following email message. "I have had five children in two weeks who have had to sit on their towels on the floor for punishment, not allowed to move for more than two hours. I felt so bad for them. If the rest of the class is in the adjoining classroom for activity, my teacher wants to be in that classroom as well. She yells for the naughty to come to that room, and generally makes an embarrassing scene for the wiggles in front of two classes. I hate that. I don't believe in non-constructive reinforcement. Many of the reflections showed the reinforcement of the core beliefs held by these preservice teachers. However, an equal number of reflections indicate a wavering of core beliefs. The following email message illustrates the self doubting of beliefs that many of these preservice teachers are experiencing. "I want to know how you feel about this situation. Am I overreacting with the 'student teacher thinks the teacher is the bad guy' syndrome or am I seeing something that could be a problem?"

Based on the data gathered from the emails and the data gleaned from the pre and post surveys, mentoring was a positive experience for most of the preservice teachers. It appears to have provided a forum where preservice teacher actively reflected upon their experiences and their reactions to these experiences. Most found the experience moved from the abstract view where mentors should provide great knowledge to the more applicable use of mentors to provide practical support regarding pedagogy, discipline, communication skills, encouragement and support. All participants felt a degree of satisfaction from the mentoring program.

Implications for Further Research and Study

This online mentoring program provides a multitude of opportunities for the professional growth and development of preservice teachers and persons involved in educational leadership alike and has implications for both that go far beyond the scope of this particular study. The emergent categories include:
the various divergent and integrated uses of technology, the importance of the reciprocal nature of the mentor/mentee relationships, and the breaking through of the traditional boundaries that exist between preservice teachers and educational leaders.

With the protected anonymity and the easy access through Web-board and subsequent email communications, the students engaged in regular discourse with their mentors which enabled networking among all participants thereby reducing isolation and increasing academic support. The structured dialogue that was designed for the online discourse provided a vehicle for honest and open inquiry and for practical problem amelioration. This practice lends itself to efficiently addressing the issues and the concerns confronting the novice practitioner. In addition to providing a means for preservice teachers to access additional support and assistance beyond the domain of their classroom environment, the absence of judgement and critique and subsequent consequences allowed for a freedom of exchange that may not have otherwise existed. The combination of these facets suggests that online mentoring can offer unique opportunities not otherwise available to preservice teachers and their online mentors.

The reciprocal nature of the mentor/mentee relationship experienced on-line provided the opportunity for professional development for all participants. This unique experience promotes collegial respect, accountability, responsibility, and support, insuring the nurturing and continued development of educators and educational leaders. The emergent communication themes and the types of issues addressed in this project indicate a need for further investigation into possible uses of electronic dialogue.

Dismantling traditional barriers that divide preservice teachers, regular faculty, administrators, and other educational leaders is a formidable obstacle. However, this project proves that this goal is feasible. The expanded community of practice that is nurtured as a result of trustworthiness and authenticity reaches beyond the theoretical into the practical applications of support and professional growth for both the mentor and mentee.

TELECOMMUNICATIONS - SYSTEMS & SERVICE
The Freeware Solution: Running an EdTech Intranet/Internet Web Server for Free

David C. Byrum, Ph.D.
Southwest Texas State University, Dept. of Curriculum and Instruction
San Marcos, TX 78666 Tel:(512) 245 2038 E-mail: db15@swt.edu

Abstract: If you feel cost is a factor that keeps you from setting up your own internet/intranet web server, there are many free software programs for the Macintosh to allow you to start with little or no money. This paper will discuss uses for, gives names and web address, and describe these freeware tools for web serving, conferencing, Ftp, e-mail, form processing, web statistics, and listservs. Also a large number of sites with free resources for webmasters will be given.

Introduction

Do you really need a web server? The answer is yes! I decided about two years ago that a web server was essential for our Educational Technology lab. With a web server you can set up an internet/intranet web site which can:

• Disseminate information about the lab and classes- We post hours, scheduled closings, systems available, new education web sites, syllabus, and assignments.
• Provide instructional guides - Guides can cover ways to search the web, lesson plans, and other general or technological information.
• Create online assignments - Many of our assignments are on the web site, which uses forms to collect the information, and we have virtually eliminated paper.
• Enhance web instruction - I teach several courses in web page design and by having our own server I can show students how to upload pages, give practice in maintaining a web site, and setting up a server.

So maybe I’ve convinced you that you need a web site, but if your department is like mine, we are on a very tight budget. Every day we have to make choices about the technology we can afford and which is essential. Do you have to give up your goal of a low cost web server? Not if you use free software! This article will describe a web server set up for the Educational Technology lab using almost all free software.

The Freeware Solution

Freeware, software that is either in the public domain or offered free by the authors, is the low cost solution to setting up a server. All of the software, with several very low-cost exceptions, is free and requires only an e-mail or postcard to let the author know you are using the program. I am currently using an old Macintosh Performa 6300 running almost all freeware to host about 25 web sites as well as the Educational Technology web site. We have received over 1,000 hits per day (the EdTech web pages alone receive about 10,000 hits per semester) and have had no server problems except occasionally losing power. In addition to a web server I have also set up a mail server to handle the labs assignments.

Several notes before we begin. All of the software described in the article is for the Macintosh platform. I’m sure with a little bit of searching you can probably find the equivalent programs for the windows platform. I would suggest however, to find an old Macintosh which you may have on campus or in your department and put it to good use.

Second, at the time that this article was written all version numbers and web address were correct but as you know in the web world everything is subject to change. A good place to check for the latest
versions is at VersionTracker <http://www.versiontracker.com>. I would now like to discuss what is available as freeware for web servers, e-mail servers, forms, listservs, and forums or conferences.

**Web Server software**

To serve web pages as well as pdf, jpgs, and binhexed files, there are four very good professional options for free. The four are *Quid Pro Quo, Apple Personal Web Sharing, Microsoft Personal Web Server*, and *Net Presenz*.

*Quid Pro Quo* 2.1.2 <http://www.socialeng.com/html/download.html> is a scaled down no-frills version of their commercial product. This free version however works great for me and has been trouble free for over 1 year. It like the other supports plugins and CGI’s written for the Starnine web server. Overall the best and most powerful choice to work with the other programs I’ll describe later.

*Apple Personal Web Sharing* (comes free with System 8.0 and above) is a good server if you don’t have a lot of web page or hits and can run in the background if you don’t want to dedicate a computer just to serving web pages.

*Microsoft Personal Web Server* <http://www.microsoft.com/mac/ie/> is part of the full download of Internet Explorer 4.01. This used to be a commercial product before Microsoft bought it to include free with IE. Has an excellent online help files included.

*Net Presenz* 4.1 <http://www.stairways.com/netpresenz/> serves web page as well as being an ftp and gopher server. Very simple and straightforward but not as many features as the other server software. The software is shareware and costs $10.

**Forms processing**

There are two main ways forms can be handled, as either e-mail or database. As an e-mail, the form information is turned into an e-mail and delivered to the selected person. As a database, the info from the form is placed into a database set up by the webmaster which can be accessed or searched by other users. Good for linking forms to software database, student information or other collected information.

In our lab we use the e-mail version to turn assignments forms into e-mail. I have set up forms for written assignments, CD-ROM reviews, Web site reviews, software lists, and signups for workshops.

*Forms.acgi* <http://www.finci.net/help/form.html> is easy to set up and use and sends form information from the fields you create on a web page to whatever e-mail address you specify.

*Lassolite* 1.2.3 <ftp://ftp.blueworld.com/Unsupported/LassoLite/> is free version of the commercial product Lasso which works with older versions of FileMaker Pro 3.

*FileMaker Pro* 4.xx <http://www.Filemaker.com> now has web database publishing features built in so webmasters can build forms to work with the database without any additional add-ons.

**E-mail servers**

E-mail servers allow you to set up your own e-mail system independent of the university you are located. I found this to be needed because many of the e-mails from the forms were taking several hours to make it to the e-mail address of the lab assistants. With my own e-mail server, the information is received immediately and reliably. More importantly, you set up listservs which will be discussed in the next section.

*Eudora Internet Mail Server* 1.3.1 <http://www.eudora.com/free/servers.html> was formerly Apple Internet Mail Server (AIMS). This is the free version of the Eudora mail server and easy to set up and use and supports all commons mail formats. I have used this software and received about 5,000 messages without any problems. A quick tutorial called “Instructions for setting up EIMS in about 5 minutes” is at:

<http://web66.coled.umn.edu/Cookbook/Mailshare/Mailshare.html>

*Stalker Internet Mail Server* 1.7 <http://www.stalker.com/SIMS/> is another free e-mail server which works extremely well. This program is updated more frequently than EIMS and is the free version of a more heavy duty commercial product.
**Listservs**

Listservs can allow you to set up discussion groups using the E-mail servers given above. As webmaster you can set up a listserv and users need only send a subscribe message to be part of the listserv. When messages are sent to the listserv, all users, which have signed up also, receive the message as e-mail. Listservs could be used in a lab setting to discuss technology assignments, articles on technology or assigned readings, or for students looking for technical help.

*AutoShare 3.0.2* [<http://www.dnai.com/~meh/autoshare/>] is the best listserv program in the freeware realm. The author’s instructions explicitly tell you how to set up AutoShare with EIMS described above. Another tutorial on setting up AutoShare can be found at “Providing Internet Service via the Mac OS” [<http://www.pism.com/chapt05/>]

**Conferencing**

Conferencing or forum type software allows users to participate in discussions or forums on the web. The user may select a topic, read the responses, and then respond so that others may see their response. The user may choose to start a completely new thread or topic to discuss and in turn let others respond.

*ConferWeb 2.0* [<www.caup.washington.edu/software/conferweb/>] is an excellent freeware that only asks you to send a post card to the author so he may list your web site. *ConferWeb* allows all of the features above as well as remote login so the webmaster can deleted threads or messages by using a password.

**FTP**

*NetPresenz 4.1* [<http://www.stairways.com/netpresenz/>] is one of the few programs in this paper which is not free but its low cost of $10 is definitely worth the money. *NetPresenz* allows the webmaster to set up the server not only to serve web pages but also to be an FTP server. This is extremely useful if you have a large file or program you want someone to download because you can set up links on your web page to ftp the file to the user.

Another use for using an ftp program is the ability to upload web pages to the server. In a real life situation, most people use an ftp program to upload their web site to a remote server. Students in my web class also learn to upload to my server by using any ftp program such as Fetch, Anarchie, or Cuteftp. The webmaster sets up a public folder by merely turning on Filesharing and designating users and passwords. *NetPresenz* uses these settings to give access to the folders for web page uploading.

**Web Page Statistics**

For many people, just knowing how many people visited their server is not enough. If you are in this category, there are numerous free web page statistics web sites for you to choose from. Many of these sites will keep statistics such as number of hits, from where, what time of day, and about 20 other categories. A good listing of free statistics sites can be found at *<http://www.markwelch.com/bannerad/baf_counter.htm>*. This site lists around 50 free web counter services. There are also web counter programs that you can run on your server, but it is usually better to use an outside server counter so your server won’t be tied up keeping web page counts.

Most of the free server software programs such as *Quid Pro Quo* keep a log of all users, pages viewed, location, time, and other stats. A freeware program called *Analog 3.1* [<http://www.summary.net/soft/analog.html>] can take your server log files and compile a dizzying array of statistics for you. Not only does it compile the statistics it publishes them as a web page. Check out the *Analog 3.1* web site to see an example.
Other Essentials

There are two other programs that are shareware and cost around $22 but can help you keep your web server up and running with little attention. These are Keep It Up and AutoBoot. <http://www.vl-brabant.be/mac/>

AutoBoot is a control panel extension which will restart your Mac server after a system error or freeze up has occurred. The program will wait several minutes and then restart itself if no action takes place. Keep It Up can relaunch selected applications should a freezeup or error occur. It also allows you to remotely manage the Mac server through using a web browser. Great for restarting many of the programs discussed in this paper from a remote location.

Lots of Free Resources

If you don’t want to have your own server but still want some free web space check out some of the following free web page posting resources:
<http://www.evandelay.com/freeinternet/fhomepgs.htm>
<http://freebyte.com/freeservices/FreeHomepages.html>
Free information and resources for webmasters:
Free Index <http://www.Freeindex.com>
Professional Web Design <http://junior.apk.net/---jbarta/weblinks/index.html>
Mikes Web Resources <http://www.websiteresources.net/dir1/>
Web Wizards <http://www.cyberhighway.net/~lzc/webwiz/>
Web Master Resources <http://www.webmaster-resources.com>
The best site for lots of free resources such as javascript, CGI’s, software, guestbooks, counters, and other free resources for web servers:
Free Internet <http://www.evandelay.com/freeinternet/>
A good online book (published on the web for free) from Addison-Wesley Developers Press titled “Providing Internet Services via the Mac OS” can be found at:

Final Note

All of the many links I’ve given in this paper can be found at my web site: <http://Edtech.ci.swt.edu/SITE/index.htm>. In addition to saving yourself a lot of tedious typing I’ll also try to make sure the URL’s are current.

All programs in this paper are copyrighted by their respective authors and both reserve and maintain that copyright.
Abstract: This paper reports on the technological aspects of Project Explorer, a Professional Development Project that encouraged a collaborative effort among preservice teachers, inservice teachers and university faculty. It explains the procedures and processes we developed for Internet publishing of large numbers of curricular materials developed by the Project Explorer participants. Further, it offers suggestions to others wishing to publish curricular materials on the Internet.

Introduction

Thirty-two preservice and inservice elementary school teachers participated in Project Explorer, a two-week Professional Development Workshop focusing on the use of technology in mathematics and science instruction. Participants were organized into grade-level teams consisting of both preservice and inservice teachers. Six university faculty members, in conjunction with subject-area specialists, planned and implemented Project Explorer, which took place in an elementary school in close proximity to the university. A constructivist stance that encouraged active participation and personal knowledge generation guided the project. For a more detailed description of project, go to <http://coe.west.asu.edu/lexplorer/intro.html>, the Project Explorer Introduction.

The ten-day project was organized in five two-day cycles:

- Day One focused on concept development, communication about concepts among team members, and reflection in order to analyze and synthesize learning.
- Day Two focused on expanding concepts learned or developed during Day One by creating curricular materials appropriate for students at each team's grade level.

This organization - which featured active learning (Day One) and sheltered work time (Day Two) - promoted opportunities for participants to both learn new processes and concepts as well as adapt them to their particular content area and grade level. During the sheltered work time of Day Two, participants had opportunities to create curricular materials that were later published on the Internet. From the onset of the project, participants knew that the curricular materials that they developed would be placed on the Project Explorer website.

University faculty members modeled both teaching strategies and a variety of curricular materials for the participants. Model activities and resources were intended for the participants' consideration and modification to meet the specific learning needs of their students. Faculty-developed curricular materials were placed on the Project Explorer (http://coe.west.asu.edu/explored) website as well as distributed in paper format to participants. Participants could view the Professional Development Resources on seeds to see many different
resources developed by university faculty. Professional Development Resources were also available on shapes, flight, weather and garbology. This site also provided links to national and state standards in mathematics and science. Participants' curricular materials are available on seeds, shapes, flight, weather and garbology. adjacent to the faculty-developed curricular materials.

Our major goal in developing the Project Explorer website was to provide participants a venue for sharing their work with a wide audience. By using the Internet, this goal was easily realized. Our other goals included providing:

- pedagogically sound models for the workshop participants
- opportunities for sharing among participants
- opportunities for sharing among other educators throughout the country

With these goals in mind, we developed the Project Explorer Website, as described in the following section of the paper.

Meeting Super Science Site Criteria

When we began building our Project Explorer website, we hoped for wide readership. To accomplish this objective, we decided to submit our site to Science NetLinks, (http://ehrweb.aaas.org/scinetlinks/) an American Association for the Advancement of Science (AAAS) site that endorses certain sites as Super Science Sites. (Although our workshop focused on math and science and we chose to submit our site to Super Science Sites, our model of a workshop and website is appropriate in any content area or at any level of education.) As we designed and built our website, we were cognizant of the major criteria specified by AAAS in their Science NetLinks. By working to meet these criteria, we not only created a better website, but we also assured ourselves of a wider readership. Our understandings and syntheses of these criteria are summarized in the table below:

<table>
<thead>
<tr>
<th>Content Criteria</th>
</tr>
</thead>
<tbody>
<tr>
<td>Does the site contain credible content from credible sources?</td>
</tr>
<tr>
<td>Is the site informed by the National Science Standards and the mission of the AAAS</td>
</tr>
<tr>
<td>Is the site a useful resource for science educators?</td>
</tr>
<tr>
<td>Does the site represent science as an enterprise connected to society?</td>
</tr>
<tr>
<td>Does the site material site contribute to the development of scientific reasoning</td>
</tr>
<tr>
<td>and problem solving?</td>
</tr>
<tr>
<td>Is the site free of bias?</td>
</tr>
<tr>
<td>Is the material appropriate for its intended audience?</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Technical Quality Criteria</th>
</tr>
</thead>
<tbody>
<tr>
<td>Is the site easy to read with clearly labeled working links?</td>
</tr>
<tr>
<td>Do the pages load quickly and display correctly?</td>
</tr>
<tr>
<td>Does the site invite feedback and provide email addresses?</td>
</tr>
<tr>
<td>Is the connection fast and reliable?</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Format and Design Criteria</th>
</tr>
</thead>
<tbody>
<tr>
<td>Are the graphics relevant to content?</td>
</tr>
<tr>
<td>Is the design clean and uncluttered?</td>
</tr>
<tr>
<td>Does the site include dates of publication and current updates?</td>
</tr>
<tr>
<td>Is the site free of errors in spelling, punctuation and grammar?</td>
</tr>
<tr>
<td>Does the site use color and graphics creatively and attractively?</td>
</tr>
</tbody>
</table>
Ease of Navigation Criteria

- Does the site have a searchable index?
- Is the site well organized with easy navigation tools?
- Do consistent graphics and page structure aid in navigation?

What We Learned about Website Publishing from *Project Explorer*

Process of Collection

The primary goal of this process was to emphasize that content was more important than format. Therefore, we chose to encourage participants to use whichever technology tools were available and familiar to them as they created their curricular materials. Although this approach made the technical construction of the website difficult, the quality and quantity of materials created by the participants offset this difficulty.

Participants used *KidPix, MicrosoftWord, MicrosoftWorks* or *ClarisWorks* on both Macintosh and PC platforms to create their curricular materials. Realizing that the conversion of these documents into HTML would be a difficult process, we asked participants to save their work in more than one format. At the conclusion of the workshop, all documents were collected in a central place for conversion at a later date.

Process of Conversion

The effort to convert over 350 individual word-processed documents into HTML was under-estimated. The complexity of this task was increased by several factors including:

- multiple file formats (PC vs. Mac, *MicrosoftWord, MicrosoftWorks* and *ClarisWorks*);
- variety and inconsistency of file-naming conventions, fonts and styles;
- difficulty converting some graphics to a web-based format.

Overall, this aspect of our project was arduous, but ultimately enlightening. The practical implications of converting such a large group of inconsistently formatted files were not completely understood. While we made it easy for our participants to generate content, the resulting variations in formatting made the final conversion of more than 350 text and graphics files into HTML tedious and difficult. Our attempt to aid the conversion process by having participants save their work in multiple formats unfortunately just introduced further variations and headaches.

For files with few problems, the typical conversion process involved opening each file with *MicrosoftWord* or *ClarisWorks* and then saving the file in HTML format. Files with more serious problems sometimes required conversion to an intermediary format (usually Rich Text Format or plain text) before conversion to HTML.

Some graphics files had to be saved separately and others had to be re-created from scratch. *MicrosoftPaint, Microsoft Image Composer,* and *ThumbsPlus* applications were all used to accomplish this task.

Although participants were encouraged to use word processors with which they were familiar, they frequently organized columns of data and lists using tabs rather than tables. Neither *MicrosoftWord* nor *ClarisWorks* interprets these constructions as tables so the formatting is completely lost in the HTML conversion. This meant that columns and tables required complete reconstruction in the HTML documents.

Because files had sometimes been organized by content and sometimes by authors, the conversion process also needed to address organizing the files into more appropriate directory structures for placement on the website. Additionally, many files needed to be re-named to eliminate illegal characters or provide more descriptive and/or appropriate names.
Considerations of Type of Server

Initially the Project Explorer website was placed on the university web server. As we developed our site further, however, we needed enhanced capabilities in two areas: searching and interactivity. Specifically, we felt it was important to add a site searching function to make our site more usable, navigable and practical. Secondly, we wanted to customize the interactive capabilities of the site to provide users easy means of feedback. Because the university search engine could not limit its search to the Project Explorer site or support the desired level of interactivity, our team moved our website to the newly acquired College of Education web server.

Our Approach for the Future

It is highly recommended that future projects make strict use of templates that have undergone thorough testing. Templates should include such things as background colors, clipart, images, tables, lists, font and style choices, and other common design elements. Even if the final version of the template doesn't include all these elements, the template should be tested before use by participants. Additionally, the templates should contain site navigation tools, tables, tools that encourage interactivity and other elements that may be part of the final version of the posted page. Word processors which permit the creation of tables should be used. Finally, word processors that allow documents to be saved in HTML should be used.

Another approach to addressing this issue of consistency is the creation of online forms that participants use to post their work. The drawback here is that without a significant investment in initial programming, there would be limited capability for allowing creative expression in the use of graphics, color, and design elements.

Another significant issue is that of directory structures and file-naming conventions. Ideally, participants should have access to a file server with a pre-established directory structure in place; this would facilitate the placing of files in the appropriate locations. If easy access to a server is impractical, participants should place their files on disks and organize them in a manner consistent with the directory structure. Having consistent file naming conventions based on content or authorship will also help ease the task of organizing the hundreds of files in a project such as this. Finally, a special requirement of web publishing is that names of files and directories or folders must not contain spaces or other illegal characters.

Conclusion

The technical aspects of our website publication proved to be quite complex. We have offered what we believe to be useful suggestions to simplify and streamline this process. When future website publication is contemplated, the following issues should be considered:

- criteria for excellence as summarized above;
- the process of collection;
- the process of conversion;
- use of consistent file-naming conventions, fonts and styles;
- server type and capabilities;
- use of templates; and
- on-line posting options.

Acknowledgements

This project was supported in part by a grant from the Arizona Board of Regents Eisenhower Mathematics and Science Education Program.
Abstract: The National Council for the Accreditation of Teacher Education (NCATE) is an accrediting body within the realm of teacher education that has become a driving force within the accreditation arena. The use of technology within this accreditation process has opened the realm of documentation dispersal towards a more workable, user-friendly focus. A primary focus at this point in time is the design and development of a documentation dispersal tool through the use of the World Wide Web. Through out the design and development process, the Web site must be carefully evaluated to ensure the usefulness and ease of navigation for the end user. These considerations are of utmost importance in light of the newly integrated technological aspects within the realm of professional education unit accreditation. NCATE is at the forefront of this push and has made great strides towards the realization of its goals.

Introduction

Professional unit accreditation is a significant event within the realm of teacher education. One organization that has taken upon itself the task of accrediting the professional units is the National Council for the Accreditation of Teacher Education (NCATE). Professional unit accreditation, also described as the schools or colleges that offer the training and real-world experience for preservice and inservice teachers towards teacher certification, is a process that is fraught with documentation. The documentation is a necessary ingredient to allow the accrediting agency the background knowledge and schema to make a knowledgeable decision concerning the professional unit’s accreditation status. This documentation must be available to the team of examiners that visit the professional education unit; the sole task of this team of examiners is to decide whether or not the professional education unit displays the standards delineated to ensure either the initial accreditation or the continuing accreditation of the unit. However, the documentation has historically been offered to the accrediting agencies in paper format, which is not only significant in its size but also cumbersome in its navigational ability.

A primary focus over the past few years, especially in NCATE, is the integration of technology into not only the educational experience of preservice and inservice teachers as well as students in the school systems, but also within the accreditation process. The design and development of World Wide Web (Web) sites specifically to house the documentation necessary for the accreditation process has been recently implemented at several university institutions through out the United States of America, with various levels of success. Looking towards the future, the possibility of online accreditation may be a possibility. At this juncture we are only beginning to scratch the surface concerning the endless possibilities, but the future may hold numerous innovations that will make online accreditation a reality. Without careful consideration through out the design and development process, a Web site may become a useless entity due to the difficulty in navigating the information. The navigation of the Web site is important to the end user’s ease of use. The design and development of a Web site is of utmost importance to the end user’s ease of use.
Design

The design of the Web site is of primary importance to the product. Without a clearly defined structure, the Web site will slowly develop into a difficult entity that will finally become too difficult to use by the primary audience. At this point in time, the persons that will be visiting the professional education unit will not necessarily have extensive technological skills unless specifically requested by the professional education institution under consideration. However, even though the professional education unit requested technologically proficient team members, the possibility is always uncertain as to whether the team members with technological proficiency will be available. Due to this possible difficulty, the Web site must be as simplistic and navigable as possible. Although this may not be a future concern, this is a definite consideration at this juncture in the developmental process timeline and one that must be taken soberly and thoughtfully contemplated.

Interface

Interface issues are of primary concern to the developing Web site. If the interface is too difficult to intuitively navigate, the end users will be unable to locate documentation of concern, will most likely become frustrated and the Web site will remain an innovative idea but one that was left unused. However, if the interface is intuitive and one which offers direction to the end users, the option to use the Web site versus the option to scrutinize hard copy documentation will most likely lead to the Web site usage. An added benefit to the Web site usage is the ability to link similar subject area documentation together; this option would not be available to the end users if using the hard copy versions of the documentation. The strongest argument concerning the usage of the Web to present documentation to the end users is the ability of the Web to present documentation in a linked fashion, which would theoretically aid the end users in their quest for information.

Home Page

The first page of the Web site, the home page, is the starting point to the rest of the documentation site. This first page must present an introductory schema for the end users so that the end users may go directly to their specific area of importance. As is clearly articulated by NCATE, each of the Board of Examiner (BOE) team members are specifically focused upon one specific standard during the professional education unit site visit. In this way, each BOE member gains knowledge pertaining to their specified standard and can critically delineate the reasoning behind either the strengths or weakness cited in the BOE Report that is presented to NCATE. Therefore, the home page is the first interaction between BOE team members and the professional education unit and must present a simplistic yet thorough persona to the BOE team members.

Template

The template is the next point of importance to the Web site. The template is the Web page structure once the end users pass the home page. The template must not only be easy to read and the navigation structure is defined, but it also must be clearly articulated as to the information available to the end user and structured in such a way that the information is linked and apparent to the end user. If the template structure is not carefully considered before beginning the development of the Web site, the usefulness of the Web site will be lessened or lost.

One consideration that was specified during a formative Web site feedback session was the inclusion of a specified area running along the side of the Web site which offered direct links to the areas under discussion in the Web page. More succinctly, the appraiser offering feedback noted the usefulness of allowing for the text on the page to be further useful by offering a table running along side the text with links to areas within the Web site that would further present the information that the end user was reading. In this way, the information would not only be presented on the Web, but would be further linked to information of importance to the BOE team member end user.
Development

The actual hands-on development of the Web site was not necessarily time consuming; the consumption of time mainly surrounded the thought processes and planning that went into the Web site home page, Web site page template, integration of documentation and cross-referencing of information. Once the planning, discussion, further planning and further discussion was underway, the hands-on development of the Web site actually amounted to very little time. The ease of the Web site development software, Microsoft FrontPage 98 (Microsoft 1997) offered very little HyperText Markup Language (HTML) scripting needs to the developer and offered numerous instances of simplistic request implementation. Through the use of this software, the developer had more time available to plan and discuss Web site issues concerning design, interface and navigation ability.

Navigation

The navigation of the Web site was the most difficult section of the Web site development. This was due to the developer's knowledge level concerning the information to be included; although the developer was familiar with overall proceedings and information, the specifics of the information was lacking within the developer's schema and was required of other members of the professional education unit. The time requirement of others within the professional education unit was a task that was completed in a timely fashion due to the feelings of ownership and desire for the positive representation of the professional education unit on a national scale. The faculty and staff at the professional education unit are to be highly commended for their efforts throughout the design and development process of the Web site.

Conclusion

The issues herein discussed are merely the beginnings of an innovative, useful concept that will prove to be an integral part of the professional education unit accreditation process in the future. The National Council for the Accreditation of Teacher Education (NCATE) is an accreditation agency who will not only remain a leader in the accrediting of professional education units but, more importantly, will remain an accreditation agency that is representative of the professional education units, their needs and desires. NCATE consists of professional educators from every single part of the educational process and represents each area of education to the strongest extent possible.

Abstract: The role of technology in all aspects of life is increasing daily. Because of this cascading growth, it is increasingly becoming an essential instructional and professional tool for teachers and trainers. To meet the needs of educators and trainers, the faculty and staff in the Teachers College at the University of Nebraska developed a Web-based training program to certify pre-service and in-service classroom teachers in instructional technology competence. Beginning in the fall of 1998 a "Certificate of Completion in Educational Technology" training program was begun. This certification program will verify that teachers are skilled in using technology to support their teaching and training. The design of the activities in this program is based on the standards recommended by the International Society for Technology in Education for a Foundation in Technology for All Teachers.

In Nebraska 96 percent of the state's larger K-12 school districts have access to the Internet, and Nebraska ranks second nationally in student-to-computer ratio with 13 students per computer. The state's Department of Education has begun to emphasize the training of teachers, and pre-service students, to use this technology in meaningful ways within their schools and classrooms. In fact, many teachers already have taken advantage of the availability of technology to support their teaching and learning, but these teachers require some method by which their computer literacy can be measured and verified. A need existed, then, for teachers and pre-service students to have access to specialized programs and role models to help them develop the competencies necessary for integrating instructional technology into their classrooms, and to receive documentation from an accredited institution that verifies they can demonstrate such competencies.

To meet the needs of educators and trainers, Teachers College formed a development team consisting of three faculty and staff from the College and two K-12 teachers from the Lincoln Public School System. This team designed a Web-based training program to certify pre-service and in-service classroom teachers in instructional technology competence. Beginning in the fall of 1998 a "Certificate of Completion in Educational Technology" training program was begun. This certification program verifies that teachers are skilled in using technology to support their teaching and training. The design of the activities in this program is based on the standards recommended by the International Society for Technology in Education for a Foundation in Technology for All Teachers.

The course design contains eight modules of study and is delivered via the Internet. To qualify for the certificate, the participants must complete all the self-study modules. The following course objectives are emphasized 1) to enhance understanding of the basic communication and productivity tools in educational technology 2) to integrate basic and advanced technology productivity tools into instruction and professional
growth, and 3) to demonstrate competence in the use of computers and other technologies in research, problem solving and product development.

**Guiding Design Principles**

The development of the Technology Competency Certification Program was based on a number of decisions regarding the targeted audience, the focus of the content, delivery options and the performance expectations of the participants.

**Audience:**
- The Technology Certificate Program was designed as a learning opportunity for teachers who were currently employed in K-12 schools.
- Teachers participating in the program have access to equipment, software, and the Internet either through their school or at home. This includes the opportunity for teachers to utilize technology in teaching and learning.
- Teacher time is limited and the training should be flexible to meet the skills and styles of participating teachers. Teachers needs could best be met if learning activities occurred on their schedule and as close to their home and classroom as possible.
- Skill levels vary widely. Some teachers may be novice users who require a structured program to assist them in the process of gaining skills. Other teachers may have considerable skills and need a means to demonstrate expertise. The program should provide resources for both types of participants.
- Very basic computer skills, such as starting the computer and software and managing files, are prerequisites to participation in the program. A large number of teachers possess these skills. If teachers do not yet have these skills, an alternative program with more face-to-face contact probably would be more effective. Resources for teaching these basic skills are available from a variety of other sources including local schools.
- School administrators had voiced a need to have a program that could be used to identify the technology competencies of teachers in their district.

**Content:**
- The Technology Certification Program focuses on basic technology skills required of all teachers.
- The program is based on identified standards including ISTE Technology Standards for All Teachers and proposed Nebraska Technology Competencies for All Teachers.
- The program focuses on application of hardware and software tools in the classroom including productivity, classroom management, teaching and learning.
- The program focuses on instructional and administrative issues related to the use of technology.
- The program focuses on identifying and using existing resources such as manuals, Web resources, and to support learning technology. This supports continuous and independent learning in participants. Participants are also directed to local support resources when they are available.

**Content Delivery:**
- Activities should be self-paced and student work should be done asynchronously to provide flexibility for the varied schedules of students and instructors.
- The program should be developed so that participants are aware of what is expected and where they are in completing the program.
- The program should provide resources, learning activities and assessment of participant skills. Emphasis should be on assessing application of skills in teaching and learning.
- Use of a browser for access to the program allows universal access regardless of platform and software used by the teacher or the school district.

**Learning /Mastery Activities:**
- The Technology Skills Certificate Program provides a structure set of learning activities as the primary focus of the training. Less structured resources are made available to participants to assist in completing the activities.
Project-based learning activities have value and application to the student beyond the requirements of this course (i.e., students' projects will be classroom-ready and will meet their own, individual classroom needs).

Project-based learning activities allow more in depth evaluation of students application of technology skills in the classroom.

Students should utilize productivity and learning software that they have available in the school to demonstrate proficiency.

Students enrolled for the course should be encouraged to become self-directing, self-learning technology users (e.g., students will be directed toward preexisting resources, especially those that are local, for skills training and software/hardware support).

Participants are viewed as professionals who are responsible for completing work independently. They are encouraged to utilize resources to gain knowledge necessary to complete the activities.

Students should receive prompt and quality feedback on their work from a qualified instructor. This requires that an instructor reads and evaluates projects.

Instructors are available to support students in the process of completing learning activities.

Course Content, Activities, and Delivery

The home page created for the program contains separate links for information about the course and using the Web site, as well as links to an online forum and general resources students may find helpful. The link to the modules themselves, however, is password-protected, and students must use a login and password that is sent to them after enrolling for the course.

There are eight modules students must complete for a grade in the course:

- Basic Computer Operations and Communication Tools
- Basic Productivity Tools
- Integrating Basic Productivity Tools in Instruction
- Advanced Productivity Tools
- Integrating Advanced Productivity Tools in Instruction
- Application of Telecommunication Tools in Teaching
- Social, Ethical and Human Issues
- Technology for Professional Growth

Each module is consistent in design, with links to a standard set of module elements. These elements include information about the purpose and goal of the module, requirements and prerequisites, the mastery project and activities required, and resources useful for completing that specific module.

The mastery project is the heart of each module and is tied to specific computer competency standards identified in the Nebraska Standards on Instructional Technology and in the ISTE Standards. By successfully completing the project, students demonstrate they are competent in these standards. The mastery projects require students to use a variety of instructional technology tools to create multimedia presentations, thematic multimedia projects, and Web pages to produce materials that support teaching, learning, and the school organization. For example, Module 3 asks students to develop a detailed lesson plan that incorporates instructional technology, and Module 7 requires students to develop a set of technology-use guidelines for their school.

Students send their completed work to the instructor in one of three ways: taking a quiz online, submitting text online, and uploading a file through the Web page. For example, Module 3 requires student's to write a reflection piece that describes the rationale for designing the lesson as he or she did. As seen in the example below, students send the reflection to the instructor by clicking the Update button that follows the text field. Students also have the option to send notification to the instructor that their work is ready for evaluation.
Projects created using software programs (e.g., Microsoft PowerPoint) are submitted by uploading them to student folders on the Web server. The student creates the project on his or her hard drive and, when ready, uploads the project by clicking an upload button located on the Web page. When the student clicks on the upload button, a dialog window opens so they may locate and select the appropriate file.

Administering the Course—Evaluation and Communication

Instructional management is a key issue in establishing an online training and certification program. The development team was challenged to create a Web site that would allow students to effectively and privately communicate their knowledge and skills to the instructor, store and organize student work so that it would be easily accessible to both instructor and student, and allow the instructor to provide feedback and track student progress. These goals were achieved within a single, secure Web page generated for each student by the instructor. Within this single Web page, the instructor retrieves and evaluates student work, and the student can verify that work has been received and can read evaluations from the instructor.

The instructor has access to an administrator’s Web page that is password protected. This page allows the instructor to create student records, access student work, and send comments to each student. At the beginning of the semester, the instructor creates new files for each student enrolled in the course. Each student record, an example of which is shown below, includes administrative information (e.g., student’s name, address, and password), as well as a Progress Summary.

The evaluation process begins when the instructor clicks on the Projects links in the student’s record to retrieve files uploaded by the student and written projects stored in the database. Each Project link opens a new page with links to the student’s work. After evaluating the project, the instructor clicks on the Module links to input comments and progress information, as shown below.
The student can access a similar page to see if his or her work has been received, whether or not the work has been accepted, and any comments on the work from the instructor. Additionally, the student has access to the Projects links for easy reference to the work he or she created. In this way students can verify if their projects were uploaded correctly, and they can more quickly relate the instructor's comments to their work.

Implementation and the Future

The project has been successfully field tested and implemented. In the spring of 1998, a group of five Lincoln Public School teachers completed the course and provided valuable feedback. Specifically, this test group identified design and mechanical problems within the Web site used for the course. The test group was also instrumental in establishing clear and specific guidelines and expectations for each module.

The course was offered for the first time to 20 students in the fall of 1998. This first offering has been successful, but not without challenges. For example, it has become clear that the course should include a few, basic prerequisites (e.g., familiarity with a standard software suite). Evaluation of this initial offering of the course will be completed by summer 1999 using both pre- and post-surveys.

In future this course will be offered, with modifications, to pre-service students in Teachers College as part of the undergraduate technology requirements. The modules will be modified for students who do not have classroom experience, but the activities and projects will encourage students to model the use of instructional technology as they use it to support their own learning. Additionally, by requiring undergraduate students to complete this course, Teachers College will be able to certify to prospective employers that each graduating student has demonstrated competency in all areas of the ISTE and Nebraska technology standards.

Creating Internet Based Learning Environments

Wallace Hannum  
School of Education  
University of North Carolina at Chapel Hill  
United States  
whannum@mindspring.com

Abstract: This paper presents a formulation for creating educationally sound Internet based learning environments. The mere use of the Internet does not necessarily add educational value. Rather careful attention to the design of learning environments is essential, regardless of the technology used. Suggestions are offered for designing Internet based learning environments based on well researched and widely accepted "best practices" for education. These suggestions show how email, chat rooms, web pages, discussion forums and listservs can be used to create educationally rich learning environments.

Introduction

The Internet offers considerable potential for expanding educational opportunity, and educators have been quick in seizing this opportunity. Faculty put syllabi on the Web; traditional courses use links to websites as learning resources; students communicate with students at other schools by email; students use the Web as a research tool; teachers share lesson plans through websites; students and teachers conduct discussions over the Internet; schools offer classes through the Internet; universities offer degree programs over the Internet. Many use the Internet as a tack-on to traditional courses while others are using the Internet as an alternative delivery means.

Regardless of how the Internet is used in education, considerable attention must be placed on ensuring that the use is educationally sound. Simply creating a website for a course, putting lesson plans online, having students use email, or starting a discussion forum does not guarantee education will be enhanced. In short there is no magic in the technology. As many studies of technology applications to instruction indicate, it is not the technology itself that improves the instruction (Clark, 1994; Russell, 1997; Gagne and Medsker, 1996). Rather it is careful attention to the design that impacts learning (Duchastel and Spahn, 1996). If the Internet is to be an effective resource for educators, then we must consider how the Internet can be used to provide educationally sound experiences (Richie and Hoffman, 1997). We must carefully craft designs for Internet use in education. In short, we must create Internet based learning environments.

Because the Internet is fairly recent, we do not have a wealth of research on Internet based learning environments. However we do have well researched and widely accepted guidelines, or "best practices", for facilitating learning, independent of the method of delivery. One such set of guidelines was developed for undergraduate education but is applicable to K-12 education as well. These guidelines are the Seven Principles for Good Practice in Undergraduate Education (Chickering and Gamson, 1991). When the features and capabilities of the Internet are used to implement these known good practices, the instructional experience is very likely to be effective. The remainder of this proposal will outline how these Principles for Good Practice can be used to guide the creation of Internet based learning environments.
Best Practices

An appropriate starting point for considering how to use the Internet in education is with an examination of proven best practices in education – the Seven Principles for Good Practice specified by Chickering and Gamson (1991). Suggestions for creating Internet based learning environments are organized around these principles. These principles are:

1. Good practice encourages student-faculty contact.
2. Good practice encourages cooperation among students.
4. Good practice gives prompt feedback.
5. Good practice emphasizes time on task.
6. Good practice communicates high expectations.
7. Good practice respects diverse talents and ways of learning.

These Seven Principles for Good Practice can be implemented in Internet based learning environments in several ways. The following offers suggestions for implementing each principle in an Internet based learning environment.

Principle 1. Good practice encourages student-instructor contact.
Student-instructor is essential to a high quality learning environment. This principle can be implemented through:

- **E-mail** as a means of student-instructor interaction in web-based courses. The quality of the interaction will depend on the instructor's willingness to respond meaningfully and promptly to many e-mail messages each week.

- **Listservs** that allow instructors to easily communicate with a group of students. In essence, this is a form of group email in which one message is sent from any member of a group to all other members. An instructor could serve as listservs moderator to facilitate relevance of the messages to the class.

- **Web pages** to allow instructors to distribute materials to students and to support interactivity through forms, scripts, and applets. Developing interactive web pages, like developing interactive courseware, is time-consuming, technically challenging, and expensive but promotes better interactions.

- **Chat rooms** which are similar to discussion forums, but happen in “real time”. The discussion occurs immediately as students and teachers interact at the same point in time.

- **Desktop videoconferencing** which allows students and instructors to interact over the Internet in real time seeing and hearing each other. This is a low cost form of interactive distance learning.

Principle 2. Good practice encourages cooperation among students.
Learning environments are enhanced when students work cooperatively rather than competitively. This principle can be implemented through:

- **Web pages** could allow students to have a shared work space that might include each student's contribution to a group project, resources he or she found useful to the group project, a timeline for the project, and specific assignments. Individual students could update their work on the site for the other students to see and use.

- **E-mail** as a means of student-student interaction in web-based courses. Students can collaborate with each other on a course assignment, such as a case study, by communicating through email. Students can also
share work products or other resources, such as reference materials, with other students by attaching them to email transmissions. This will allow students to work cooperatively on group projects.

*Threaded discussion forums* that provide a web-based mechanism for asynchronous group conversation based around course topics with multiple responses possible for each topic or "thread". The instructor can assign questions or discussion topics and have students post their responses in the discussion forum. Students can read and respond to classmates' postings. Because discussion forums are asynchronous, students can read and respond when they wish. This feature reduces the immediacy of the exchange but may promotes more thoughtful replies.

*Chat rooms* for students to interact in real time regarding some aspect of courses they are taking. Students could use chat rooms for working cooperatively on a case study, developing a group paper, creating a group presentation, discussing questions that have been posed, or most any other activity requiring group interaction.

*Desktop videoconferencing* which allows students to interact in real time to carry out discussions or joint planning for a project. A shared "white board" or shared screens allow all participants to view the same information for planning or critique. This could be used to create virtual work teams or study groups among students in a course.

**Principle 3. Good practice encourages active learning.**  
When students are actively engaged in learning activities they learn more. This principle can be implemented through:

*Web pages* could provide exercises for students to complete or could present problems for them to resolve. This would require their active participation in construction of responses.

*Hyperlinks* that allow the students to control navigation through the web environment. This learner control promotes active involvement and lets learners choose what they want or need to see.

*Independent learning environments* so students are no longer passive listeners to instructors who function as the source of all information. Students can be actively involved in and guided through their learning by instructions on web pages. They can work independently on problem-based learning assignments. When necessary, they can contact the instructor or other students for assistance.

**Principle 4. Good practice gives prompt feedback.**  
Providing prompt feedback to students facilitates their learning. This principle can be implemented through:

*E-mail* that provides students with a mechanism for asking questions and getting individual feedback. Instructors can also use email to provide students with feedback on assignments.

*Listservs* that allow instructors to easily communicate with a group of students and provide feedback on projects or other group activities.

*Threaded discussion forums* that allow any subscriber to provide feedback on any comment made in the discussion forum. Thus both the instructor and other students can contribute feedback.

**Principle 5. Good practice emphasizes time on task.**  
When students are directly focused on and engaged with the learning task for a greater amount of time, they learn more. This principle can be implemented through:
Website with a course syllabus that provides explicit directions for students to proceed through the course. All assignments and expectations are clearly stated and available for reference at any time. This would allow students to focus their time appropriately on the learning tasks.

Flexible mastery learning that allows learners to invest the amount of time needed to learn the material. Students with high prior knowledge of the subject matter may spend less time while students with lower prior knowledge require longer to read and process the same information to complete assignments.

Email that allows students to ask for guidance at any time when they are getting off track or confused.

Hyperlinks with annotations to help students keep on task by guiding them to essential sites. Otherwise students may become distracted or diverted when following external hyperlinks.

**Principle 6. Good practice communicates high expectations.**

When instructors have high expectations for the students and communicate these to the students, the students learn more. This principle can be implemented through:

Website with a course syllabus that clearly states expectations of students. The roles and responsibilities of the students can be clearly communicated through information on the website. Expectations about the quality of their learning and their work can be made explicit through objectives, examples, and practice examinations.

Listservs that allow faculty to communicate expectations to students. Careful advising of students is important in Internet based courses to make sure they understand course requirements and directions for completing course assignments.

**Principle 7. Good practice respects diverse talents and ways of learning.**

Students have different talents and different ways of approaching learning tasks. Learning can be enhanced by taking these into account. This principle can be implemented through:

Multimedia environments that incorporate text, graphics, audio, animation, and video thus appealing to multiple senses and learning approaches. An Internet based learning environment is multimedia oriented which gives the students freedom to learn as they wish.

Independent learning environments that allow students to participate in a class when it is most convenient for them, when they have time and energy for learning. An Internet based learning environment is time and place independent which gives the students freedom to access instruction when and where they wish.

**Summary**

To take advantage of the educational opportunity offered by the Internet requires careful consideration of how the Internet is used in education. Appropriate use of the Internet, or any technology, in education should be based on proven educational practices. There is no magic in technology to compensate for or improve on poor educational practices. Principles for good educational practice such as the Seven Principles for Good Practice in Undergraduate Education (Chickering and Gamson, 1991) should form the basis for developing Internet based learning environments. This paper shows how the Internet can operationalize these best practices. By using these research-based principles, educators can create educationally rich learning environments on the Internet.

Abstract: There has been great emphasis on utilizing the Internet and the World Wide Web as a teaching tool and instructional medium in teacher education programs across the country. This paper describes the elements of web-enhancements to teacher education courses in thirty-nine classes offered at eleven colleges and universities with teacher education programs. Web enhancements from a sample of teacher education courses at the top 20 graduate schools (according to 1998 U.S. News Graduate School Rankings) were examined. Elements of sample web pages are organized into six areas, Web Syllabi, Web References and Readings, Web-based Instruction, Web-based Communication, Students' Work on the Web, and Distance Education. Conclusions on the future of web resources in teacher education are presented.

Introduction

According to the National Center for Education Statistics (NCES) March 1998 Issue Brief, approximately 78% of all public schools have some sort of access to the Internet (NCES, 1998). This report goes on to indicate that one challenge to use of the Internet in schools is time for and access to professional development by teachers and administrators. However, in 1994 only 15% of teachers had at least nine hours of training in education technology (Edwards, 1997). In a 1990 national survey, 81% of student teachers surveyed rated their undergraduate preparation in technology use as inadequate (Fratianni, Decker, & Korver-Baum, 1990). Although teacher preparation in the area of technology has evolved since the early 1990s, teacher educators continue to evaluate how they can capitalize on the features of technology to expand student understanding (Garofalo, 1998). To help teachers better utilize technology effectively as an instructional tool, teacher educators in colleges and universities must rethink their courses to provide training and hands-on experience to students (Cradler & Parish, 1995). Faculty modeling the use of technology, through integrating computers and the Internet into the curriculum, is an ideal method for preparing teachers (Thomas, Larson, Clift, & Levin, 1996).

In addition to the need to prepare future teachers to use computers and networks simply because of the influx of technology in society, teacher education institutions are also being persuaded to use technology by accrediting agencies. The National Council for Accreditation of Teacher Education (NCATE) has incorporated the need for technology into standards for teacher accreditation. For example, one standard in the area of Content Studies for Initial Teacher Preparation expects candidates to "complete a sequence of courses and/or
experiences to develop an understanding of the structure, skills, core concepts, ideas, values, facts, methods of inquiry, and uses of technology for the subjects they plan to teach" (NCATE, 1997). The International Society for Technology in Education (ISTE) and the International Technology Education Association (ITEA), two professional organizations in the area of educational technology, have devised standards for all pre-service teachers in the area of technology. Important elements of these standards include demonstrating strategies for the educational use of electronic networks, such as the Internet, interpreting knowledge about computers, and illustrating the effective use of computers in classrooms (Wetzel, 1992).

Given that the web is the most common tool used on the Internet, it is important for teacher educators to model the educational use of on-line materials. In a report developed by the North Central Regional Educational Laboratory entitled Plugging In: Choosing and Using Educational Technology, indicators for engaged learning and high technology are outlined (Jones, Valdez, Nowakowski, & Rasmussen, 1995). These indicators were designed to create a framework for using technology that complements learning. The report calls for technology-based instruction that is engaging, distributed, designed for user contributions and collaborative projects, and provide guided participation.

Classification of web-based activities range from those that allow the user to access materials and materials at any time, to those that permit synchronous (real time) communication. Berenfeld (1996) discusses a continuum of educational activities that may take place on the internet, such as "Tele-access", in which students retrieve information from remote sources, "Tele-mentoring", in which student are mentored by online experts, and "Tele-sharing" in which students collaborate and share information they have developed or discovered. In the Apple Classrooms of Tomorrow (ACOT) model, teachers' adoption and evolutionary processes with technology can be identified at the lowest level (the entry phase) which includes information distribution to the highest level (invention) where students interact in cooperative, project-based, and interdisciplinary learning activities (Apple Computer, 1995).

As teacher educators strive to develop web-based materials that are matched to accreditation standards and that create cooperative learning environments for pre-service teachers, reflection on current practices can be a valuable tool. This paper is not intended to be an exhaustive description of web-based teacher education, but a snapshot of how the web is being used in some highly regarded teacher education institutions.

Methodology

For this project, a sample of web-based course materials were examined from colleges and universities included in 1998 U.S. News Graduate School Rankings in elementary, secondary, and special education. Web pages were identified and monitored that were offered during the fall of 1997 and spring of 1998. In cases where web-based course material was not readily identifiable via the departments' main web page, institutions were contacted via phone or email to identify the Universal Resource Locator (URL, also known as web-address) of web-based courses, if any. In total, 39 web pages were identified and monitored, representing eleven colleges and universities. Courses represented in the sample included educational psychology courses, methods courses for math, science, language arts, and special education, educational technology courses, and educational leadership/educational administration courses. Courses were taught in departments, schools, and colleges of education, as well as in related departments outside education, such as human resources or instructional technology. All course instructors were contacted for permission to include their course in the project, and were all guaranteed anonymity.

The 1998 U.S. News Graduate School Rankings is based on the ratings of academic quality of 191 graduate schools that offer Ph.D. or Ed.D. degrees (Harrison, 1998). The ranking are based on four attributes; reputation, student selectivity, faculty resources, and research activity. For more information about the U.S. News ranking, visit their web site at http://www.usnews.com/usnews/edu/beyond/gradrank/ghedmeth.htm.

Results

Web pages for teacher education courses were monitored over the course of the 1997-1998 academic school year. Elements of the Web pages were identified and categorized based the amount of student interaction and communication encouraged, the degree of cooperative activities, and the resources available for instructional purposes. These general guidelines for classification were derived from other systems, such as
those used by Berenfeld (1996) and ACOT (1997). Table 1 illustrates the elements of the web pages that were identified.

</table>

Table 1: Elements of Teacher Education Web Pages

Web-Syllabi

In this first level of web-enhancements, the web page contains the course syllabus, schedule, requirements, and related assignments. All but one of the class web pages (or 97%) that were accessed for this project contained at least this information. Information on these web pages was often adjusted or updated through the course of the semester in which the class was offered, including changes in schedule or special announcements about course meeting locations.

Web references and web readings

The next level of web-enhancement used the web page to provide timely readings and research that are matched to the course content. For example, in an educational psychology course, links to readings related to topic of in-class discussion in class are presented via the class web page. Links to professional organizations, newsgroups and government agencies are common on this type of class web page. Also included at this level of web enhancement might be access to the professors' email address, office hours and location, and information about instructional support, such as teaching assistants' names and email addresses, and campus resources for tutoring. Often, these materials were updated throughout the course of the semester in which the course was offered. Approximately 70% of the web pages included these materials.

Providing instruction via web pages

At this level of web-enhancement, instruction related to course content was presented via the class web page. This included lecture outlines, detailed instructions for completing assignments, and sample projects or papers. This level of web-enhancement might also include simulations or detailed written materials relating to the course lectures, in most cases developed by the course instructor. Instructional materials where found on 40% of the web pages.
Web-based communication

On 30% of the web pages sampled, some sort of communication took place between students and the course instructor(s). This may include web-based chat areas, web-based discussions, and links to the class email (listserv) discussion group. In about half of these classes, the students' participation in this discussion was required as either a component of the attendance policy or as a separate, graded activity.

Students' work on the web

One component of approximately 48% of the course web pages was student designed materials. These may include students' web pages designed in educational technology course, students' lecture notes or review materials for tests, and sample reports and projects created by students in previous sections of the course. On four (13%) of the web pages in the sample, students' grades were available (through a password-protected secure server).

Distance Education

Two (or 3%) of the courses monitored in this project were truly "distance education" courses. In these classes, students participated in web-based discussion, used web-based readings and references, and submitted all work via the class web page or via email. In one of the course, a textbook was required, and in the other, there were six optional on-campus class meetings. When the instructor for the course with the "optional" class meetings was contacted, she indicated that approximately 70% of the students who successfully completed this course showed up at least once to these on-campus meetings.

Conclusions

Teacher educators are using the web to teach, interact with students, and create safe environments for experimentation and discovery. Of the Web pages sampled, only 30% were classes that focused primarily on technology. Courses from early childhood education to adult learning are were included in this sample, which indicates that technology has begun to infiltrate classes across the teacher education curriculum. Pre-service teachers are being given the opportunity to collaborate in virtual communities, and explore the social, ethical, and human issues of using technology as a tool to teach children.

As mentioned in the previous section of this paper, two of the courses in this sample could be labeled as "distance education" courses. In both classes, students were able to register for the course on-line, and obtain course materials, read lectures, watch simulations, and interact with fellow students all via the class Web page. Many universities and colleges are preparing to offer (or are currently offering) a variety of distance education courses to pre-service and in-service teachers, and based on the two examples represented in this sample, these on-line courses will be valuable tools in teacher training no matter the location of the student.

The Department of Education estimates that by the year 2000, 95% of all schools will have some sort of access to the Internet (NCES, 1998). As teacher educators confront the challenge of training teachers for these classrooms of tomorrow, the importance of providing appropriate models of Internet use is of great importance. There is no question that teachers in tomorrow's classrooms will use the Internet to continue their professional development well into the next century. Therefore, it is the responsibility of teacher education institutions to develop programs and courses that meet the demand for greater technically expertise, and that these program and courses be available to teachers no matter their distance from university and college campuses.

Abstract: Children in today's society must function in many environments. The home, family, school, neighborhood, peers, and society generally shape our children for the future. Teachers, partners of this cyclical challenge, have to be prepared to help students meet the challenges of the world 2000. Teachers can learn to meet this goal by creating learning communities through technology and sound teacher preparation programs. A program that allows preservice and inservice teachers to use online communication to enhance their personal growth is the beginning of an online community. The availability of synchronous and asynchronous activity, through the use of WebBoard, is demonstrated and explained in this paper. Samples of assignments, solutions to problems teachers faced online, and ideas for future assignments will be discussed.

Introduction

Communication, defined loosely as an exchange of information, is essential to both preservice and inservice teachers. Without effective communication skills, a preservice teacher may quickly leave the profession or an inservice teacher may have the anxiety of being lost in a "vacuum". Feelings of isolation may come from being in a classroom with no one to turn to, but the students who sit before them daily. Communication with colleagues at the school, during the instructional hours, is often limited to handling and discussing problems, which may increase feelings of isolation and frustration, as educators do not have the opportunity to look at their situations from a larger perspective, and to realize that their problems are often unique – and that other educators may have found some solutions. The opening of communication channels with the outside world, often enabled through the latest technology, may help educators feel a part of the larger professional community of educators.

The Computer and Communication

Within the past twenty years the computer has become a facilitator for managing different types of communication for educators. It has literally become the bridge for educators with the community. For example, by using the Internet, both preservice and inservice teachers communicate with all kinds of businesses such as banks, retail stores, airlines, and others through email. They have learned to access numerous databases to obtain the latest weather reports, stock market information, news stories, or medical information for the classroom. The classrooms have become more student centered, collaborative, and interactive by the use of telecommunication networking. (Kellough & Kellough, 1998) The students learn new inquiry and analytical skills in stimulating environments, increasing their awareness of their role as world citizens. (Cohen, 1994) The computer and the teacher become facilitators in the classroom. Now the challenge becomes how to connect them more with fellow educators so the feeling of isolation is dismissed.

Learning and producing learners is a lifelong endeavor for a teacher. Participating in a teacher preparation program that emphasizes technological skills for the classroom and the world can help teachers enhance their
professional growth. When preservice and inservice teachers know that they can communicate freely with university instructors and each other on line, the base of the learning community broadens. Basic skills start in the university class where preservice and inservice teachers receive training using email, mailing list, and bulletin boards. Demonstrations of how to use chat rooms to review for test, to seek advice from colleagues or educator – supervisors, to discuss research, and to complete many other tasks become the objective. This kind of communication leads to self-inquiry and more knowledge of the teaching profession. A profession that produces better-prepared and knowledgeable personnel who lead their students one step further into a technological society is a definite benefit.

One University's Program

The mission of our teacher preparation program is to provide, through a collaborative commitment, relevant field-based teacher education and staff development programs that integrate research supported, innovative teaching and assessment practices with technology so that educators share a common vision of improving the learning and achievement of all students. This collaboration has resulted in partners integrating technology with the best teaching practices in a more effective manner. The placement of technology in the classrooms rather than labs and providing ongoing staff development and support in the public school has been the heart of the program. This allows for multiple levels of communication. For example, professors and preservice teachers have used email for basic communication while demonstrating their content mastery through multimedia presentations. This starts the process of moving professionals into the 21st century.

Preservice Teachers and Email

On the university campus preservice teachers use email to send their weekly journals. These reflective journals demonstrate their teaching activities and their observations of the school environment. Preservice teachers also discuss classroom problems and professors send back responses in the form of advice. A sample entry follows:

Dr. Justice:

With Halloween coming last Saturday we did a lot of activities directed at the holiday in my LIFE class. By doing these projects the students met most of their objectives including working cooperatively/sharing space and following functional commands. These were a lot of fun for the students and gave me the opportunity to observe and work with the students on new and alternative activities. We also included the regular activities and lessons that we do each week. Next week we will wrap up the six weeks by reviewing. This is the first six weeks we have done colors fully and it will be interesting to see how much retention the students will have after this period of time.

**We are going on a field trip during the A.M. (9-11) on Tues., Nov. 3.

Health is going pretty well. I still get a little discouraged; having such a big class sometimes presents behavior problems. I am working on disciplining and feel I have a much better idea about it now that we have discussed what causes misbehaviors and ways to address them. As far as instruction, I have had a much more student-centered teaching environment and the test grades this time were somewhat improved so I will continue to have the students be involved in the instruction like we discussed. With the six weeks wrapping up I am worried about a couple of low grades but I have discussed this with my mentor and the students involved. We are working toward having a successful six weeks for everyone.

The response of the professor:

L,

I enjoyed both of your classes. The students in the LIFE class are doing fine. They are learning a lot. Let me know the date of the field trip.
Is next week the end of the six weeks? What is the exam schedule? How many students are not doing well? What have you done to provide assistance?
Continue to lecture less and let the students do more of the work. This takes some thinking and arranging. Make it fun and relevant! Make sure that you call on everyone in the class. Hopefully, I can give you more advice on Monday.
See you Monday!!!!
Madeline Justice

This type of email shows the preservice teacher making thoughtful decisions in the classroom.

Preservice Teacher and the WebBoard

Additional communication was set up by the use of a WebBoard. This was to get students familiar with a different type of communication. The professor showed students how to register on the WebBoard system and how to respond to a posted assignment. On the WebBoard, six rooms were set up and three students were assigned to a room to answer a review question over a reading assignment. A sample of a posted assignment with student responses is below:

Dr. Justice's Online Office (0)
Rm 1 (5, 5 New)
Rm 2 (5, 5 New)
Rm 3 (3, 3 New)
Rm 4 (3, 3 New)
Rm 5 (5, 5 New)
Rm 6 (4, 4 New)

Classroom Management (1 of 1), Read 11 times
Conf Rm 2
From: Dr.Justice. (madeline_justice@tamu-commerce.edu)
Date: Sunday, October 11, 1998 03:31 PM

Give at least three different examples of a student wanting attention in the classroom. Discuss the many ways in which you would solve each problem. Each member in this room should give an example and solutions to the problems.

The preservice teachers' reflections after being in the chat room:

Topic: Classroom Management Reflection (1 of 1), Read 11 times
Conf: Rm 2
From: D C (_____@juno.com)
Date: Monday, October 12, 1998 08:47 AM

We talked about students that seek attention in the classroom. We covered many of the methods for handling this situation. Many of the methods that we covered came from the book, and we also discussed experiences in the classroom.

The chat room was pretty fun, and it seemed like it could be a very useful tool if you could find a chat room on a topic that you needed to discuss with someone maybe to get another opinion, or maybe a place to vent frustrations.

Another sample message on the same topic follows:

Conf: Rm 6
From: L L (_____@tamu-commerce.edu)
Date: Monday, October 12, 1998 08:47 AM
EM and I discussed the four goals of misbehavior in the classroom. What some examples of these might include and how it might be good to deal with them. I enjoyed the chat room because it was more like a discussion than a question-answer set-up. It was nice to talk about the question and get help and another person’s viewpoint.

In the next session students were shown how to use web board to communicate with each other.

They were shown how to enter a chat room, chat about their experience in the schools, and again summarize their experience by posting a message to the professor. A sample follows:

Date: Monday, October 26, 1998 09:22 AM

This is from A I. The last couple of weeks have been great. I had some reservations about the shift to regular history but it has been great. I enjoy the format of the American history class and most of my classes are great. Eighth period is a little loud but I think they are basically good students and generally bright, I think. Next week will be great. I am more confident with my lectures and ability in front of the class.

A I

A sample chat by student teachers to the past week’s experience went like this:

10/12/98 08:20

E S: Hi D__ and S__
D. C.: Hi! Everyone!
D. C.: How are your classes going?
E S: Pretty Good. Where’s S__?
D. C.: I have one student that had decided to cuss a student from across the room. My response was to write a referral on her. Would you do the same? I haven’t heard from S____ yet.
E S: I probably would have done the same. That way all the other students could see that this was a major offense and it would not be tolerated. E____ S____: I haven’t had anything quite that severe yet. Thank goodness.
E S: Hey S____
D. C.: Friday, the same student asked if we could leave class two minutes early. I told her no, of course. She waited a few minutes, then asked again. My response was the same. Hi, S____!
D. C.: How are your students acting when Dr. Justice observes you? S____ S____: Hello, this is S____, copy?
D. C.: Copy.
E S: Dr. Bennett observes me. They usually act pretty well. He comes and observes one of my....

This way preservice teachers are able to get quick responses and also feel that they are not the only ones having problems. It is always an eye opening experience for the preservice teachers to talk to someone who is going through the same or different experiences. They use each other as sounding boards and get a sense of relief that helps them to grow. After this experience, a student sent the following email message to the professor from his computer at home.

From: J F S <___@tamu-commerce.edu>
To: Madeline_Justice@tamu-commerce.edu
Subject: Re: Welcome to Dr. Justice's WebBoard!

Dr. Justice,

I really had fun using the web board it was quite interesting. Thank you for the experience maybe in future I will the become more comfortable with the board. Thanks again!
Preservice Teachers and the Professor

Email is an excellent way of communicating, but the students and professor wanted to engage in a conversation with students from their own environment, home or the classroom. This communication was from the home. A distance of forty-eight miles was between them. Using the web board both parties (professor and student) went online. They were able to chat for an hour about what the professor had observed in the classroom. On that particular night the travel of communication was slow, but effective and beneficial. The professor talked classroom observations and the preservice asked for advice in managing several of the students. The preservice teacher took the advice and incorporated several strategies discussed in the online chat.

The Preservice Teachers Communicating with Inservice Teachers from the University

Preservice and Inservice teachers were able to communicate about online resources. Inservice teachers in graduate classes had created online resource pages, and the preservice teachers had the opportunity to visit and critique them. This provided the preservice teachers with a chance to participate in the professional educational community, as they provided feedback to veteran teachers. As students sent their comments to teachers, and the teachers responded, it helped these future teachers consider what is needed in the classroom, and maybe some strategies to accomplish this. This activity reinforced the importance of getting and giving support.

Another activity, along the same lines, required students to visit web sites of schools around the United States. Each student selected a school to visit, and then chose a faculty member to write to. The message included an introduction from the preservice teacher, and a question about an area of concern related to classroom management. This opened up the doors to broadening the perspectives of our preservice teachers about schools around the country, as well as about some possible job openings. These communication activities gave the students a chance to develop skills that will hopefully encourage them, in the future, to find other professionals in their teaching fields from whom to seek support.

Preservice Teachers Communicating with Other Professionals Around the World

In another class preservice teachers were asked to contact other schools in and outside the United States. They were to send a letters of introduction and ask questions of concern about their classrooms. A response to the student follows:

From: Charles Campbell Secondary School <____@____.edu.au>
To: _____@koyote.com
Subject: Re: School Info
Date: Friday, November 27, 1998 12:02 AM

At 08:33 AM 11/24/98 -0600, you wrote:
>Hello.
>My name is E____ M____, and I am a recent graduate of Texas A&M University at Commerce. I plan to teach English on the secondary level. I would like to hear about your English Department and your community. I have always wanted to go to Australia, so I am extremely interested in your school. Thank you for your time.

Dear E____,

Thanks for your note. It is a huge task to do as you requested, and as we are at the end of our school year and into exam marking. I am unable to tell you very much. English here is very interesting, as we do a balance of activities, from classic to popular literature, and media and everyday texts, in addition to a wide variety of writing about these texts and of a more general and creative nature. Speaking and Listening tasks are also important. Students also do independent reading and writing.
tasks. We have recently moved towards a national curriculum although not all states embrace the move. The aim is to establish some uniformity of curriculum and assessment levels.

I love English as we can choose our texts and tasks from a huge range of possibilities, so it is easier to interest students than it was in the days of set texts. Our school is well resourced and much better than many schools as it was recently refurbished and is a bit of a showpiece.

This school is a very diverse one. We have a large number of Italian students - now 3rd or 4th generation, and also many Asian students and some from the Middle East. It is a suburban area where most people live comfortably and have high regard for education. I am not going to be here next year, as I am moving to a school nearer my home. I will no longer have email, but if you want to contact me at all, my address is 1B Sylvia Court, Coromandel Valley, South Australia. 5051.

Will you look for a teaching exchange? I did one last year to Ontario in Canada and lived near Niagara Falls, an interesting experience! Good luck with your ambitions. Our email is off from Monday due to the upgrading of the system, so don't reply. We finish school on Dec 18th for 5 weeks and our summer vacation - I am going to New Zealand.

Conclusions

It is very important that a preservice and inservice teacher communicate with professionals in and outside of the school. If they seek advice in the area of classroom tips, then they are engaging in growth. If they are growing by the use of technology, they are able to encourage their students to do the same, and therefore become a part of the world community.

Abstract: This paper is a report on the findings of an on-going research program on teachers' learning of new pedagogies supported by telelearning tools. Computer-supported learning communities that involve high school learners, preservice teachers, inservice teachers, and teacher educators are designed, and reflected upon at a number of sites and between sites (TL•PDSs). Emerging trends of effective use of online resources and tools serve as guidelines. Researchers' data points to emerging patterns of time management in communities of learners that combine face-to-face and online interaction. Three of such patterns are emphasized: 1) interacting with others before, during, and after class; 2) planning on a longer time scale; 3) evaluating participants' past and future ways to contribute effectively to one another's learning. TL•PDSs evolve as complex dynamic systems, ones likely to encourage participation in new practices of inquiry and sense-making.

This paper points to time management advances related to the effective use of online resources and tools for extending or transforming teacher professional development practices.

Networked Learning Communities in Teacher Education

Networked learning environments require professional knowledge in order to effectively use telelearning resources and tools. A key area where professional knowledge must be applied in the networked classroom is time management. For instance, time management takes new dimensions when the networked classroom opens up to other classrooms (schools and universities).

The telelearning professional development schools (TL•PDSs), which are part of the research program of the TeleLearning Network of Centres of Excellence (TL*NCE), are anchored in both school and university settings. Collaborative learning is computer-supported, and networked learning communities are exploring ways to effectively use online resources and tools (see Breuleux, Laferrière, and Bracewell, 1998). This multi-year research program is building on the works of SITE leaders such as Glenn Bull who with his team showed, ten years ago, the way to the "electronic academic village" (1989).

Computer support for collaborative learning, mainly developed by other TL*NCE researchers, are experimented with. The two main telelearning tools that support collaboration in the TL•PDSs are Virtual-U and WebCsile/Knowledge Forum. Websites (Internet) and local networks (intranets) support individuals' or teams' learning and teaching projects (TACT being the main site, Quebec City, and interconnecting with associate websites such as Studio A in Vancouver, McGill Teacher Knowledge in Montreal, and
WebCsile/Knowledge Forum at OISE/UT in Toronto. TACT is the acronym of the interactive website named Technology for Advanced Collaboration between Teachers, dedicated to supporting preservice teachers, the communications between themselves, and with teachers and teacher educators, and their collaborative learning projects (http://www.tact.fse.ulaval.ca).

The network that we are developing in Canada, which builds also on the Professional development school model (Holmes Group, 1990), reaches far beyond a school or a university by including among their active participants, teachers, students, undergraduates and various other experts from a number of schools, universities, and associations.

Effective Uses of Online Resources and Tools

The online materials, tools, and collaborative teaching and learning activities that are part of the TL*PDS are used in a mixed mode, that is, combined with face-to-face meetings. Collaborative teaching and learning is being practiced in a differentiated manner at each site. The development side of this R & D project aims at building teachers' declarative, procedural, and conditional knowledge with respect to the effective use of time for learning and teaching purposes, whether they are student teachers, teachers, or teacher educators. The research side aims at documenting the ways in which online resources and tools enhance the interaction of knowers with knowledge and with one another (see Harasim, 1995, the leader of the TL*NCE research program).

The contribution of our research program to the study of how telelearning technologies may be effectively used for information, communication and collaboration purposes takes an inside-out classroom perspective. The most recent documentary review conducted (Bracewell, Breuleux, Laferrière, Benoit, and Abdous, 1998; see also Grégoire, Bracewell, and Laferrière, 1996), led to the identification of models of use, trends, and research gaps on the contribution of effective uses of online resources and tools in the classroom of the elementary and secondary schools and post secondary institutions (http://www.tact.fse.ulaval.ca/ang/html/review98.html).

For the purpose of this review, online resources and tools were defined as the information technology applied to teaching and learning for 1) the delivery of educational material, 2) the guidance and facilitation of the learning experience of the student, and 3) the support of collaborative learning and communities of learners. How the new technology is adopted is related to 1) the users' interest in doing what they do well and in a better way, and 2) the users' interest in doing things of a different nature than the ones they are used to do (see Maddux, Johnson, and Willis, 1997). It is important to emphasize that both uses of technology are relevant to classroom learning.

The thrust of research on the use of online technologies is to support the development of teaching practices and curricula which give numerous opportunities to the learners to use the resources and tools in autonomous, creative, and collaborative ways. This work is more recent, thus at an earlier stage of development. Initiatives include the work of Bereiter and Scardamalia (1993) and Harasim, Hiltz, Teles, and Turoff (1995). Pertinent to this paper on time management, we point to the following trends and issues in elementary, secondary, and university classrooms:

- Higher levels of control by learners are called for as classrooms are getting more online (e.g. responsibility of effective use of time is shared between learners and teacher; time devoted to searching information, and communicating online).
- Learning situations become more realistic and authentic as classrooms are getting online (e.g. time devoted to didactic teaching versus deep understanding of concepts, notions, and principles; time devoted to text elaboration versus multimedia presentations).
- Online resources boost student interest and motivation in the classroom through a greater diversity of learning goals, projects, and outcomes (e.g. the guidance or coaching of multiple tasks occurring at once in the classroom).
- The successful online classroom combines information technology with appropriate pedagogy (e.g. increased time for interactions between learners).
- The classroom is extended to online learning communities with the potential to support or even challenge the locally-established curriculum (e.g. time devoted to face-to-face and online interaction).
- The education of educators is broadened to include just-in-time and/or collaborative learning (e.g. blurring boundaries: web-extended courses, prerequisite courses, undergraduate/graduate courses).
The university classroom is also being transformed as a new mixed mode of learning emerges (face-to-face and online learning activities), thus making information access more direct, interactive, and flexible, and testing collaborative learning arrangements in a great number of ways.

Related to the above trends, are professional knowledge areas to be investigated in order to manage time effectively in and beyond the networked classroom.

Emerging Patterns of Time Management

As we assist pre-service teachers, in-service teachers, and other educators gaining knowledge and skills of a practical or intellectual nature which they are called upon to master, we uncover new possibilities, experiment new practices, and reflect on results. A technology of use (see Scardamalia, Bereiter & Lamon, 1994) for teacher education is in development, that is, the intentional and deliberate use of technology to foster professional knowledge at a number of intersecting levels.

In the literature on distance learning, the use of time is mainly considered from the point of view of the learner — lifelong learning as well as learning anywhere and anytime being the key notions that capture the essence of the possibilities that learning networks enable and support. Our own reflective use of electronic networks for professional development is grounded in local PDSs' activities. Bring us to consider a network as "a shared collaborative space" that departs from the basic linear sequence of action prevailing in another shared space, that is, the classroom (e.g., a workshop, a course, or a program): pre-action (planning), inter-action (intervention), and post-action (evaluation).

As the networked-enabled classroom takes shape, be it at the school or at the university levels, the time and space boundaries that defined and brought order in the classroom are blurring. The availability of online resources creates new learning and teaching opportunities, challenges, and issues. The teachers (preservice and inservice teachers as well as teacher educators) that are exploring the possibilities of online resources and tools for learning purposes are at the forefront of an emerging professional practice, one still very much unknown but one that could move us beyond fragmented teaching/learning units (human interaction or human-computer interaction), and into hybrid learning environments likely to seriously challenge current time management practices.

Emerging patterns in what appears to be a socially organized activity in need of redefinition may be clustered as follows:

Interacting With Others Before, During, and After Class

Courses are getting web-extended. This means 1) that students may consult information about the course ahead of time, the professor's web page, or the course web page; 2) that course activities may be conducted throughout the weekly student schedule; and 3) that courses extend past their regular schedule; etc. Thought of as interactive systems of activity in a shared collaborative space (for instance, TACT, the TL*PDS created out of the collaboration between Laval University and associated schools and universities), one may observe 1) incoming participants getting information and communicating with more advanced participants in order to plan their learning/teaching activities; 2) individual participants coordinating or evaluating their activities; 3) participants engaging in sustained collaborative activities such as the writing, in co-operation, of a professional journal, or the elaboration of a database. As these new patterns of activity emerge, the extended course or practicum transforms itself into a community of learners. With respect to time management, regularities may concern an individual interacting at different times in a community, or participating in different communities of learners (see Greeno, 1998). Along with him, we are convinced that it is a propitious time to explore ways of integrating the two following lines of research:

Cognitive science analyzes structures of the informational contents of activity, but has little to say about the mutual interactions that people have with each other and with the material and technological resources of their environments. Interactional studies analyze patterns of coordination of activity but have little to say about the informational contents of interaction that are involved in achieving task goals and functions (p. 6)
It is unlikely that the principles of coordination that have underlined time management for so long in the classroom will remain intact in a networked learning environments. As we uncover the affordances that support a variety of asynchronous/synchronous interactions in a TL\textbullet PDS, new patterns of time management will be conceptualized. Activity being "a continual negotiation of people with each other and with the resources of their environments" (Greeno, p. 9), networked learning environments are transforming teaching and learning activities in ways that are forcing the uncovering of new regularities of practice relating to time management, both within the classroom between teacher and students, and within the school, board and profession between teacher and teacher. As our pioneering research evolves, we see current coordination patterns being challenged not only during the inter-active phase, but also during the pre- and post-active phases.

Planning on a Longer Time Scale

An additional implication with respect to time management in a TL\textbullet PDS is the increased time scale within which we design professional development activities: rather than the traditional isolated or short-term events (a scale of days or weeks), we envisage a series of activities extending over a much longer period of time (years). The changing time scale requires the other time management modifications mentioned in this paper: Educators accessing educational resources on the networks, or using the networks to engage in professional dialogues, at any time, on their own time at home through dial-up access to the Internet, or from their classroom computer as part of classroom time reorganize to allow students and teachers to learn. In other words, extended professional development in a TL\textbullet PDS requires educators who stay connected.

A concrete example of such a design is the TL\textbullet PDS in Montreal (McGill University and associated schools, \url{http://www.education.mcgill.ca/olit/institute/}, involving a blend of student-teachers, practicing teachers, and teacher educators. The Summer Institute is the centre of gravity for learning activities that extend during the whole year: students from the Faculty work together with teachers from the school in which they will be doing their field experiences in the months following the Institute. The learning activities during the Institute revolve around authentic, school-based projects to design or improve the design of the school web-site in support of student learning and professional improvement of educators. The work that is conducted during the Institute therefore affects other activities that place months after the Institute. The teachers returning to their school after the Institute can remain "connected" with the student teachers, via the telelearning tools that they have learned to use during the Institute, and therefore the time between the Institute and the field experience does not imply a disconnection between the participants.

Evaluating Participants' Past and Future Ways to Contribute Effectively to One Another's Learning

The third basic element of the teaching sequence, post-action, includes the ways which encouraged and supported participants' contributions to the community of learners as well as the ways in which future participation might occur, and be structured. At this design stage of the TL\textbullet PDS, it is important that opportunities be provided for the construction of shared understandings of teaching and learning in networked learning environments. For instance, preservice students create databases that inservice teachers use, and build on. Graduating preservice teachers who have worked in networked junior high classrooms have practices and reflective analysis to share with incoming student-teachers. Teachers that are integrating online resources and tools into their classroom have recognized different possibilities of organizing educational activities, one that they want to discuss with other practicing teachers (assumptions, goals, roles, processes, tasks, procedures, and the like). Teacher educators engage in more continuous interactions through time as they become integrative agents of theoretical perspectives and practices within learning communities.

Conclusion

From our own reflective analysis on how telelearning technologies enhance and shape our practice, we identified the above emerging patterns of time management. They all contribute to the creation of functional
asynchronous collaborative communities of inquiry. As the TL*PDS evolves as a complex dynamic system, it is likely to encourage participation in new practices of inquiry and sense-making that foster teachers' identity as lifelong individual learners and effective participants in the learning communities that will help them become better informed practitioners.

Abstract: This paper describes web-accessible databases which form the core of three similar resources for infusing technology into teacher education. The Technology Competency Database is built around the NCATE/ISTE Foundation Standards. Projects in a master's-level distance education course employ a variant called CTERbase. Undergraduate courses make use of competencies-linked activities databases known as TEbases. Each kind of web-enabled database allows students to enter descriptive information which teachers evaluate with grades and written responses. Exemplary student work can automatically be published for other students to see. Research and design initiatives are coupled with formative evaluation as part of ongoing development of these resources.

Preparing preservice teachers for classrooms of the 21st century poses new challenges in the wake of rapidly changing technologies throughout our society. As electronic resources for learning become increasingly important to schools across the country and around the world, technology instruction needs to become a major integrated component of preservice teacher education programs. Too often, this is still an unmet challenge, owing to lack of time in the curriculum and unclear instructional focus. Curriculum restructuring is an important step on the road to reform.

For the past three years, the teacher education program at the University of Illinois has engaged in curricular reforms to promote constructivist learning and provide strong foundational skills in instructional technology. What began as a pilot program for a select group of senior-year students was expanded in Fall, 1998 to cover all juniors and seniors pursuing certification as elementary or secondary school teachers. In support of these program reforms, there has been ongoing development and formative evaluation of a set of instructional resources known as Teacher Education Databases, or TEbases. This paper describes the historical, current and planned uses of TEbases as aids to educational reform.

Background

TEbases first took shape as a Technology Competencies Database (TCD), built directly upon the NCATE/ISTE Foundation Standards. The TCD was developed at the University of Illinois during the 1996-97 academic year and piloted in 1997 and 1998.

The TCD is built around a web-enabled database created with Claris Filemaker Pro 4.0. The databases are linked via Filemaker's WebCompanion to a set of web pages running on a Macintosh server in the University's College of Education. Each student has access via a password to her or his own record in the database. Via the web pages, students can submit to the database information about how they have...
met the competencies, in the form of written descriptions and URL pointers. Their instructors have access to a separate set of web pages allowing them to view the students’ records, grade the submissions, and provide written feedback about the students’ work.

Student work which has met with faculty approval can automatically become available for other students to see and learn from. In this manner, the somewhat dry language of a set of competencies becomes the basis for a rich exchange of ideas among a group of learners. For students, the end result is an individualized "electronic portfolio" linking to their best work, which can be of use to them in reviewing what they have learned and in searching for work after graduation.

Working with the TCD throughout their preservice program, students develop the competencies through different course experiences. Students might first satisfy a competency during a course experience by giving a simple example, but as they have opportunities to observe a body of best practices they might later meet the competency in another way and revise or supplement their first efforts. When students interact with faculty members via the TCD, they engage in reflective processes, display their knowledge, and negotiate meanings in individualized ways. The TCD is also an avenue through which elementary and secondary education faculty increase their own technological competencies because they need to assess the appropriateness of student submissions. Faculty at each institution work together to create the exemplars and criteria needed to assess student submissions.

From TCD to CTERbase

Formative evaluation efforts between Spring semester 1997 and Spring Semester 1998 has given us insights into the strengths and weaknesses of the TCD. Students and faculty members found the TCD easy to understand and use, and students added to it regularly. However, faculty in a class using it on a voluntary basis had great difficulty keeping up with the workload imposed by the TCD. A major factor appeared to be the fluid nature of the TCD itself—because students were invited to tackle the competencies in any order they chose, their teacher was faced with a bewildering array of information to evaluate. At the end of the 1997-1998 school year, fewer than half of the descriptions submitted by students had been graded. This led the developers to wonder if the TCD might be adapted to serve better the educational goals of teachers, as well as the students.

Two new kinds of course offerings within the College of Education in recent months have allowed us opportunities to redesign and enhance the usefulness of the TCD in major ways. In Summer, 1998, the College began offering via distance education an online master’s degree program in Curriculum, Technology, and Educational Reform (CTER). The CTER program was created to afford an opportunity for practicing K-12 teachers around Illinois and elsewhere to earn an advanced degree while building up their skill set with educational technologies. The 26 students in CTER’s first cohort group are working toward completing an eight-course, two-year program which offers theoretical and practical instruction in resources, methods, critical evaluation, and societal aspects related to teaching with technology.

Instructors who taught CTER courses realized that they would need a mechanism to allow their students to submit their work online, have it graded, and receive feedback. It turned out that a suitable mechanism for this already existed in the form of the Technology Competencies Database. By taking out the descriptions of NCATE/ISTE competencies, and replacing these with short descriptions of assignments due, a mechanism was created which could support project-based learning for individual students. Just as with the TCD, users of this initial version of the newly dubbed CTERbase could submit descriptions and URL pointers for their teachers to evaluate, and the teachers could provide grades and written feedback. To supplement the project-based CTERbase with competencies-based instruction, students in the summer course were assigned as one of their activities during the semester to complete the original TCD; this assignment offered them an opportunity to “measure” their learning individually according to the NCATE/ISTE Foundation Standards.

The Summer semester’s trial use of a CTERbase showed us that a web-enabled database could support instruction at a distance. Based on this success, use of CTERbase was continued in another CTER course offered in Fall, 1998. In this course, the 26-member CTER cohort were joined by nine on-campus UIUC students. Group projects were a major component of the Fall, 1998 course, which focused on educational evaluation. Therefore, an additional, key feature was added to the CTERbase which supported
this course: the ability to create groups, each with its own assignments, for which descriptions and grades would be matched with sets of individual students' records.

The Technology Strand

In the 1998-1999 school year, the College of Education at UIUC began implementation of a redesigned teacher certification program. Included in this redesign was a new course, Curriculum & Instruction 235: Content Area Applications of Educational Technology (referred to hereafter as C&I 235). In this new program, preservice teachers are not required to take a separate introductory course in the use of technology in education. Instead, the technology instruction is stranded through all the preservice courses, early field and student teaching experiences. The activities for the technology strand are based on the NCATE /ISTE Foundation Standards. In this framework, students are actively engaged in learning how to use technology in their content area or grade level and how to develop and implement lesson plans that will include the use of technology in their teaching. From our previous research on the level of technology experience of students coming into the teacher education program, we assumed that students would have basic familiarity with word processing and web browsers, although there are some students who come into the program with much more technology expertise.

This stranded course is coordinated by a faculty member experienced in the use of technologies across content areas and grade levels. A course syllabus was developed to be implemented over a two-year period. A number of meetings between the content specialists and the technology instructor were held to discuss what kinds of technology would be most useful for faculty and students to use in their teaching and learning. Hands-on instruction was provided in a computer lab setting by various content specialists and teaching assistants with support from the coordinating technology instructor. Five major topics are included in the technology strand: Computers in the K-12 classroom, Computer networks, Instructional & classroom management strategies, Social issues, and Keeping current with technology.

Implementation of the New Curriculum

The C&I 235 "distributed course" began in the Fall, 1998 semester. Students in four content areas in the Secondary Certification Program were given hands-on instruction in a computer lab throughout the semester within the context of a required course in the redesigned program, Teaching in a Diverse Society. This gave the teacher education faculty an opportunity to refine the syllabus integrating technology activities while gaining familiarity with technologies.

During this first semester, students learned how to use email for one-to-one communication and web-based asynchronous conferencing systems for group discussions. Students were assigned readings related to the use of technology in K-12 classrooms, searched the World Wide Web for content related resources, and learned how to evaluate the content of web pages and CD-ROM software for use in their content areas. Students also learned how to create personal web pages and upload files to a student server. Based on the course content, some students also began using digital cameras, presentation software, graphing calculators and spreadsheet programs. As students completed these assignments, they submitted them to a C&I 235 TEbase for grading.

The C&I 235 TEbase

The reconstituted TEbase has become an organization and management tool for students and faculty. Students use TEbase to submit individual and group assignments for each course taken over a two-year period. Using a web interface, these assignments can be typed directly into the database or students can enter a URL that points to the location of their assignment (usually linked to their personal homepage or web-based discussion archive) that can be accessed at a later date in the development of a professional portfolio which is a requirement for graduation. At the present time, all students are required to develop a hard copy portfolio although we are beginning to see many students developing both a hard copy and an
electronic portfolio we call e-portfolio. This portfolio will be used by students looking for teaching positions after graduation and later in their professional careers.

While students use TEbase as an organizational tool, faculty use TEbase to provide students with feedback on their assignments, grade and record assignments, track students progress of their work, publish exemplary student work, and map technology standards to the different assignments. While teachers do have the option of requesting paper copies of the assignments, faculty have expressed appreciation for the ease of using the Web to access students' assignments either from the university or their home.

The secondary content area courses are taught by different faculty members, each with their own teaching style and focus, so technology activities identified by the technology instructor have been adapted accordingly and integrated at different times during each semester. Since students use technology in each of their courses throughout a two-year period, TEbase was redesigned after the first semester of implementation to monitor technology assignments and competencies by student rather than by course. This redesign was needed to help the technology instructor monitor the integration of technology into the content area courses across the entire certification program, to provide a more flexible database to accommodate unlimited numbers of activities, and to provide a tool for faculty that is easy to use.

The TEbase Results

In Fall, 1998, there were six junior-year education classes using TEbases: two elementary education methods classes and four methods classes for students preparing for secondary-level certification in math, science, English and social studies. In all, there were 74 elementary education students and 148 secondary education students using the TEbases. Each TEbase was built around a different set of activities, and all of these activities were related back to the 18 NCATE/ISTE Foundation Standards.

By the end of November, it was apparent that the TEbases had been adopted as integral parts of their respective courses in all but one instance. It had been used to record five observation assignments in each of the two elementary methods courses, for seven activities in the secondary social science section; for five assignments in the secondary math section; and for 14 assignments in the secondary science section. In the secondary English section, the teacher did not use the TEbase with her students but the technology course coordinator used it to track two assignments with those students.

There were few difficulties with the technical operation of the TEbases. Nearly 2,000 logins had been recorded as of Nov. 30, with fewer than a half-dozen students reporting difficulties (in all but one case the problem was an incorrectly entered login name or password). Most encouragingly, there was no evidence of any shortfall in grading or provision of feedback for any of the courses using the TEbases, in marked contrast to the previous year's experience with the Technology Competencies Database. In the TCD and TEbase grading scheme, work that is judged acceptable appears on the web page with a “star” icon for a grade, and exemplary work is given a “double star.” Work awaiting a grade appears with an “hourglass” icon, while work which requires revision receives a “question mark” icon, and assignments which the students have not yet attempted appear with “blank” icons. As of Nov. 30, 1998, the breakdown of grades awarded by class was as follows:

- Elementary classes (74 students on five assignments): 292 stars; 7 hourglasses; 57 blanks; 14 question marks
- Math class (36 students on five activities due to date): 45 stars; 1 double star; 8 hourglasses; 120 blanks; 6 question marks
- Science class (25 students on one assignment due to date): 7 stars; 3 double stars; 7 hourglasses; 8 blanks
- Social science class (33 students on six assignments due to date): 160 stars, 11 double stars, 10 hourglasses, 8 blanks, 9 question marks
- English class (54 on 2 assignments): 85 stars, 23 blanks

In total, 604 submissions were graded acceptable (star) or exemplary (double star) during the period ending Nov. 30, 1998. Decisions were pending (hourglasses) on 32 submissions, for a grading completion rate of 95 percent. In many instances, the teachers supplemented these grades with written feedback, adding to the pedagogical value of the grades awarded. (It remains to be learned how this
feedback would compare in substance and length to what instructors might have given had the assignments been completed on paper.)

Discussion

Handler and Strudler (1997) recommend that the NCATE/ISTE Foundation Standards should be integrated systematically into the curricula of teacher preparation programs, in ways which might vary from one context to another. Our experience provides strong support for this recommendation. Whereas the initial instructor and graduate assistant were unable to grade more than 50 percent of the 176 competencies descriptions submitted by their students even by the end of the school year, the teachers and coordinator of the Fall, 1998 classes were able to grade 95 percent of their students' submissions soon after the submissions were made. Individual differences between this year's and last year's teachers and students may account for some part of this, as may the shift from voluntary to required participation. Yet it appears likely that in large measure the improvement is due to the difference in activity types. The activities in the Technology Competencies Database were the NCATE/ISTE standards themselves, and students were instructed to complete these in any order they chose. The activities in the TEbases were the instructors' own assignments, and these were due in a specific sequence on specific dates. We believe the improvement we have found offers strong evidence that it is more efficient to give instructors the leeway to set their own assignments in the TEbase than to require them to grade students' completions of the competencies.

The TEbase mechanism performs several important bridging functions within UIUC's new teacher education curricula. First is the bridge between individual class activities and the ISTE Foundation Standards. Methods teachers and the technology course teacher work together to construct assignments which promote learning in each competency area. Second is the bridge across courses - the TEbases function as electronic gradebooks which operate much the same from one class to the next, permitting students and faculty members to track learning consistently across the two-year program. Furthermore, the TEbases offer bridges between individual learning experiences and a coherent body of knowledge. At the individual level, this coherence takes the form of an electronic portfolio which each student can point to as documentation of their learning about educational technology. At the social level, the TEbases' ability to automate publication of exemplary work allows students to contributed to a high quality web resource that grows into something of value not only to the particular students and faculty, but to the educational world more generally.

There is a great deal more to be learned about the workings of the TEbases, and how they may be adapted further in order to ensure that the promise of instructional reform contained in the new teacher education curricula is in fact met. For this reason, we will be embarking in the coming year on more formal evaluation procedures, to investigate in an unbiased manner whether the benefits we think are occurring really are. Our course of action so far has been a continuing cycle of design-evaluation-adaptation. We believe this general course represents the best manner of attaining an optimal match of resources and curriculum. As evaluation efforts are formalized in the months ahead, we believe it will be important to maintain close ties to the evaluation itself, so as to benefit maximally from the process of investigation.

Abstract: This paper describes the contents and results of a pilot program of study for freshmen engineering students at a medium sized private university. The specifically designed courses incorporate active learning, strong teaming, use of common computer technology, team design projects, and a variety of well-documented assessment practices. A major component of this program is the use of the campus network and the Internet for all courses in the program: each course has its own web-site on which are posted all daily lessons, tutorials, reference materials and exam results. In addition, students in the program can communicate with faculty and with each other via forums, emails, and group communications. Although the students were drawn from engineering, the underlying philosophy is applicable to a wide spectrum of programs of study as well as the general education component of many degrees. In particular, it should be of interest to colleges and universities that offer degrees in teacher education, particularly programs in mathematics and science.

Introduction

Embry-Riddle Aeronautical University (ERAU) has completed the third semester of a pilot project for an Integrated Curriculum in Engineering (ICE). Sixty-five entering freshmen engineering student volunteers began in the Fall 97 semester and were placed into specifically designed sections of calculus, physics, humanities, and introductory engineering courses required of all engineering students at ERAU. These sections incorporate active learning, teaming, use of common computer technology, team design projects, and weekly assessment of progress.

Background

For many years faculty in both Mathematics and Physics have recognized that the freshman calculus and physics courses were very disjointed. The topics taught in calculus were not in line with topics covered in physics. Although we teach calculus as a support to physics, this was not at all clear to the students.

In addition, we were concerned with the high attrition rates of engineering students. Finally, in 1993 a group of faculty from Mathematics, Physics, Humanities and Aerospace Engineering started to meet regularly to seek better ways of educating the engineering students. These discussions focused on the NSF initiated Engineering Coalitions (Winkel & Froyd 1992). In particular, the Foundation Coalition, headed by Texas A&M University (TAMU) (Glover et al. 1992) which uses an integrated first year program (Glover & Erdman 1992), pioneered at Rose-Hulman Institute of Technology (RHIT) (Rogers & Winkel 1992), and adapted by TAMU (Erdman et al. 1992), was of interest to the faculty at ERAU.

The faculty team from ERAU visited both RHIT (Froyd et al.) and TAMU (Barrow et al. 1996) to observe and learn about each of the integrated program models they had developed and adopted. Although each program had
similarities, it was the TAMU program that the ERAU faculty decided to use as the basis for our Integrated Curriculum in Engineering (ICE) program.

Studying what was occurring at other colleges led us to begin to examine the detailed content of our courses, when these courses were taught and how they were taught. What became the eye opening exercise that really demonstrated the misalignment of the calculus and physics topics was when the faculty generated a matrix with all physics topics down one side and all the calculus and differential equation topics along the top. As an example of the misalignment between the two courses, our matrix showed that some topics in physics which required knowledge of vectors was being taught in the first semester course, whereas vectors were not being covered in calculus until the third semester. In addition to redesigning the content of the mathematics and physics courses, we decided to also incorporate teaming, active learning and the use of technology into the daily content of all the courses we would offer in the ICE program.

**Physics and Calculus Content**

The first problem to be addressed was that of the misalignment of topics between physics and calculus. Upon close examination of the topics in the matrix, we found several instances of serious misalignment of topics. In the first week the physics course was using vectors which included the dot and cross products. Vectors topics were not covered in the calculus sequence until the third semester. Also, the physics course used differentiation much earlier than it was being taught in calculus. However, the most surprising topic covered early in physics was the notion of a line integral. Although they were very elementary line integrals, this topic was not even mentioned in the calculus sequence at all. In fact, line integrals were not covered until the advanced engineering mathematics course. (Tab. 1) illustrates the topics covered in the first five weeks of the semester in a traditional freshman calculus and physics course.

*Table 1: Traditional Calculus and Physics Topics*

Although we accepted on principle that calculus was a necessary support to physics, our curriculum did not reflect that; we were expecting students to use mathematical principles in their physics curriculum that they were not being taught till later. Once the problem had been defined, it was apparent that the topics in the calculus sequence needed to be reordered. It was decided that the calculus sequence needed to follow the needs of the physics course. In order to gain some time at the beginning of the semester the first topic in the physics course was optics, a topic that required no calculus.

Keeping in mind that our goal was an Integrated Curriculum, we aimed for a program in which the math was taught, then used and re-enforced in physics. The first topics in the ICE calculus I was functions and parametric equations. This enabled us to then define vector-valued functions and polar coordinates. Next differentiation was introduced and applied to vector-valued functions as well as the traditional collection of functions. This allowed us to immediately cover integration of polynomial and simple trigonometric functions. With vector-valued functions and integration covered we were then able to introduce simple line integrals before they were needed in physics. These are only a few examples how calculus was reordered, so that the mathematical concepts were first taught in calculus before being used and applied physics. (Tab. 2) illustrates the reordering of topics in the first five weeks of the ICE program.
**Course Format**

Integrated courses across the curriculum

Another important goal was to align the entire curriculum for first year engineering students, including mathematics, physics, humanities and the introductory engineering course. In addition to linking courses across the curriculum, we also wanted to enhance the delivery of the courses by using active learning as appropriate and to foster in students an attitude of shared responsibility for their learning. We rewrote the content of every course in the ICE program with these goals in mind.

**Technology in the classroom**

In cooperation with our Informational Technology department we set up a website for each course in the ICE program. On these websites we posted the syllabus, daily lessons, team problems, exam reviews and solutions and any reference materials the instructor wanted the students to have. Having the worksheets posted on the web allowed the students access to them prior to class as well as in class on their laptop.

**Active Learning and Teaming**

In calculus, we produced daily worksheets for the course (Fig. 1). These worksheets were standardized to include the following information. The objectives for the lesson were stated at the top of each worksheet. Next were three or four exercises representative of the concept to be covered. Then the text reference and homework were listed at the bottom of these worksheets.

**Table 2. Calculus and Physics Topics in ICE**

**Objectives:**

1. The student will understand the term parametric curved path.
2. The student will be able to find the coordinates \((x, y)\) using a parametric curve given by \(x = f(t)\) and \(y = g(t)\).
3. The student will be able to graph a parametric curve given parametric equations over an interval \(a \leq t \leq b\).
4. The student will be able to eliminate the parameter to determine the relation between \(x\) and \(y\).

**Class Exercises:**

1. Obtain parametric equations that give the position of a particle on the path \(y = 2x\) given the following information:
   - When \(t = 0\), \(x = 0\), and \(y = 0\)
   - When \(t = 1\), \(x = 1\), and \(y = 2\)
   - When \(t = 2\), \(x = 2\), and \(y = 4\)
   - etc.

2. When \(t = 0\), \(x = 0\), and \(y = 0\)

**Figure 1: Example of a Daily Worksheet**
In class, the students would work from these worksheets in their teams. The instructor would give a short lead-in to the topic to be covered, and then the students would discuss the exercises on the worksheet. Care was taken when preparing the class exercises to accommodate active learning. One exercise would require the students to explore and develop the concept in their teams, and then the next exercise would be an applications type problem. In this way the students were involved in the derivation and not just using a formula.

After working on the problem for a set amount of time, the instructor chooses a team to present the solution to the class. In some cases the solution a team gives may not be completely correct, which prompts a general discussion on the problem. This additional class discussion proved to be very useful in identifying the problem area for the students, which could then be clarified by the instructor.

In addition to working in teams in class, several team problems are assigned to the students throughout the semester. These problems are more challenging and may cover multiple concepts. These problems are submitted in report format with each team member signing the cover sheet to indicate his/her participation in the solution. One team is chosen to present their solution. Students grade the presentation for accuracy, clarity of presentation and style.

Common Computer Technology

In developing the ICE program we agreed that there should be some standard software used throughout the program. For word processing and data analysis, Microsoft Office was chosen. This included Microsoft Word, Excel and Powerpoint. The engineering department had adopted Bentley Microstation as the computer graphics software, so it was also used in the ICE program.

In recent years there has been more and more use been made of Computer Algebra Systems (CAS) such as Maple in the teaching of Mathematics. Over the past few years we have incorporated the use of Maple into our calculus sequence. However, this came in the form of being in a computer lab one day a week and using Maple on assigned problems. Everyone involved in the ICE program had taught one or more of the calculus sections using Maple, so it was agreed to use Maple in the CAS in the ICE sections of calculus.

Unlike the traditional sections where the student went to a computer lab one day a week, the students in the ICE program would use Maple on a daily basis on their laptops. In fact, we wrote the exercises on the worksheet to incorporate and encourage the use of Maple. Having the students use Maple has allowed us to challenge them with problems that require more complex algebraic manipulation or do not have nice integer solutions, yet still illustrate the basic mathematical concepts. Maple has been especially useful in the multivariable calculus course. The plot package allowed a much more visual approach to some topics.

Assessment

We have gathered assessment data in numerous ways. The ICE faculty meet weekly to discuss where each course is in its planned program and the progress of each student in each course. We used plus/deltas - anonymous written comments on post-it notes to the instructor about anything positive in the course and suggestions for improving anything in the course that is not working. Also, a town meeting of all students and faculty is held three times a semester; this enables students to ask questions about anything they wish. Immediate feedback is provided to the students in the framework of the town meeting.

A student/faculty advisory committee meets every other week to share additional information from the students. These matters are fully discussed by the ICE faculty at their weekly meeting.

Formal assessment of the students is done using surveys constructed by the Office of Institutional Research. Also, comparison data with students not in the program is collected. This data included the number of completions, withdrawals, grades, GPA and retention.
Offer

The authors are quite willing to share additional in depth information with any institution -- high school, community college, university -- that wishes to learn more about these matters. Faculty who wish to visit ERAU to observe the ICE program in action may contact either about arranging a visit.

References

Over the last two decades, the growth of the Internet has truly been staggering. Electronic communities have flourished as hardware, software, and network infrastructures have become more accessible, more affordable, and simpler to use. In education, we have witnessed an extraordinary evolution, from the days when only a few educators were familiar with the Internet, to today, when almost all educators have access to email, the web, and other Internet resources. On today’s college and university campuses, electronic communication between students and faculty is a common occurrence, and new electronic communities are forming as educators and their students use online communications resources to discuss issues related to their courses. With the growing popularity of distance education, asynchronous discussion mechanisms are an essential part of most online course management system or OCMS (Graziadei, 1997). They also serve as the primary communication channel for other kinds of virtual communities including special interest groups (SIGs), discussion forums, committees, collaborative workgroups and the like.

Mailing Lists

Long before the emergence of the web, email was one of the early services to become popular on the Internet. As early as the mid 1970s, email distribution lists were being used for asynchronous, one-to-many and many-to-many communications (Bennahum, 1996). Named distribution lists containing hundreds or thousands of email addresses were kept on mainframe computers connected to the Arpanet (the Internet’s predecessor). Participants could share their messages with the group by sending their message to the named list (e.g. wine-lovers@ucb.arpa). The message would then be copied and delivered to each person on the list.

Mail lists worked quite well and caught on rapidly at participating universities as the early Internet continued to grow. However, this arrangement had numerous problems and limitations. It resulted in a significant burden on the list administrator because many requests would arrive each day from users wanting to be added or removed from a list or wanting to receive missed postings and additional information. The administrator would also need to contend with daily batches of mail delivery errors many of which were the result of invalid email addresses submitted for addition to the list. Running a large list was reported to have become a full-time job at a number of sites (L-Soft International, 1996).

Out of this was born the idea of a list server or "listserv" that could automate many of these administrative tasks. Eric Thomas --- cited by many as inventor of the list server --- began development of his list server in the mid 1980s, a system which he named LISTSERV. He conceived of a list server as an autonomous software agent that would
respond to user requests sent to it via email. This meant that users could interact with a list server using the same email tool they already used to communicate with their friends and colleagues. Initially, users were allowed to subscribe to, unsubscribe from, and request general information about a given list and also to request a list of lists that the server managed.

Other features evolved in response to the needs of the user community. A verification step was added to the subscription process to insure that invalid address weren't added to the list and unwanted third-party subscriptions weren't accepted from hackers. Archive mechanisms were added so that a request could be made to retrieve past messages from a list's archive. Also, a "digest mode" appeared in most list servers that allowed an entire day's (or week's) postings to be collected into a single message that would be sent to the members requesting this mode of delivery.

List servers have remained in this form up to the present day and are still widely used. These packages have been ported from the mainframe to today's popular server platforms including Linux (Unix) and Windows NT/95/98. Two popular packages are Majordomo for Unix/Linux (freeware available from Great Circle Associates at ftp://ftp.greatcircle.com/pub/majordomo/) and LISTSERV for Windows NT/95/98 (commercial software from L-Soft International, http://www.lsoft.com).

**Usenet Newsgroups**

Another form of asynchronous group conferencing to emerge during the 1980s was the Usenet newsgroup. Newsgroup reader software of the day was designed solely for the rapid browsing of sets of messages posted to a given forum or "newsgroup." Newsreader programs displayed related messages together, usually with responses indented beneath the message that began a new discussion topic. Users of list servers have traditionally complained that it is difficult to follow a discussion on a busy list because messages in their "in box" are displayed in chronological order. But unlike email programs, "threaded" newsreaders allowed users to follow the thread of a discussion visually.

Usenet-style newsgroups are still in operation today but they have evolved in several ways. Local, private newsgroups have become popular for teaching and learning applications as they limit the distribution of a group's messages to a single server rather than distributing them to regional or national news sites on Usenet. Many of the private news servers also allow access to be restricted to a specific set of participants (e.g. students in a course). Newsreaders and servers now typically support multimedia attachments so that messages can contain formatted text with images and attached documents. With both Netscape and Microsoft providing full-featured newsreaders within their browsers, Usenet-style newsgroups are still widely used for asynchronous conferencing. News server software is available from Netscape, Microsoft and a number of other smaller Internet software companies.
Web-Based Conferencing

With the advent of the web and its extraordinary popularity, the development of web-based asynchronous conferencing mechanisms was inevitable. These packages are variously described as "web bulletin boards", "hypertext newsgroups", "web groupware", "web guestbooks", and "graffiti walls" by those trying to put a label on this concept. Web conferencing packages provide easy access to the current and past postings of a group by providing multiple ways of viewing and searching the message titles and content. By exploiting the hypertext capabilities of the browser, web conferencing packages provide threaded views of a group’s messages as well as views sorted by author, order of arrival, and subject line. By means of a web form, participants can reply to an existing discussion or post messages to begin a new "thread."

By the close of 1996, it was estimated (Woolley, 1996) that there were more than 60 different software packages for web conferencing. The actual figure is probably a good deal higher when you consider that web conferencing systems are also incorporated into many web course construction packages such as Top Class, WebCT and Web Course in a Box and some web site authoring products such as Microsoft FrontPage. Rather than presenting a feature comparison of these products in the short space available here we will instead describe the development of a web conferencing package the authors undertook to support university course offerings. The evolution of the feature set and user interface is then described. A review of a number of commercial web conferencing packages can be found in the Woolley reference.

The Development of HyperGroups

HyperGroups --- a contraction of "hypertextual groupware" --- was conceived from its beginning about two years ago to be a hybrid email and web conferencing mechanism for use with web-supported courses. Bennahum (1996) and others have observed that email is the most widely accessible application on the Internet even when compared to the web.

For this reason, it has been a design goal from the outset that users should be able to choose to participate in conferencing either through email messages or through a web browser interface. Many students choose to participate in the discussions via email, where messages are delivered to the “in-box,” of their email programs, eliminating the need actively search out new messages. However, other students prefer the convenience of a web-based interface, which eliminates the need to launch a separate email program.

In HyperGroups, a discussion forum is called a hypergroup or simply a “group” and within each there can be any number of message threads. A single group often corresponds to a course although a professor may request a set of groups and assign different functions to each (e.g. - announcements, group collaboration, homework submission, etc.) Groups are created by the system administrator and take only a few minutes to create. A creation request needs to indicate the group name (e.g. ECON4203), a brief description or course
title and a list administrator's name and email address. Though we can accept requests through a web form or in written form, most are taken by telephone.

Once a group has been created, the professor (or someone designated to serve as group administrator) uses a web form to subscribe the initial list of students and participants. If that information is unavailable to the professor, she may at the first class meeting instruct the students to subscribe themselves via another web form. The professor also composes a welcome message and posts it to the group. This message may be very brief or it may be an entire course syllabus. The professor may also make a series of postings at the beginning of a term to open discussion topics, present course assignments or distribute reading materials. Preformatted documents can be easily attached to hypergroup postings further facilitating the exchange of information between professor and student.

If students choose to participate in the course via email, they subscribe to the group, although this step is unnecessary if the professor has already done this on the student's behalf. Students may also unsubscribe themselves if they do not wish to receive postings by email and would rather use the web interface only. The description that follows assumes participation via the web browser although in most cases the student could carry out the same action through email messages and list server commands.

Students and other participants are encouraged to begin by visiting the course hypergroup at the URL provided by the professor. Interested readers will find many current courses located in the public course index on our server at: http://www.coe.uh.edu/hypergroups/courses/

In the group index for public courses, as shown in Figure 1, each entry displays basic information about the group and provides buttons to browse its messages (LOOK), to post a new thread (POST), to subscribe (JOIN), to obtain more information (INFO) and to inquire about group membership (WHO). Each button brings up a new screen or form. Students click LOOK to enter the group and are prompted to login if the administrator has restricted access to the group. There they view the group's message activity sorted by author, date, subject or discussion thread. Clicking on a message entry displays the full text of the message. A nice feature of the web interface is that any URLs or email addresses in the body of the message will be displayed as active links.

Students can respond to any message by clicking a REPLY button in the header and footer of each message. A message composition form appears which presents the standard fields (e.g. To, From, Subject, etc.) that email users will immediately recognize (see Figure 2.) The To field is pre-addressed to the group but the PRIVATE option allows the sender to route the reply to the author of the original message only. The From field must be filled in with the sender's email address as that information cannot always be obtained from the
browser and is often incorrect. The Subject field is initialized with "RE:" plus the subject line of the original message, however users may enter something more informative and the message will still be placed in the proper thread. The message text field scrolls and allows for a plain text message of any size to be composed directly within it. Nonetheless, we recommend the use of a familiar word processor to compose messages of more than a few paragraphs. The completed and spell-checked text can then be easily copied from the application window and pasted to the browser window.

![HyperGroup Message Composition Form](image)

**Figure 2. HyperGroup Message Composition Form**

The size of a posting should ideally be no more than one to two pages (about 100 lines). Readers sometimes become disoriented reading large quantities of unformatted text. For larger documents, or documents that contain formatted elements, the ATTACH option (see Figure 3) allows users to post a normal text message that will serve to introduce the attached document. The attachment will appear as an active link in the message body and when clicked will cause the document to be downloaded to reader's desktop.

With attachments, care should be taken to insure that all members of the group have an application that can open and display the attached document or that they can easily obtain one. Free viewers can be downloaded from the web for common document formats such Microsoft Word 7.0, Adobe Acrobat 3.0 and many others. Our advice is to include concise information in each message about attached documents including the application,
vendor and version number or come to an agreement at the beginning of a term regarding the attachment formats that will be used by all group members.

Attachments used with HyperGroups can provide an attractive alternative to the creation of original HTML content for online courses. Online course management tools (OCMS) and course design templates can often require weeks or months of preparation before a course is ready for use. But for simple online courses or web-supported courses, a hypergroup often meets the basic communications requirement. Often the material needed will already exist in electronic form (e.g. slides shows, word processor documents, spreadsheets and instructional multimedia) or can be easily scanned from print materials. These materials can be easily distributed to students via HyperGroup’s attachment option as needed during the term. Furthermore, students can submit papers and other kinds of electronic documents via attachments.

Figure 3. The Help Screen for Using Attachments with HyperGroups

Conclusion

Originally planned as a communication resource only for the College of Education, the use of HyperGroups has spread to other colleges on our campus. The convenience of the Web-based interface and the automatic archiving feature make this a popular communication mechanism for a variety of audiences. Faculty members from many disciplines are using this tool with their students and several departments and program areas are also using HyperGroups as a way to keep discussions going between regularly
scheduled meetings. As the number of users increases, feedback and suggestions are being passed onto the developers. Additional maintenance tools are being discussed which will make HyperGroups an even more efficient and desirable resource that will bring together more electronic communities of learners.

CREATING AN INTERACTIVE VIDEO CONFERENCING NETWORK: STRATEGIES FOR SUCCESS

Paula Nichols, Ed.D., Educational Technology Center, Lamar University, USA, pnichols@tenet.edu

The Southeast Texas Telecommunications Education Network links school districts served by Region 5 Education Service Center into one communications system. The network is part of a statewide effort by the Texas Education Agency to create a K-12 telecommunications infrastructure. The Commissioner’s Access Initiative drives the growth of the infrastructure to provide PEIMS, TAAS and other instructional resources to educators in classrooms and campus offices. The ultimate connection goal of the SETTEN network is to create a telecommunications infrastructure which will be compatible with other regional, state, national and international telecommunications networks.

SETTEN began in the spring of 1997 with a vision to connect educational entities in the Southeast Texas together for the purpose of offering Internet access, data transmission capability and distance education for students and teachers through videoconferencing. Twenty-six local education entities formed the charter membership group to receive internet access and email via high-speed T-1 transmission lines through an Internet hub located at Region 5’s Beaumont site.

The project design involves three stages of installation:
1) Phase I provides for Internet access to all member schools,
2) Phase II integrates videoconferencing capabilities throughout the system,
3) Phase III will link the regional wide area network to other similar networks around the state through connection to the state’s Texas Education Telecommunications Network (TETN).

With the completion of Phase I of the project, public school districts in a six-county area now have high-speed access to the Internet and email service through a hub located at Region 5 Education Service Center in Beaumont. The network infrastructure is currently expanding to include additional connections to other educational entities, such as colleges, private schools and other districts outside the Region 5 service area.

Concurrently, Phase II of SETTEN’s growth began in the summer of 1998 with the installation of a videoconferencing hub at the Region 5 site. The network takes advantage of the high-speed infrastructure already in place to deliver standards-based videoconferencing to participating members for credit courses, graduate courses for educators and professional development opportunities to the rural communities offered by Lamar University. Videoconferencing will provide dual credit courses for high school students.

The SETTEN project is a true collaborative in that each charter member entity contributed a prorated share of the installation costs for the hub and local site equipment needed to obtain Internet access. New members contribute a similar financial commitment to guarantee adequate hub expansion.

Phase II proved to be the most cost-prohibitive part of the project with the high expense associated with...
expense of videoconferencing equipment. Region 5 Education Service Center is helping districts to actively seek assistance with these one-time costs from a variety of funding sources. Grant monies have funded the hardware and human infrastructure costs for installing a video hub at the regional service center and local distance learning classrooms at approximately half of the high schools in the region.

Members share ongoing costs for maintaining a network staff at the hub location, maintenance contracts on the system and periodic upgrades to the system through a cost averaging process. In addition, all classroom sites require a trained facilitator to monitor/troubleshoot the local equipment and to work with the network staff to ensure proper operation of the system.

The network is governed locally by a team of representatives elected by their peers. The nine-member Board consists of six charter member superintendents (one from each county served), Region 5’s executive director and two representatives from the Southeast Texas Higher Education Regional Council. With the addition of non-charter members, the board will grow to include other representatives. The SETTEN Management Board is empowered to make local decisions regarding policy and growth issues and meets on a monthly basis.

Representatives from Region 5 schools with distance learning classrooms met in October to plan projects to be implemented in the spring semester of 1999. The group addressed the following regional goals by brainstorming and voting on activities that will receive priority. Those goals and activities are as follows

1) Use distance learning and distributed learning for expanded curricular offerings and meeting the needs of students
   A. Offer SAT/ACT prep classes
   B. Summer School courses for high school
   C. Electronic field trips
   D. Teacher sharing (AP, Microsoft Academy, Cisco Academy)

2) Use distance learning to provide educational services and information about education to parents and community members
   A. GED courses
   B. Nursing courses
   C. Post-graduate courses

3) Deliver professional development and degree programs for staff and dual credit for students through distance learning
   A. Staff development
   B. Post-graduate courses
   C. Dual credit courses
   D. Sharing an expert
Training is an integral part of the successful growth and use of the network. Since its implementation, training has been provided in the following areas:

- Basic networking concepts - participants are introduced to the basic terminology of networks and learn to identify integral network components such as hubs, routers, and servers, etc.
- Using the Internet to locate educational resources - administrators, teachers, and other school staff learn to "surf" to locate areas of interest. They are introduced to the resources offered by websites such as the Texas Education Agency, the regional service center, and others.
- Email - Educators learn to send and read basic mail, build address books and lists, send and download attachments, appropriate protocol for electronic communication, etc.
- Hands-on System Training - Technical support persons receive hands-on training in troubleshooting, maintaining and daily use of hardware installed for Internet and distance learning purposes.
- Fundamentals of distance learning for educators - facilitators, Service Center personnel, college faculty, and public school teachers who will be teaching and presenting over the network have received training in instructional strategies and materials for interactive delivery.

Through these varied training opportunities SETTEN will build a human infrastructure to support the operation and programming of the video network.

The interactive network offers many valuable services for rural school districts. Many small high schools have limited curriculum offerings. Teachers for specialized subjects are not available or the number of students cannot justify offering an advanced class. Teacher sharing among several districts enables each high school to increase their curriculum offerings.

Dual credit courses from the university enable academically talented high school students to receive college credit during the junior and senior year. These students meet the administrative standards of the university and take college courses that fulfill their high school course requirements and carry college credit. Through the video network many rural high school students will be able to earn college credit before high school graduation.

Graduate courses are offered from the College of Education and Human Development at Lamar University. Many educators have the opportunity to pursue graduate degrees or additional professional certification while employed in rural districts. Since many districts seek to develop administrators from among their current faculty, access to graduate courses in their own community is especially important.
The video network brings many educational opportunities to rural communities that do not ordinarily exist in small Texas towns. These opportunities are valuable to residents both for professional development and for personal growth. SAT review courses are offered to assist students and community residents in preparing to take the SAT test. Non-credit workshops offer citizens the opportunity to take classes in organization, tax preparation and other personal enrichment areas.

The collaboration necessary to support and sustain the video network has proved to be a valuable part of the project. The relationship between the university, the school districts and the Region Service Center has been enhanced and extended. The extensive scope of the project has required that business, public school educators and university faculty work closely together. Regular communication among all stakeholders has proved to be essential in projects like this one. A variety of methods including video conferencing, email, fax, and phone are employed regularly to ensure that everyone is informed and included.

The SETTEN system has already proven to be a valuable asset to Southeast Texas. As additional districts join the collaborative and the participants explore additional ways to share resources and expertise, the benefits of these technology applications will continue to increase. The vision for the future includes the application of current and future technologies to overcome geographic restrictions and form a community of learners that will benefit the Southeast Texas area.
ARGUMENTATION ONLINE: THE USE OF COMPUTER CONFERENCING

Abstract: The paper will examine the mechanics of argumentation, some features of computer conferencing software that might support this teaching and learning method (e.g., strategies for sharing, examining and commenting on various kinds of evidence, threading a conversation, indicating type of message, linking to outside information, highlighting new information, different methods for engaging in a conversation and retrieving a record of claims and assertions, security and privacy, and other technical aspects), types of appropriate assignments, ways web conferencing might be used in courses.

Web conferencing has been touted as a vital component of distance education courses. A wide variety of inexpensive and free software is available for facilitating a discussion of a group online. The question is, “what are we using it for?” What type of interactions do we promote with our questions and assignments. What type of problem solving and critical thinking do we require from our students online, and how successful are we? Software features might facilitate higher level discussions, but we believe achieving this is a pedagogical issue more than a technical one. Web conferencing offers the opportunity for engaging students in arguments where they critically analyze and synthesize information to support a position, present that argument to others and defend their conclusions. These are important skills for both our education students and their present and future students.

The Technical Side of Web Conferencing

The Internet provides a channel for one to one and one to many communication between humans with the computer as a mediating device (Collins 1996). Synchronously, chat rooms, MUDs, MOOs, telephony and videoconferencing provide the ability for widely dispersed users to converse concurrently. While this has immediate feedback and social advantages, it can also produce disjointed, superficial threads of conversation and put those with poor typing or reading skills at a distinct disadvantage. Asynchronous modes of communication such as email, listservs, newsgroups, groupware, and web conferencing allow widely dispersed users to converse in a time-independent, self-paced, reflective manner with or without a structure built into the conversation. While this, too, can become disjointed and dragged out, it allows the user to review the structure and content of discussions and more time to reflect and compose their response.

Bulletin boards, newsgroups, and listservs have been in use for these online discussions for years. More recently, centralized forums designed specifically for group discussions, such as Web Board, Hotwired, HyperNews, First Class and Ceilidh, assign each message a place in a discussion structure. Workgroup collaboration software, such as LotusNotes, takes this one step further by providing computer-based systems that support groups of people engaged in a common task in a shared environment. These systems allow for both interactive communication and document sharing. It is these last two categories of software that provide the capabilities needed to carry out argumentation in an online environment.

1915
Skills in Argumentation

Students need skill in the process of argumentation to engage in critical thinking and persuasive writing, to understand and evaluate arguments in specific subject domains, to construct their own knowledge (Mason & Santi 1998) and to participate in socially constructed knowledge. Unfortunately, their arguments are often fallacious, based on invalid arguments, inadequate evidence, and representations of argument and evidence altered to accommodate naive argument structures and regression to core beliefs (Zeidler 1995).

Toulmin’s six stage model of an argument includes claims, grounds, warrants, backing, qualifiers, and rebuttals (Toulmin et al. 1979). To develop skill in using this model, students must have access to, and command over, the information resources and skills required to frame the research problem. They need to assess previous research and identify key issues, synthesize ideas and articulate their own hypothesis or claim. To support their claim or proposition, they need to gather evidence, identifying and evaluating sources, making observations and gathering, processing and evaluating data. This gathering of evidence may require a wide range of specific kinds of resources, expertise and software, depending on the domain of argument (Foote 1994).

Skill in identifying and communicating warrants and backing that support claims requires an understanding of the issues and the ability to reason with evidence. It needs articulate and convincing connections that may require databases, maps, graphs, charts, tables, video and sound as well as print. Analysis of expert versus student arguments shows students are weak in developing reasoning to connect their evidence to a claim through warrants and backing (Crammond 1998). At advanced levels, they need an understanding of both context and audience to use the expert’s communication strategy of an implicit rather than explicit warrant. They need to be able to identify the most effective foundation for argumentative appeal and use reason, ethics and emotion (Paradigm) as well as specific skills, tools and multimedia resources to communicate in ways that support these approaches.

As students modulate an argument with qualifiers and rebuttals, they need to be able to access, evaluate and analyze a wide range of related information (Foote 1994). This is especially so if they are to anticipate opposition and exercise the more sophisticated countered-rebuttal strategies of expert argumentation. Inferential reasoning and powerful communication of qualifiers and countered-rebuttals of evidence and warrants demands facility with databases, simulations and statistics. In this process, skill in constructing and communicating probabilistic arguments is essential (Leeman 1987) and requires access to and command of such tools as statistical analysis and graphic expression.

Assignments Requiring Argumentation

To develop, evaluate, accept or refute arguments, students at all levels need experience in identifying, gathering, evaluating, organizing and presenting evidence to support claims. Traditionally, that has been done in the context of papers, oral reports, and debates. Students are asked to support their arguments before teachers and fellow students with, however, limited opportunity for critique and refutation. They learn to create a claim, gather evidence (factual or opinion), and test the reliability and validity of the evidence. As emerging technologies offer new forums for distributed learning, there is the very real concern that the context will impoverish pedagogy and diminish the quality of learning. We propose that they can do just the opposite when use is thoughtfully structured. Pedagogical methodologies for engaging students in argumentation online are needed on top of the simple technical capacity for carrying on asynchronous conversations.

The type of assignment influences the type of argumentation structure used by students. They might be asked to defend or refute a position, present pros and cons of a position, critically evaluate one or more sides of an issue, support and/or develop their own position, reach a new position, solve an existing problem, make a decision, or persuade (Voss & Means 1991). No matter what type of assignment, the student needs to understand the rules, timeline and structure required.
Debate often refers to competitive oral debate with precise rules where students alternate to defend opposite points of view. They operate in a formal structure with points for style, arrangement and delivery of a position within specified time limits. This could be done by individuals debating before the rest of the class or by groups of students taking different sides. Judging by peers or outsiders could be set up in electronic format by asking the judges to submit an electronic ballot to each side at the end as a web conferencing message. The linear order of presentation could structure the debate as in the email debate between fourth and fifth graders on the right of US citizens to protest in time of war (Clark 1992) or it could be set up so that each side could go back and view past statements or examine a claim and its refutation side by side in windows. Related points could be linked within a web conferencing program so readers could see relationships between ideas. Ideally, a web conferencing program would allow hyperlinking or linking to specific sections within a message for greater ease of connecting threads of the debate.

Students required to take both sides of an issue can be encouraged to “see” an opponent’s point of view. As students investigate, they generally “discover differences of reasoned, rational opinion on both sides” (Leeman 1987). This type of assignment forces students to confront confusion in the research, become part of the decision-making process and avoid viewing only one side of an issue. In debates conducted via web conferencing, students can easily link to “experts” on a side of the argument, and the opposition can examine the authority or bias of the evidence. Intellectually, such assignments give students experience in the multiplicitic and relativistic perceptions of issues sought in Perry’s model of intellectual development (Battaglini & Schenkat 1987).

Mimicking a real conference, web conferencing could be used for presentations with a discussant and questions from the audience or an online symposium or panel discussion. The discussant could tie together different presentations, point out similarities and differences, add their own knowledge, or critique the presentations.

In a role play, students are given a specific character role, asked to research that role’s position, and present that perspective in an argument. There may be multiple roles in support of a point of view, each with its own perspective. This type of assignment is less structured than a debate, but could develop the same skills. The group could work for consensus or have a panel or body making a decision based on the arguments made.

This role playing could be part of a case study based on a real, relevant situation “complex enough to warrant analysis” (Seaman & Fellenz 1989, 111). Background for the case study could be available electronically to support real-world research and data gathering. Students could go beyond the classroom to contact experts, perhaps even inviting them to join the web conference to provide testimonials or evidence. Others might interview these experts through the web conferencing. The experts might even provide feedback to the group’s decisions.

In a jury trial, students may take various prosecution or defense roles, act at judge or jury, or provide testimony as a witness based on research. Teams of lawyers could work together to develop questions for witnesses and provide opening and summary statements. The jury could continue deliberations through web conferencing without the input the lawyers. In a web environment, real lawyers and real judges could be asked to participate. The judge could be called on to moderate throughout. All this could be examined after the fact through the web conference transcripts. Committee hearings could be conducted the same way.

Any of these assignments could be enriched by examination of the transcripts either by participants after the conference is concluded or by other students during the conference. Such conversations remain on the web for an indefinite period of time in the same order they were created. Comments can be appended to any message for clarification, questions, or comment. New messages or specific types of messages can be flagged by different types of icons in some web conferencing programs. Readers can be lead to new, unread messages by date, special icons, or sorting. Some even allow email notification if a new message appears on the conference. Moderators might be asked to pull together comments on a topic or students might be asked to critique the argument from a particular perspective, or explain how they agree or disagree. Students might even be asked to reflect back on changes in their thinking through the discussion.
Web Conferencing Features

To construct and communicate argumentation online, students need to understand both the elements of an argument and methods for developing, communicating and supporting their argument in a web conferencing structure. As the basis of any argument, one must understand the opponent, the audience and the context. “Arguments respond to specific situations: a need is not being met, a person is being treated unfairly, an important concept is misunderstood, an outdated policy needs to be reexamined.” (Guilford 1996). Understanding the adversary, audience and context in an online environment may involve formal research, informal, unstructured discussions, electronic introductions, or even online surveys concerning the area of interest. It involves the same basic type of research used in a written or oral presentation, but the information might be accessible in different, often multiple, formats.

Many of the new web conferencing tools offer a forum for creation and support of a logical argument across distances and time and strategies for attaching some kinds of evidence. Various features of web conferencing software can facilitate the argumentation process. Claims can be stated as a new thread or forum in a web conference with various forms of media used to supplement the text proposition and put it in context. Different audiences might be accommodated by providing hyperlinks to additional relevant information or more in depth levels of explanation.

As students develop hunches or good guesses into propositions and move beyond fact or opinion into statements open to debate in a web environment, they need the versatility to develop the scope of their argument in the context of web documents illustrated with multimedia. As they anticipate opposition, expand and communicate their argument, they need to have an environment that enables graphic portrayal of both sides with links to supporting evidence (Buckingham Shum et al 1996). Their audience needs similar mechanisms to contribute feedback.

Gathering, examining, and assessing the relevance and reliability of evidence from a variety of data sources, including observation and formal research can be done either electronically or in traditional formats. Using a variety of software tools, students can collate and organize data for presentation in a argument structure. If working as a group, they may choose to conduct their own private web discussion to select, relate, and organize appropriate grounds. For some, a concept map of related ideas might help in the organization of the argument. Ideally, a web conferencing tool would allow creation and online manipulation of a shared concept map. This same graphical organizer might be used to present the argument and lead the reader through a web of hyperlinked information. Andrews (1993), in a study of 150 Year 8 students, found that planning for argumentation tends to go before writing & most plans were in the form of spider diagrams, numbered notes, or connected boxes. Only 2% of those in his sample took the polar form (e.g., the for-and-against model). This differs from writing narrative, where the students planned during the act of composing. Groups need a way to collaboratively plan arguments across distances in this graphical format.

At the same time, both the small collaborative groups and the larger discussion may require a moderator to keep the group on task, move around mislinked messages, and make connections that seem to have been missed. This might be accomplished by allowing administrator rights to a limited number of participants in a particular forum. Security and privacy of individuals may also be an issue in some discussions. There are web conferences where the participants use aliases rather than actual names to protect their privacy. Only the instructor knows the identify of each participant. Even the instructor may want to use an alias to avoid influencing the conversation with “authoritative” comments and questions.

Individuals or groups can strengthen their reasoning by adding specificity, qualifications, and elaborations to already stated reasons. This can be in the form of additional textual messages or links to graphical, auditory, spatial, or motion evidence. This multimedia evidence can provide a new perspective on a claim. Links to simulations or statistical models that the reader can actually test, allowing readers to modify existing spreadsheets or graphs, or providing connections to experts for further clarification or elaboration are all possible through web conferencing programs. This is true hypermedia, which may incorporate text, images, maps, motion video, and sound linked electronically through multiple routes.
Reasoning from the evidence, or developing the warrant with backing, requires close examination of the evidence for patterns and relationships, reasoning and analysis, and inference. One of the most difficult things to do in a web conference is to make this warrant evident in a series of connected messages. Other readers may insert comments or questions in the thread of the argument, questioning the warrant or adding opposing viewpoints, depending on the rules of the assignment. An overall outline or graphical portrayal of the parts of the argument would make it easier to see the structure of the warrant and its backing.

Some web conferencing programs allow for the collapse and expansion of the outline of the message thread so that only the top level of the conversation is visible. With appropriately chosen subject headings, this might be used to point out the major evidence. If there were a way to indicate the types of links between these messages, it might facilitate making the warrant. For example, on concept maps, it is often possible to label the links between the nodes, indicating types of relationships. In some web conferencing programs, it is possible to add an icon to each message indicating the type of message, but indicating the type of relationship between messages is generally not possible other than indicating hierarchical relationships.

The structure of the online argument may vary in different web conferencing programs. In some a hierarchical structure is created, in others a linear structure. HyperNews is one program that actually creates both with an outline and inline mode, accommodating both structures. The hierarchical mode allows threading a conversation with each response connected directly to its referent. Many readers prefer a more linear structure as that is how most oral and written communication takes place. Developing and following a hierarchically arranged conversation requires a different type of cognitive organization. One must keep in mind the overall structure of the discussion to place each message in its appropriate context. Highly skilled reasoners tend to reason hierarchically by placing reasons in category form (Voss & Means 1991). With time to reflect on the development of their argument, this should be fairly simple. Use of the ability to view only high level messages would allow this organization to stand out as a type of advanced organizer.

Careful sequencing of an argument requires thought. Analysis of an argument is easier if there is a record of the structure of the argument and associated evidence for concurrent, and subsequent, evaluation and scrutiny. Refutation and response to refutation is more likely if there is opportunity for a delayed response that permits evaluation of evidence, reflection and consultation.

As the students anticipate their opposition, it is possible to link these qualifiers and rebuttals directly to the points they wish to question or refute. This can be done easily in a hierarchical structure. In some programs it is possible to add an icon indicating that the response is a question or disagreement with the previous statement. In the style of a pros and cons chart, students might want to create a matrix of points and counter points viewed side by side, possible if a program allowed parallel threads to be displayed in adjacent windows. Again, a concept map or other graphical portrayal of both sides would allow hyperlinking between related points. With the ability to link out to other sources on the web, experts or their writing could also be brought in to present contradictory evidence, question the accuracy of evidence presented or draw attention to a fallacy of reasoning.

Navigation in web conferences may allow the reader to search for specific points or terms within the messages or the subject headings, jump out to related evidence in a variety of formats, search for additional information on the issue, follow a chain of reasoning set up by the arguer, examine specific types of messages, or view only related messages on a specific point. The students creating the argument can link relevant points together through the placement of the messages, tie evidence together to support a claim through inductive or deductive reasoning through a hierarchical structure, indicate relationships between linked messages through subject headings or icons, add refutation to any opponent's point, and highlight new information through the program's dating or icon system.

Transcripts of these conversations are constantly available to anyone participating in the conference. This allows an individual or group to carefully examine the opposing points of view and critique their own evidence and reasoning. At the end of the discussion, individuals can look back to assess the strength and validity of the reasoning and evidence, their own contribution, changes in their thinking, and their skill in argumentation. Instructors can similarly use these transcripts to gauge student understanding and skill. These discussions can be archived for comparison to subsequent discussions, either by the same group or by a later class.
New forms of community and collaboration are possible in online discourse. The impediment of authority structures can change; students and teachers can become part of an academic discourse where everyone has an equal say. All students have the opportunity to structure and present their thoughts to the group as well as to examine and question the work of others. The roles of both students and teachers can change. Students can become both publishers and critics. They may be asked to do more than simply present a summary of their findings, and instead defend their claim or thesis to others. Their peers may be asked to do more than simply listen and add a few polite comments, and instead be prepared to act as discussants. Teachers can act as leaders, facilitators, moderators, or observers. The community evaluating the argument can expand; outsiders may join the discussion as experts, mentors, or critics.

For online discussion to support argumentation, students must understand how to create an argument, and respond to critiques or refutations of their work. Equally, as listeners, readers or responders, they must be prepared to evaluate the claims and evidence of others. Regardless of the discipline, instructors must structure assignments to require arguments, encourage participation, and move students toward critical thinking. Equally, the technologies used must also support an accessible, free-flowing and coherent discussion.

Real-Time Collaboration over the Internet: What Actually Works?

Dr. Kathleen M. Swigger, Dr. Robert Brazile, Suzanne Byron, Alan Livingston, Victor Lopez, Josie Reynes, Laboratory for Applied Software Technology University of North Texas United States Kathy@cs.unt.edu

Abstract: While the growth of the Internet and collaborative software has greatly impacted the way students work together, little is known about what actually works and what doesn't. Some researchers argue that both structural and cultural problems impact effectiveness, while others suggest that a lack of "critical mass" may be affecting the results. This paper suggests that all of these things are true. In also contends that the type of task required of the group and collaborative style influences effective real-time collaboration. While this paper confirms that collaborative interfaces help most people work more effectively, it also shows that some groups are less successful, have fewer interactions, and remain hostile towards the system even though they complete the required task. More importantly, the results of our research raise additional questions about how technology can support distributed groups, and what is the nature of the mismatches.

Introduction

As the number of distance learning and online courses continues to increase, we are being forced to re-examine the way we teach students to think. The idea of the "classroom teacher" is gradually being replaced by a web page or "talking head" that emanates from a remote site. Because of the rapid growth of this type of technology, we are beginning to question whether technology can support the in-depth contact between subject-matter expert and a small group of learners that is at the heart of our nation's peerless reputation in higher education. While both the Internet and other types of distance learning systems provide interesting pedagogical experiences, they lack many of the features that are associated with traditional educational classrooms such as laboratory exercises and small group discussions.

If one of our goals is to improve education (Willis 1993), then we need find ways to provide teachers and students with electronic learning environments that support both mentoring and collaboration through electronic means.

In order to address this challenge, the authors developed special software that supports same time/different place educational collaborative activities over the Internet. These activities focus on teaching students how to organize and systematize their explorations for information and to share this information with members of a group. The software is composed of a unique interface that connects to the hyperlink, text, graphics, video and sound capabilities of a browser to a World Wide Web (WWW) client-server environment, and is augmented by local electronic help tools and computer supported collaborative tools. Collaborative activities are supported through specially designed whiteboard, chat, file and application sharing tools. Students can access online schedules and determine whether faculty or other students are available. The system is also equipped with both management and record keeping capabilities that allow teachers or trainers to analyze the various collaborative activities. Over 200 students enrolled in a variety of different courses at the University of North Texas used the system during the past year to collaborate with both students and teachers throughout the campus and different parts of the Metroplex. Information was logged concerning overall student performance, activities performed while using
the collaborative system, and attitudes related to technology and collaboration. Results from these history files were then analyzed to determine which factors contributed to successful/unsuccessful collaboration.

While the past year's research show that collaborative interfaces help most groups work effectively, it also shows that some groups are less successful, perform fewer group interactions as compared to successful groups, or are uncomfortable with the system even after several hours of training. For example, we observed that some individuals completed the stated task but never shared information with other members of the group. Other subjects were disruptive, eventually causing the group to fail. In contrast, there were groups who learned how to complete tasks successfully, even when faced with adverse network conditions. Although the results of this research show that most distributed groups produced work that was indistinguishable from groups doing the same work face-to-face, some groups’ performed poorly, some had members who never participated, and some work teams complained about the system, even though they performed well. Thus, over the course of two years, the authors have discovered many factors that both encourage and deter collaboration among students. The nature of these factors and how they impact effectiveness are discussed below.

Relevant Literature

 Much has already been accomplished in demonstrating the potential of using the Internet for educating, sharing, connecting, and communicating. For example, students enrolled in political science courses use the net to access large databases (Baker 1993; Newton 1993), students in high school use it to contact experts in the field (Press 1995), and students in business use it to learn about changing stock prices (Winner 1994). An ever increasing number of virtual classrooms are now available to students living in different cities or states (Huang 1997; Foster 1995). However, increasing educational opportunities have resulted in decreasing classroom time, and hence, decreasing the number of occasions where students and teachers interact with one another face-to-face. Thus, the question remains of how to make distance leaning environments support real-time educational activities such as academic advising, mentoring, laboratory experiments and small group exchanges (Reinhart 1995). While we know that network technology can be used to empower learners with the latest tools of the trade, we also know that it lacks the personal element that can give meaning to an educational experience. Thus, our prototypes and models must clearly demonstrate how network technology can evolve into an educational ecosystem of information, computation, communication, collaboration, and innovative mentoring. At the same time, the models must emphasize information access and visualization to provide easy derivation of an interactive information experience.

 In response to these problems, the authors engaged in a number of innovative collaborative software projects sponsored by various funding agencies over the past several years (Swigger & Brazile 1995; Swigger et al., 1997). In order to enhance students' understanding of the cooperative process, we built several computer-supported cooperative interfaces that teach students how to cooperate more effectively in the accomplishment of specific tasks (e.g., library database searching, requirements elicitation, and cost center analysis). The cooperative interfaces all emphasize shared window systems (i.e., What You See Is What I See) that allow students who are geographically distanced from one another to work together at the same time. While several of the original interfaces proved effective, they did not support shared activities over the Internet. Thus, we developed an Internet-based tool that supports real-time collaborative learning over the network. The major focus of the research is on showing students and teachers how to work together over the Internet, and how to locate, synthesize, and analyze vast amounts of available
information. The long-term goal of the project, therefore, is to study what factors (in terms of both the interface and instructional materials) lead to effective collaborations. Thus, we are analyzing how teachers and students move from their specialized classrooms into shared, multi-user settings where diverse groups can collectively solve problems.

**Collaborative Software**

As previously mentioned, the project’s major objectives are (1) to develop software that allows students to collaborate, and (2) to determine whether the software can be effective in an educational setting. Thus, the first task, to develop software, has resulted in a series of programs that allows students to access special tools, libraries, and the network, to pose questions and conduct exchanges with teachers and other students in real-time. As a consequence, the system supports students who are located in different geographical areas, but who need real-time (i.e., What You See Is What I See) access to information from a number of different sources, including a university, the Web, and local networks as well as other students and teachers. Students are free to perform activities, find information, conduct experiments, and engage in collaborative activities to obtain information. Since the system supports both synchronous and asynchronous communication, the collaborative activities can occur either at the same or different times.

The current application comes equipped with a number of collaborative capabilities that enable teachers and students located in different geographical locations to “enter” each other’s worlds. For example, the system allows groups to share applications and perform a specific task such as completing an experiment, writing a paper, using a software package. Thus, the major software components include (1) a special graphical user interface, (2) support programs that manage the communications and data gathering functions, and (3) administrative programs that support activities such as student/group registration and report generation. The special graphical user interface consists of a shared Browser for the WWW, and a set of collaborative tools that permit groups to chat, use a whiteboard, and share both applications and files. The support programs that manage the communications and data gathering functions include a polling application that maintains the user and group lists, and a suite of programs that create, maintain, and update the database. Finally, the system performs administrative functions such as installation, student and group registration, and report writing.

**Evaluation**

As previously mentioned, a major component of this research is the evaluation of the effectiveness of the collaborative interface to determine what is and is not effective. During the past two years, over 400 students have used the collaborative software in seven different courses. Courses using the collaborative courses were compared to control courses using a pre-test post-test, matched controls design. The evaluation was designed to determine the effect of the collaborative technology on student learning outcomes, student attitudes, and attitudes about collaboration. Results from comparisons of just the performance variables (i.e., that course grades and scores on the questions concerning analysis and synthesis of information) indicate no significant difference between the control and experimental groups.

We also collected information from the computer sessions through our data collection programs. The system logs information such as source, time, and type of interaction. Thus, we were able to capture a detailed record of the types of activities that students (and groups) perform while using the interface. Analysis of this data indicates that group chat was the most frequently
used collaborative tool regardless of course content or activity. The shared web browser was the second most frequently used tool, while usage totals for all other tools corresponded to the type of task that was performed by a particular group. The system log information was also correlated with factors such as age, a student’s major, and gender and indicated that these variables often impact a group’s productivity (as measured by total time to complete a task and the activities performed during the task). For example, students enrolled in non-technical courses used the chat tool more frequently and longer than students enrolled in science course. Groups who were dissatisfied with the system did not necessarily perform less well than groups who were satisfied. And finally, as network delays increased, remote groups spent more time managing their work or verifying that a message had been either sent or received. Although our observations seem sound, they are based on a limited amount of data. In the next year, we will gather additional information about a group’s work, learning, and communication style to determine their effect on distributed problem solving.

From both observation and data gathered during the project, a number of conclusions were made concerning how students used the interface and which parts were successful and unsuccessful. These conclusions are as follows:

1. Students seem unable to manage multi-tasking or multiple windows. As new applications are opened, existing windows or applications are hidden. Once removed, students mistakenly believe that the application has shut down and must be re-opened. This can reek havoc in a synchronous communication environment.

2. Students seem unable to distinguish between the different modes of a computer. For example, they fail to understand that there is a difference between “shared” and “individual” modes of work.

3. Students need to know how to map the computer-collaborative tools onto the specific tasks. (I.e., Which collaborative tool should be used for which task?).

4. Students become frustrated when they do not know what other members of the group are doing. As the students become more proficient with the software, they learn to use awareness tools that provide them with information about the other members of the group.

5. Students lack metaphors for shared software applications. As a result, they have no established protocol for how to interact with team members while using this type of software.

We also examined the various collaborative exercises used in this project to determine which factors contributed to success. Examples of these activities can be found on the project’s web page (i.e., www.vcuproject.edu). The types of activities developed by different faculty tend to vary according to the nature of a particular discipline and the faculty member’s particular style. However, based on both observation and data, we are able to make a number of conclusions about what types of tasks were most successful. For example, successful collaborative experiences tended to be both extremely focused and small. Initially, faculty members modeled their collaborative exercises after classroom exercises in which both groups and teacher are free to roam around the room. Unlike the classroom, however, a teacher cannot always sense when a group is frustrated or confused and must often wait until it is too late to correct the problem. As a result, many of the computer-supported collaborative activities were scaled down to accommodate the loss of visual cues. At the same time, the set of instructions provided to students were greatly increased and posted on both the faculty and course web pages.
We also found that it was not always possible to adapt a classroom group activity to a computer-supported collaborative environment. Tasks that worked well in the classroom did not always translate into the new environment. One such activity was an environmental science project that asked students to collect data on a number of different events and then share this data with other members of the group. Given the location of the data collection source (e.g., an outdoor pond), it was neither convenient nor possible for students to share their data in a machine-readable format. As a result, the collaborative software became more a hindrance than help in supporting collaboration.

Data on faculty satisfaction also tended to vary. Faculty were surprised that Internet communication was sometimes slow and inconsistent. While some faculty experienced no problems with the hardware or software, others were overwhelmed with the technology. Successful experiences with both software and student collaboration tended to occur when the faculty member was well organized, and the student activities were well structured, small, and self-contained. As the complexity of the educational activity increased, the level of unsatisfaction among both faculty and students also increased. Finally, our interviews with faculty that participated in this project clearly indicate that most do not realize that collaborative skills have not been mastered at an earlier age. However, our data suggests that most students lack both organizational and interaction skills and, as a result, often end up working alone to complete the task. For example, the most frequent statement recorded in or study’s database was the question: “Ok, what do we do now?” This is then followed by a series of responses, all echoing the phrase, “I don’t know.” As a result, the training sessions included information about the use of the system and how to collaborate. For example, students were shown how to use the chat tool to establish their group’s procedures and distribute the work. After such training, the collaborative exercises were much more successful.

Conclusions and Impact of Research

In conclusion, we believe that we have identified a number of factors that contribute to successful computer-supported collaboration. After developing a system that supports real-time collaboration for students in different locations, we examined how students enrolled in a number of different courses at the University of North Texas used the software to complete specific tasks. While our research shows that the collaborative system helps most groups work effectively, it also shows that some groups are less successful, perform at a slower rate than face-to-face groups, or are intimidated by the system even after several hours of training. Success with the system seems to be affected by task, training, and experience. Knowledge of how to perform as a leader also seems to be an important factor.

Furthermore, groups’ preferences for and use of certain collaborative tools, as well as their use of features within those tools, greatly varies. However, judged by the total time spent completing the task and by their scores on a series of related questions, performance seems unaffected by whether distributed groups used all or some of the collaborative tools. Our studies also show that the collaborative interface allowed groups to brainstorm and co-author documents and, in doing so, encourages both talking and doing in the same meeting. On the other hand, because of the often-restrictive nature of the interface, groups are forced to talk to each other via their fingers rather than their mouths. As a consequence, team members with inadequate typing skills feel inhibited or restrained. In addition, we noticed that many students learned to adjust their communication style and adapt to the more delayed mode required by the chat tool.
In our research, we have found that while software allows groups to work more effectively, group performance is often impacted by a variety of individual personality, communication, and work style preferences. We have also observed that groups tend to react to individual preferences in a number of different ways. Some groups engage in additional procedural or management activities, while others perform fewer clarification or solution activities. It is our observation that the need for low cost, distributed education occurs frequently in this technological society. Yet rarely do we use network technology to actually meet these educational goals, nor do we provide students and teachers with the tools to communicate in this mode. As such, this research should provide insight and software tools for broad-based interactive learning by electronic means. Moreover, it provides a rich research environment that allows us to investigate various issues related to improving the performance of student and organizational teams that work together across distances.

Web-based Instruction and Motivation: Some Useful Guidelines for Educators

Shahrzad Vafa
University of Houston
United States
sghorban@bayou.uh.edu

Abstract: The purpose of this paper is to point out the importance of motivation and describe a model that provides a useful framework for both the design and improvement of the motivational quality of Web-based instruction. This paper presents an overview of the primary components of motivation as well as a motivational instructional model. In addition, it discusses an instrument used for designing and assessing the motivational quality of World Wide Web sites.

Introduction

Web-based instruction is rapidly increasing in our educational system. More and more educators are utilizing the great potential of the World Wide Web, including the use of hypertext and hypermedia, in their teaching. As Web-based instruction continues to grow, the need for design guidelines also increases. Although there are some guidelines for the structure and content of Web-based instruction, very few address the motivational aspects. One of the important issues to consider when designing Web-based instruction is motivation.

Motivation is relevant to learning and must be included in any instruction. Most students only learn to pass their tests or meet the necessary guidelines to finish their degree. However, students who become both extrinsically and intrinsically motivated will continue learning even when formal education has ended. Moreover, motivating lessons will encourage students to become more curious as well as make learning experiences enjoyable. These aspects allow students to remain at a task longer until they master the skills and knowledge presented to them.

In order to improve the motivational quality of Web-based instruction rationally, there is a need to understand the components of motivation. Thus, the first part of the paper presents an overview of the primary components of motivation. Furthermore, a motivational instructional model that takes into consideration the motivational aspects of instruction is discussed. The last part of the paper describes an instrument used for designing and assessing the quality of World Wide Web sites.

Components of Motivation

The components of motivation presented in this paper are three cognitive theories: Rotter's social learning theory, Weiner's attribution theory, and Atkinson's expectancy x value theory. These motivational theories are discussed to help educators predict and influence students' behavior. Cognitive motivation theorists regard "cognition" or "beliefs" as mediators of behavior (Stipek, 1998). These theorists believe that changes in behavior are a result of change in individual cognition and belief. However, these cognitive theorists have different regards on the "beliefs" and "cognition" they emphasize.

In Rotter's social learning theory (1966) thoughts affect achievement behavior. Rotter proposed that an individual's belief about what brought the reward increases the frequency of behavior, not the reward itself (1966, 1975, and 1990). Rewards need to be associated on the individual's personal abilities or characteristics in order to have any influence on their behavior in the future.

Rotter refers to an individual's belief regarding the contingency of reinforcement as locus of control (LOC). "Internal locus of control" refers to the belief that an outcome is possible based on one's own behavior, such as ability or effort. Other factors that are beyond an individual's outcome such as luck
are considered “external locus of control.” Rotter believes that it is very important for students to link their academic achievement with their locus of control. In order to work harder on tasks and progress in their studies, it is necessary that students attribute their success based on internal factors such as effort and ability rather than external factors such as luck. For example, if rewards are the same for all students (everybody in class gets an "A"), students will not work hard because they feel that the rewards are not contingent on their behavior. Increased learning and future success will occur only if students believe that their own behavior has caused the reward.

Attribution theorists such as Weiner have refined and elaborated upon Rotter’s concept of locus of control. Attribution theorists believe that humans are intrinsically motivated to understand the world around them, to "attain a cognitive mastery of the casual structure of the environment" (Kelly, 1967, p.193). Weiner also believes that individuals naturally want to know why events occur, especially when the outcome is important or unexpected. Perceptions of the cause of achievement outcomes are referred to as "casual attributions." Weiner, claimed that "the specific casual attributions are less important in determining achievement behavior than the underlying dimension of the attribution" (1979, 1985, 1986, 1992, 1994). In Weiner's attribution theory, the "casual attributions" are similar to Rotter's external-internal locus of control. However, Weiner believes that internal-external locus of control does not completely justify the cognition process. He further distinguishes between different internal causes of achievement outcomes with regard to their stability and controllability. For Rotter ability and effort were internal factors and were treated the same. Weiner regards ability as a stable cause that cannot be controllable. However, effort is controllable and changes from one situation to another. Graham (1994) stated that the two dimension stability and control that Wiener has added to Rotter's original external and internal dimension allow much more specific behavioral predictions from beliefs about the cause of reinforcement.

For attribution theorists an individual's own interpretation of success or failure is very important. Weiner believes that an individual's interpretation influences how much the individual will try to achieve a behavior.

The goal in Atkinson's value theory is to predict whether an individual would want to approach or to avoid an achievement task. Atkinson (1964) proposed that a motive, or need to achieve (Nach), directs individuals toward achievement tasks. Nach is a stable disposition that directs individuals to strive for success. Atkinson defines Nach as a "capacity to experience pride in accomplishment" (Atkinson, 1964, p.214). The motive to avoid failure (MAF) is the stable factor directing individuals away from achievement tasks. MAF is unconscious and is conceived as a capacity to experience shame given failure (Stipek, 1998, p.54).

Even though the motives to strive for success and to avoid failure are both unconscious, Atkinson also believed that individuals' behavior is also influenced by their conscious belief. The two conscious variables to approach tasks are: Perceived probability of success (Ps) and the expectations of pride which Atkinson refers to as the "Incentive value of success (Is). The other conscious variables to avoid tasks are probability of failure (Pf) and the anticipation of shame, which Atkinson refers to as the incentive value of failure (If). The resultant tendency to approach or avoid an achievement activity is called TA.

Thus, the expectancy x value theory is $TA = (Ms*Ps*Is)-(MAF*PP*If)$.

According to Atkinson's expectancy x value theory, "individuals who expect to succeed at a particular task are more likely to approach it than individuals who are less certain about their chance for success" (Stipek, 1998, p. 61). For example in this theory “effort” is identified as the major motivational outcome. For “effort” to occur, two necessary perquisites are specified. First it is very important for the individual to value a task. Also, the person must believe that he or she can succeed at a task. Thus, in instructional settings the tasks should be presented in a way that is meaningful to the student and promote positive expectations for successful achievement of behavior (Small, 1997).

It is possible to understand and predict at an abstract level the theories discussed above. However, it is very difficult to give "concrete, generalizable prescriptions for what will motivate any given audience or individual. There is too much variability in the attitudes, values and expectancies of learners (Keller, 1987, p. 1). One design model that takes into consideration the components of motivation and is based on a problem solving and heuristic approach is the ARCS Model of Motivational Design (Keller, 1983, 1987).
ARCS MODEL

ARCS is a research-based systematic design model that interfaces with typical instructional design and development models to improve the motivational appeal of instructional materials. In this model, the motivational components of instruction are embedded within the instructional design model (Main, 1993). The description of the model, which provides strategies that a course designer or teacher can use to make instruction responsive to the needs and interest of learners, includes four major conditions: Attention, Relevance, Confidence and Satisfaction. Keller in 1987 breaks each of the four ARCS components into three strategy sub-components for motivating instruction.

Attention strategies are for arousing and sustaining curiosity and interest. Moreover, the techniques should maintain and even increase the level of curiosity and interest throughout the learning experience. Attention strategies arouse and perplex students' thought processes and build inquiry and critical thinking skills (Curtis, 1992, p.32). Examples in Web-based instruction can be using multimedia and providing surprise or novelty at the beginning of instruction.

Relevance strategies link to learners' needs, interests, and motives. Relevance techniques help students link their own needs and styles to the instructional content and methods. Keller believes that it is very important to inform the learner of the importance of the learning outcome. Examples in Web-based instruction can be users-control, clearly stated objectives and comprehendible examples.

Confidence strategies help students develop a positive expectation for successful achievement. Confidence is related to how learners expect to succeed in an instruction. Keller states that personal expectancy for success is influenced by past experiences. Difficulty of tasks, locus of control and personal causation also contribute to confidence. Examples in Web-based instruction can be simple clear directions, readable font size, and hyperlinks to definition.

Satisfaction strategies provide extrinsic and intrinsic reinforcement for effort. Keller believes that satisfaction is derived from achieving performance goals. He assumes that the gratification of goal achievement is confounded to some degree by whether the evaluation of learning outcomes is externally based or made by the learner internally (Keller, 1983). Examples in Web-based instruction can be appropriate feedback, effective hyperlinks, and saving and printing options.

The sub-categories of the ARCS model is described on the table below.

<table>
<thead>
<tr>
<th>Categories and sub-categories of the ARCS model</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Attention</strong></td>
</tr>
<tr>
<td>A.1. Perceptual Arousal: To provide novelty, surprise, incongruity or uncertainty.</td>
</tr>
<tr>
<td>A.2. Inquiry Arousal: To stimulate curiosity by posing questions or problems.</td>
</tr>
<tr>
<td>A.3. Variability: To incorporate a range of methods and media to meet students' needs and to maintain their attention.</td>
</tr>
<tr>
<td><strong>Relevance</strong></td>
</tr>
<tr>
<td>R.1. Goal Orientation To present objectives and useful purposes.</td>
</tr>
<tr>
<td>R.2. Motive Matching Match objectives to students needs and motives.</td>
</tr>
<tr>
<td>R.3. Familiarity Present content in ways that are understandable and related to learners' experience and values.</td>
</tr>
<tr>
<td><strong>Confidence</strong></td>
</tr>
<tr>
<td>C.1. Learning Requirements Inform students about learning and performance requirements.</td>
</tr>
</tbody>
</table>
C.2. Success
   Opportunities: Provide meaningful opportunities for successful learning.

C.3. Personal Control
   Link learning success to students' personal effort and ability.

Satisfaction

S.1. Natural Consequences
   Encourage and support intrinsic enjoyment.

S.2. Positive Consequences
   Provide positive reinforcement and feedback.

S.3. Equity
   Maintain consistent standards and consequences.

Table 1: The categories and sub-categories of the ARCS model.

WebMAC Instrument

The Website Motivational Analysis Checklist (WebMAC) (Small, 1997) is an instrument used for designing and assessing the motivational quality of World Wide Web sites. This instrument is based on a number of theories including the ARCS Model of Motivational Design. The WebMAC provides an opportunity for structured analysis of the motivational quality of World Wide Web sites (Small, 1997).

The WebMAC has four general categories that are similar to the ARCS model. Web sites according to WebMAC should be Engaging (e.g., an eye catching title), Meaningful (e.g., stating the purpose of the Website), Organized (logical sequence of information) and Enjoyable (links to other Websites of interest). These categories are further divided into 60 items, 15 for each category.

The first version of the instrument was used in an assignment for a graduate-level class on "Motivational Aspects of Information Use" at Syracuse University in the spring of 1997. The WebMAC allows the designer to rate the motivational quality of Web-based instruction and draw a graph. The graph will help educators have a visual picture of strengths and weaknesses of their design for further improvement.

Conclusion

Motivating instruction will make learning experience appealing for learners. Moreover, this form of instruction will display students' intellectual curiosity and develop lifelong learners who will become intellectually curious to continue learning even when formal education has ended.

Motivating instruction is important in any kind of instruction. However, because of the nature of web-based instruction, designing motivating lessons will become more critical. In order to design an appealing and motivating web-based instruction there is a need for educators to acquire knowledge of the components of motivation. Also, educators should implement a systematic motivational design model in their instruction. Formal knowledge of motivation and using a systematic motivational design model can be powerful tools in improving the motivational appeal of web-based instruction.

THEORY
The Role of Skepticism in Preparing Teachers for the Implementation of Technology

Patti R. Albaugh, Ph.D.
Associate Professor
Otterbein College
Westerville, Ohio USA
PAlbaugh@otterbein.edu

Abstract: Many educational professionals, including teachers, embrace the potential that computer technology has for learning and teaching. Many classroom teachers, however, do not share this enthusiasm. Some of these teachers are skeptics, and some are fearful...afraid of change. Understanding the differences between skepticism and the resistance to change is critical in teacher education and technology training. If we do not pay attention to the skeptics or address the concerns of fear of change, the benefits of technology to education will be lost to inertia. Listening to the skeptics provide us insight into thoughtful consideration of the usefulness and purpose of instructional technologies. Listening to those resistant to change helps direct teacher educators to encourage risk-taking in pre-service and in-service teachers as well as helping teachers change their fear into healthy skepticism. Strategies are given for listening to the skeptics and for paying attention to the origins of technology resistance.

Introduction

Speaking to technology groups is like preaching to the choir. Everyone knows the message and believes in it. Speaking to and training teachers about technology is different; some of the audience already believes in the message, but the majority are both skeptical and fearful. In preparing this paper, I began to reflect on my own relationship with computers and the consequent mission of preparing other teachers to use this technology. When I was a 4th grade teacher in a small rural central Ohio school district, my principal approached some other teachers and me about attending a Radio Shack© training course for teachers. Although I was one of the more confused members of the training class, which by the way focused on teaching BASIC, there was something intriguing about those machines. When I saw examples of software that kept grades, tutored spelling, and simulated problem solving, I was hooked. Membership in the programming course dropped, but I hung in there and was rewarded by a new Apple IIe computer in my classroom. Soon I had my class grades automated, and I demonstrated the electronic grade book at parent conferences. The parents in that rural community were supportive of computer use; many saw it as a way to manage their farms. But I was disappointed in my colleagues' reactions. Fortunately I began to listen to their doubts and negative responses and wondered why they were so resistant to the technology by which I felt so empowered.

Even after a long journey through graduate school, industrial research, and current travels of college teaching, I struggle with a variety of emotions: the enthusiasm I have and see in others for the potential of computers in education as well as the confusion and respect I have for those who are reluctant to adopt computer technology for their classrooms. I have decided, however, that listening to the skeptics keeps the enthusiastic technophiles more honest to the task of making technology serve the education of our children, rather than having education serve the technology.

The Nature of Skepticism

Skepticism is the position that knowledge is limited and is denoted by a questioning attitude. The Spanish philosopher, Minguel de Unamuno, once said that, "The skeptic does not mean him who doubts, but
him who investigates or researches..." (Microsoft, 1995). Robert Frost's slant on skepticism is: "'Skepticism,' is that anything more than we used to mean when we said, 'Well, what have we here?' " (Microsoft).

What I first took to be unhealthy skepticism on the part of my colleagues proved to not be skepticism at all; what I was seeing was really fear and the inability to allow for new ideas. It is what George Kelly called "hardening of the categories" (Kelly, 1963). Kelly explains how we can effectively resist change to our beliefs. In technology training we witness both skepticism and hardening of the categories. Acknowledging both phenomena helps us understand how we should and could approach the training of teachers to use, and wisely use, technology. In serving pre-service and in-service teachers, there is a complex audience of early adopters, skeptics, and resistors (these same categories apply to teacher educators too, which is part of the problem). How do we address this complex audience?

The Nature of Teaching and the Pattern of Technology Adoption

The complexity of technology training for teachers can be partially explained in terms of three phenomena: the historical resistance of teachers to use media, the nature of teaching itself, and the life cycle of technological innovations. In his study of teachers and their use of media in their classrooms, Larry Cuban (1989) found that three factors influenced teachers' use of machines: (1) accessibility of hardware and software (is the equipment available and easy to use), (2) implementation of the innovation (is there administrative expectation and support), and (3) classroom and work settings (is the tool versatile and adaptable and does the setting accommodate the tool). Picture in your minds the successful technology using schools that you have seen... how many fit the criteria just mentioned? Picture the non-using schools and you will see the absence of these critical criteria.

The life cycle of innovations is fairly predictable and explains the cry of "fad" that we hear so much from educators. Innovations typically have a birth, used in light of a current idea, they die from lack of interest or innovative application, and then they are resurrected in a new form (DeBloois, 1982, p. 144). This life cycle entwines itself throughout the structure of society and education and causes fortunes to be made and lost, technology to be used and misused, and professors to be published by academic journals and scorned by practicing teachers. Drawing from his research, Cuban claims that teachers adopt a technology when that technology helps them do better what they are currently doing (Cuban, 1989, p. 66). This may seem appropriate but as a result they continue to use technology as an aid to teaching. They are consequently reinforcing the status quo. Teaching itself engenders a cautious attitude towards change (p. 60). Add to this cultural scenario a perception of video and film as entertainment and therefore to be suspicious as teaching tools (p. 61). Given the influx of computer games and simulations, one can see how computer technology can be suspect as a legitimate educational tool. Given additionally the historical and cultural resistance to change, how are we going to expand the potential that computer technology has for educating our children? This is not an easy task. Cuban says, "To question computer use in schools is to ask what schools are for, why teachers teach certain content, how they should teach, and how children learn" (p. 98).

Consequences of Not Listening to the Skeptics

As practical professionals, teachers are suspicious of new claims. Some of the fault lies with those who implement new ideas without proof of effectiveness and some fault lies with the technocists who invent the technology for shortsighted purposes or without seeking input from the people who will be using the technology. There is also the strong possibility of hubris developing among the technocists. Hubris is an exaggerated pride that usually leads to some form of retribution to the prideful. There can be such pride in a technological device, that purpose is limited only to what the machine does well, rather than to which human need it fulfills. Skepticism can be a form of conscience, which helps maintain a balance between the "must-do" people and the "wait a minute" people. Conscience is a steadying force in technological development. Thomas Green (1984) speaks of the role of conscience in a technological age. He says:
There is thus a profound and tenuous balance that must be secured in our institutions. They must be maleable [sic] enough so the good and skillful persons who dream of what is not yet, but might be so, can be set free to decide and to act. But our institution must also be sufficiently resistent [sic]to change so that those whose conscience is merely technical and limited to skills of managing the political apparatus, but who are rootless in their souls, may not do irreparable harm.

What happens too if we convince teachers to use the technology and then not support with maintenance or training dollars? Millions of dollars are being spent on classroom technology, but if plans are not made to maintain and routinely replace technology, and help teachers use the technology, teachers will rightly complain that they were, again, led down a dead-end faddish road.

The Invitation

So what does this mean for the technology training of teachers? Here are some concrete guidelines based upon what we know about the life of technology, teacher adoption of innovations, and the nature of teaching:

- Provide teachers with numerous opportunities for training and practice.
- Provide administrative support for training and for taking risks to try new approaches with technology.
- Acknowledge the professional concerns of the teacher and base implementation on evidence of what works.
- Acknowledge the teachers' need for practicality while encouraging risk-taking.
- Provide post-training follow-up
- Whenever possible, provide just-in-time support
- Have sound pedagogical reasons for investing in and implementing the technology.

If we want to change pedagogy we have to change a teacher's beliefs that he or she has practiced and seen practiced for a long time (Cuban, p. 109). If, as teacher educators, we want to change a belief system, we had better be grounded in scientific, practical and artful evidence that the change will serve the client. We also ought to consult those who work more directly with the children: the teachers. An anonymous quote is an excellent reminder of our interdependency: "None of us is as smart as all of us." "All of us" include teachers, teacher educators, Boards of Education, parents and all other aspects of the community. We all have a stake in the education of our children and their preparation to live productive lives in a democratic society. I invite us to be skeptics, to ask "what do we have here?" , to not be doubters but be collaborative investigators of the opportunities that technology provides us.

Computer-mediated cooperative work groups (virtual teams) have been used and studied for several years in corporate settings. This paper will discuss and describe the background of computer-mediated communication in the schools and the culture it creates because of its unique characteristics. The advantages and disadvantages of virtual teams will be outlined and illustrated with real-life classroom examples. The second part of the paper will discuss using virtual teams in a learning environment. Several questions will be addressed, such as: What is the best way to structure the teams? How should the team and the communication be monitored and encouraged? How should the team work out difficulties that are encountered? What types of projects and activities work the best? How should the team and the outcome be assessed? Hopefully, this paper will cause teachers and teacher educators to consider the use of virtual teams in their classroom projects.

This paper, through literature review, examines social and behavioral issues and norms of computer-supported cooperative work (CSCW) in K-12 classrooms. The main body of research on CSCW has been growing steadily since 1984 when Irene Greif and Paul Cashman first used the term (Bannon 1992; Woodcock 1997). The two computer scientists organized a workshop to address issues about computers and people in the workplace, and they coined the phrase computer-supported cooperative work. The field of study has grown steadily since then. However, most research has examined CSCW in the workplace, and little is understood about the use of CSCW in classrooms (Fishman, 1997), including whether conclusions about CSCW in the workplace can logically be extended to CSCW in the K-12 classroom.

THE NATURE AND ADVANTAGES OF COMPUTER-MEDIATED COMMUNICATION AND WORKGROUPS

Research has established that "CMC [computer-mediated communication] produces much different affective and relational patterns than do other types of communication," because fewer and different cues are available to participants (Walther & Burgoon as cited in Lane 1994). That view has been borne out by other studies (Bordia 1997, Grenier & Metes 1995, Lipnack and Stamps 1997, Musthaler 1997). In
addition, Scharlotte and Christ (cited by Lane, 1994) said that CMC can facilitate the formation of relationships, help people overcome shyness, inhibitions, and physical handicaps that may make face-to-face situations difficult. Drawing on the foundation of those previous researchers, Lane examined CMC in the context of social interaction and developing interpersonal relationships among college students at the University of Oklahoma. The students’ electronic postings resulted in a fairly exhaustive list of attributes that Lane suggests are primary advantages of CMC, which included 1) enhanced flow of information and creativity; 2) enhanced and new interaction patterns; 3) elimination of stereotypical communication barriers because of neutrality, anonymity; 4) increased communication; timely and accessible information and ideas; 5) expanded communication (beyond the classroom); and 5) fun, exciting, and challenging communication.

Again, these are not new revelations to those who have studied CMC in the business workplace over the last decade. In fact, Gordin, Gomez, Pea, and Fishman (1996) describe “increasing levels of interaction” in school learning communities using the World Wide Web (the Web) as those wherein students access published work; access tools and raw data; engage in written and oral dialogue with community members; perform in joint coordinated activities with work-based learning communities, and; incorporate their class work into published archives of a community’s work.

Ryan (1992) believes that with the emergence of computer-mediated communication, people have discovered CMC as a means of connecting with peers, colleagues, and family. “CMC and the presence of international CMC networks provide a collaborative environment in which people can bridge the cultural and national differences that separate them”(Ryan, 1992). Thus in CMC, people all around the world can share and exchange their values, language, and icons without barriers. Even more, they start to construct their own unique ways of communication through this new medium. Gradually, with the participants’ experiences and interactions in CMC, a new culture has been created unconsciously. Just like Howard Rheingold says in his book The Virtual Community (1993), “Most people who get their news from conventional media have been unaware of the widely varied assortment of new cultures that have evolved in the world’s computer networks over the past ten years.” Rheingold goes on to define “virtual communities as groups of people linked not by geography but by their participation in computer networks. They share many of the characteristics of people in ordinary communities, yet they have no face-to-face contact, are not bound by the constraints of time or place, and use computers to communicate with one another.” (Rheingold, 1993, chap5)

DISADVANTAGES OF COMPUTER-MEDIATED COMMUNICATION AND WORKGROUPS

Some of the negative effects of extensive use of computer-mediated communication in the classroom are that students will perceive their world differently and thereby acquire some incorrect ideas about reality and ineffective thinking strategies. Doubters of technology hold two main concerns about very young children and computers. Their first concern is that time spent in front of a computer robs a child of the necessary development of the all five senses. The computer’s one-dimensional characteristic does not let a child experience everything. Doubters of computers for very young children also fear that the computer does not give a student the broad base in learning that the physical world gives (Oppenheimer 1998). In the book Silicon Snake Oil, Clifford Stoll warns that anyone who is directed away from social interaction might become socially maladjusted and that the real sensations of true-life experiences can never be replaced by technology.

Some of the biggest disadvantages of computer mediated communication extend to the classroom teacher. These disadvantages are usually in the area of time and training. In an interview with David Dwyer (Salpeter 1998), the vice president of advanced learning technologies at Computer Curriculum Corporation and previous director of the Apple Classrooms of Tomorrow research program, Mr. Dwyer explained that teachers usually go through four stages when it comes to integrating computers into their classrooms. Each stage is about one year. Because teachers are the main instruments of the diffusion of computers in the classrooms the training for teachers must be extensive.

ADDRESSING THE ISSUES
What is the purpose of the team and how should it be structured?
Determining objectives for learning outcomes in virtual teams is much like traditional learning activities. Any relevant, purposeful learning objective can be used to guide learning in a virtual environment. The major consideration is determining how collaboration through CMC will be used to achieve the objective. In addition to print based resources, computer oriented resources will be added to enhance the learning process. Additionally, similar to planning activities for traditional learning activities, alternative activities to accomplish or support the objective should be available in the event of equipment problems.

Consideration must be given to the architecture of the available technology when determining the structure of a workgroup. An intranet (computer connections within a building or district) will allow creating workgroups with local students or classes. However, workgroups can be created without either configuration. Stand alone computers with, at a minimum, word processing and reference software can be used to create workgroups in a localized area. On the other hand, an Internet connection (requires service provider) will allow participation in workgroups with students and experts around the world.

What types of projects and activities will work the best?
Project selection should be determined based on the content area. Ideas for creating computer-based projects, collaborating with an established work group, and teacher resources are available on several web sites and in printed media. Teachers in Cyberspace (Meyers & McIsaac 1996) covers basic technical information and contains a disk with project ideas. Web resources created by educational organizations, universities, software manufacturers, and teachers are steadily growing. The National Aeronautics and Space Administration (NASA) and the National Science Foundation (NSF) have created several CMC based projects.

In the experience gained through our experimental CMC localized workgroup, the distance factor may play an important role in the selection process of the project. Heterogeneous partnering, student's skill level, availability of expert consultants, as well as functioning equipment will increase the likelihood of success.

How should the team and the communication be monitored and encouraged?
The responsibility for monitoring student progress and the encouragement of participation in academic activities is the ultimate responsibility of the teacher. However, since students will be involved in small group or independent computer related activities, sharing responsibility of monitoring with students should be considered. Each student should keep a journal of interactions and results that could be turned in weekly to the teacher or the group leader.

How should the team work out difficulties that are encountered?
Guidelines and rules for the workgroup should be determined before the activity is initiated. Students should have the primary responsibility for creating the rules and consequences for expected behavior. These expected on-line behaviors, as well as methods for reporting and resolving common problems, should be clearly stated and available to all students and should be kept in the journal notebook.

How should the team and the outcome be assessed?
Objectives for the team should be developed concurrently with learning objectives. The type of project, level of the students, and process versus product will guide the development of an appropriate assessment tool. Checklists for specific workgroup behavioral outcomes may be appropriate if the objective is to increase skills in collaborative teamwork. On the other hand if the objective specifies a completed project, guidelines for evaluating the content, composition, and clarity of the final product should be used for assessment.

CONCLUSIONS
A single attempt at using CMC workgroups as a learning tool should not determine their usefulness. Problems and mistakes encountered in the initial attempt should serve as guidelines for improving the next activity. Hopefully, teachers will examine the benefits of CMC workgroups and begin to integrate them into the curriculum.
In addition to the implicit and broad-based learning applications available through virtual teams in K-12 classrooms, the structure and administration of such cooperative projects can help teachers and students succeed in achieving educational competencies. This includes the competencies established for educators in the State of Texas—the Technology Education Essential Knowledge and Skills Standards (TEKS), developed and approved by the Texas Education Agency in 1997.

The technology naysayers may warn that too much computer use stifles creativity, socialization, and teamwork. However, technology proponents say that just the opposite is true and that computer use in schools draws participation from students who are less outgoing or withdrawn during traditional classroom activities. Besides, the use of technology is just another tool, another means to reach and teach the students. The anti-technology stance argues against the expense, the learning curve, and the disruption of a changing pedagogy, whereas the pro-technology stance argues the need to change with the times to produce a competent, skilled workforce for the future. An argument against the growing use of technology in classrooms is that teachers don’t have the time to learn it; however, in the corporate world self-learning and lifetime learning are trends that employees are finding they must embrace to remain viable and current in the workforce.

That is not to say that the sole responsibility should lie with the teachers. Increasingly, state and federal government agencies are supporting technology in schools with some grants and mandated telecommunications rate reductions for schools. But Baker and Buller (1995), and others, acknowledge that cost and administrative support remain major barriers. "This is not an easy task when administrators do not understand the benefits, teachers might not have the knowledge to make it work, and school boards will not find the money."

Mandinach and Kline (1994) echo those sentiments, and suggest a model for a computer-based curriculum. Their work documents a then six-year effort to introduce computer-based curriculum to middle- and high-school students, and says that "[a] decade is not an unreasonable time frame for this type of endeavor." Success of the Madinach and Kline model relies upon several factors, including (1) computer hardware and software in a suitable setting; (2) support resources (e.g. stipends) for teachers learning the technology; (3) teacher release time and use of paraprofessional staff; (4) initial and continuing teacher training; (5) access to subject-matter experts; (6) technical assistance, and; (7) administration support and commitment.

Whereas Mandinach and Kline present a weighty technical documentation of their experience and model, Harris’ 1998 work takes a lighter tone based on the analogy of building a house. In addition, teachers increasingly are documenting and presenting their experiences at various conferences, including those of information science and computer professionals. This is to say that resources exist that suggest methods to integrate technology into K-12 classrooms. However, the wired classroom is still a new venture. It is an evolving process as all facets of society struggle to learn and adapt to this medium, which is ever changing. The challenges are to overcome the resistance and barriers, to find the balanced middle ground of technological/fine arts curriculum, and to move forward with and into the information age.

Korzybski Revisited: General Semantics for the Information Age

Charles D. Dickens, Ph. D., Department of Teaching & Learning, Tennessee State University, USA, cdickens@posiedon.tnstate.edu
David Hartmann, Meigs Magnet School, USA, hartmannnd@home.com

Abstract: Key notions in Alfred Korzybski's General Semantics are described. Similarities between the development of a non-Aristotelian language more appropriate for the modern (1933) world and the need for a language for hypermedia is then suggested.

Science and Sanity was first published in 1933. Subtitled: An Introduction to Non-Aristotelian Systems and General Semantics, it was Alfred Korzybski's attempt at formulating a system "based on a rejection of [the aristotelian notion of] identity and its derivatives" (Korzybski 1958) which would be structurally more similar than the empirical world than its predecessor. To Korzybski, the prevailing logic and language(s) of the twentieth century embodied a pre-scientific worldview that was fallacious and misleading. "Structure," he asserts (Korzybski 1958), "and structure alone, is the only link between languages and the empirical world." The claim that he makes for this newer, non-elementalistic, system is a closer similarity of structure to the undifferentiated world of experience (circa 1933).

It is beyond the scope of this paper to go into the full development of Korzybski's General Semantics or the extensions which have continued to be developed since 1933. The purpose of this paper is to examine several of Korzybski's notions of structure as they relate to the language of "hypermediated" communication.

To lay a foundation for considering the non-Aristotelian (null-A) system as appropriate to this task, a representation of Korzybski's model of the "Structural Differentiation" is presented (Fig. 1) and discussed.

![Figure 1: The Structural Differential](image)

The broken parabola (E) at the top of the figure represents an event in the world, the small circles (C) indicate characteristics of the event. The parabola extends indefinitely as indicated by the broken edge (B) and the number of characteristics is, in reality, infinitely great. The circle (O) below the event represents the object with its characteristics likewise indicated by small circles (C') which may be a large number, but finite. By naming the object, we ascribe to it a label (L) which will have even fewer characteristics (C'').
Lines not connected (B', B'') indicate characteristics ignored or not abstracted from the previous level. The level of this first level may be considered as a descriptive level or a statement about the object. Subsequent labels (L_1, L_2, ..., L_n) are statements about the previous level's statement. The descriptive statement is an abstraction of the first order, the statement about it (L_1) of the second order, and so forth.

The event as depicted in the model (Fig. 1) exists in space-time, as must all events in the physical reality of post-Newtonian physics, which contributes to the infinity of characteristics. The object is abstracted at a moment of an ongoing process of tendencies and probabilities. The orders of abstraction underlie one of Korzybski's fundamental concepts, the multiordinality (m.o) of terms. The main characteristic of m.o terms is that at different levels or orders of abstraction they may have different meanings, meanings that are context bound and which establish their order of abstraction.

As Korzybski points out repeatedly, the map is not the territory. A good map, however, is one whose structure is similar to the territory that it represents. So, too, with language, the word can never be the thing it describes, but a language with structural similarity to what is being described is most useful. An Aristotelian subject-predicate language treats objects in isolation and not as members of collections having relations, order, etc. "Only a language that originates in the analysis of collections," claims Korzybski (1958) would have a similar structure to the world around us. Much of his book is spent providing the proofs that the structure of the null-A system provides a language of similar structure to the four-dimensional empirical reality posited by Einstein and Minkowski where time and space cannot be separated. The new language considers "the facts of the world as a series of interrelated ordered events...." (Korzybski 1958)

In Korzybski's system several devices are employed to acknowledge a consciousness of multiordinality of terms and levels of abstraction. One such device was the use of *et cetera* to indicate that whatever was said descriptively about anything, there were always characteristics left unstated. Indeed, the use of ‘etc.’ is so prevalent in the work that he provides special null-A punctuation as shown in Table 1.

Table 1

Much has changed in the world in the half century since *Science and Sanity* was first published. The null-A system was created to fulfill a need for a language, i.e., structure, that matched reality (1933) to replace a structure that had not changed its logic since the Fourth Century B.C. There are, however, characteristics of reality (1999) that also share a structural similarity to the conditions that Korzybski was so concerned about. It is some of these characteristics that the rest of this paper addresses.

The empirical world as described above now contains an informational world with which it shares salient features. The union of space-time as a four-dimensional reality in the physical universe and the electronic information on a constantly changing network of networks of computers would seem one case in point. Not only has the “wiring” of the nation’s schools, homes, and other institutions made electronic information access available to virtually anyone, it has also created, at a low level of abstraction, a structure similar to the reality of the modern physicist. The parallel exists between the situation Korzybski described that a changing view of the very nature of reality required a change in how people thought and spoke about it. It is no great leap to propose that traditional methods of teaching share the same difficulties in correspondence to the knowledge reality as classical logic had with a relational, ordered, and probabilistic reality. The growing use of Internet resources for information gathering by children and adults alike suggests the need for developing new structures. Perhaps there are clues to be found in General Semantics.
In 1933 technology, the new structure was confined to the linear form of speech and writing. Today we are looking at ready access to means of expression that can be as multiordinal as the language used to describe, propose, or critique. The advent of hypermodal means of communication offers the potential of a communication medium that allows for numerous representations at any level which more closely resembles the reality that has been suggested here. The tools are available with computers and software for hypermodal creation. What is not currently present seems to be a well developed structure that we might call a language of this kind of communication. That was precisely the situation faced by Korzybski in his era.

In my graduate classes in teacher education, I teach teachers about using the technology to facilitate learning. Over the past few years that has centered on creating projects using Internet resources and on hypermedia creations using HyperStudio. One phenomenon I have observed is that novices to the hypermedia forms will typically begin their first project as a strictly linear structure, relying heavily on textual descriptions and explanations of subject matter. Their print orientation seems to govern the possibilities they can initially see for meaningful communication. The power, flexibility and complexity possible with these new tools would seem to elude, intimidate and frustrate the teachers, at least at first. There is a need for a new language that takes advantage of the new capabilities that technology offers us. Perhaps by looking to the past in Korzybski’s efforts to create a more appropriate language circa 1933 we can find some guidance that will facilitate the creation of a new structure that will be usable and useful in the new century soon to come.

Abstract: Amphion is a generic Knowledge Based Software Engineering (KBSE) system that targets scientific subroutine libraries. It was developed at NASA Ames' Computational Sciences Division. Amphion has proven useful for experts in the space science domain. One of the current challenges is to apply the system to different domains, educational settings, and the Internet. In order to assess the applicability of Amphion for educational settings, educators have been invited to try the system and to collaborate with the Amphion team. This paper describes the results of one such collaboration, which involved the development of educational web sites supported by Amphion-generated materials.

1. Introduction

The current implementation of Amphion (e.g. Amphion/NAIF) allows users to specify problems in the domain of solar system kinematics. These problems are specified using high-level terms that are relevant to the user, such as planet, ray, spacecraft, etc. The user-specified problems are then translated into programs that are composed of calls to the target library subroutines, in this case the FORTRAN libraries called SPICE developed by NASA JPL's NAIF group (see http://naif.jpl.nasa.gov/naifhtml).

The translation is performed in two steps. First, a theorem prover, guided by a domain theory, solves the logical formula that represents the user-specified problem. The domain theory is a collection of rules and definitions that define how to convert a user-level formula into a low-level expression. Second, the resulting expression is converted by a translator into the final FORTRAN program. The execution of these programs may result in either an animation, or a calculation of specific pieces of information. The correctness of the resulting program, relative to the domain theory, is assured by the application of formal methods and artificial intelligence techniques. A description of the technical details can be found in (Lowry 1994).

Amphion (see http://ic-www.arc.nasa.gov/ic/projects/amphion/index.html) has proven useful for experts in the space science domain. One of the current challenges is to take the benefits of the system into different domains, to educational settings, and to the ever-growing audience of the Internet. In order to meet this challenge, a new version of Amphion, based on client-server technology has been recently developed. This new version allows access through WWW, supports different interfaces, and provides immediate execution of the programs generated by Amphion. A description of this architecture can be found in (Lazzeri 1998).

Different domain theories, such as computational fluid dynamics (CFD) are being developed for Amphion to operate on. Furthermore, in order to assess the applicability of Amphion for educational settings, educators have been invited to try the system. Dr. Jane Friedman was a NASA faculty fellow during the summers of '97 and '98. She is a faculty member in the mathematics and computer science department of the University of San Diego, with major teaching and research interests in mathematics education, particularly teacher training. Dr. Friedman worked with the Amphion group to develop materials for web based lessons on astronomy. This paper describes this collaborative experience and the web pages that were produced.
2. Motivation

There is quite a lot of excitement and even hype these days about the potential of the Internet and the World Wide Web to have a positive impact on education. There are an ever-increasing number of web sites which purport to be educational, and these vary greatly in quality and in their teacher-user friendliness. It is easy to create a web-site, but much harder to create one which will actually be useful to classroom teachers. As Cleborne Maddox notes "... the general state of the art in Web-based learning is in its infancy." (Maddox 1996).

Another problem is how to best prepare prospective and practicing teachers to use the resources available online effectively in their classrooms. New research is beginning to illuminate the substantial difficulties that exist in convincing teachers that the Web belongs in their classrooms, and then providing them with the necessary training (Wiesenmayer & Meadows 1997).

Thus there are two sides to the problem of how to ensure that the Internet realizes its potential as an educational tool, the problem of preparing appropriate Internet materials, and that of preparing teachers appropriately to use these materials. Both of these areas are poorly understood. Different kinds of expertise will be needed to create solutions to these problems, and this paper presents an example of the power of a synthesis between technological experts and educational experts. Amphion was developed by researchers at NASA for the use of other NASA scientists. It is not a toy program developed for the use of children, but a serious tool that has been used fruitfully by scientists. This can be a powerful motivating force for children. Even the most uneducated and deprived children can be turned on to space science. (See (Fierro 1997) for a moving account of the response of homeless Mexican children to presentations about Astronomy). It is exciting for children to know that they are working with the same tool that NASA scientists, real Astronomers, use in their work.

Amphion, as an educational tool, is under development. This means that the possibility exists of modifying Amphion in order to improve its usefulness to educators as well as to scientists. This is best accomplished by collaborative efforts between Amphion researchers, and educators including classroom teachers. The work described in this paper represents a first stage in developing such a collaboration. Each web page created was developed in response to published papers in educational journals. Thus, each is connected to work of educators and is responsive to their concerns. This is the power of such collaborative efforts.

3. Topic Selection

The Web is not necessarily the best teaching tool in all situations. There are many topics that may be taught just as well or better with books, other traditional teaching methods or manipulatives. The topics selected for use with Amphion, the causes of phases of heavenly bodies, and the causes of seasons, were ones which have proved resistant to teaching with traditional methods. Both topics are difficult for children and adults to understand. (See for example, (Atwood & Atwood 1996), (Kikas 1998), (Parker & Heywood 1998), (Sharp 1996)). In each case Amphion had a feature which could potentially aid in understanding.

The first web page developed was based on a paper by John Lamb (Lamb 1990), in which he posed the question of whether or not a crescent Mars could ever be seen from earth. In this paper he analyzed the problem geometrically and then presented a computer program which could be used to calculate the portion of Mars which would be seen at any given time. The difficulty in understanding the phases of Mars, or any heavenly body, is in understanding how the phases depend on the relative positions of the body viewed, the body from which the viewing is done and the sun. Using models and light bulbs can be helpful, but then the inaccuracies of scale can create misleading impressions. With Amphion we were able to create a pair of dynamically linked windows, which were displayed side by side to present animations that showed how the view of Mars from the Earth changes with the changing relative positions of the Earth, the Sun and Mars.

The causes of the seasons is difficult even for many prospective and practicing teachers to understand. (Atwood & Atwood 1997) showed that while physical models were completely effective in enabling prospective teachers to understand the causes of day and night, they were much less effective in helping these same teachers to understand the causes of the seasons. Atwood and Atwood suggest that the models might usefully be supplemented by a computer simulation. This again seemed a useful role for Amphion. The seasons are caused by the tilt of the Earth on its axis. The areas of the Earth which are tilted away from the Sun at any given time, receive less direct sunlight, and therefore less warming. Amphion was used to create an animation which displays the solar incidence angle as it changes with the changing seasons. This could be used to
supplement other teaching methods to help K-12 students and their current and future teachers understand this complex phenomenon. Curriculum in K-12 is guided by various levels of educational standards, which are used by teachers to look for relevant materials. The topics selected for this project are identified as important in the National Science Education Standards: [http://www.nap.edu/readingroom/books/nse/html/](http://www.nap.edu/readingroom/books/nse/html/).

4. **Lesson 1: “The Phases of the Heavenly Bodies”**

4.1 **Original Explanation**

(Lamb 1990) asks the question "Can a crescent Mars ever be seen from Earth?". He was primarily interested in the mathematics used in answering this question. A full half of Mars will always be illuminated by the Sun, but the portion of Mars which is seen from the Earth will depend on the relative positions of the Earth, the Sun, and Mars. Let SME be the angle between the Sun, Mars and the Earth, and let SEM be the angle between the Sun, Earth and Mars; then the portion of Mars which appears dark will be directly proportional to SME. The larger SME is, the larger the dark portion of Mars and the smaller the illuminated portion. If we were to see a crescent Mars, the dark portion would be most of the visible portion of the planet. We can find the maximum value of SME by using traditional methods of the calculus (differentiating an expression involving trigonometric functions).

Lamb's paper is aimed at college level teachers. Yet in the National Science Standards, changes in objects in the sky, in particular the phases of the moon, are mentioned even in the K-4 content standards. These young children could not possibly understand the mathematics involved in Lamb's paper, but they can understand some of the basic science. In particular they can understand that the phases are caused by the light of the Sun shining on the bodies and the effect of relative position on the appearance of the illuminated body.

4.2 **Amphion’s Explanation**

Amphion can be used to supplement traditional teaching methods involving the use of light bulbs and physical models. Lamb suggests using a computer as a computational aid. We use Amphion as a computational and a visualization tool. We not only calculate angles, but we create two dynamically linked animations; one which shows the relative positions of the bodies and another that shows how the planet would appear viewed from earth.

One of the benefits of using Amphion for this explanation is that once a given animation is generated, it is very easy to get similar animations for other configurations. For example, it would be easy to modify the program to observe the phases of the moon as seen from Earth, or the phases of Pluto as seen from Neptune. This ability allows the student to make several observations to support the generalization of a concept. In fact, we have developed a template that allows the user to designate the observed planet, observing planet, and bright body for a given animation. This template is shown in (Fig. 1), which is a snapshot of the graphical editor, one of the specification editors that can be used to input problems for Amphion.

![Sample Amphion Editor Screen.](http://example.com/sample_screen.png)
All the user has to do is to replace the “refine-this-X” items by actual values and then to call the automated software engineering engine to produce an animation. Templates like the one in (Fig. 1) will allow students to easily create their own animations and formulate and solve their own problems, such as: As we move further away from the Earth, what happens to the maximum shadowed area of the planet as seen from Earth?

(Fig. 2) illustrates Amphion’s generated view of Mars as seen from Earth. The left side of the figure shows a view of Mars as seen from Earth on the date 11/12/94 at the time 17:35:17. The right side of the figure displays the relative position of the planets on the same specific date and time. The planets are not drawn to scale in order to better illustrate the different phases of Mars, otherwise, Earth and Mars wouldn’t be visible given the great size disparity as compared to the Sun. In that figure, the Sun is yellow, the Earth is cyan, and Mars is shaded so that it is possible to tell how much of its dark side is seen from Earth.

In a live animation, the positions of the planets in the right side change continuously, and the view of Mars from Earth in the left side change accordingly. Amphion generates automatically most of this image. However, the legends “Angle SME=40.9”, and “Maximum shadowed area of Mars visible from Earth”, as well as the lines that form the triangle and indicate the angles between the planets in the right side of the figure were manually added to enhance the expressive power of the picture for this particularly critical frame. Besides Amphion’s generated materials, the web site for this lesson contains background information about this concept.

The URL for this lesson is http://ic-www.arc.nasa.gov/ic/projects/amphion/MARS-PHASES/phases.html.

![Figure 2: Still from Amphion-generated animation used to illustrate the phases of Mars as seen from Earth.](image)

5. Lesson 2: “The Seasons”

5.1 Original Explanation

Children and adults alike have trouble understanding the causes of the seasons. Many will express the belief that the change in seasons is caused by the change in the distance between the Sun and the Earth. This
explanation would imply that winter and summer occur simultaneously in the northern and southern hemisphere, which is not true. When it is winter in the northern hemisphere it is summer in the southern hemisphere and vice versa. Winter occurs in the northern hemisphere when the Sun is closer to the Earth. The seasons are caused by the tilt of the earth on its axis, and the effect this has on the angle with which the Sun’s rays strike the earth’s surface. Now in fact this angle will not be constant over the course of the day. The Sun’s rays will strike the earth most directly at noon. In winter, when the days are shorter, the Sun’s rays strike less directly and over less time. To actually calculate the amount of energy absorbed by the earth would again require fairly sophisticated mathematics -- college level mathematics. But the National Science standards specifically mention the causes of the seasons as important content for grades 5-8. What these students need to understand is not the precise mathematical relationship, but the general relationship between the angle of the Sun’s rays and the amount of warming energy which this transfers to the earth. Traditional teaching methods with physical models and lights are helpful for some students, but many still do not understand.

5.2 Amphion’s Explanation

Amphion’s capabilities are excellent for providing additional teaching tools that may help some learners understand this difficult but important concept. Amphion can produce an animation that shows how the angle of incidence of the Sun’s rays changes over the course of a day, or at noon over the course of a year. This can show students the correlation between this angle and the seasons.

In order to explain the concept of seasons, an animation showing the view of the Earth from the Sun for a period of time is used. Two reference points are displayed in this animation, one of them is Canberra (Australia), and the other one is its mirror image in the Northern Hemisphere. The solar incidence angle computed from the Normal to the Earth’s surface is displayed at each of these points. Then each point is color coded according to the corresponding season of the year. The incidence angle is computed at around 12:00 noon local Canberra time, which is the warmest time of the day. The smaller the angle, the closer the Sun’s rays are to the perpendicular to the Earth’s surface at that point.

![Figure 3: Still from Amphion-generated animation used to illustrate the seasons on Earth.](image-url)
(Fig. 3) shows a snapshot of the live animation where we can see that the angle is smaller in the summer (i.e. when it is red in the animation). Likewise, the angle is much larger in the winter. Also, a summer point is visible longer than a winter point, indicating that summer days are longer than winter days. Several misconceptions, such as the belief that the seasons are due to the change in the distance between the Sun and the Earth, can be eliminated by experimenting with this animation.

The URL for this lesson is http://ic-www.arc.nasa.gov/ic/projects/ amphion/SEASONS/seasons.html.

6. Conclusions

This project has demonstrated that Amphion has the potential to be useful in K-12 education. Amphion was used to create animations that became the heart of two different web sites, each dedicated to a notoriously difficult space science concept. In each case, Amphion was able to do something a bit different than traditional methods, and thus was a powerful supplementary teaching tool. But in fact this is only the beginning for the development of educational uses for Amphion. In the future, students will be able to interact more directly with Amphion and through the use of simplified templates conduct their own investigations of space science phenomenon. Each of these web sites is a rough draft, they need refinement, rewriting and the inclusion of supplementary materials, such as lesson plans, correlations with standards, and follow up assignments and activities, which will make them more useful to classroom teachers. In refining these web sites we hope to get input from the educational community to make them as practical and useful as possible.

Learning Styles, Technology Attitude and Usage: What are the Connections for Teachers and Technology in the Classroom?

Pamela Galowich
Center for Educational Studies, Claremont Graduate University, USA, E-mail: pamela.galowich@cgu.edu

Abstract: The question for educators is no longer how much better do students learn with technology, but instead how do we integrate technology into our classrooms in a way that benefits students. A specific part of integrating technology into the classroom examines how to encourage teachers to use technology to teach. To study this question, a survey was used to create connections between teachers' technology attitudes, technology usage, and learning style. Teachers from five elementary schools in a large southern California school district participated in the study. Results and implications are discussed.

Whether people want to embrace technology or not, it is necessary to be able to use it to learn, problem solve, and function on a daily basis with it. Our personal and professional lives are affected increasingly by a variety of technologies. Therefore the question for educators is no longer how much better do students learn with technology, but instead how do we integrate technology into our classrooms in a way that benefits students. A specific part of integrating technology into the classroom examines how to encourage teachers to use technology to teach. Luke, Moore, & Sawyer (1998) write that teachers need to use technology to teach if students are to learn with it. Additionally, Collis (1996) reflects on research conducted worldwide over the past decade and states, "...one type of result consistently occurs; a result that acknowledges the teacher as the key figure in the eventual success or lack of success on any computers-in-education initiative" (p. 21).

To begin understanding how to increase a teacher's technology usage in the classroom, we must learn why teachers choose to use technology. Does a person's technology usage in the world outside of work have any bearing on whether he or she uses technology at work? Is there a connection between someone's attitude and his or her technology usage? Does a person's thinking style matter when he or she considers whether to use technology or how to use it? Are there any relationships among technology usage, attitude toward technology, and thinking style? This paper examines a study that was conducted to address these issues.

Background

The researcher's experiences within the business and teaching worlds allowed informal observation of people who do and do not use technology. Why are some people willing to use technology within their jobs while others resisted? It seems logical that how you learn and how you feel about something affects what you choose to do or use. In the case of technology and teachers, this would imply that attitude towards technology and a person's learning style affect if one uses technological innovations inside the classroom. Also, if a person uses a variety of technological items at home, he or she is probably more likely to use technology to teach in the classroom.

To support these beliefs and perceptions, a literature and research review was conducted to locate studies dealing with technology attitude, technology usage and learning style. There is an abundance of research on computers, technology, and education. Many studies concentrate on attitude toward computers (Knezak & Christensen, 1998; McFarlane, Green, & Hoffman, 1997; Woodrow, 1991), or computer usage and attitude toward technology (Byrd & Koohang, 1989; Levin & Gordon, 1989; Marshall & Bannon, 1986). Fewer studies consider computer usage and thinking or learning style (Knupfer, 1989; Smith, Munday, & Windham, 1995). And, there are no studies that consider all three threads together; technology usage, attitude toward technology, and learning style.

Another issue found while researching these topics, is that it is difficult to find surveys and other research tools that examine the broader concept of technology rather than computers. Until recently, conversations about technology in education meant talking about how to use computers as teaching devices. As new technologies develop faster and faster, we are realizing that "technology" does not equal "computer" and it
has not for a long time in classrooms. Video recorders, televisions, and satellite dishes have been in schools for quite awhile, yet usually these other pieces of technology are ignored.

A survey was created to try to create connections between technology attitude, technology usage, and learning style. The survey included three scales: the Technology Attitude Scale (TAS) (McFarlane, Green, & Hoffman, 1997), the General Technology Usage Scale (GTUS) (Galowich, 1998) and the Learning Styles Inventory (LSI) (Kolb, 1985). The survey is an initial attempt to collect data from teachers about their respective attitudes toward technology, technology usage outside of the classroom, and learning style and explore the connections among these variables.

Description of Survey and Sample

The survey instrument was constructed to examine teachers' attitude toward technology, technology usage outside of work, and learning style. As already mentioned, there were many computer attitude scales but only a few technology attitude scales. Of these few scales, only one, the Technology Attitude Scale (TAS) was up-to-date when considering current technological advances. An additional benefit is that the scale was created to use with teachers. The TAS was used to assess attitude toward technology for this survey.

A few research studies examined technology usage in work settings but none of them examined technology usage outside of work situations, therefore a scale was created. In an effort to create a scale, the researcher began listing all types of technology that people encounter in their daily lives. To capture a range of technology usage common technological items (e.g., sewing machine, television, stereo, and microwave) were included, as well as more unusual technological items (e.g., digital video disk [DVD], scanner, and electronic datebook/organizer). The original list had approximately 40 technology items found in households or non-work environments. The list was narrowed down to 20 items to make it a more acceptable length and to avoid score inflation due to including too many common technological innovations. The final scale was measured with a six point frequency scale that was used to assess usage patterns (an example item: I use a cordless phone... 1=never, 2=rarely, 3=several times a year, 4=at least once a month, 5=at least once a week, 6=daily). Additionally, a question was included to determine if a teacher uses technology to teach in the classroom. These 20 usage questions compose the General Technology Usage Scale (GTUS).

The final scale included in the survey needed to provide a way to assess cognitive learning or thinking style. Previous research (Knupfer, 1989; Smith et al, 1995) examining thinking/learning style and technology attitude used the Myers-Briggs Type Indicator (Myers & Briggs 1976) scale but this is a personality type preference, not a learning or thinking type. David Kolb (1976, 1985) created the Learning Style Inventory (LSI) to assess learning styles based within the Jungian idea that styles represent different modes of learning and people use all modes with the predominant one being the designated "style" or "type". The four styles are Accommodator, Diverger, Converger, and Assimilator. The styles are created based on a preference for learning actively versus reflectively and in an abstract versus concrete way. The 1985 revised scale was used for this study.

A large school district in southern California agreed to have teachers from five schools participate in the study. Surveys (with an attached, stamped envelope) were given to principals to pass out to their teachers. Of the 120 surveys given to the principals, 79 were returned and 74 were used for statistical analysis. Both the TAS and GTUS included a definition of what should be considered as technology, "For this survey, technology is defined as materials such as computers, VCRs (video recorders), televisions, radio/tape cassette players, laser discs, printers, scanners, microwaves, etc."

Data Analysis and Results

Description of Sample

Each teacher was asked to pick the appropriate age range for his or her age. The ranges were 20-29 years old (n=26), 30-39 years old (n=22), 40-49 years old (n=10), 50-59 years old (n=12), and 60 or over (n=1). The ethnicity/racial identity of the sample is split mainly between Hispanic American/Latino/Chicano teachers (n=29) and European American/White teachers (n=32); with 1 teacher identifying him or herself as Asian American/Asian; three teachers identifying themselves as Multiracial/Multiethnic and three teachers identifying themselves as "Other".
Using Technology to Teach

The question, "How often do you use technology to teach in the classroom?", that was used to ascertain whether teachers use technology to teach in the classroom is a categorical variable with six choices (See Fig. 1). Yet, the statistical tests are run according to whether teachers use technology to teach in the classroom or not. So, the original variable was recoded to create a dichotomous (yes/no) variable, "How often do you use technology to teach in the classroom?" as shown in Fig. 1. The decision was made to make the cut off point at 5 hours per week for the response "no". Many teachers may use an overhead, VCR, tape recorder, etc., to present lessons throughout a week, yet not really using the technology as an active part of their teaching. So, it is necessary to include a small amount of use in the "no" response category.

![Graph](image)

Figure 1. Teacher Use of Technology to Teach, Original Variable and Dichotomous Variable Frequencies

Crosstabs were run to allow comparisons of whether teachers of different ages and ethnicity use technology to teach. First, technology usage and age were examined. More teachers use technology to teach than do not across each age range (20-29, no=7, yes=15; 40-49, no=2, yes=5; 50-59, no=4, yes=7) except for the age range 30-39 where the opposite occurred (no=13, yes=8). The next crosstab displayed ethnicity and whether teachers use technology to teach. More Hispanic American/Latino/Chicano teachers use technology to teach (n=21) than do not (n=8), while less European American/White teachers use technology to teach (n=12) than do not (n=17). Something more interesting to consider is the crosstab that displays age, ethnicity, and teachers who use technology to teach as shown in Tab. 1. The Asian American/Asian, Multiracial/Multiethnic, and Other ethnicity categories along with the age range 40-49 category were not included in the table because each category had a sample of five or less. The trend in this sample is that more Hispanic American/Latino/Chicano teachers in each age range use technology to teach than do not while less European American/White teachers in each age range use technology to teach than do not.

Table 1. Crosstab for Ethnicity by Do You Use Technology to Teach Across Selected Age Ranges
Learning Style

The final score for the LSI allows one to categorize each teacher’s responses to the 12 items into one “style”. The learning style frequency indicated there were 20 teachers classified as Accomodators, 10 teachers as Divergers, 12 teachers as Convergers, and 12 teachers as Assimilators. It is more interesting to examine the LSI when age and ethnicity are considered. A crosstab, as shown in Tab. 2, was created to examine trends across age and ethnicity for learning style. The Hispanic American/Latino/Chicano 20-39 year old teachers tend to be Accomodators (n=9) but Assimilators (n=5) and Divergers (n=4) are represented in this sample as well. European American/White 50-59 year old teachers were all classified as Accomodators (n=5). Finally the 30-39 year old European American/White teachers were evenly split across all four styles (n=2 for each).

Table 2. Crosstab for Ethnicity by Learning Style Across Selected Age Ranges

Learning Style and Using Technology to Teach

Finally as shown in Tab. 3, a crosstab was run to examine if there is a relationship between learning style and whether or not teachers use technology to teach. For all learning styles except Accomodator, there were about as many teachers who use technology to teach as those who do not except for the Accomodator style. Even with the slight difference among Accomodators, there are no significant differences (a chi-square was calculated to test significance) when examining each learning style and whether or not a teacher uses technology to teach. This trend continues when correlations and t-tests are run.

Table 3. Learning Style by Do You Use Technology to Teach Crosstab

Correlations and T-tests

The learning style could not be used for statistical analysis because one style is not better than another one. However, the styles are determined by deriving “scores” on two continuous scales. These two scales are the Abstract Conceptualization-Concrete Experience scale and the Active Experimental-Reflective Observation scale. So, LSI1 represents the Abstract Conceptualization-Concrete Experience scale while LSI2 represents the Active Experimentation-Reflective Observation scale. Variables included in the correlation were TAS total score, GTUS total score, LSI1, LSI2, and how often technology is used to teach in the classroom (TECTEACH). Due to a low response rate on the LSI (some subjects filled out this scale incorrectly while others chose not to complete it at all), correlations with one of the two LSI variables had n=52 or 54. Other correlations had n=70, 74, or 75.
There were two significant correlations (see Tab. 4) both involving how often technology is used to teach in classroom. The relationship between technology usage outside of work and technology usage to teach in the classroom is moderate. Attitude toward technology and use of technology to teach in the classroom has a slightly stronger relationship than the GTUS/TECTEACH correlation. Interestingly, there was not a significant correlation between the TAS and GTUS total scores ($r=.203$, $p=.084$, $n=74$). Neither LSI variables had significant correlations with any of the other variables.

Table 4. Significant Correlations for Technology Survey

To examine if there were differences between teachers who use technology to teach and those who do not, t-tests were performed. Of the four T-tests run (TAS, GTUS, LSI1, and LSI2), TAS and GTUS had significant results as shown in Tab. 5. So, while learning style did not vary significantly between teachers who use technology and those who do not, technology attitude and usage outside of work did.

Implications

From the correlation analysis, we know a teacher's use of technology to teach in the classroom is more likely to be higher when his or her attitude (separate from usage) and technology usage outside of work (separate from attitude) are higher. Yet, in this study there was no significant relationship between technology attitude and usage of technology outside of work. This relationship needs to be studied further to determine if there might be an interrelationship between attitude and outside usage when using a larger, more diverse sample.

In addition to the significant correlations found in the study, there were significant differences between teachers that use technology to teach and those who do not, in their technology attitude and technology usage. This seems to make sense since the more experience one has with something, the more comfortable one feels in using it in a variety of situations. The question becomes which variable(s) causes the other(s). More research with a larger, more diverse sample needs to be conducted to see if these relationships continue to exist and if the direction of the relationship can be determined.

With this sample, there was not a statistically significant relationship between attitude and usage outside of work. Also, there are no relationships or significant differences between groups of teachers with learning style. In both instances, low sample size, the sample itself, and/or no relevance may be why there were no significant findings. To find out if these results (both the significant and non-significant) are accurate, more research must be conducted with this survey.

Contemplating what the data analysis means to the questions posed in the beginning of the paper, it seems there is a relationship between a person's technology usage outside of work and whether or not a teacher uses technology to teach in the classroom. Likewise, there is a relationship between technology attitude and whether or not a teacher uses technology to teach in the classroom. Whether there are interrelationships between technology attitude, usage, and learning style was unable to be determined. Future research must include statistical analysis that produces a MANOVA, multiple regression, or other similar analysis techniques to determine interrelationships among the dependent variables, as well as to examine the unique contributions each variable may make to explain or predict whether teachers use technology to teach.

The results of this study suggest the possibility that relationships exist across technology attitude, usage outside of work, as well as usage to teach. Additionally, the descriptive analysis points out differences
across age ranges and ethnicity in whether teachers use technology. Further research must be done to explore how strong these relationships and trends are and whether attitude and usage can help predict a teacher's usage of technology to teach. This is important to find out because if we can figure out why teachers are inclined to use technology to teach, then we can try to create technology training programs that foster teachers' positive attitudes and usage. Additionally if there are correlations with learning styles, we can better tailor these training programs to meet the needs of different types of learners.

Designing Curriculum-Based Telecomputing
Using Activity Structures and Action Sequences

Judi Harris
Department of Curriculum and Instruction
University of Texas at Austin
U.S.A.
jbharris@tenet.edu

Abstract: Curriculum-based educational projects that involve use of Internetworked tools are quite different from telecomputing projects that have some curricular connections. The former (tool application) is far more important in students' learning than the latter (tool operation). How can we design curriculum-based telecollaboration that is worth the time, effort, and expense involved? Thinking tools for teachers ("wetware") called "activity structures" and "action sequences" can help provide practical answers to this rarely-asked question. The 25 tools, along with their etiologies, example implementations, and reasons for use, are shared in this paper.

Most of our Internet-related learning to date has been about tools; specifically, software which can help us to locate and create information, either individually or collaboratively. When we’ve been teaching about the Internet, for the most part, we’ve been teaching students to use Internetworked tools.

Yet, as teacher educators, we know that tools, no matter how powerful their educational potential, don’t directly help students to learn. What’s important is how we use the tools to assist teaching and learning. In other words, there is a big and important difference between:

\[
\begin{align*}
&\text{(using the tools (operation) and)} \\
&\text{(using the tools (application).)}
\end{align*}
\]

Operating Internetworked tools is an important, but merely prerequisite step toward creating powerful telecollaboration and teleresearch in classrooms. How to apply the tools in curriculum-based educational activities, although less frequently the target of careful thought and in-depth investigation, is a much richer, more complex, longer-term, and more critical area for teacher educators to explore at this point in time.

Why haven’t more of our workshops, conference sessions, and Internet-related publications addressed how to apply Internet-based tools in elementary through secondary curricula? There’s a common, but usually unstated, assumption held that explains the pattern. It presumes that learning to operate hardware and software is most of what is involved in successfully integrating use of computer-mediated tools into K-12 classrooms. How to create and enact successful educational applications which integrate use of software and hardware is assumed to be obvious, once the tools themselves are known. This is part of what Seymour Papert long ago dubbed "technocentric thinking" (1987 p. 22). The tool, in and of itself, no matter how powerful its features, cannot make learning happen. The tool’s user/teacher, no matter how technically competent, enters a related, but distinct realm for inquiry when s/he plans for educational application of any new tool. It is into this educentric realm that I invite you.

Lesson Plans? Not!

How is curriculum integration of Internet tools and resources usually addressed? By examining existing projects...period. Yet when teachers are asked to wade through large collections of lesson plans, replicate projects from other classrooms, or follow overly-prescriptive directions for educational activities written by folks who can’t possibly know their students as they do, they are asked to ignore much of what experience and reflection have taught us. Using Internet tools and resources in our classrooms in ways that will benefit students and teachers - in ways
that are truly worth the time, effort, energy, and expense - call upon us to function more as *instructional designers* than direction-followers. Creating and implementing learning activities as a designer is an artisan's endeavor. I suggest that we speak to each teacher as that artisan; as chef rather than cook; conductor rather than metronome; educator rather than automaton.

How can we, as teacher educators, encourage teachers to use telecomputing tools and resources in powerful, worthwhile, curriculum-based ways, functioning as instructional designers without overburdening an already-challenging workload and schedule? We can teach them to consciously utilize two complementary sets of thinking tools ("wetware"), illustrated with a wealth of corresponding real-world, classroom-tested project examples, to efficiently and effectively create curriculum-based activities for their unique classrooms. These design tools are not prescriptions, or step-by-step directions, or blackline masters. They are two special types of thinking tools that I call *activity structures* and *action sequences*.

**Is it “worth it?”**

What's one way to save time and energy in our classrooms? Choose educational activities that give students maximal return for the amount of time and effort that all of us must expend to ensure success. There is a point of diminishing returns, the location for which each of us estimates when we consider the implementation of a new technique. In a phrase, teachers decide whether the new application is *worth it*. In terms specific to educational telecomputing, is a particular use of an Internet-based tool or resource in a particular situation for a particular group of students and teachers worth the time, effort, expense that it will take to use the tool or resource in this particular way? Note that this is not a unilateral decision about all Internetworked information and implements for all time. Instead, the “Is it worth it?” test is applied *each time* the use of the Internet is considered in an educational situation. That implies that answers to the “Is it worth it?” question will change as people and resources change. The ease and speed of Internet access in your school and classroom will continue to change. What is possible and available on the Internet will continue to change. As teachers and students learn more about and do more with Internetworked tools and resources, they (and we!) will continue to change, too.

How can we best make this decision each of the many times that we will be called upon to do so, and to help others in doing so? I suggest that, keeping in mind a specific, feasible educational use of the Internet, and in terms of both content and processes that students need/want to learn, we consider the honest answers to two questions:

1. *Will this use of the Internet enable students to do something that they couldn’t do before?*
2. *Will this use of the Internet enable students to do something that they could do before, but in a better way?*

If the honest answer to both of these questions is “no,” there is no reason to use Internet tools or resources in the way that we are considering. Our time, effort, and resources would be better used in another way. In any particular instance, if using traditional tools and approaches can allow students to learn just as well or better than using new tools and approaches, it doesn’t make sense to use new tools in traditional ways. It isn’t “worth it” to do so, for students or for teachers.

This implies that when we do use these new tools, usually it will only be “worth it” for us to do so if they can be applied in new ways to help new and worthwhile things to happen in our classrooms. “Well, that’s obvious,” you might be thinking. Perhaps. Yet, whenever we are offered new tools, something interesting happens. Most of what we initially do with the new tools looks very similar to what we did with older tools that were functionally similar to the innovations. When teachers first began to use electronic mail and electronic bulletin boards in elementary, middle-level, and secondary classrooms in the early 1980’s, for example, what kinds of projects were most prevalent? *Keypal* projects! This pattern makes sense if we realize that electronic mail was first seen with reference to its similar predecessor, surface mail. *Penpal* projects, using paper, envelopes, and stamps, were successful educational activities in classrooms long before networked computers were in the world. At first, electronic mail was seen as faster surface mail. Later, as users continued to experiment with and exploit this global communications tool, our visions of how e-mail can be used for educational purposes expanded. Now there are at least seven different ways (of which keypals is only one) that interpersonal exchanges can help students to learn.
How can we encourage teachers to use telecomputing tools and resources in powerful, curriculum-based ways that are “worth it,” making sure that they function as instructional designers without overburdening an already-challenging workload and schedule? We can help them to consciously utilize a set of design tools, along with a wealth of corresponding real-world, classroom-tested project examples, to efficiently and effectively create curriculum-based activities for unique classrooms. These design tools are not prescriptions, or step-by-step directions, or blackline masters. They are a special type of thinking tool that I call an activity structure.

Wetware Tools: Activity Structures

What’s an activity structure? Let me begin by telling you what it’s not. It’s not a model, template, plan, mold, or example. It’s a flexible framework, much like the wooden frame of a house or the skeletons in our bodies. Its basic shape is clear, strong, and simple, but, as with houses and humans, the same frame can support a myriad of different architectural or bodily expressions. The structure literally holds up the house, creating spaces for living. In a similar way, activity structures can support the generation of powerful educational environments, or spaces for learning and teaching, which are constructed, decorated, and used in customized and ever-changing ways, according to the needs and preferences of their inhabitants.

The activity structure, then, is a teacher’s instructional design tool; a piece of “wetware.” It is a way for us, in our conversations with ourselves and others, to capture what is most powerful in a particular type of learning activity, and communicate that in such a way as to encourage the creation (not replication) of individualized, context-appropriate environments for learning. It’s as if the activity structure is the frame of the house, resting firmly upon the conceptual foundation of this architectural approach to building potentially powerful learning spaces. The frame gives shape and strength to the actual learning activity, but it is completely flexible, so that the walls, roof, doors, windows, and decor are content-specific, student-centered, individualized according to preference and past experience, and reflective of locally available resources. The same frame can support many houses whose external appearances and intended functions are actually quite different. Which do you think would result in houses that are maximally serviceable and aesthetically appealing: limiting architects to a standard procedure for design with little room for variation, or inviting the exercise of their expertise and creativity? It is important for us to practice instructional design in the traditions of architecture and crafting, rather than replication and assembly.

There are 18 telecollaborative activity structures that I have identified to date. Due to space limitations, and since I described earlier versions of each of these structures in a previous SITE Annual (Harris 1994), I will merely list the structures here, adding online and off-line references through which more detailed information can be obtained. The structures group themselves into three genres of educational online activity. Interpersonal Exchanges include: keypals, global classrooms, electronic appearances, telementoring, question-and-answer activities, and impersonations. Information Collection and Analysis activity structures include: information exchanges, database creation, electronic publishing, telefieldtrips, and pooled data analysis. Problem Solving structures include: information searches, peer feedback activities, parallel problem solving, sequential problem solving, telepresent problem solving, simulations, and social action projects.

You may be wondering why I am emphasizing this notion of flexible frameworks for instructional design. Do you think that activity structures need not be consciously processed, because we use them quite effectively without realizing that we do so? This may be so, with one important proviso. Specific activity structures are often limited in scope and application according to the tools and resources that are available for their implementation. In other words, existing activity structures are often best applied using existing instructional tools. Remember the “worth it?” test? If a particular educational use of Internet tools and resources is going to be “worth it,” according to the definition that I suggested above, it must enable students to do something that they need or want to do, either that they haven’t been able to do before, or they haven’t been able to do as well. Using new structures to design curriculum-based educational telecomputing activities can help us to increase the chances that these applications will be both “worth it” and custom-tailored to the unique combination of characteristics that describe a particular group of students, working with a particular teacher, in a particular classroom, school, and community context.

Want to learn more about activity structures for curriculum-based telecomputing projects? Additional information is available online at: http://cwf.cc.utexas.edu/~jbharris/Virtual-Architecture/ and in the September 1998 issue of Learning and Leading With Technology. In-depth information on this professional development/instructional design
approach is available in the book, Virtual Architecture: Designing and Directing Curriculum-Based Telecomputing (Harris 1998).

**OK...Then What?**

Designing curriculum-based learning experiences for and with students is like planning, building, finishing, and furnishing a home. When houses are built, spaces for living are created. When educational activities are designed, spaces for learning are established. Different rooms in the home serve different purposes, but rooms with similar purposes (like kitchens) in different dwellings can look and function quite differently. Similarly, the same activity structures can be used to help students at different levels and with different curricula learn in differentiated ways that are best suited to their interests and needs.

Once an educational activity is conceptualized, however, it should not, in most cases, be implemented until students’ learning-related actions are planned. In order for teachers to know that a learning activity is ready for implementation in the classroom, the component processes in which students will engage, their approximate sequence, and the resources needed to support learning must be determined. Analogously, designing a kitchen doesn’t directly imply what we need to do to fix dinner tonight.

A house’s frame and finishing help to create different spaces, or rooms, with different purposes. Actions in various parts of the house differ, in part, based upon the nature of the spaces in which they occur. Yet similar actions can happen in different ways in different parts of the house. Analogously, once teachers have designed an Internet-supported educational activity (the flexible frame), how can they know how to help students to participate in and with it? To assist with this more process-focused kind of planning, I have recently identified seven action sequences that can be combined within and across activity structures, which also are combined to create viable curriculum-based learning experiences. Activity structures help form the general plan for the learning project, while action sequences help plot the steps that students will take as they use the activity’s structure to engage in active learning.

**Action “C-Quences”**

The seven action sequences used in Internet-supported, curriculum-based activities that I have observed to date are described, with project examples, below. Additional examples are available online at: http://www.tapr.org/~jbharris/action-sequences.html

**Correspond:**

*Prepare a communication locally then send it to others. They respond, and the process continues.*

Journey North’s Phenology Data Exchange project (http://www.learner.org/jnorth/pde/PhenDataExchange.html) asks students, “Using nature’s clues, can you find your partner?” Locally, participating classes observe natural phenomena such as number of hours of daylight, length of a meter stick’s shadow at noon, temperatures, date of last snowfall, dates tulips and tree leaves emerge and bloom, and dates when the first frog, robin, hummingbird, butterfly, or monarch egg is seen and/or heard. Students share these data, usually by e-mail, with classes in other parts of the world without knowing where the other classes are located geographically. Participants then communicate across the miles, using the data exchanged to deduce the approximate locations of partner classes, and to compare and contrast how and when seasons arrive in different places on the Earth.

**Compete:**

*Register to participate, then do an activity locally. Submit completed work by a deadline, then receive feedback.*
Teams of K-12 students and student-selected coaches (usually teachers) compete each year in Advanced Network & Services’ ThinkQuest (http://www.thinkquest.org/), a contest that encourages students to create educationally sound, Web-based learning environments for other students to use. Large monetary and scholarship prizes are awarded in several categories each year to participating students, coaches, and schools. More importantly, all ThinkQuest educational site entries remain online for learners and teachers around the world to use.

Comprehend:

*Locate online resources, then make primarily local use of them.*

Bernie Dodge and Tom March created WebQuests (http://edweb.sdsu.edu/webquest/webquest.html) in 1995 at San Diego State University. Since then, this powerful illustration of the “comprehend” action sequence has spawned many rich learning activities for students and worthwhile professional development for teachers. What’s a WebQuest?

A WebQuest is an inquiry-oriented activity in which most or all of the information used by learners is drawn from the Web. WebQuests are designed to use learners’ time well, to focus on using information rather than looking for it, and to support learners’ thinking at the levels of analysis, synthesis and evaluation.

(Dodge & March, http://edweb.sdsu.edu/webquest/overview.htm)

Collect, Share & Compare:

*Create something locally, then add it to a group of similarly-created works, combined to form a centrally-located collection.*

David Warlick’s Global Grocery List Project (http://landmark-project.com/ggl.html), now in its 11th year, helps students from all over the world to collect prices for each component of a common 15-item grocery list. The list includes items such as rice, oranges, peanut butter, coffee, and premium unleaded gasoline. Participating classes use the price lists contributed by their peers and posted at the GGL Web site to discover which items are more expensive in which places. Once these patterns are identified, students can begin to research and discuss why these differences in cost are observed, using additional data on average housing costs, average per capita income, and specific geographic location that each participating class posts.

Chain:

*Do an activity locally, create records of that activity, then send something on so that the next group can do something similar.*

First grade teacher Evelyn Kelley’s Backpack Buddies (http://scottnet/~ekelley/bkpkbuddies/), one of several Travel Buddies (http://rite.ed.qut.edu.au/oz-teachernet/projects/travel-buddies/travel-buddies.html) projects conceptualized and supported by Lindy McKeown in Australia, are “traveling teddy bears that visit your room for one week.” They come in backpacks, along with postcards, journal entries, and other artifacts added by classes whom the teddy visited earlier. There are also suggested learning activities to be done while the bear is visiting, and pictures, stories, and reports of special activities in which the bear was engaged in each classroom are displayed on the project’s Web page. Once a visit is over, the bear is packed into its backpack and shipped by first-class surface mail to the next classroom in the project’s sequence.

Come Along:

*Shadow others as they travel either physically or cognitively, perhaps communicating briefly in the process.*

There are many rich telefieldtrip experiences available on the Web.
GlobaLearn's spring 1999 Eastern Mediterranean Expedition (http://www.globalearn.com/expeditions/eme.html), for example, allows us to shadow a team of adult and student explorers as they travel through countries that border the Mediterranean sea on its eastern shores. In the process, virtual travelers can learn much about the history, current conditions, cultures, and people - especially children - in this important area of the world. The route for this expedition is overviewed at the GlobaLearn site in this way:

The GlobaLearn expedition team will begin in Alexandria, Egypt, and travel through many of the countries that border the eastern Mediterranean, including Israel, Lebanon, Turkey, Greece, Italy, and Tunisia. Visit the ruins of Athens and learn about the Ottoman Empire, while meeting local children living today in these historically significant countries. (GlobaLearn 1998 http://www.globalearn.com/expeditions/eme.html)

Collaborate:

*Work with remotely-located others to realize a common goal.*

On April 1, 1999, Canada will have a new territory called Nunavut (noo-na-voot), an Inuktitut word that means “our land.” Students in Canada have been participating in teacher Bill Belsey’s Countdown to Nunavut Project (http://www.arctic.ca/LUS/Nunavut.html), learning much about the new territory and collaboratively designing aspects of the new government that will serve the people of Nunavut. Student teams’ suggestions have been submitted as reports to the Nunavut Implementation Commission, the group of governmental officials which has been given the task of creating the territory’s infrastructure and policies.

**Designs into Actions**

As teachers who guide other teachers’ learning, we know that true knowing comes from doing. Teaching and learning are inextricably intertwined, and since teachers are pedagogical learners, they often must take action themselves before real professional development can occur, and therefore should be willing to admit that the same is true for their students. This is why it is important to include action sequences in plans for curriculum-based learning activities. The most engagingly-structured educational project serves nobody unless it is operationalized appropriately. Such action must proceed from careful thought (hence including action sequences in project planning), because as Georges Bernanos once wrote,

“A thought which does not result in an action is nothing much, and an action which does not proceed from a thought is nothing at all. (Tripp 1970 p. 5)

Using “wetware” (thinking tools) like activity structures and action sequences can help us - and in doing so, help us to help our other educators - create effective and engaging spaces for, and feats of, Internet-supported learning.

Abstract: The electronic classroom in web-world is one of important and hot topics, when we consider educational system in the situation that all computers have been connected through network. Cooperative learning is a subject that arises from the topic and several researches for organizing electronic classroom aim at supporting the cooperative learning effectively. However, there are few researches that focus on promoting or supporting students smartly during the learning. Our objective is to organize electronic classroom which promotes the interactions among students successively and assists the learning process if necessary. The issue of electronic classroom, when compared with classroom in the real world, is that students cannot know others directly. Our idea for supporting the learning among such unspecified participants is to manage the progressive situation as collections of different understanding levels, but not to identify participants individually.

In this paper, we address the idea of our electronic classroom and our approach that supports cooperative learning on the basis of scenario for deriving answer. Scenario for deriving answer is a sequence of steps for an answering process attended inherently with each exercise. Additionally, three kinds of indicators are introduced to point out learning situation in accordance with actions/reactions of students.

1. Introduction

Now that many computers are connected through Internet or Intranet, the researches related closely to web-world have also been increasing in educational field. Electronic classroom is one of interesting and hot subjects among such researches. It is regarded as a learning space shared virtually by plural students to study together. Electronic classroom mainly supports students who study separately, but have the same objective. There are several researches with different purposes that focus on constructing electronic classroom. For instance, (Maeda et al. 1998) introduced virtual classroom for studying among particular members from a viewpoint of teacher. They proposed the useful lecture materials for teachers who organize the cooperative learning through web and supported real time communication between teacher and students. Also, (Hosoya et al. 1997) regarded electronic classroom as collaborate workspace among participants and addressed a virtual space in which all participants are able to change the states of shared objects freely.

Cooperative learning is a kind of group activity that all students share the same exercise at once and exchange their opinions mutually to attain to the goal. Students improve their abilities to think logically as well as get the right process of solving exercises by insisting their opinions to other students. (Liu et al. 1998) provided effective discussion environment for all participants, who are divided into five levels: teachers, operators, assistants, analysts, and students, according to the roles for each level. This research focuses on constructing interface that provides meaningful discussion means and displays the user model which represents the attitude of each student to make learning process clear. Many researches for cooperative learning aim at making up useful interfaces. However, there are few researches that focus on grasping the contents of learning and supporting participants intellectually.

In cooperative learning, sometimes interaction among students does not effect on the learning effectively: e.g. when there are no opinions from any students or when the understanding levels among participants are very different. For such cases, the promotion/assistance function that organizes an effectual learning environment and encourages the learning processes of individual students smartly takes an important role. Our objective is to construct electronic classroom in which assistant mechanism is supplied. Namely, such functional mechanism observes the learning processes among students, grasps the situation, and gives them some advices, if necessary (Kojiri et al. 1998). In this paper, we focus on representing the situation of cooperative learning, which is the foundation to achieve our final goal, and promote the learning effectively.

The classroom in the real world is physically constrained space that gives a well-defined interaction field to all participants, and makes the multi-modal specific communication among all participants possible. While, electronic classroom in web-world is a logically formed space that supports undeterministically by an ill-defined society in which all participants cannot know other participants directly, and enforces that all participants can act/react with
other participants freely. Our idea for supporting a group of unspecified participants in the logically formed web-world is to manage the progressive situation as collections of different understanding levels, but not to identify participants individually.

2. Framework

![Conceptual illustration of electronic classroom](image)

Figure 1: Conceptual illustration of electronic classroom

Figure 1 shows an imagination of cooperative learning through electronic classroom. In this classroom, students are not able to see each other directly, but they project themselves to virtual agents in electronic classroom and participate the learning by exchanging their opinions through computers. The assistant mechanism which is embedded in the electronic classroom observes the interaction among virtual agents and grasps the learning situation.

In electronic classroom, characters input by students are only means to interact with other students. In order to understand intentions of other students precisely and proceed cooperative learning effectively, it is important that students express themselves freely. Therefore, our basic idea is that minimum constraint is permitted for communication means. Also, our stance is that the system does not observe each student individually, but approximates their understanding levels to a few representative levels. In cooperative learning, students may support each other so that it is enough for the system to grasp only an approximate situation of learning.

Here are conditions of our system that we are going to investigate.

1. All students have fundamental knowledge for exercises.
2. Each exercise has only one answer and one answering process.

The process of deriving answer may be constructed differently in accordance with the levels of participants. When the learning group consists of students who have enough knowledge for exercises, they are able to solve the exercises by themselves. On the other hand, when few students have fundamental knowledge, they may need explanation in most of answering process so that the learning would be organized as a private lesson rather than cooperative learning. Since under the condition 1, there are few students who do not understand answering process at all, the interaction among students should be cooperative and progressive in many cases. Under the condition 2, the exercise which students are going to solve has always a right answer and one ideal answering process and the system enables to grasp the stage of deriving answer easily. Currently, we focus on the solution problem of mathematical expressions as exercises: especially, roots computation of equations.

2.2 Approach

In physically constrained space, we exchange our opinions and proceed cooperative learning mainly by talking each other. Also, writing sometimes takes an important role to arrange the derived answering process. Therefore, our electronic classroom provides two communication means to make logically constrained space closer to physically constrained space; one is interaction space and another is answer-board screen. Interaction space supports our ordinary conversation and it would be a main media to proceed learning. In addition to the conversation, answer-board screen is to make the learning contents that have already been derived clear. It plays a role of blackboard in physically constrained space.

For our assistant mechanism, it is necessary to grasp the path to answer in order to detect whether students are in right process for the goal. Our approach is to embed stepwise answering scenes into electronic classroom, which we define as scenario for deriving answer. Each scene in the scenario corresponds to the eventual answering scene along
time sequence: namely, scenario starts with the scene of opening question and ends with the scene of final goal. In order for the system to understand the situation of learning, we set three kinds of pointers called indicators on the scenario. One is called current which points out current answering scene, and the others are upper and lower which express the extents of understanding levels for learning groups. Our idea is to represent learning situation under relationships among these indicators.

3. Collaboration Support Media

3.1 Interaction Space

Interaction space is a communication media which enables to support free conversation among students. However, in order to grasp learning situation, the system must provide some commands to distinguish particular words, which are to specify answering scene on the scenario, from other parts of utterances. Now we prepare the commands shown in Table 1.

<table>
<thead>
<tr>
<th>Command</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>APPRECIATE (equation, utterance)</td>
<td>Proposal of new solving means</td>
</tr>
<tr>
<td>INQUIRE (target, utterance)</td>
<td>Question about opinion</td>
</tr>
<tr>
<td>CONFIRM (target)</td>
<td>Confirmation of student’s understanding</td>
</tr>
<tr>
<td>ASSERT (utterance)</td>
<td>Other opinion</td>
</tr>
</tbody>
</table>

APPRECIATE is to suggest new answering method or new stage of deriving answer; INQUIRE is to question about already derived process; CONFIRM is to make sure for all other students whether they do not have any problems toward an asked stage in deriving process; and ASSERT is used for all other utterances. In spite of these commands, students are able to interact freely by filling what they want to say on utterance.

3.2 Answer-board Screen

Answer-board screen is a bulletin media to show derived answering process in order to arrange the learning process. We set writing right on answer-screen, since if plural students can input on this screen at one time, this screen would be a disordered memo and hardly plays a part of its original role.

Learning process in our electronic classroom is proceeded with these means. Figure 2 shows the progress of learning. These commands are prepared by the system as an interface. Students are able to express their opinions freely at utterance on interaction space. Target on the commands indicates the number labeled on answer-board screen, which is used to indicate the relationship between input on the interaction space and that on the answer-board screen. Since we focus on mathematical exercises, we set equations as particular words to specify answering scene so that equations must be written separately in some commands.
4. Collaboration Support Mechanism

4.1 Scenario for Deriving Answer

The scenario for deriving answer is a collection of ordered answering scenes prepared for each exercise. The scenario is a foundation of assistant mechanism which is embedded into the electronic classroom. For mathematical exercise, the answering process is often divided into several stages according to the content. Figure 3 is an example of mathematical exercise and answer that were divided into several answering stages.

<table>
<thead>
<tr>
<th>(a) EXERCISE</th>
</tr>
</thead>
<tbody>
<tr>
<td>When the equation (x^3+ax^2+bx+6=0) has an imaginary root (1+\sqrt{-21}), compute the values of (a) and (b).</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>(b) ANSWER</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stage1: For (x^3+ax^2+bx+6=0), set ((1+\sqrt{-21})) to (x)</td>
</tr>
<tr>
<td>(1+\sqrt{-21})^3+a(1+\sqrt{-21})^2+b(1+\sqrt{-21})+6=0 \ldots (1))</td>
</tr>
<tr>
<td>Stage2: Arrange the real part and imaginary part for (1)</td>
</tr>
<tr>
<td>((1-a+b)+(1+2a+b)\sqrt{-21}=0 \ldots (2))</td>
</tr>
<tr>
<td>Stage3: To satisfy (2), the following equations are necessarily required.</td>
</tr>
<tr>
<td>(1-a+b=0, 1+2a+b=0 \ldots (3))</td>
</tr>
<tr>
<td>Stage4: Compute (3) for (a) and (b), which satisfies (3) at once.</td>
</tr>
<tr>
<td>Thus (a=0, b=-1 \ldots (4))</td>
</tr>
</tbody>
</table>

**Figure 3: Example of exercise and answer**

It is assumed that answering scene also changes among divided stages. Our idea is to define each stage as a state in the scenario, so that scenario is composed of ordered states. Individual states have particular words to distinguish from other states, which we call state-words. For mathematical exercises, each stage contains one or more important equations, like equations underlined in Figure 3. Thus, we set state-words to each state for equations in the stages. From these definitions, Figure 4 represents the scenario for exercise in Figure 3.

**Figure 4: Scenario for exercise in Figure 4**

4.2 Indicators

As we mentioned in Section 2.3, we prepare three indicators on the scenario, current, upper and lower, to express learning situation of the group. Current points out current discussing state; upper indicates the state that best understandable student reached until now; and lower indicates the state that worst understandable student does until now. The system grasps the learning situation from the relationships among these indicators. For instance, the system detects that the whole learning has completely finished when lower points to the last state, or that some students may not join on learning effectively if the distance between upper and lower is too long.

Indicators move according to the inputs from students. Namely, indicators change the pointing state when there are state-words in the corresponding inputs. Current reacts from the inputs that may change discussing states forward or backward, which are equations on answer-board screen or command APPRECIATE or INQUIRE on interaction space. Upper moves according to inputs on answer-board screen or command APPRECIATE on interaction space, and lower changes state from command CONFIRM on interaction space, because asking is only way to grasp other students' understanding levels.

Figure 5 is an example of situations changed according to the inputs by students. In this example, it is clear that indicators express approximate learning situation according to students' input, if they write state-word correctly. While the indicators do not move so often, this approach is enough for representing and grasping learning situation and supporting the learning effectively.
5. Conclusion

In this paper, we mentioned our idea of constructing the electronic classroom which contains assistant mechanism. We also introduced our approach to realize assistant mechanism (especially, representing the learning situation) by introducing the scenario for deriving answer and three indicators on the scenario. Currently, we imposed on a lot of constraints for developing our framework, but the approach may be available for more flexible situation. It is because our system does not support students individually, but grasps only the situation approximately.

Our next step is to consider the following problems;

- constructing more flexible interface which makes interactions among students more natural,
- updating scenario structure, and
- grasping more complicate learning situation.

Our electronic classroom through web certainly provides learning space for plural students, but is far from physically constrained space in our real world. It is important to construct more flexible interface to be aware of other students easily and to communicate each other more naturally. Currently our scenario can represent only one process of deriving answer, but most exercises have more than one. So it is necessary to update scenario structure in order to adapt more complicate answering process, and then grasp the learning situation from relationships among indicators. In addition, the situation that students do not have fundamental knowledge is one of important issues. In such situation, current moves much frequently so that it is hard to express learning situation by only these three indicators. We should have more complex mechanism to be able to cope with such cases.

Abstract: As student teachers proceed to become teachers in classrooms, they are faced with real-world challenges that involve infusing theories acquired from their teacher education programs into existing school curricula. These new teachers are finding it increasingly difficult to attain a balance between conventional pedagogical objectives for students and market-driven needs to produce knowledge workers in their teaching practices. This is especially prevalent in a teaching-learning domain that uses web-based instruction, where teachers are compelled to deal with issues that arise from integrating the culture of Internet use with the learning culture of the more conventional classroom. In this paper, we will examine issues that emerged from an analysis of qualitative data from new teachers' reflections and videotaped interviews. The thrust of our discussion is on these teachers' practices and decisions regarding adapting web-based instruction to suit or adapt to the conventional classroom learning culture.

Introduction

Entering the teaching profession is most challenging when one is unacquainted with what lies ahead. This is especially true of a teaching-learning domain that uses web-based instruction, where teachers have to learn to resolve issues that arise from integrating the culture of Internet use with the learning culture of the more conventional classroom. Much has been said about the power of the Internet for classroom use today. We have witnessed its significant impact on information technology, as Internet tools and applications are enhanced and improved to cater to the aggressive and creative thirst of the public who uses them. For example, communication has improved substantially with the advent of the Internet technologies. As we progress into the new millennium, academia has also taken serious considerations on the impact of the World Wide Web onto its teaching-learning and research activities.

This paper attempts to address these key issues:

- Factors that facilitate or impede the use of the World Wide Web (WWW) in classroom instruction
- Considerations that new teachers have to take into consideration in making curricular decisions that involve the use of the Internet in their classrooms

Preliminary results from a larger research study have been tabulated to arrive at insights into the current perceptions of teachers on computer technology and the use of the Internet in the classroom.

Theoretical Framework

Web-learning paradigms

Learning on a novel channel, such as the Internet, redefines the way knowledge is presented and acquired. Learners will no longer be dependent on oral instructions from the instructor in front of the classroom. Polyson et al. (1998) identified some of the apparent strengths of web-based instruction:

- Personalized learning environment
Restructuring web-based curricular

As web-based resources become the basis of the curriculum, the curricular issues in education increasingly become those of ensuring that WWW tools are available and optimally utilized by teachers and their students to enable the latter to enhance participation in learning activities. Some of these issues involve making policies and decisions that will need to:

- encourage schools to shape their curricula, teachers to redesign their courses, and teachers as well as students to restructure the management of time.
- situate the locus of learning in small groups interacting with learners from all over the world to work on genuinely difficult and real-world problems.
- shift issues of curriculum design away from questions of scope and sequence towards those of problem solving and project initiation.
- redirect assessment away from measuring how well students know the mandated knowledge core to disclosing their ability to manage inquiry and solve problems.

Thus we can see how the roles of teachers in these essential schools are reconfigured just as much as the curricular structures are. Furthermore, as the contents of the curriculum increasingly become electronic ones accessed via digital networks, the range of skills required of teachers is broadening rapidly. All these changes point to a need to rethink the processes of professional development for student teachers and their trainers.

Methodology

Instrument

A set of questionnaires was distributed among 63 pre-service and in-service teachers in an undergraduate program at Universiti Malaysia Sarawak. The questionnaire consists of items on student demography, and beliefs and perceptions about language teaching and learning with the infusion of technology in the lessons. In addition, to find out these student teachers' perceptions on web-based instruction, several interviews were conducted to elicit their response to relevant issues. Due to spatial limitations, the outcome of the interviews will only be presented during the conference presentation.

Participant profile

The sample group for this study is student teachers (teacher trainees) who were enrolled in the TESL degree program at Universiti Malaysia Sarawak. They ranged from inexperienced teachers to teachers who have been teaching for ten years. The group represented six ethnic groups in Malaysia, and their native languages varied from Bahasa Melayu to Iban. English is spoken mainly as a second language, and is used in formal contexts on and off campus. English is also taught formally in school as a subject, and most of them had ten to twelve hours per week for English language learning.

The participants of the interview sessions were graduating students who had completed 95% of their undergraduate coursework, and had taken the Educational Technology module in the TESL program. They had also done projects on creating web-based learning environments for English Language learning in Malaysian English as a Second Language (ESL) classrooms.

Findings
The response rate for the questionnaire survey is 82.54% (N=63, n=52). Part A of the survey elicits general perceptions about the functions of computers in their lives. Part B narrows the scope to their perceptions about efforts to integrate computers into the language classrooms in Malaysia. Part C, focuses on their views on the use of computer-assisted instructional materials in their teaching environment (including materials available on the web). All three parts have fifteen items in each of them.

Descriptive Statistics

The data analysis, on the whole, showed a positively inclined attitude and perception toward the existence of the computer and its applications among these student teachers. The sample group was represented by a group of young teachers (indicated by the number of years they had taught, and the majority fell between 0 to 10 years' of teaching experience). They also range between 18-35 years of age.

Table 1: Mean and Standard Deviation Ratings for all Variables

Using the Pearson Correlation formula, it is indicated that there exists a very strong correlation between the student perceptions on computers (in general) and efforts of integrating computers into the language classroom (0.790). This corroborates that the sample group found computers favorable for use in language lessons and in their daily activities. This group also showed an understanding of the need to infuse technology (especially computer-based applications) into their language classrooms in Malaysia. The data indicate a strong correlation between responses for Parts B and C (0.659). It is slightly weaker than that of the first comparison, but this result shows that the sample group is optimistic and receptive about the use of technology-enhanced materials and tools in their language classrooms. Although weakest, the correlation between the first and final parts of the questionnaire indicated a moderately strong correlation between them (0.495). This data further enhance the assertion that these Malaysian undergraduate teacher trainees are generally sanguine about the opportunities to infuse technology effectively into the teaching of English language within the Malaysian educational context.

Table 2: Analysis of Correlation between three sections in survey

To find out the strength of relationships between the sample groups’ convictions on specific issues, an analysis was conducted on several questionnaire items, namely:
- Item A15: I believe that computers will be an important asset for everyone in the world in the 21st century.
- Item B14: I am trained to use computers and technology creatively and effectively in an English language learning environment.
- Item B15: I am ready to use computers in teaching English to my students.
- Item C13: I believe that Information technology offers a new skill to be acquired by language teachers to excel in teaching English today.
- Item C15: I am open to opportunities and innovations in multimedia technology in education.

All of these items generally investigated the degree of student-teachers' self-enthusiasm and confidence to deal with computers and technology for their language classrooms.

1974
From the data analysis, as tabled below, the strongest correlation (0.561) was recorded between the items that dealt with training preparation and confidence level to use computers in classroom activities. There is also a strong correlation between items that evaluated their perceptions on technology applications for these student teachers and their optimism to the developments of multimedia technology in education. It is also vital to note that the number of years that they have been teaching do not affect their perceptions and optimism about the infusion of technology into their language teaching environments.

Discussion

Student teachers indicated that they need to cope with two challenges in their teaching environment: they have to acquire the target language in a non-native environment, and simultaneously adapt to the medium to present and educate their non-native speaking learners using the Internet. There are infinite ways in which web-based instruction can be used to empower and build strategic learner techniques directed toward good language learning behaviors. The following techniques are drawn from Brown's (1994) teaching tips for language learning and teaching, and have been infused with some apparent strengths in web-based instruction (as advocated by Polyson et al., 1998):

Lowering inhibitions: Lowering the affective filter by incorporating a variety of hypertext and graphics to create a wealth of entertaining and communicational games, and social interaction activities like chatting, discussion forums, role-plays and simulations as learning activities.

Encouraging risk-taking: Using fluency exercises, and giving outside-of-class assignments to practice speaking or writing skills; providing opportunities for communicating with other global learners using WWW resources (this accounts for the popularity of some language learning web sites, like Dave Sperling’s ESL Café)

Helping them to develop intrinsic motivation: Reminding students explicitly about the rewards for learning English, for example, encouraging learners to look-up jobs on the WWW that require a good command of English.

Promoting cooperative learning: Directing students on how they can share their knowledge gained from the Internet through paired and group work.

Encouraging them to use right-brain processing: Using movies and audio files, texts for rapid reading and skimming, writing and oral fluency exercises, and other multimedia WWW resources to cater to different learning styles.

Promoting ambiguity tolerance: Encouraging students to ask the instructor and other students questions when they do not understand something they have encountered on the WWW; keeping theoretical explanations very simple and brief; dealing with just a few rules at a time; and occasionally resorting to translation into a native language to clarify a word or meaning.

Helping students to use and rely on their own intuition: Praising students for good guesses and choices they make while “surfing” the WWW; not always giving explanations of errors (letting correction suffice and correcting only selected errors, preferably just those that interfere with learning).
**Encouraging students to reflect on correcting their own mistakes:** Recording students' oral production using the sound recording facilities available on the computer and getting them to play back the recording and identify their own errors; letting students catch and correct each other's errors; not always giving them the correct form; encouraging students to make lists of their common errors from the recordings and to work on them on their own.

**Getting students to set their own goals:** Explicitly encouraging or directing students to go beyond classroom goals; having them make lists of what they will accomplish on their own in a particular week; getting students to make specific time commitments at home to study the language; giving "extra credit" work that is achievable by utilizing resources on the WWW.

The previous techniques are clearly manifestations of the strengths that web-based instruction brings with it. By lowering inhibitions, encouraging risk-taking, intuitive abilities and setting of goals by learners, the Web lends itself to student-centeredness, self-directed or personalized learning, collaborative learning, multimedia presentation of content, experiential learning, utilization of up-to-date information as well as global resources, learning in real-world contexts, and new assessment models.

Paired or group work, desktop forums and web-based conferencing all encourage cooperative or collaborative learning. Duffy and Cunningham (1996) are among educators who encourage using group learning not just as a classroom management strategy but more so to promote dialogical interchange and reflexivity among learners. This involves having learners use the Internet to share alternative viewpoints, support each other’s inquiry processes, and develop critical thinking skills that include the ability to reflect and improve on their own learning.

Taking into account Polyson's *New Assessment Models* paradigm, a curriculum centered upon web-based instruction will need to consider appropriate assessment models in order to evaluate and monitor the progress of the learners “we can’t see, hear and interact with in person”. One way to attempt to solve this ambiguity is a model proposed by Duschastel (in Gan, 1998) that provides necessary navigation for the tertiary institutions to capitalize on web-based instruction:

1. Specify goals for students to pursue rather than content to teach/learn
2. Accept diversity of learning outcomes rather than demand common learning results
3. Request production of knowledge from students rather than communication of knowledge
4. Evaluate students' learning at the task level rather than knowledge level
5. Build learning teams rather than focus on individual work, and
6. Encourage learning in global communities rather than only local communities

To optimize these learning opportunities, we first need to find out to what extent teachers and their learners are adaptive to the web-based instructional environments. How would such invaluable interactions like collaborative web-based learning be organized and used optimally in Malaysian classrooms? Also, how far are current Malaysian learners able to fit comfortably into this individualized learning environment given that they have so far been predisposed to a classroom-based rather than an individualized or self-directed approach to learning in the Malaysian classroom? Or is this more a dilemma for teachers who have been so used to taking center stage in the classroom that implementing a more learner-centered approach would pose uncertainties?

It is crucial to embed into the teacher-training curriculum the imperative need to embark on action research efforts when these new teachers begin to teach. The above questions will be answered if teachers are prepared to inquire into and seek answers to problems that arise within their own teaching environments.

**Conclusion**

Much has yet to be dispelled about web-based technology and its implications on teacher training curricula. The World Wide Web may perhaps have the best offer for multimedia production of lessons and self-access materials. However, effective web-based instruction and learning require a significant quantity of maturity and patience. This paper and the study findings discussed offer a perspective of the many systemic reforms in teacher thinking needed in making curricular decisions aimed at meeting learners' needs in web-based instruction.

Some Concerns About the Concerns-Based Adoption Model (CBAM) and Technology

Scott W. Slough, Department of Early Childhood Education and Reading, Georgia Southern University, Statesboro, GA 30458 USA, sslough@gasou.edu

Abstract The Concerns-Based Adoption Model (CBAM) originally proposed by Hall & Hord (1987) and modified by Bailey and Palsha (1992) provided a conceptual framework for the study discussed (Slough, 1998). According to the model, as innovations—in this case telecommunications technology—are implemented, individuals progress through a typical set of concerns that are progressive and to some extent sequential; and progress in one innovation does not always transfer to the newest innovation (Hall & Hord, 1987). In general, the basic assumptions of CBAM were supported by this study. Teachers at different stages of the implementation of telecommunications did have different concerns; and further, teachers at similar stages of implementations did have similar concerns. Two noted short-comings of CBAM discussed in this paper are that CBAM assumes a static innovation and that all individuals progress to adoption of the innovation.

Scientists, science educators, business leaders, and the government have all called for increased integration of technology in the science classroom, including telecommunications. The federal government, state governments, business, industry, and varied private foundations cooperated to a degree to develop the backbone of the Internet that will provide access to the schools. School districts are spending local money and competing for outside money via grants to access the Internet and all of its proffered promise. Yet, little is known about how to implement this technology, especially in the high school science classroom.

The purpose of this study was to examine and describe the high school science environment within an emerging telecommunications-rich setting in an effort to provide a better framework for implementation of telecommunications technology in science classrooms. Research questions focused on teacher and students' use of telecommunications, barriers and supporting conditions to telecommunications implementation, and the effect of telecommunications on the teaching and learning of science. Data was collected through open-ended ethnographic interviews with 24 high school science teachers who had been in an emerging telecommunications-rich environment for at least two and one-half years as of the Fall Semester, 1997. The teachers were from a single, large, suburban school district with five high schools. The district was chosen because it provided an emerging telecommunications-rich environment and because it provided a fairly large stable population of high school science teachers who had been in that emerging telecommunications-rich environment for at least two and one-half years. In this case, the emerging telecommunications-rich environment included a district-wide infrastructure that had been in place for two and one-half years that included 24 network connections in each classroom, full Internet access from the network, four computers per classroom (teachers were required to attend training before receiving), and a variety of mandated and optional professional development opportunities within and outside the district. Teachers in the study were well distributed across each of the five high schools, across typical high school science courses, across all levels of educational attainment, and included fairly new to veteran teachers. In short, they represent a cross-section of the high school science teachers within the school district.

Five-Stage Model of Concerns

The Concerns-Based Adoption Model (CBAM) originally proposed by Hall and Hord (1987) and modified by others (Bailey & Palsha, 1992) has been employed to explain the adoption of innovations. Specifically, a five-stage CBAM model (Bailey & Palsha, 1992) provided a conceptual framework for the study discussed (Slough, 1998). The resulting five-stage model (see Table 1) includes descriptors for each of the stages awareness, personal, management, impact, and collaboration concerns. The awareness stage is characterized by
the teachers having little knowledge about the innovation but interested in learning more about it. The personal stage is characterized by the teachers who are primarily concerned with how the innovation will affect them, with a specific focus on required changes in roles and tasks. The management stage is characterized by the teacher who is primarily concerned with time management, organization, and prioritizing responsibilities. The impact stage is characterized by the teachers who focus on the effects of the innovation on learners and how this innovation can be used to change or improve learning. The collaboration stage is characterized by the teachers who focus on working with others to implement the innovation as well as sharing information about the innovation with other teachers. According to the model, as innovations—in this case telecommunications technologies—are implemented, individuals progress through a typical set of concerns that are progressive and to some extent sequential; and progress in one innovation does not always transfer to the newest innovation (Hall & Hord, 1987).

Table 1
Five-Stages of Concerns Descriptors
In general, the basic assumptions of CBAM were supported by this study. Teachers at different stages of the implementation of telecommunications did have different concerns; and further, teachers at similar stages of implementations did have similar concerns. Two noted short-comings of CBAM as a theoretical framework for this study were that CBAM assumes a static innovation and that all individuals progress to adoption of the innovation. Telecommunications and the associated technologies are not a static innovation. Teachers at all levels reported that one of the difficulties with implementing telecommunications and the associated information technologies was that it was always changing, in effect constantly creating a new innovation. Also, teachers in this study—especially at the management, or third stage—seemed to have made a specific decision NOT to adopt the innovation due to their experiences, mostly negative, with telecommunications.

Technology as a Non-static Innovation

CBAM assumes a static innovation. In general, technology—specifically telecommunications in this study—does not represent a static innovation. Teachers at the lower stages, in particular, seem to be intimidated by the changing knowledge base for telecommunications. Additionally, teachers who were most comfortable with implementing telecommunications were most comfortable with the changes associated with telecommunications. In fact, they considered the challenges created by the changes to be a driving force for their involvement with telecommunications.

Telecommunications and the associated technologies clearly were an innovation. Prior to district-wide training with telecommunications, the majority of the teachers (16 of 24) did not consider themselves to even be competent computer users. To varying degrees, each teacher at the lower three stages mentioned the variability and changing nature of the technology to be a barrier to their learning and ultimately implementing telecommunications. Even with mandated district-wide training, all of the teachers at the lowest stage of adoption, awareness, had significant misconceptions about telecommunications network and technology in general. Simple changes in the log-in protocol were noted as significant reasons that teachers at the awareness level did not pursue additional training. This was also noted by teachers at the next stage, personal, as well. All six teachers had expressed dissatisfaction with having to have both a username and a password to use the system. Specifically, four of the six mentioned having using a computer for "surfing the Web" when another teacher had already logged on because that way they did not have to remember their own passwords (the district automatically changed passwords on a periodic basis for network security reasons).

Teachers at the management stage were less concerned with network changes and more concerned with the validity of information and that was available on the Web and its occasional lack of permanence. Instead of envisioning the value in using the Web as a tool to check the validity of data—and subsequent conclusions, or to publish original work, or to supplement traditional knowledge sources, teachers at the management stage focused on their bookmarks working one day and not working another day. One teacher remarked, "How can I send students to a Web site if I do not know that it will be up, or if the site will ever be available again?" Teachers at the highest two stages, impact and collaboration, generally considered the changing nature of telecommunications to be positive because it kept them and their students motivated to learn as the technology changed. Finally, the changing nature of the innovation—telecommunications—definitely had an effect on the implementation. Teachers that had not already adopted telecommunications considered the changing nature of telecommunications to be a barrier and those who had adopted considered the changing nature to be a supporting condition for implementation.

Non-progression to Adoption

CBAM also assumes that individuals progress along the stages of concern in a fairly linear fashion, going through successive stages to ultimately reach the highest stage (Hall & Hord, 1987). In general, this study did support a progression of concerns consistent with the five-stage model proposed by Bailey and Palsha (1992). The clear exception to this general trend was the third stage, management. Teachers at this level appeared to be resistant to significant district-wide and individual attempts to introduce telecommunications in their classroom. Teachers at the management stage clearly restricted student use of telecommunications, listed significantly more barriers and less supporting conditions for implementing telecommunications, and rejected the notion that telecommunications could, or even should, change the teaching and learning of science. These
teachers have chosen not to implement telecommunications and subsequently do not appear to be candidates for progression to the subsequent stages of adoption.

The restriction of student use was one of the major delineating factors in identifying teachers at the management stage. The teachers reported two primary reasons for restricting student access. The first was a fear of students gaining access to inappropriate material—including adult material, and the second was students using the Internet to cheat. All six of the teachers at this stage were concerned with student access to inappropriate material and eventually being held responsible for "student mistakes." The most vocal of the group described a rumor of "a teacher at another district who had lost their job because students were downloading pornographic images." Another quoted a recent headline about a rape/murder where the suspect had met the victim through a chat room. The fact that this had not occurred at school was apparently not as important as the fact that it might happen. The teachers were also concerned about the validity of scientific information found on the Web.

Five of the six teachers were concerned with students cheating by using the Internet. Again, rumor and speculation drove the teachers' concerns. None had actually caught a student cheating using the telecommunications; and other than copying something from the World Wide Web, they were not terribly familiar with how the student would actually cheat. One teacher said, "I know that they are doing it [cheating]; I just don't know how. And if I don't know how they are doing it, I can't stop them." He continued by saying that he had completely dropped any "library assignments because they could just download reports from those places that sold term papers when we were in college."

Teachers at the management stage had not made any instructional changes as a result of telecommunications. In fact, telecommunications had to some extent caused them to become more entrenched as "traditional" teachers. One teacher said, "I am not sure what you mean. Are you asking if I have changed how I teach because of telecommunications?" When this was indeed confirmed as the question, he said, "I certainly hope not! That seems to be the wrong way to do it. If telecommunications can't fit into how I teach, it shouldn't be in my class." Another teacher echoed a similar statement, "I would never change instructional strategies to accommodate a machine; it needs to fit into what I do." A third described another similar scenario,

Change it? No, I don't think so. I have worked very hard to get my curriculum just the way that I want it, and I don't have any fluff in there. I don't have time to waste on this feel good stuff that some of the teachers are doing on the Internet.

All six teachers at the management stage were in various ways adamant that telecommunications would not change their teaching.

Perhaps most significant was that teachers at the management stage had considered the question of whether or how telecommunications were affecting student learning and the answer was—*it was no*; or at least, they had not seen it. Most of the teachers at the management stage were openly skeptical of telecommunications' future in the classroom. Each expressed it a slightly different manner but one teacher did summarize many others words when he said, "The proof is in the pudding, and I don't see any pudding." Others focused on the hype of telecommunications verses what it had actually produced. One teacher described the situation:

I know that several teachers have reported that their students are doing some amazing things on the Net, but at what cost? With that much money, you would think that we would have seen something a little more concrete. Like TAAS scores, they haven't gone up. SAT scores haven't gone up. Graduation rate hasn't gone up. What are these amazing new things, and why haven't they translated into higher scores?

Not all of the six teachers at the management stage were as openly skeptical; two in particular seemed to still be open to telecommunications potential if someone would show them. In fact, the one teacher said, "I still don't know. I haven't seen any real student learning beyond finding a few new sources; I think the jury is still out." She continued that she "certainly would have to rethink her position if positive student learning outcomes were shown to her."

CBAM assumes a general linear model where teachers go through each successive stage. There are no accommodations for individuals who reject an innovation. Teachers at the management stage were the exception to a linear trend for all of the research questions. Teachers at this stage were so concerned with classroom management and instructional design issues that they restricted student use, in effect rejecting the
innovation for the time being. The management teachers' decision to restrict student access was based on their experiences using telecommunications. They had seen that it was possible to access inappropriate material that included sites that contained adult material, sites with inaccurate scientific information, and sites designed purely for entertainment. They had personal experience with the amount of time that telecommunications often takes to learn. In short, they had experience with telecommunications and had made a conscious decision not to use it in their classroom with their students.

Limitations

This study, like all others, has some limitations. Some of the limitations of this study include the restricted population, one-time interviews, and dependence upon self-reported data. A longitudinal study of the population is warranted to monitor teachers' concerns over a longer time span, especially in light of the fact that telecommunications represent a changing innovation. Additionally, teachers were not asked about specific requirements to take the next step in implementing telecommunications. They were simply asked for supporting conditions. A long-term study would allow collection of data from participants as they were transitioning from one stage to another. This might also identify individuals for case-studies who were transitioning from one stage to another. All the data in the study was a result of teacher self-reporting. Self-reported data has been found to be less reliable than observational data. Specifically, independent observations of teacher use, student use, and reported positive effects of telecommunications on instruction and student learning would enhance any conclusions drawn from this study.

A Student Model for Representing Learning Process, Based on TMS Framework

Toyohide Watanabe and Taiga Ohno
Department of Information Engineering,
Graduate School of Engineering, Nagoya University, JAPAN
E-mail: {watanabe,ohno}@watanabe.nuie.nagoya-u.ac.jp

Abstract: Although the student model which is an important composite module to distinguish ITS from CAI has been developed until today, this model can be classified into overlay model and perturbation model, as the basic paradigm. These models have mutually a complementary relationship, and the abilities are not always powerful because they manage only individual learning items for understanding contents. In this paper, we propose a progressive student model to manage learning items effectively with a view to making error-diagnosis/detection mechanism successful and making up effective schedules of learning processes personally. The basic idea is derived from TMS framework. Our objective is to represent understood/mis-understood situation of student under consistently unified relationship.

1. Introduction

ITS (Intelligent Tutoring System) or ICAI (Intelligent Computer Aided Instruction) is investigated with a view to instructing individual students personally. In order to attain this subject, the student model is introduced as a most important module in comparison with the traditional CAI. It is necessary for the student model to represent understanding level or learning situation of student individually, and assist the instruction process to be next expanded in accordance with past learning history and understanding level (Kopec et al. 1992). The most basic function of student model is to manage sufficiently the information about which learning items are learned, which learning items are already understood, and which learning items are not yet understood. Thus, until today, two typical classes of student models were proposed: overlay model and perturbation model.

The overlay model manages learning items which students could understand one by one, while the perturbation model does learning items which students could not understand or mis-understood. These models have mutually a complementary relationship for representing the understanding level of student, and also the representative abilities are not always powerful because they have only individual learning items for understanding contents. Additionally, they are not successful to infer dependency among learning items, diagnose mis-understanding of learning items and detect the original causes for wrong comprehension. Namely, they are in short of the representation for management/control mechanism of dependency relationships among related learning items.

In this paper, we propose a progressive student model to represent the learning process by inductive relationship among learning items effectively. The basic idea is conveniently derived from TMS (Truth Maintenance System) framework, proposed by (Doyle 1979). In TMS, the world is always maintained truly so that the denotation relationships among currently accommodated terms should be believed interpretatively. If any contradiction were suddenly found among interrelated terms, TMS reorganizes the belief relationship of interrelated terms so as to make consistent interpretation possible. This mechanism is useful to manage the successful dependency relationships among already understood learning items and next instructing learning items. Of course, in our objective the subject to be maintained is different from that in TMS, and the mechanism is not the same as that in TMS. In comparison with TMS, our interpretation is grown up/down sequently by instructing new learning items.

Our objective is to maintain understood/mis-understood learning items under consistently unified relationship among already instructed learning items, and manage the learning process and understanding level of student successfully in accordance with their actions/reactions. In order to attain this objective two new justifications such as CR (Correct) and WR (Wrong) are introduced in points of specifying the historical dependency relationships among derivedly acquired learning items and previously understood learning items and recording the cause-effect relationship among understood/mis-understood learning items, respectively, in place of two justifications SL (Support-list) and CP (Conditional-proof) in TMS. Using two different justifications, our student model can represent the understood/mis-understood situation among individual learning items and inferable relationship among derived learning items. In this paper, we address such a student model useful to diagnose errors and detect the causes. Additionally, we discuss these mechanisms on LISP tutoring system.
2. Framework

It is important for tutoring system to instruct learning items to student in accordance with his understanding level or learning situation or act/react to the learning process of student timely and smartly. In order to satisfy this requirement, the tutoring system must grasp the successive learning process. Thus, it is so necessary that the student model should represent the historical interrelation among individual learning items, which student has ever learned, in addition to the specification for understanding level of individual learning items, which were applied in the traditional student models. So, individual learning items have mutual dependencies: one learning item to be newly learned is derivedly composed of some other learning items which have been already learned as the prerequisite terms. Of course, these dependencies among learning items are implicitly predefined in the authoring text, as domain knowledge for learning items. In many cases, the student model can be organized under the mapping from the authoring text (Ohnuma et al. 1997) (Watanabe et al. 1993) and (Watanabe et al. 1993).

Figure 1: Construct in student model for authoring text

Figure 1 shows such a mapping. In Figure 1(b), the mapping moves only learning items, associated individually with some evaluated score values, into the student model from the authoring text; In Figure 1(c), the mapping transforms the learning items with dependency relationships into the student model, as a subgraph. The former was applied in the traditional student model, while the latter is organized in our student model.

In our framework, the student model is designed under the following viewpoints:
1) to keep historical information about successive learning items;
2) to support recovery mechanism for understanding errors;
3) to keep historical information about understanding errors;
4) to maintain understanding level of student inferably;
5) to indicate learning process of student explicitly.

Although the viewpoints 1) and 5) may be supported even by the ordinary overlay model and the viewpoint 3) may be done by perturbation model, our framework is more progressive. With a view to attaining these viewpoints the truth maintenance mechanism in TMS is very useful to our student model.

In TMS, individual terms are composed basically under the dependency relationships for other terms, and are justified with the relationships. If the contradiction among already accommodated terms is occurred, TMS establishes uniform belief interpretation among all terms with respect to the resolution of contradiction. This mechanism is adaptable to our viewpoints 1), 2) and 4).

In our student model, the system configuration is illustrated in Figure 2. The error-diagnosis/detection module and instruction module for LISP program interact with the student model module and refer to the student record directly in order to identify the error statement (or function) or select the next learning item from authoring text. Of course, our student model module manages the historical understanding information of student so as to indicate current situation for understood learning items or not yet understood learning items under the relationship for the previously instructed learning items.
3. Representation Form in Student Model

Our student model is fundamentally organized on the basis of truth maintenance mechanism in TMS. Of course, our objective is to manage the learning process of each student with respect to information about how student has learned, what he could understand, what he could not understand, which errors or mis-understanding terms he has until now.

We introduce two different forms for representing understanding level of student: CR justification form and WR justification form. CR justification form is as follows:

$$\left( \text{CR (} \langle \text{in-list} \rangle \text{)} \langle \text{out-list} \rangle \right)$$

This justification indicates that when terms in $\langle \text{in-list} \rangle$ are "in-belief" and terms in $\langle \text{out-list} \rangle$ are "out-belief" this phrase is "in-belief". Namely, this justification represents inferably that the learning item for this phrase was understood by student. Here, "in-belief" means that the phrase is believed currently, like the concept of "in-belief" in TMS, and "out-belief" does that the phrase is not believed now. For example, consider the learning process, shown in Figure 3. Figure 3 shows a dependency graph with respect to the relationship among individual learning items. In this case, we can represent our historical understanding record for justification forms, as shown in Figure 4.
On the other hand, WR justification is as follows:

\[
( \text{WR} ( \text{<term>} ) ( \text{<in-list>} ) ( \text{<out-list>} ) )
\]

This justification indicates that this term was understood wrongly when terms in \text{<in-list>} are "in-belief" and terms in \text{<out-list>} are "out-belief". For example, in the previous example WR justification is generated when the term N4 is "out-belief" (it is inferred when SETQ was not understood correctly). In this case, our historical understanding record represents a set of terms in Figure 5. In Figure 5, the term N5 which was inserted into \text{<out-list>} of term N3 with "( CR (N2)(N5) )" and term N4 with "( CR (N1,N3)(N5) )" represents the cause that terms N3 and N4 are changed from "in-belief" to "out-belief". Also, the term N5 is generated, using the information that errors were found out for exercise of SETQ: the fact that the term N3 is the cause for term N4 is transferred from the error-diagnosis/detection module. Of course, when errors depend on several terms, \text{<out-list>} in WR accommodates every error cause: Figure 6 shows that the causes for term N4 depend on two learning items: term N1 and N3.

4. **Maintenance Mechanism in Student Model**

CR and WR justifications indicate that the corresponding learning items could or could not be understood correctly in accordance with the diagnosis result, respectively. In this section, we focus on the instruction strategy based on this student model. This topic makes our student model mechanism clear and makes the representation means of our two different justifications successful.
Figure 7 shows the transitional stages of belief values by re-instruction strategy for Figure 6. Thus, Stage1 as the initial stage is the same as that in Figure 6.

1) Stage1: (1) student cannot code function SETQ (term N4 is "out-belief").
   (2) the cause depends on mis-understanding of concepts of variable and function (terms N1 and N3 are "out-belief").
2) Stage2: (1) re-instruct term N1 because of term N1 of <out-list> in term N5.
   (2) by this, term N1 was understood correctly (term N1 changes from "out-belief" to "in-belief").
3) Stage3: (1) re-instruct term N3 because of term N3 of <out-list> in term N5.
   (2) by this, term N3 was understood correctly (term N1 changes from "out-belief" to "in-belief").
4) Stage4: (1) erase error indication of term N5 for term N4 because terms N1 and N3 were understood (term N5 changes from "in-belief" to "out-belief").
5) Stage5: (1) re-instruct term N4, because term N5 was erased.
   (2) by this, term N4 was understood correctly (term N4 changes from "out-belief" to "in-belief").

Here, the student model represents that all learning items for terms N1, N2, N3 and N4 were understood correctly. Namely, our student model points out that the instruction module should retry the learning items, contained in <in-list> and <out-list> of term "nogood" (error), and sets up the corresponding terms to "in-belief" after having learned re-instructed learning items correctly. This procedure is repeated until every learning item contained in <in-list> and <out-list> of term "nogood" have been re-instructed and understood.

5. Conclusion

We proposed a functional student model, based on the feature of TMS framework in this paper. Our student model not only represents understanding level or learning process of student but also contains historical learning information in comparison with the traditional student model such as overlay model and perturbation model. Additionally, under such feature our student model can indicate re-instruction strategy clearly with the cooperation among instruction module and error-diagnosis/detection module so as to maintain uniform interpretation of evaluation effects for learning items. Our framework is strong because the understanding maintenance mechanism which depends on the relationships among historical collection of learning items is effective.

As for our future work, the following issues must be investigated from a practical point of view:
1) application to large scale of learning items.
2) performance evaluation for understanding maintenance.

Abstract: This paper presents a project-based learning environment engaging inservice and preservice teachers in obtaining technology competencies. It summarizes the methods used to organize the collaborative learning group and the process of producing technology-related projects with instructional use in the various classroom settings. It also provides an analysis of the artifacts that were produced by the preservice teachers and the feedback from the school children and the inservice teachers involved in the project.

1. Introduction

The National Council for the Accreditation of Teacher Education (NCATE) has developed technology standards stating that a prospective teacher should be educated in "the use of computer and other technologies in instruction, assessment, and professional productivity." (NCATE, 1994). In the collaboration with NCATE, the International Society for Technology and Education (ISTE) established 13 guidelines for NCATE accreditation of educational computing and technology competencies for associated teacher education programs (ISTE, 1992). Many states have also required detailed competency requirements for each teacher education program in order to promote technology use in the classroom. Although many organizations have determined their own lists of technology standards, there is no universal agreement on even a base set of standards (Fisher, M., 1997). This general lack of agreement creates difficulties in establishing effective instructional training programs, as well as in promoting effective practice environments in the preparation of preservice teachers. In most cases, teacher education programs require two or three hours of technology-related coursework for each teacher candidate. Even so, the value so provided by such coursework is as variable as the available technologies in the offering institutions.

Cognitive psychology has contributed the idea that the mind actively constructs its own interpretations of information and draws inferences from them" (Wittrock, 1990, p.348). Based on this belief, the constructivist perspective describes learning as a change in meaning constructed from experience. According to constructivism, "learning is determined by the interplay among students' existing knowledge, the social context, and the problem to be solved. Instruction refers to providing students with collaborative situations in which they have both the means and the opportunity to construct" (Newby, T. J., Stepich, D. A., Lehman, J. D. and Russell, J. D. 1996, p. 34).

Project-based learning has shown some merits in terms of student learning because the very act of completing a project requires the students to engage themselves in a complex process of inquiry and design. The result can be thought of as an artifact, a product that can be shared and critiqued (Guzdial, 1998). Furthermore, the completion of a project ideally provides opportunities for cooperative learning among students and collaborative learning between students and more experienced professionals with expertise in specific areas.

Cognitive science has also shown that learning improves when skills and knowledge are explicit (Brown, Bransford, Ferrara, and Campione 1983). The processes involved in project-based learning have such features, often having well-explained goals set for students as well as explicit descriptions of the required skills. We have learned, however, through years of experience, that many skills and forms of knowledge can be deeply embedded within given educational experiences, and projects provide the best available method to help students learn these embedded or non-decomposable skills and knowledge.

2. Project-Based Learning -- an Example

An instructive example of project-based learning through collaboration between preservice teachers and inservice teachers took place in a town in Nebraska where students enrolled in a college technology course.
required of education majors at Concordia College (now Concordia University) were matched one-on-one with classroom teachers in a K-8 elementary school and in a nearby high school.

2.1 Course Format and Rationale

The criteria used to match preservice teachers with inservice teachers consisted of their emphasized areas and their preferred grade levels. One of the learning processes was for these students (preservice teachers) to produce disciplinary-based (e.g., history, social studies, mathematics, etc.) multimedia instructional material using a multimedia application available at both the college as well as at the elementary (in the case of elementary education students) or at the high school (in the case of secondary education students). Each preservice teacher was matched with one inservice teacher. The preservice teachers were required to make three contacts with the designated inservice teacher: first to discuss the theme of the project and to locate relevant printed material; next to show the first draft of the project and solicit suggestions for modifications; and lastly to submit the final product as part of the final project evaluation. It was made very clear that the collaborative project was part of their learning experience and that the final product -- the artifact) would be factored into their academic performances for this course. At first they expressed reservations about the setting and the requirements, and some even complained about the lack of time to make meaningful contacts or to visit the classroom. As they became more aware of the ramifications of the project, they warmed to the concept. In addition, the Education Department at Concordia College was very supportive of the project and decided to appoint one of the faculty members to be in charge of recruiting inservice teachers to participate in the collaboration.

2.2 Recruitment of Inservice Teachers

Recruitment of the inservice teachers as mentors often turns out to be a difficult process. The main reasons are that schools lack necessary computer technologies and that inservice teachers are often not sufficiently competent in implementing instructional technology in their own classrooms, nor are they confident to make what they feel are significant contributions to the collaboration.

Another common concern is the time required of the inservice teachers. If viewed simply as an addition to their normal load weight, it would be virtually impossible to find willing participants. The course instructor can facilitate the recruitment of inservice teachers by emphasizing the mutual benefit for all parties to be gained by the project-based collaboration. The role of inservice teachers is, of course, to bring their rich classroom experience to bear on the collaborative project, helping to smooth the transition for the preservice teachers as they try to apply classroom knowledge to classroom teaching. However, they need to be made to feel that they are supported throughout by the course instructors, and that the collaboration is between them and the course instructor as well as between them and the preservice teachers.

Fortunately, most inservice teachers approached for the present project were very enthusiastic about the collaboration, especially after they were apprised of the mutual benefits of the cooperative project. In turn, each student enrolled in the course was provided with one inservice teacher in their designated subject area and the grade level. The tangible benefits extracted from such experiences clearly indicates that those primary/secondary schools strategically located relative the education institutes need to be more active in seeking out (rather than simply responding to) opportunities to engage in collaborative experiences with preservice teachers.

2.3 Communication among the Participants

The course instructor's primary role in the project, apart from the final evaluation of the preservice teachers' projects is as a liaison between the preservice and inservice teachers. However, after the initial matching of preservice teachers with inservice teachers, the initiative shifts to the preservice teachers to maintain contact with their mentors. Even before the first meeting with the inservice teacher, the preservice teachers need to have drafted a rough outline of the proposed instructional materials, as well as a general strategy for piecing together the various multimedia components. Thus the first meeting can be devoted to a reconciliation of the preservice teacher's aspirations against the inservice teacher's resources and expertise. Note that even in those cases where the inservice teacher's technological expertise might even be below that of the preservice teacher's, the inservice teacher's experience in developing discipline-based curricula will be crucial to the collaboration. Once the
in-service teacher feels that he/she has the necessary components of the instructional materials, the "programming" stage begins, where the technology becomes a medium through which the curriculum is delivered.

Once a draft of the multimedia package has been prepared, a second meeting with the in-service teacher is scheduled, where it is expected that the in-service teacher will once again be a valuable resource in critiquing the curriculum. Based on the result of this meeting, the preservice teacher will prepare a final draft of the multimedia-based curriculum, to be evaluated by the in-service teacher during the last meeting, and then later by the course instructor. Ideally, the final product is a curriculum enhanced by modern technology so as to be assimilated by a greater number of students and to a greater depth. If this ideal is met, then not only will the preservice teacher have developed materials that will likely eventually be used in the classroom, but also the in-service teacher is apt to be willing to test the curriculum in his/her own classroom, especially since he/she already had a hand in its development. Fortunately, this ideal was frequently realized in the present project, resulting in a number of newly developed instructional materials.

3. The Final Product

The artifact of project-based learning provides a focus for review and reflection. Projects have a context associated with them, and in the present case the resulting artifacts can be used for teaching as part of the instructional material. This greatly raises the level of relevance to the preservice teachers; indeed, more than being mere "dress rehearsals," these finished products are likely to eventually be used in real classroom settings. Two very important secondary effects were the elevation of the students' appreciation of the role and utility of collaborative-based projects, and the improved attitudes toward technology implementation. With the preservice students having assumed the primary responsibility for keeping the collaboration active, there was an obvious sense of ownership of the final project. More than 80% of the preservice teachers discussed in their journals not only how much they valued the exchange in working with the in-service teachers, but also their appreciation in gaining valuable classroom practice.

Many of the in-service teachers openly demonstrated their enthusiasm for the project; some of them took the extra effort to arrange times for preservice teachers to work directly with the K-12 students, thereby providing a tangible environment within which to use those instructional materials that they were developing; others brought school children to the computer lab to teach them skills in using the multimedia applications developed by the preservice teachers. As a result, a significant number of the in-service teachers thought enough of the collaborative project that they viewed their interactions with the preservice teachers not so much in terms of professional altruism as in terms of professional development and a sense that a tangible contribution to teacher education was being realized.

4. Conclusions

The above-mentioned project underscores the possibility of harmonizing teacher training for preservice teachers and professional development for in-service teachers in a mutually reinforcing environment. However, preparing our preservice teachers with the knowledge and skills necessary to integrate technology into the classroom continues to be a challenge for all teacher educators. Most of our preservice teachers are traditional students who have little to no classroom teaching experience, and it is understandably difficult for them to make the connection between what they are learning in the technology course and real classroom implementation. While organizations have attempted to establish various guidelines and standards for teacher education programs as they relate to technology competency, very few studies detailing the efficacy of technology-related coursework in such programs are available. Requiring credit hours with no detailed standardized competencies does not assist in the quality preparation of teachers. Most teacher-educators are still struggling to identify the most efficient format and practical strategies to better prepare our preservice teachers for classroom practice in today's Information Age within the framework of the general requirements set forth by the accreditation organizations and teaching institutions. On the other hand, in spite of the many efforts on the part of professional educators to bring more technology into classroom teaching and learning, there are schools where teachers use very little technology in their instruction due to lack of facilities or lack of training or support from
administrators at various levels. However, as the present study argues, with only a modicum of technological facilities, a collaboration between preservice and inservice teachers can be initiated with a common goal to share in this country's "technology-transfer" initiative; seen in this way, the benefits to both groups become manifest.

Finally, and most importantly, the purpose of involving inservice teachers as mentors to preservice teachers in project-based learning was to seek more opportunities for authentic learning environments for preservice teachers and to reinforce inservice teachers' move to integrate technology into their own classroom instruction. After two semesters of such practice, a model emerged on the basis of which a formal proposal to require all preservice teachers enrolled in the corresponding technology course to engage in similar collaborative work with inservice teachers. This model continues to provide tangible training for the preservice teachers and, of equal importance, provides continual reinforcement for the inservice teachers to continue and expand classroom use of technology. The above project, now an ongoing one, continues to show great promise. However, this and similar models will continue to require further research and analysis.

Introduction

An assumption can be made, based on its evolution during the past 20 years, that technology will play an instrumental role in the future. How technology is used by today's students, especially in the classroom, will affect the students' perspective on the function of technology. Is technology used as a digital worksheet, as a game source, or as a way to extend student thinking and learning? The ultimate goal of schools and classroom teachers should be to help students develop the ability to think and act creatively when using technology. How may this goal be accomplished? The following discourse offers suggestions on what to look for in software and how to use technology to promote creative thinking.

Selection and Utilization of Software

"The most critical decision a teacher can make is that of software selection. After all, a computer is little more than plastic and electronic circuitry until the software is loaded" (Shade, 1996, p.17). Initially, there are three primary areas to be examined when evaluating software. They include child features, teacher features and technical features. Child features relate to the focus of developmentally appropriate physical aspects of the software. In other words, are the physical and mental capabilities of the child matched to the software or are additional prerequisite skills required? Teacher features incorporate the design functions of the software that include instructions, documentation, supplemental activities, and ideas for integrating the software into the curriculum. Technical features combine all elements of a program such as color, sound, and motion. They are designed so that the program can be operated effectively by the user. Following examination of these features both general and specific guidelines for the selection and utilization of software programs should be addressed.

General Guidelines

Selection of software requires pre-planning and preparation by the teacher. This approach is sometimes considered time consuming. Goals and objectives that foster creativity and allow time for exploration of the software should be built into any activities that are planned. Software should not be selected as a reward for good behavior. Research has shown that when software is selected as a reward it reduces creativity.

Software should be selected as a tool in conjunction with other materials and activities. When selecting software, following an assessment of the intended learners and required prerequisite skills, the emphasis on attaining stated learning goals and objectives is important. Following the selection of goals and objectives,
the documentation and software program should be completely reviewed before it is used with students in the classroom.

Specific Guidelines

Software programs should be evaluated using criteria that include program characteristics, content, usage, and technical aspects. Program characteristics relate to the subject matter, grade or age level, number of users, type of programs (drill and practice, tutorial, simulation, etc.) Appropriate consideration of the program characteristics is important. Normally, software, especially commercial software, has been designed to appeal to multiple age or grade levels. Additionally, there is also a trend toward incorporating several content areas within a single package that may or may not be relevant for the age or grade level. The content should reflect accurate and up-to-date information that is organized, presented effectively, and complies with the district curriculum and is free of bias and stereotypes. Appropriate vocabulary, spelling and grammar are also considered part of content evaluation. Vocabulary should reflect the designated grade or age level as stated in the software program and refrain from the use of stereotypes, bias and slang. Usage focuses on clear and understandable instructions for teachers and students. Help screens, interaction with appropriate feedback and reinforcement, self pacing features and a range of skill levels that include branching should also be evaluated when considering the usage of a software program. Technical considerations for evaluating software programs should reflect appropriate screen design. It is important that software incorporate screens that can be easily seen, graphics and color that are age appropriate, sound and motion that run smoothly without glitches or an excessive amount of manipulation. The screen design should also include icons that clearly indicate what the user is expected to do when a specific icon is selected.

While the above mentioned criteria are vital considerations when software is being selected, they alone do not provide for a challenging atmosphere to encourage spontaneity and inspire creativity. The selection process should focus on alternative ways that software may be used. The alternative approaches would foster exploration of the what "if" possibilities relating to specific software that would help foster the creative process.

Learning Opportunities

Learning opportunities emphasizing the creative process need to promote creative thinking. Creative thinking involves an individual exploring a problem, making associations between the current situation and prior experiences, evaluating the situation in order to respond to it, and generating a unique solution to the problem (Hubbard, 1996; Isenberg & Jalongo, 1997). To encourage creativity, these four actions are considered when a teacher plans learning opportunities incorporating software. Mentally engaging the students by having them plan and make decisions to solve a problem is a key step when designing such learning opportunities. Select problems relevant to the learners where the use of technology facilitates and extends thought. The selected software may allow the students to create scenarios or provide information in order to problem solve. Learners are encouraged to use knowledge and skills across curriculum areas within the activities. Integration across content areas enables students to see how knowledge and skills are meaningful, useful, and linked. Essentially, the students should utilize and apply what they have learned to approach and solve problems. Learning opportunities are planned where students collaborate and interact with one another to complete the task. Seeing other perspectives allows learners to experience alternative approaches, techniques, and strategies to solving problems. Cooperative learning also allows the exchange of ideas that can stimulate and clarify thinking. Involvement in the process and with the use of technology must be encouraged for every student. Open-ended learning opportunities are required where the students create the plan to follow and their decisions decide the final outcome, not the software. The promotion of fluent, flexible, and original thinking is highlighted so the students are able to actively learn, plan, decide, and problem solve using technology (NAEYC, 1996).
Conclusion

Technology should be utilized as a resource where an individual directs the technology to solve problems, to seek solutions. The use of technology in the classroom needs to be evaluated and when appropriate, modified to achieve this purpose. Students need to go beyond rote learning and practice or game playing. Technology should become the tool that enables learners to seek information, generate lots of ideas, and explore potential solutions as they decide how to solve problems. When used in such a way, technology encourages and stimulates creativity in the learner.

Computer Applications for Preschoolers with Disabilities

Joy V. McGehee, Ph.D.
College of Education, Special Education
Northwestern State University of Louisiana
Natchitoches, Louisiana, U.S.A.
mcgeheej@alpha.nsula.edu

Abstract: There are many benefits to using computers in preschool classrooms. Research and experience indicate that assistive technologies which enable access to computers are of tremendous benefit for people with disabilities. It should be of some concern, therefore, that there is very little work reported in the area of assistive technology and computer use in preschools for young children with disabilities. Reasons for this include the unfamiliar set of skills associated both with computer use and assistive technologies. Another reason for lack of computer use with young children with disabilities could be lack of information relative to the distinct cognitive and physical prerequisites required for use of assistive technologies and computer use. This paper discusses the training issues which should be addressed when teaching preschool teachers of young children with disabilities to use computers as learning tools. Assistive technologies which are of particular use in preschool classrooms, issues surrounding developmentally appropriate software, and cognitive prerequisites for computer use are discussed.

Recent years have seen a dramatic increase in the availability of computer software for young children. Trend analysis in market research has shown that, recently, the largest area of software growth has been in new titles and companies serving the preschool market. (Haugland, 1997). Such issues as the desirability of computers in preschools and appropriateness of software have been addressed in the preschool literature. The arena in which young children have the most to gain from early computer use is, however, relatively unexplored. This arena is computer based early educational interventions for young children with disabilities. This paper explores what the literature has to say about young children using computers and the special factors one must consider when planning to use computers with young children with disabilities. Attention is given, also, to the specific skills preschool teachers of young children with disabilities must have in order to use computers for the maximum educational benefit possible.

In general, the considerations surrounding computer use with preschoolers are the same whether we are considering young children with disabilities or typically developing youngsters. All children, two through six years of age, learn from exploring their environments and interacting with other children. Early concerns regarding the desirability and applicability of computers with young children centered primarily among constructivist thinkers who noted that young children need sensori-motor and concrete experiences in order to learn from their environments. Specifically there were concerns that computer use in preschool classrooms might socially isolate children (Barnes and Hill, 1983), and squelch creativity (Pardeck, 1986). Elkind (1987) maintained that children should reach the level of "concrete operations" (around the age of seven) before attempting to use the more abstract dimensions of a computer screen. Although there are many questions left unanswered about preschool computer use, research is beginning to suggest that the concerns expressed in the 1980's and early 1990's are unfounded.

Recent research in computer use with young children has resulted in some optimistic conclusions. Initial studies confirm that computer environments with concrete manipulable events teach pre-mathematics skills as well as interactions with traditional concrete objects. (Clements, Natasi, and Swaminathan, 1993). Furthermore, research continues to provide overwhelming evidence that pre-school children prefer to socialize around a computer than play with it alone. (Clements and Natasi, 1992). Even children who tend to be social isolates tend to socialize more when playing with a computer. (Clements, 1994). The question of whether computers are appropriate in preschool classrooms has been answered. The remaining questions regarding preschool computer use (aside from training for teachers) are questions of developmental appropriateness and access for all children.

Assistive technologies, input and output devices that enable alternative access to computers, have changed the face of education and training for people with disabilities dramatically. Remarkable and sophisticated assistive technology devices exist which enable people to communicate with computers via eye gaze, breath, or a neck movement. Computer output devices can now speak text, print in braille, and enlarge portions of a screen. Despite the existence
of these devices, and despite universal agreement that very early intervention in the lives of young children with disabilities is critical to development, there is little work reported in the literature which extends the use of technology into preschool classrooms for children with disabilities. None of the studies referenced previously in this paper involved young children with disabilities. Two notable exceptions exist to the seeming lack of interest in the literature; the "Macomb Projects" and Project ACTT (Activating Children Through Technology), both at Western Illinois University, have contributed greatly to the body of knowledge regarding early switch use and computer applications for very young children with severe disabilities (Huntinger, 1994).

One can only speculate as to why tools which have proven so useful in the education of school-age children and adults with disabilities remain curiously unexplored in the preschool arena. Educational services for preschoolers were not mandated until 1986 when the "Education of the Handicapped Act Amendments" were passed. Early efforts on behalf of young children with disabilities focused upon the cultural institutionalization of early intervention programs. Such new methodologies as computer use in preschool classrooms, which require considerable resources and teacher training, have not received the attention that such critical issues as service delivery and interdisciplinary collaboration, family focused intervention, and inclusion with typically developing peers have received. Another factor which might contribute to lack of attention to computer use with preschoolers is the "unfamiliar" and "challenging" set of new skills which preschool teachers must learn in order to use computers as learning tools. (Huntinger, 1994.) Although all of these factors may be involved in the lack of focus on computer use for preschoolers with disabilities, there are other training needs of teachers which should be considered, namely: complex cognitive prerequisites which enable young children to both use and benefit from computer use, and the level and developmental appropriateness of commercial software.

During the Spring of 1998, a project sponsored by the “Louisiana Educational Quality Support Fund” and awarded to Northwestern State University of Louisiana, enabled the training of approximately 100 preschool teachers of children with disabilities in computer use in their classrooms. Prior to the workshops, teachers were asked to complete a "needs assessment" in order to determine which areas of training in computer use they felt would be most useful. Participants were asked to rank order 4 possible training areas including installing software, using assistive technology devices, identifying developmentally appropriate software, and using the internet. Surprisingly, almost all of the participants gave equal ranking and importance to all four topics. In order to address all 4 training needs, mini work-stations, manned by one or two trainers, were set up to accommodate no more than 4 participants at a time. Workshops lasted 6 hours and were limited to a maximum of twenty five teachers. Teachers rotated among the work stations and received training in the four areas mentioned previously.

During the workshops, in addition to technical training in software installation, assistive technology devices, preschool software, and use of the internet, participants were asked to consider several issues. Among them; the types of assistive technology devices which will encourage full student participation, a system for teaching cause and effect relative to software use, and the cognitive and language development levels of the children in their classrooms. Teachers should have a system for evaluating whether or not software is “developmentally appropriate” and whether it matches and will enhance the cognitive and language levels of the children interacting with the software. Each of these issues is discussed in subsequent sections of this paper.

Although many adaptive input devices exist, there are several which are particularly useful for preschoolers with disabilities. Many preschoolers (including children without disabilities) have not developed the fine and gross motor skills required for standard keyboard or mouse manipulation. Other children who benefit from adaptive input devices include children with fine and/or gross motor delays, children with upper torso physical disabilities, children with vision and/or hearing impairments and children with severe or moderate cognitive deficits. When children are not able to use a standard keyboard or mouse several adaptations which allow computer access are possible. These include modifications of standard keyboards, alternative styles of keyboards, and use of single switch devices. Standard keyboard modifications could include headsticks, mouthsticks, locks for selected keys, and speed enhancement. Alternative keyboards include such devices as touch windows (touch screens), PowerPads, IntelliKeys, or Muppet Learning Keys. Single switch devices allow input via a light touch of hand, foot, head, voice or breath and must be connected to a computer interface box. Many preschool teachers prefer the use of alternative keyboards to keyboard modifications.

“Touch windows” are popular items with many preschool teachers and students. Touch windows can be placed on a computer monitor and will allow direct activation of programs by a touch on the screen. PowerPads and Intellikeys both include a board which is attached to the computer and overlays which are placed on the board thus allowing children to perform many activities such as turning pages, selecting answers, etc. Both devices are somewhat less useful currently than touch screens due to the special training a teacher must receive in order to use these peripherals. They can, however, be of great benefit to children who should make a transition to mouse use. The reason
they can assist in making the transition to mouse use is that a child must understand that a device which is being
manipulated adjacent to a computer will actually produce results on the screen. And, more importantly, that where one
touches the peripheral will create distinctions in what occurs on the screen. These cause/effect associations (sometimes
referred to as contingency awareness) are important prerequisites to successful mouse use but may not be learned
automatically by some children with disabilities.

One of the most powerful tools for young children with disabilities is a single switch input device. There are
many different styles of switches including big red round switches, button sized switches activated by minute muscle
movement, and tread switches which may be activated by stepping on a top plate. Preschool teachers who use switches
in their classrooms tend to prefer the larger round versions although switch use should be determined by the physical
strengths and needs of a child.

Some young children with disabilities are not prepared cognitively for computer use despite modifications to
the computer. The cognitive prerequisites for computer use have not been studied to any great degree and most of the
information available to us comes from observations of young children and teachers attempting to use computers for
the first time. Although some children may be able to hit a switch and produce a result on the screen, they do not seem
to understand that they are the agent and that the result may be duplicated. Simple random practice with the computer
does not teach some children contingency awareness. For these children (frequently with severe and/or multiple
disabilities) it is most appropriate to teach switch use with items such as toys and music. Children should be taught that
they can activate an item or action, through switch use, to obtain desired results. When children learn this, given the
necessary assistive technologies, they are ready to use computers.

The Early Communication Process Using Microswitch Technology (Rowland, D. & Schweigert, P., 1993) describes a series of procedures an early intervention teacher may use to teach a child with severe and/or multiple
disabilities how to use switches. Specifically, the recommended procedures describe how to teach a child to use a
switch to gain attention, make requests and express interests, make and express choices, and, finally, to use symbols to
express preferences. These important components of language development also may be considered prerequisites to
successful computer use for young children.

Finally, any preschool teacher must consider whether software is “developmentally appropriate.” The term
“developmentally appropriate” is widely used in preschool literature to describe procedures and practices which are
appropriate for use with young children. In Developmentally Appropriate Practice, Bredecamp (1986), enumerated
the practices recommended by the NAEYC for the education of young children. Age appropriateness, child initiated
activity, and concrete and manipulable activities all are important components of developmentally appropriate practice.

These components should characterize preschool software. In a complete review of preschool software, Haugland
(1997) states “of approximately 750 software programs being marketed for use by young children ... about 20% of
the software meets young children’s developmental needs” (p. 26). In the same review, Haugland presents the
“Haugland/Shade Developmental Scale - Revised Edition” (p.27) which is a resource preschool teachers may use to
evaluate the developmental appropriateness of software.

Computers in preschool classrooms are becoming a common sight. Evidence exists which supports the notion
that computers can be very useful in the education of young children. The potential of computer use with young
children with disabilities is enormous but has yet to be realized. When early intervention teachers receive the training
they need in early switch use, assistive technologies, and software selection, computers may, indeed, prove to be the
tools which transform potential into reality in the lives of young children with disabilities.

Education of Young Children.

June Wright and Daniel Shade (Eds.). Young Children: Active Learners in a Technological Age. Washington D.C.: NAEYC.

Abstract: Technology skills standards at the local, state, and national levels may serve as an adequate yardstick for satisfying set requirements; yet, they have another useful purpose. A careful selection and testing of those skills through a progressive demonstration by third grade subjects reveals how an individual school might adjust its own approach to technology at every grade level, thus, tailoring its own guidelines and satisfying standards. This paper describes the development of two instruments which measure and assess young children's computing skills and related learning needs.

The Early Childhood Development Center (ECDC) School at Texas A&M University – Corpus Christi (TAMU-CC) affords unique and ongoing opportunities to document and research uses of technology by young children and their teachers. The ECDC presently serves over 100 three-year-old through third grade students. This discussion and ongoing research serve to first, examine an overview of teachers' backgrounds, approaches, and ideas on technology, then measure the degree to which a sample of the third graders can demonstrate skill proficiency.

Our search for standards began at the state level where students are uniformly tested in all disciplines. The Texas Essential Knowledge and Skills (TEKS) standards laid the foundation with only few variations from those standards required by the Corpus Christi Independent School District (CCISD) or those suggested by the International Society for Technology in Education's National Educational Technology Standards (NETS). For logistical purposes, we selected skills most readily demonstrated that test higher level skills, such as information acquisition and evaluation, and a few remedial skills expected of any third grader navigating about the personal computer.

The Pre-test Interview

Before proceeding with the testing of student subjects, we interviewed three teachers at the pre-K, kindergarten, and third grade levels asking general questions regarding training and technology integration. The survey (refer to Figure 1) provided the researchers with the teachers' perspective and a sense of direction for this study and studies to come.

Figure 1: Preview Survey

<table>
<thead>
<tr>
<th>Instructor</th>
<th>Grade level</th>
<th>Subject area</th>
<th>Date</th>
</tr>
</thead>
</table>

2002
I. Phase 1 Topics introduced at the commencement of the teacher interview

a. Identification of project: An examination of technology and its integration at the pre-K through third grade levels at the Corpus Christi Independent School District Early Childhood Development Center.

b. Purpose: The immediate purpose is to develop measurement tools, beginning with the following pre-survey, an oral case study of three grades (pre-K, kindergarten, and third) to preclude a follow-up examination through written surveys and observation.

c. Results to: Texas A&M University – Corpus Christi College of Education; Dr. Stephen Rodriguez, Head of Educational Technology; Dr. Jane Wilhour, Director, & Mark Hughes, Principal, Early Childhood Development Center.

II. Phase II General questions

a. Identify hardware available in the classroom
b. Address its usefulness/uselessness
c. Could you provide a “wish list” for hardware?
d. Identify available software
e. What productivity software do you have or use?
f. Could you name some technology activities that work for you – gaming; simulation; tutorials?
g. Could you identify the useful/useless software products?
h. What would be your software “wish list”?
i. Do you have a home computer? It’s format? For leisure or work?
j. Do you make use of the web in your classroom?

III. Phase III

Prior/current teacher technology training and support

a. Where (if any) did you receive your past technology training?
b. Was technology training or skills a prerequisite to ECDC instruction?
c. Does current training come from the district? School?
d. Is it curriculum integration or skills training?
e. Are you trained in web resources?
f. Who or what is your in-house (technical) support?
g. What are your other resources?
h. Could you make any training suggestion?

Teacher’s assessment of own student skills and technology in the classroom

a. What are their previous skills?
b. What is their in-class skills training (time per day/week)?
c. What are the student attitudes?
d. Do computers serve as motivators?
e. How are skills assessed?
f. How are skills integrated into curriculum?
g. Could you make suggestions? - What works? What does not?

Survey Results

The survey was revealing for reasons outside of the skills standards evaluation. We unearthed unique observations of which only the classroom teacher could be aware. There were warnings about the dangerous mix of kindergartners and printers and suggestions for the practical such as washcloths and CD holders or a headset to accommodate the smaller heads of the pre-K future tech whizzes. We discovered glitches in software and received advice and evaluation of software and hardware. We also discovered that with teacher’s guidance a three-year-old can maintain a portfolio of work – a useful tracking device for
monitoring throughout the ECDC. Common among the teachers was a desire for an in-house technologist to assist with supplemental lessons. Though equipped with ten iMacs and its accompanying software in a technology-conducive environment, teachers could use that extra guidance, particularly to help with the integration of technology into lessons.

Skills Testing

Our assessment measured students' computing skills as prescribed by three bodies of academic standards at the local, state, and national levels: Corpus Christi Independent School District (CCISD), Texas Essential Knowledge and Skills (TEKS), and International Society for Technology in Education's National Educational Technology Standards (NETS).

We developed an observation and interview checklist (See Figure 2) to guide us in assessing skills. To develop the instrument we selected third grade skills from a broad range of categories under the CCISD, TEKS, and NETS standards: Foundations, word processing/keyboarding, software/multimedia, and information acquisition. The testing followed a logical progression where the subject could answer some questions, open, perform, and close programs, then proceed to the higher order skills.

The degree to which the standards are met were measured as “ample” (4) where no suggestions were given as to how to proceed (for example, opening a write or paint program), “adequate” (3) which required a minimal suggestion or repetition of the command from the researchers, “meager” (2) where the skill is barely demonstrated and requires aid in navigation, and “inadequate” (1) in which the subject lacks knowledge, much less performance, of the skill in question. Figure 2 shows the checklist of the skills questions. Figure3 shows how the questions are posed to subjects.

Part I: Foundations

- Pointing to various, visible hardware components, the subject must identify 4 devices.
- After confirming the identification of the input devices (mouse, keyboard), the CPU, and output devices (monitor, printer), the observer asks the subject to explain what happens when information is put into the computer.
- Ask the subject how and if the technology in the classroom may also be used at home, work, and everyday life.

Part II: Word processing, keyboarding, and language skills

- Ask the subject to write a brief (two to three sentences) description of self by opening a word processing program.
- Observe keyboarding techniques (proper use of alpha-numeric characters and function keys).
- Does the subject read work carefully and make corrections without being prompted by the observer?
- No specific WPM is demanded; however, the subject should demonstrate fluidity.
- Ask the subject to name and save the file, then print a hard copy.

Part III: Software and Multimedia

- Ask the subject to open a favorite multimedia program, follow the instructions, and demonstrate its proper use. The observer may select a program from the menu if no favorites are available.
- Using Paint or similar program, the user must draw, color, or compose an original image.
- Following the given directions, the subject must input any data into a spreadsheet application.

Part IV: Information acquisition/Telecommunications

- Ask the subject to open the Internet.
- Ask for the subject’s favorite academic subject, person, hobby, or sport. The subject then must conduct a search on the subject by entering it on a search engine.
- Once the subject/site is located, the subject is to evaluate/comment on the found information.
- Using the previously-saved file or by creating a new one, the subject must send an e-mail message.
- After exiting the Internet, the subject properly shuts down the computer.

The Results
At this writing, we are only a few days shy of complete collection of the data. While most of the subjects have been tested, definitive conclusions are forthcoming by the end of the year. Meanwhile, the results currently reveal that while the majority of the subjects have "ample" to "adequate" foundational skills, most are lacking keyboarding skills. There is, of course, the question of environmental factors and whether the observer, by his very presence, impeded with the motor skill demonstration; nevertheless, it may be necessary to further examine these skills at the lower levels.

When it came to maneuvering the mouse for multimedia programs, the subjects seemed adept. Those familiar with the paint programs demonstrated ample creativity. There were those, however, who were surprisingly unfamiliar with creating a graphic. It seemed as though no students were comfortable on the Internet. Navigation required heavy guidance. A full report of our observations of third graders may be obtained by contacting the authors.

Until all the results are in, final analysis is pending. However, since sending email was one of the skills standards required by CCISD and NETS, rather than waiting for results that state the obvious lack of Internet prowess, we have scheduled a time to take advantage of the upcoming holiday season. Over the next few days, the subjects will send electronic Christmas cards, complete with animations and sound, to a neighboring school and/or parents. Having this much fun, it should be easier to start at the top of the skills list, and work our way back.

Closing thoughts

The ECDC School at Texas A&M – Corpus Christi offers a unique environment in which to consider young children’s computing skills. This project entailed interviews of selected teachers and the development and application of an instrument to assess third-graders’ computing skills. These activities are intended as a springboard into a sustained research effort in the student technology arena at the ECDC School.

Computers, Kids, and Crayons: Looking at the emergent writing behaviors of kindergartners using technology

Nancy Yost
University School
Indiana University of Pennsylvania
United States
njyost@grove.iup.edu

Abstract: This paper presents the findings from a study that observed and documented a kindergarten community’s writing as a response to literature and math activities. The study looked at the process, the behaviors, and the final products of these emergent writers. One of the foci was to observe and document the behaviors of the kindergartners as they composed using traditional writing materials and multimedia technology. The study provides insight into how these kindergartners transfer their assumptions about print between writing mediums and the implications these findings can have on early childhood educator’s expectations and assessments of young children using technology.

Introduction

Researchers have questioned and debated the appropriateness of using computers with young children in early childhood classrooms (Barnes & Hill, 1983a; Brady & Hill, 1984; Bredekamp & Rosegrant, 1994; Davis & Shade, 1994; Papert, 1993; Walker, 1983) since the early 1980s. It appears now that the decision regarding the placement of computers in early childhood classrooms has been taken from the early childhood professionals. The Telecommunications Act of 1996 calls for every classroom to be on the information highway by the year 2000; in 1995, one-half of our schools had access to the Internet (Kantrowitz, 1996). In 1995, 5.5 million computers were already being used in K-12 schools (Creedy, 1995), one report estimates an average of one computer for every 35 students (Kantrowitz, 1996). Computers are in our schools now, which means they are in early childhood classrooms. Early childhood professionals need to start asking what happens with these computers that are in the early childhood classrooms, instead of it the computers should be in these early childhood classrooms.

The National Association for the Education of Young Children (NAEYC) issued a position statement (NAEYC, 1996) calling for the examination of the quality of technology and its developmentally appropriate use in early childhood programs. NAEYC’s position statement addresses seven issues:

1. the teacher’s role of evaluating the appropriate use of technology;
2. the potential benefits of technology to early childhood programs;
3. the integration of technology into the learning environment and curriculum;
4. the equal access of all children to technologies;
5. the software’s portrayal of stereotypes and violence;
6. the advocacy for quality programs by teachers and parents; and professional development (p.11).

Throughout NAEYC’s statement, they remind us that technology is not to be the curriculum, but part of an entire program. Children still need to work with paints, blocks, books, and the other traditional early childhood materials. Technology is an addition to, not a replacement for, these materials. Technology becomes another medium for exploration and meaning making. We need to look closely at how technology can best be used to support the development of the children using it just as we would examine any new addition to an early childhood environment. We also need to look at how the children’s use of technology increases our knowledge of the ways children come to know and learn.

The Study
The study took place in a university laboratory school kindergarten from March through the middle of May. There were eight children enrolled class, three girls and five boys. The children's ages ranged from five years five months to six years two months. The children's literacy abilities ranged from those who were at the very beginning stages of recognizing and writing letters and numbers with little reading ability, to children who were transitioning into traditional spelling conventions and were fluent readers.

I served a dual role in this classroom, I was both the kindergarten teacher and the researcher in the study. This gave me the unique ability to look at the children with an understanding of what had happened prior in the classroom as well as what was being observed during the data collection period.

The computers had been available since the first day of kindergarten. Programs were chosen which encouraged autonomy in the children. By the time the study began the children had been using the computers for six months and were all comfortable in working with the computers. Most of the children knew how to start the computers, how to enter their own desktop area, how to access programs from their desktops, and how to print. Many of the children understood how to use programs that required compact disks (CDs) to operate, and could insert and remove the CDs. With a classroom philosophy of integrated curriculum, I felt strongly that the computers should not be in a lab setting. I also felt that to place all the computers in one area, creating a computer center, was in essence establishing a computer lab in the classroom. For this reason, all the computers were located on specially designed low carts. The computers could be moved to the center where the children wanted to use them.

Data collection happened primarily in the form of video taping. During the study, two of the computers were equipped with scan converters that fed the screen activity to video recorders. Three video cameras were used to tape the children engaged in activities through the room. The video cameras captured the children interacting while working traditional materials and at the computers. Some anecdotal notes were kept. These notes documented occasions when video taping was not an option. There were few times when there were not enough cameras to cover all the areas where the children had chosen to work. These notes included the date and description of the activity, who the children were and what they were doing, descriptions of the project, and conversations.

Another data source was the artifacts from the writing events. When children working at a computer exit a program from KidDesk, the final product was automatically saved. When the children exited other programs, they saved their own files, or asked assistance to save their file. However, data was not lost if files were not saved to the hard drive. Since all monitor activity was recorded onto videotapes, I could use a video capture program (Snappy) and print copies of any of the screens. This procedure was valuable, because it allowed me to retrieve some of the draft writing samples that had not been printed or saved. However, printing a hard copy is not an option for compositions containing sounds and movement. Again, the videotape created the data source for analysis. Items from the art table and traditional writing activities were either saved, photocopied, scanned, or photographed, depending upon which was appropriate and the individual student's wishes.

The videotapes and artifacts were examined looking for activity that fit into the categories described in Clay's "What did I write? Beginning writing behavior" (1975). The identified emergent writing activities were coded using these categories and separated into traditional and computer generated groups. This allowed for an easy comparison of the artifacts and incidents that fell into the same category using both mediums.

The coded data categories were:

**Sign Concept:** "The symbols stand for something else. The writing says something" (Schrader, 1990, p. 12). Had the child used the symbols as representations of their writing?

**Flexibility Principle:** "Letters are made up of a combination of features. Letters can be varied to produce new letters or to invent letters that do not exit" (Schrader, 1990, p. 12). The child can adapt what they know about letters to create new letters. Did the child play with letter forms, did they make up their own letters based upon what they knew about letters?

**Generating Principle:** "There is variety in the arrangement of symbols. They are repeated in different combinations" (Schrader, 1990, p. 12). I looked for examples of the children using the same symbols in different combinations, understanding that letters could be combined in different groupings, but not necessarily understanding the relationship between letters and sounds. Clay (1975, p. 27) says that if a child has command of only three signs that the child might produce a line of print like this. Another child beginning to understand the relationship to letters and words will generate a list of names simply by using the letters he knows and copying others.
Recurring Principle: "The same symbol is repeated many times in a string" (Schrader, 1990, p. 12). Did the child repeatedly use the same symbol when making a string of symbols? Did the child use the same stamp in the drawing programs, deliberately going back and making conscience choices to use that stamp? i.e.,

I like the kitten or dddddddddddddddd
I like the kitten bbbbbbbbbbbbbbb
I like the kitten &&&&&&&&&&&&&&
I like the kitten bbbbbbbbbbbbbbb.

Linear and Directional Principle: "Letter identification depends upon letter orientation. Letters are set in a pattern from left to right and top to bottom" (Schrader, 1990, p. 12). Did the child have trouble with orientation of the letters or knowing which direction to write from?

Page Arrangement: "Thought is given to how the words on the page are to be arranged" (Schrader, 1900, p. 12). Was there attention paid to where the child placed the text on the page?

Concept of a Word: "A string of letters represents a word. It may or may not be bounded by a space or a mark" (Schrader, 1990, p. 12). Had the letters been placed in their order with deliberation and thought toward a representation of speech.

Spaces Between Words: "Spaces or marks are used to indicate word boundaries" (Schrader, 1990, p. 12). Was there a consistency in the amount of space used between letters and words? Was there an obvious difference in this space, with more space being between words.

Inventory Principle: "All known words that can be produced are written. They do not convey a message" (Schrader, 1990, p. 12). Did the child write lists of words? Did they use words to label the words on the page, instead of writing sentences?

Punctuation or Signs: "Punctuation marks and/or signs are used as part of a message" (Schrader, 1990, p. 12). Was there evidence of periods, question marks, or quotation marks used in their sentences? Were there other punctuation marks used to assist with their written meaning?

Using these descriptors the artifacts were examined and coded. The artifacts were also grouped by the medium the children had used.

Findings

Based upon the results of the coding, the work of four children provided the data for the following discussion. These four children were the most consistent in their compositions, and had composed several artifacts in both mediums. The other children in the study rarely wrote text without a lot of adult support, their writing was still mostly pictorial and did not provide the type of writing examined in Clay's concepts. The artifacts of each child were examined and sorted allowing the creation of the following tables to look at how the children understood the concepts and principles of print in both mediums.

Table 1: Jessy’s demonstrated understanding of the principles and concepts in these samples looks like this:

<table>

</tbody>
</table>

There are three areas in which Jessy does not demonstrate understanding in when using both mediums. One of these was directionality. Jessy had written with the computer only using programs that controlled the directionality, so she did not have to make choices. Jessy explored the recurring principle when working with the multimedia authoring programs. Jessy’s traditional writing was in place to such a degree that she no longer explored with the understandings of letter shapes repeating or letter sounds being repeated to created new understandings. The third area of difference was that of spacing. From the beginning of the study Jessy consistently used spaces between words when writing at the computer but rarely spaced when she wrote with traditional materials.
Table 2: Paul’s demonstrated understanding of the principles and concepts in these samples looks like this:

<table>
<thead>
<tr>
<th>Principles/Concept</th>

</tr>
</tbody>
</table>

There are three areas that Paul does not demonstrate understanding in when using both mediums. The samples available for analysis impacted two of these areas, directionality and arrangement. Paul had written with the computer only using programs that controlled the directionality and page arrangement. Paul had done no writing where he had to make choices at the computer as he had with traditional writing. The third area of difference was that of spacing. Paul had begun to insert spaces into his computer writing but had not transferred this concept to his handwriting.

Table 3: Sarah’s demonstrated understanding of the principles and concepts in these samples looks like this:

<table>
<thead>

</tbody>
</table>
There are three areas that Sammy does not demonstrate understanding in when using both mediums. The samples available for analysis impacted two of these areas, directionality and arrangement. Sammy had written with the computer only using programs that controlled the directionality and page arrangement. He not written with programs where he had to make choices at the computer like those he made with traditional writing. The third area of difference was that of spacing. Sammy consistently, from the beginning of the study, inserted spaces between words in his computer writing but had not transferred this concept to his handwriting.

Conclusions

For these four children the major difference in their demonstrated understandings was in their understanding to use space as a boundary around words. None of these children consistently used spaces in their traditional writing, yet all of the children used spaces in their computer writing. I did not discuss the issue of spacing between words with the children individually. I did not deliberately teach them how to space between words in their traditional writing. Somehow, they had constructed this knowledge at the computer, and I wanted them to be able to construct this knowledge, on their own, in their traditional writing. The last day of school, I discussed the writings and the issue of spacing with these four children. I reminded Paul about what he had discovered when he typed the email message to his father he replied, "Move the letters so you’ll know what I’m writing. (He was moving his hand up and down like he was pushing keys)." I showed the children samples of their computer written messages. We discussed the spaces between the words that they all had inserted. We even discussed their use of the space bar more than once between words. We discussed their traditional writing and looked at the spaces between words. We looked closely at the Jessy’s hand written piece for Mr. Muller’s book that had no spacing between the words. "What about the spacing between the words in this piece?" I asked. Sammy was the only one to talk during this section. He was certain that there was extra spacing between the words. The other children simply nodded with him in agreement. These were normally talkative children just looked at me, appearing as perplexed by my questioning their lack of space boundaries, as I was with what I felt was their inability to see the space around their words was missing. They understood that there was extra space between their words. It became an issue of perception of “what is spacing” and the individual interpretation of space.

The study has led me to believe that what we expect of individual children as they write at the computers needs to vary from child to child. The expectations for what they produce at the table become different from what I expect them to produce at the computer. When observing and assisting Jessy at the computer it was my expectation that she would space between her words and she might be reminded if she forgot. However, this issue of spacing with her handwriting would not be expected, it would be scaffolded toward later mastery. Similar expectations would be made for each of the children.

When working with young children at the computer individual differences need to be allowed for. These differences can lead toward the child functioning at a different, frequently higher, level than they do with their traditional writing. As the teachers of these emergent writers, we need to support their writing in multiple ways. The use of technology to write provides yet another way to scaffold their development.
